Objective

To describe the internal workings of the Western Australian Data Linkage System (WADLS)

- What is data linkage?
- WADLS:
 - Creation, storage and extraction of links
 - Current processes and future directions

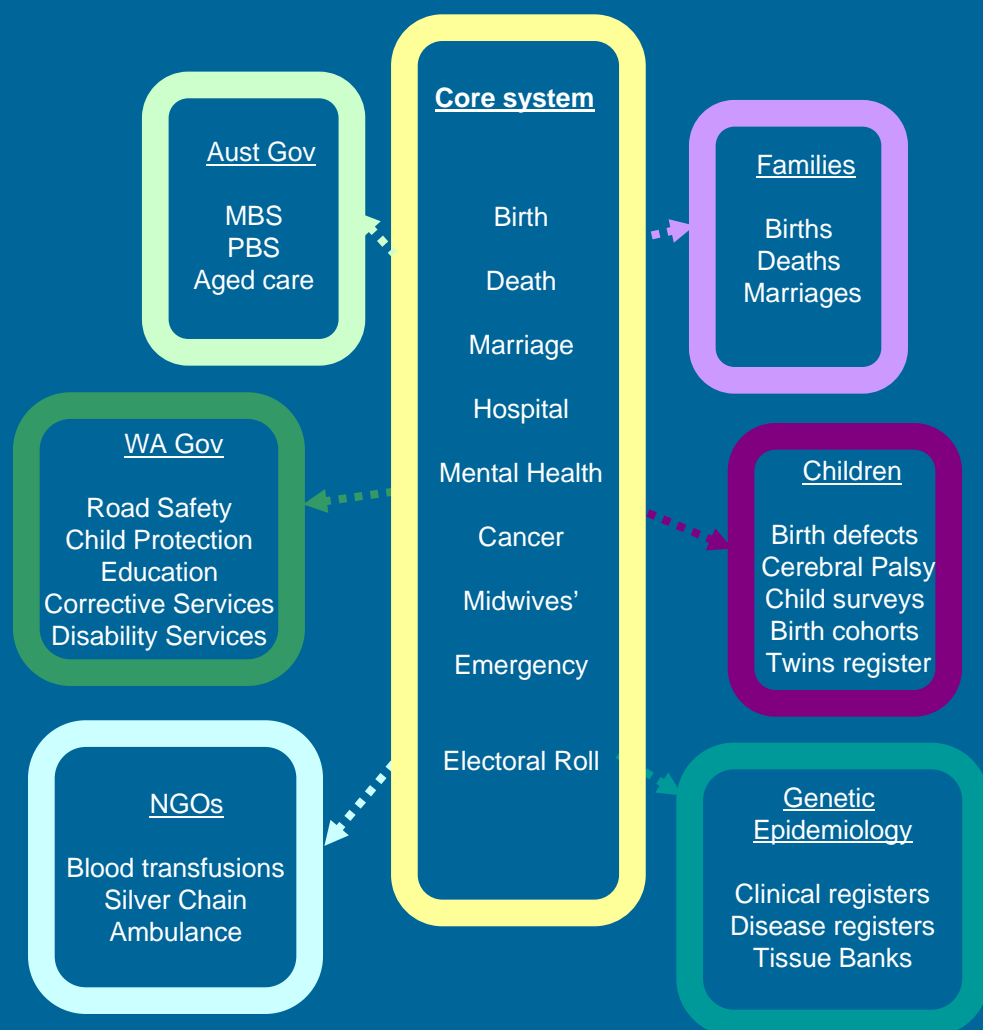

What is data linkage?

- a technique for creating links within and between data sources for information that is thought to relate to the same person, family, place or event
- probabilistic methods compare like elements and calculate the likelihood that records belong to the same entity
- thresholds are set to separate probable and improbable links with those between requiring manual review

WA Data Linkage System 2008

Differs from a static linkage which is used to link 2 or more sources as a one off and for a specific purpose. For example, linkage of emergency department attendance to road crash events to measure injury severity and fatality rates

Multiple sources of data updated regularly (as often as monthly)

> 28 data sets

> 38 millions records

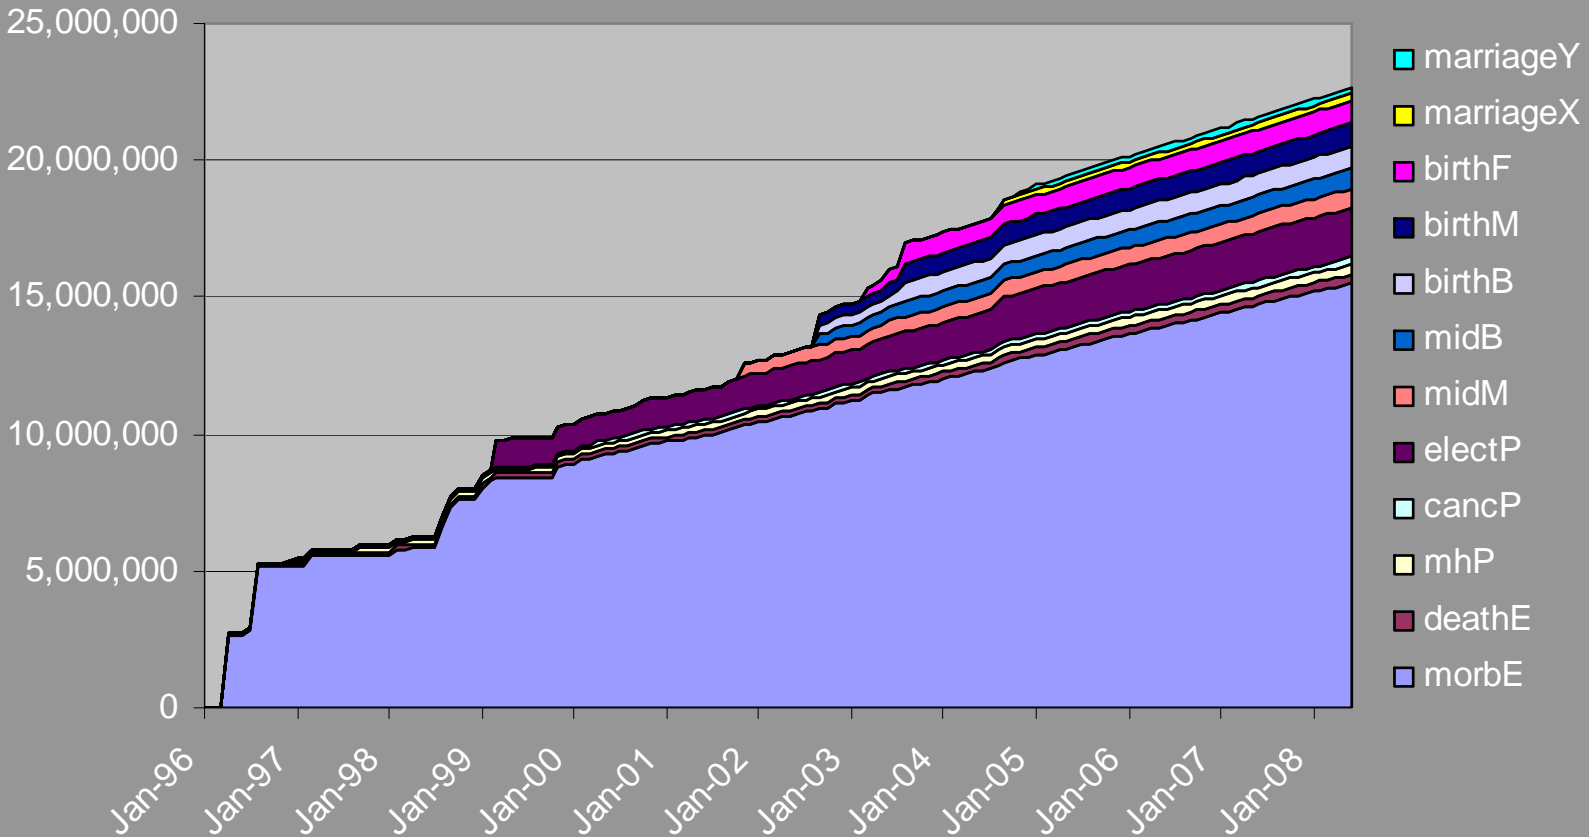

Records dated back to 1966

Dynamic with average of 10,000 links daily (for 2007)

Established as an infrastructure and used for research and planning

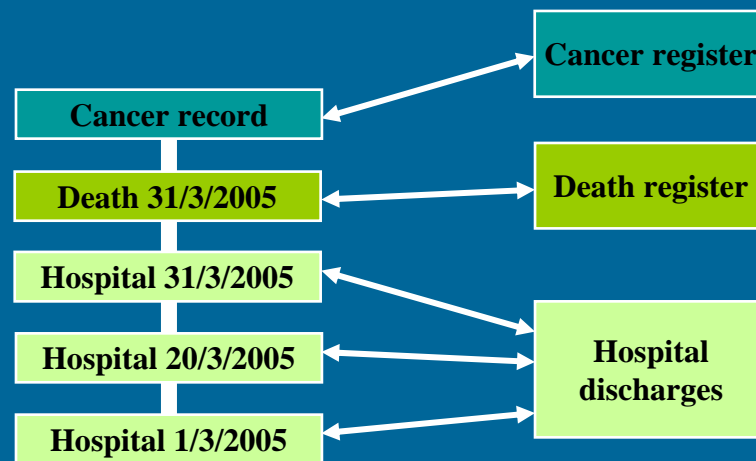

Volume of links for core datasets 1995-2008

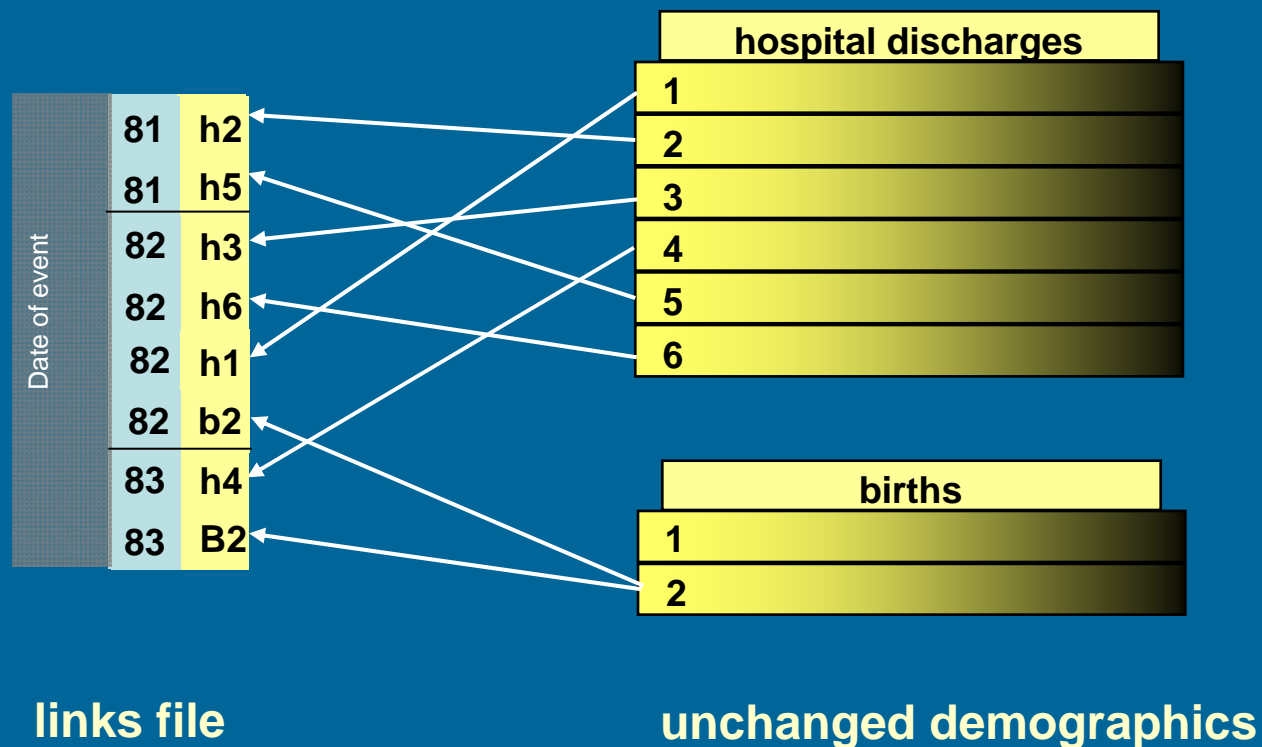

Creation and Storage of Links

- Key design concept is the separation of linkage processes from the service or clinical data used for analysis
- WADLS uses demographics such as name, DOB, sex, address to create links using a commercial software package
- Custom tools have been developed for data preparation, link storage and extraction
- Links for records belonging to one person are stored as a chain of pointers to records that can easily be added to or corrected

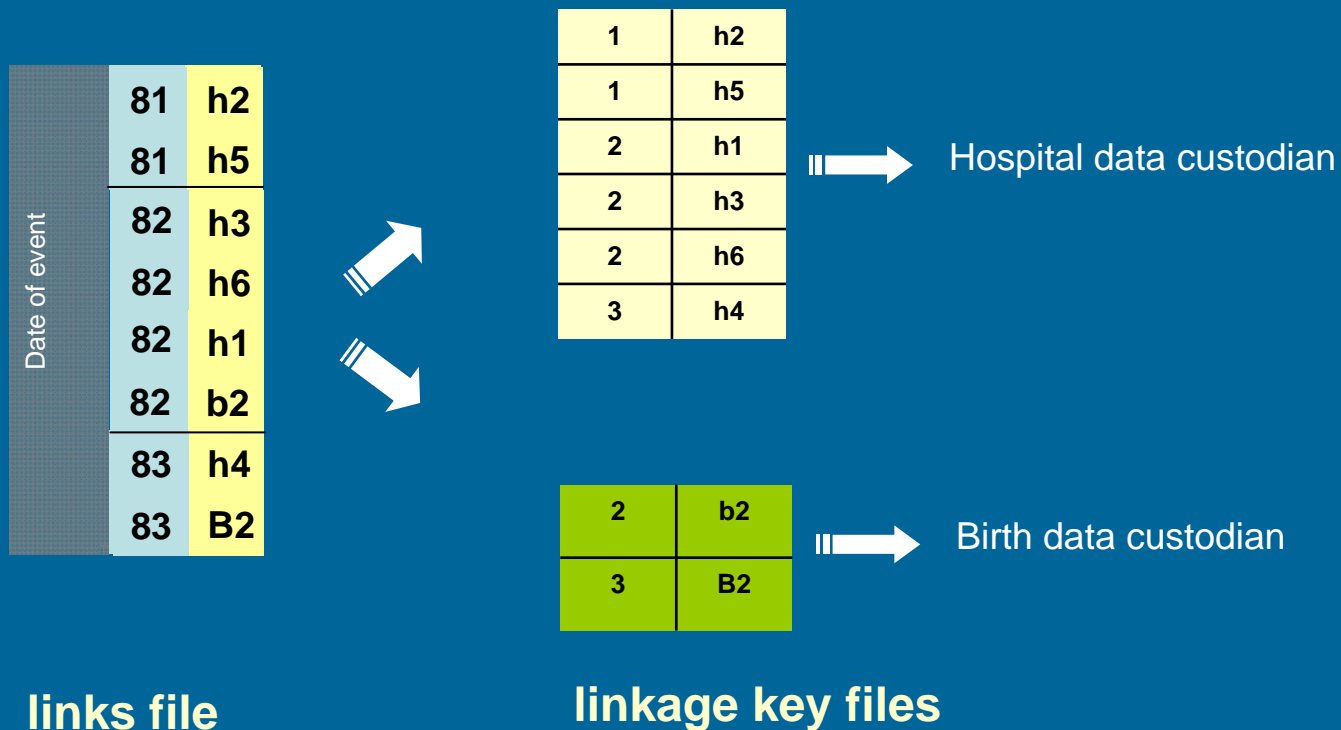

Links storage

Links found are loaded into the links file and are stored as a “chain of links”. It is a database of links not a database of linked records

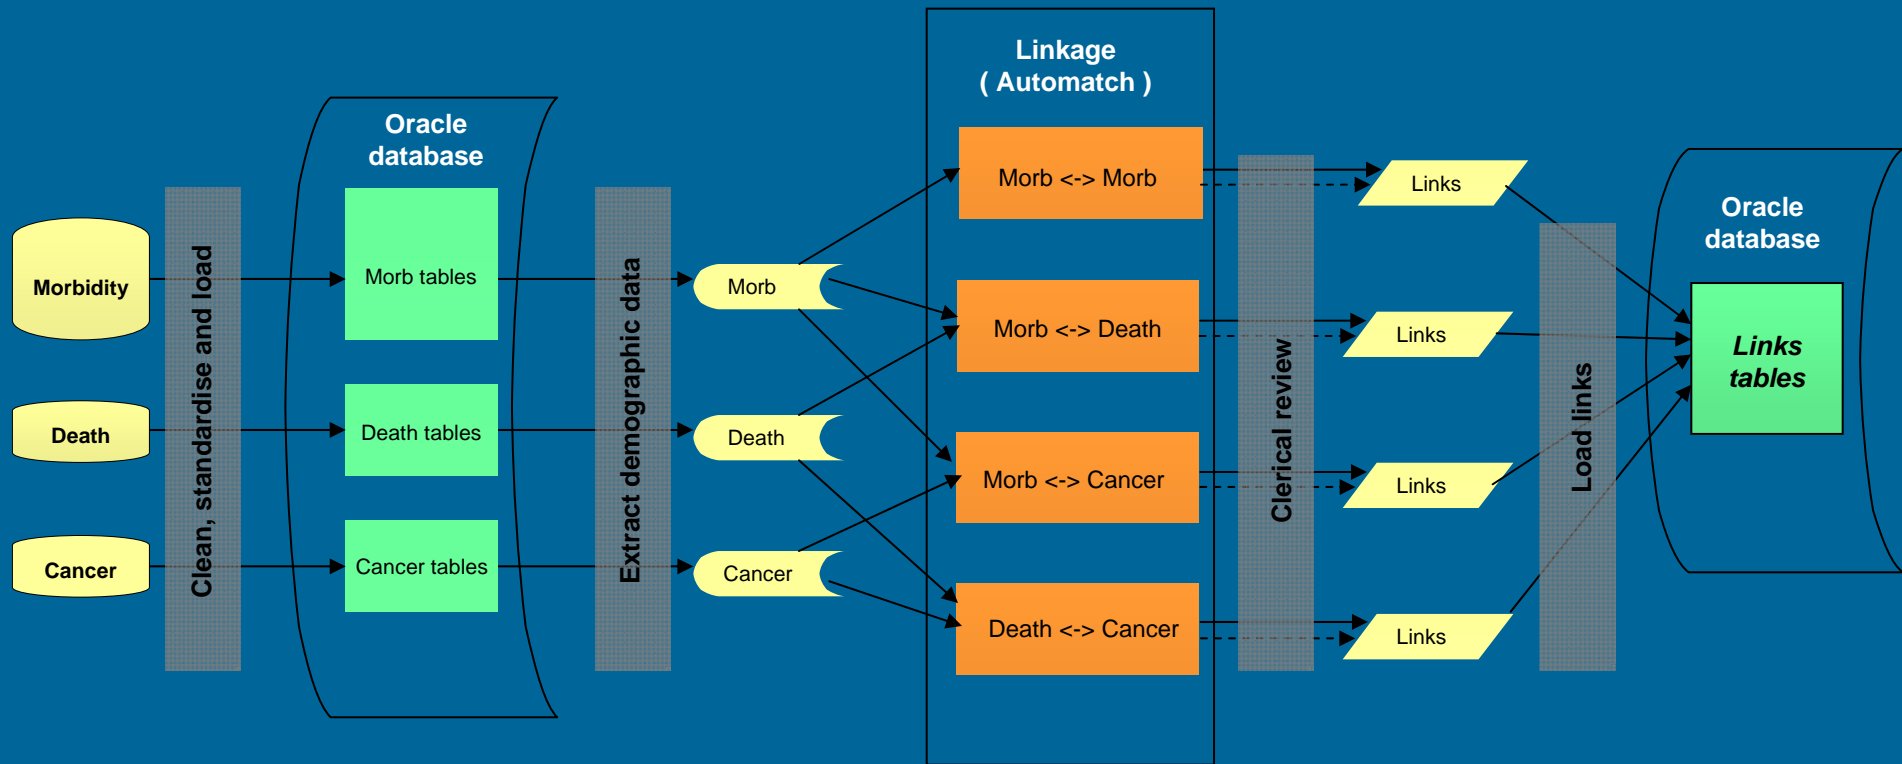

Linkage keys

Lists of source data record ids with a person id are produced from the WADLS links file and passed to data custodians for service data extraction

Data linkage process - current

Raw
data

Manual
review

Extract text-based
demographic files
for linkage

Set up and run
linkage
process

Clerical
reviews

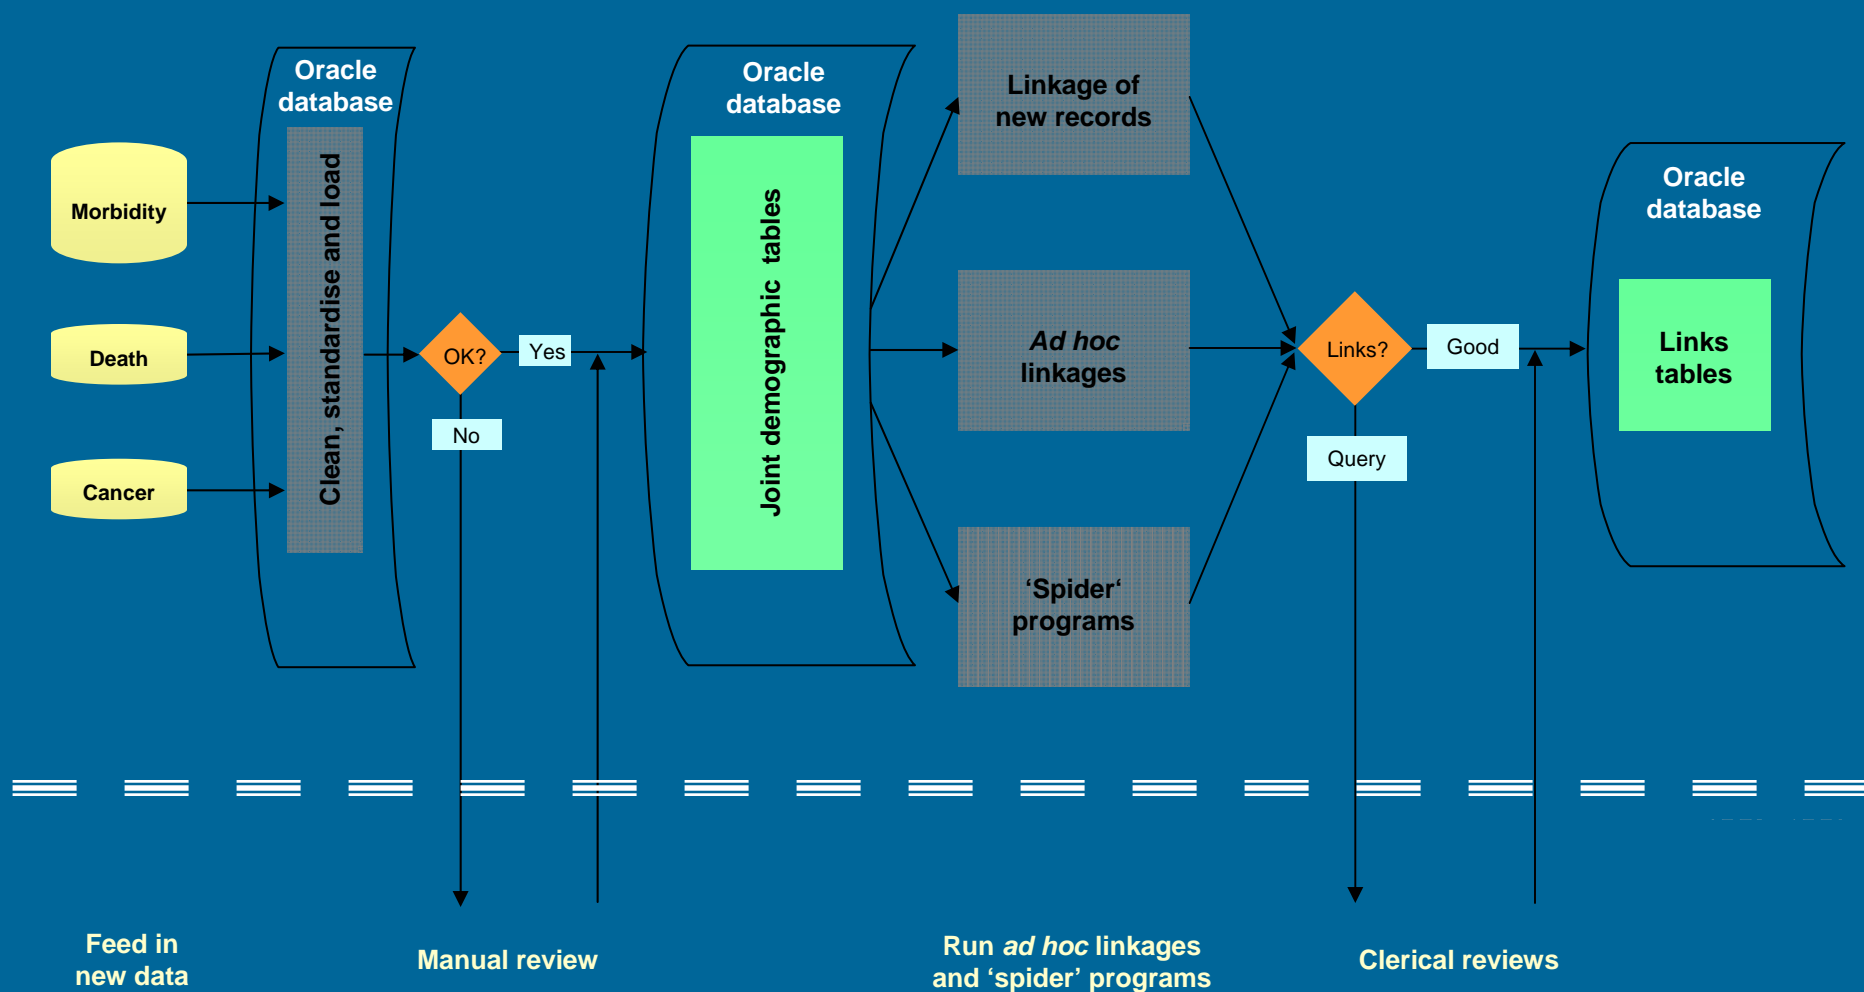

Extract text-based linkage
results & load into links
storage system

Data linkage process - current

- Multi-step, iterative process requiring constant operator intervention
- Command line driven with text based interfaces
- Every record in a batch must complete a phase before any records move to next step
- Approx 90% of records do NOT require any clerical cleaning or linkage

DLU linkage process - future

DLU linkage process - future

- 3 main stages
 - Cleaning and loading of demographics
 - Linking
 - Storage of links
- Individual records will continue to next stage automatically unless clerical intervention is needed
- User interfaces GUI
- Linkage engine is being developed but could use other package
- Storage of links based on existing “chain of links” model currently in use
