

Biomedical Informatics,
Transforming Healthcare
one individual at a time

NIA 2009
Canberra, Australia

Omid A. Moghadam
Harvard Medical School
Center for Biomedical Informatics

Key Determinants of one's health

Themes

Healthcare has always been an information business, but never to this extent

- Availability of Health data under individual control
- Inexpensive Genotype & Phenotype data
- Next Generation Gene Sequencing and bio informatics tools
- Availability to combine health and environment data
- Personalized Therapies

Evolution of Health Record Architectures

Stalinist

Feudal

Evolution of Health Record Architectures

Confederate

Individual

Why the individual Model?

The history behind the PCHR model of HCIT

- Developed to solve the interoperability issues in the US healthcare system, where business models encourage a lack of interoperability
- It has benefits outside of the US system, it transfers risks to third party and solves the privacy and authentication issue once
- Platform function allows for an App Store style ecosystem to develop
- Replaces a very complex IT problem with a much simpler one

What does a PCHR look like?

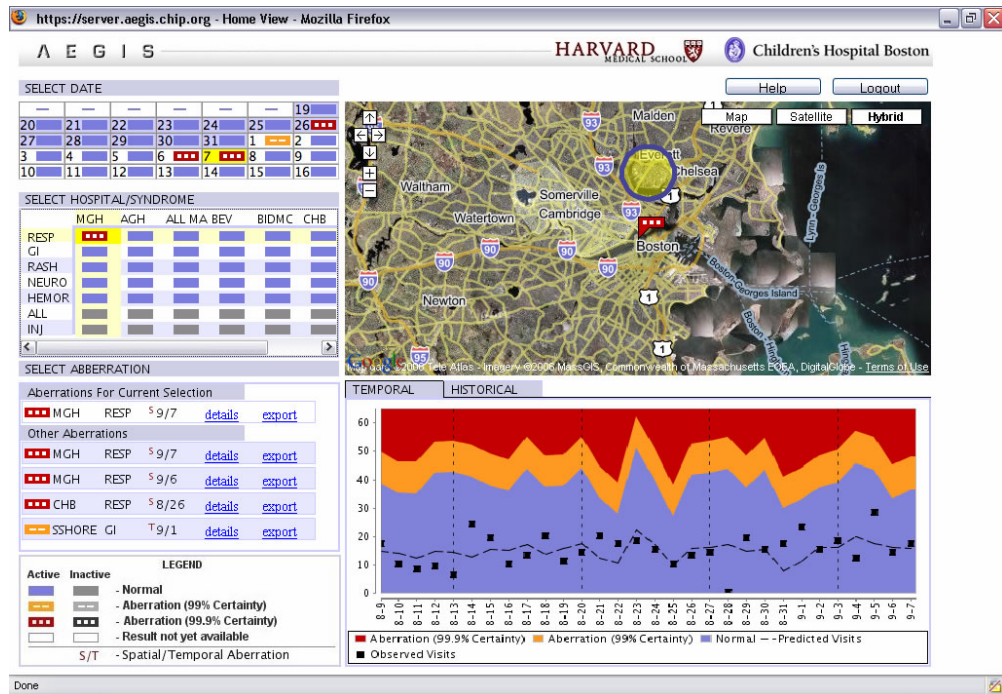

Oh, to be
in
England

Telegraph.co.uk

National database of NHS medical records to be dismantled under Tory plans

The national database of NHS medical records would be dismantled under Tory plans which could see records available online with Google or Microsoft.

Public Health Applications

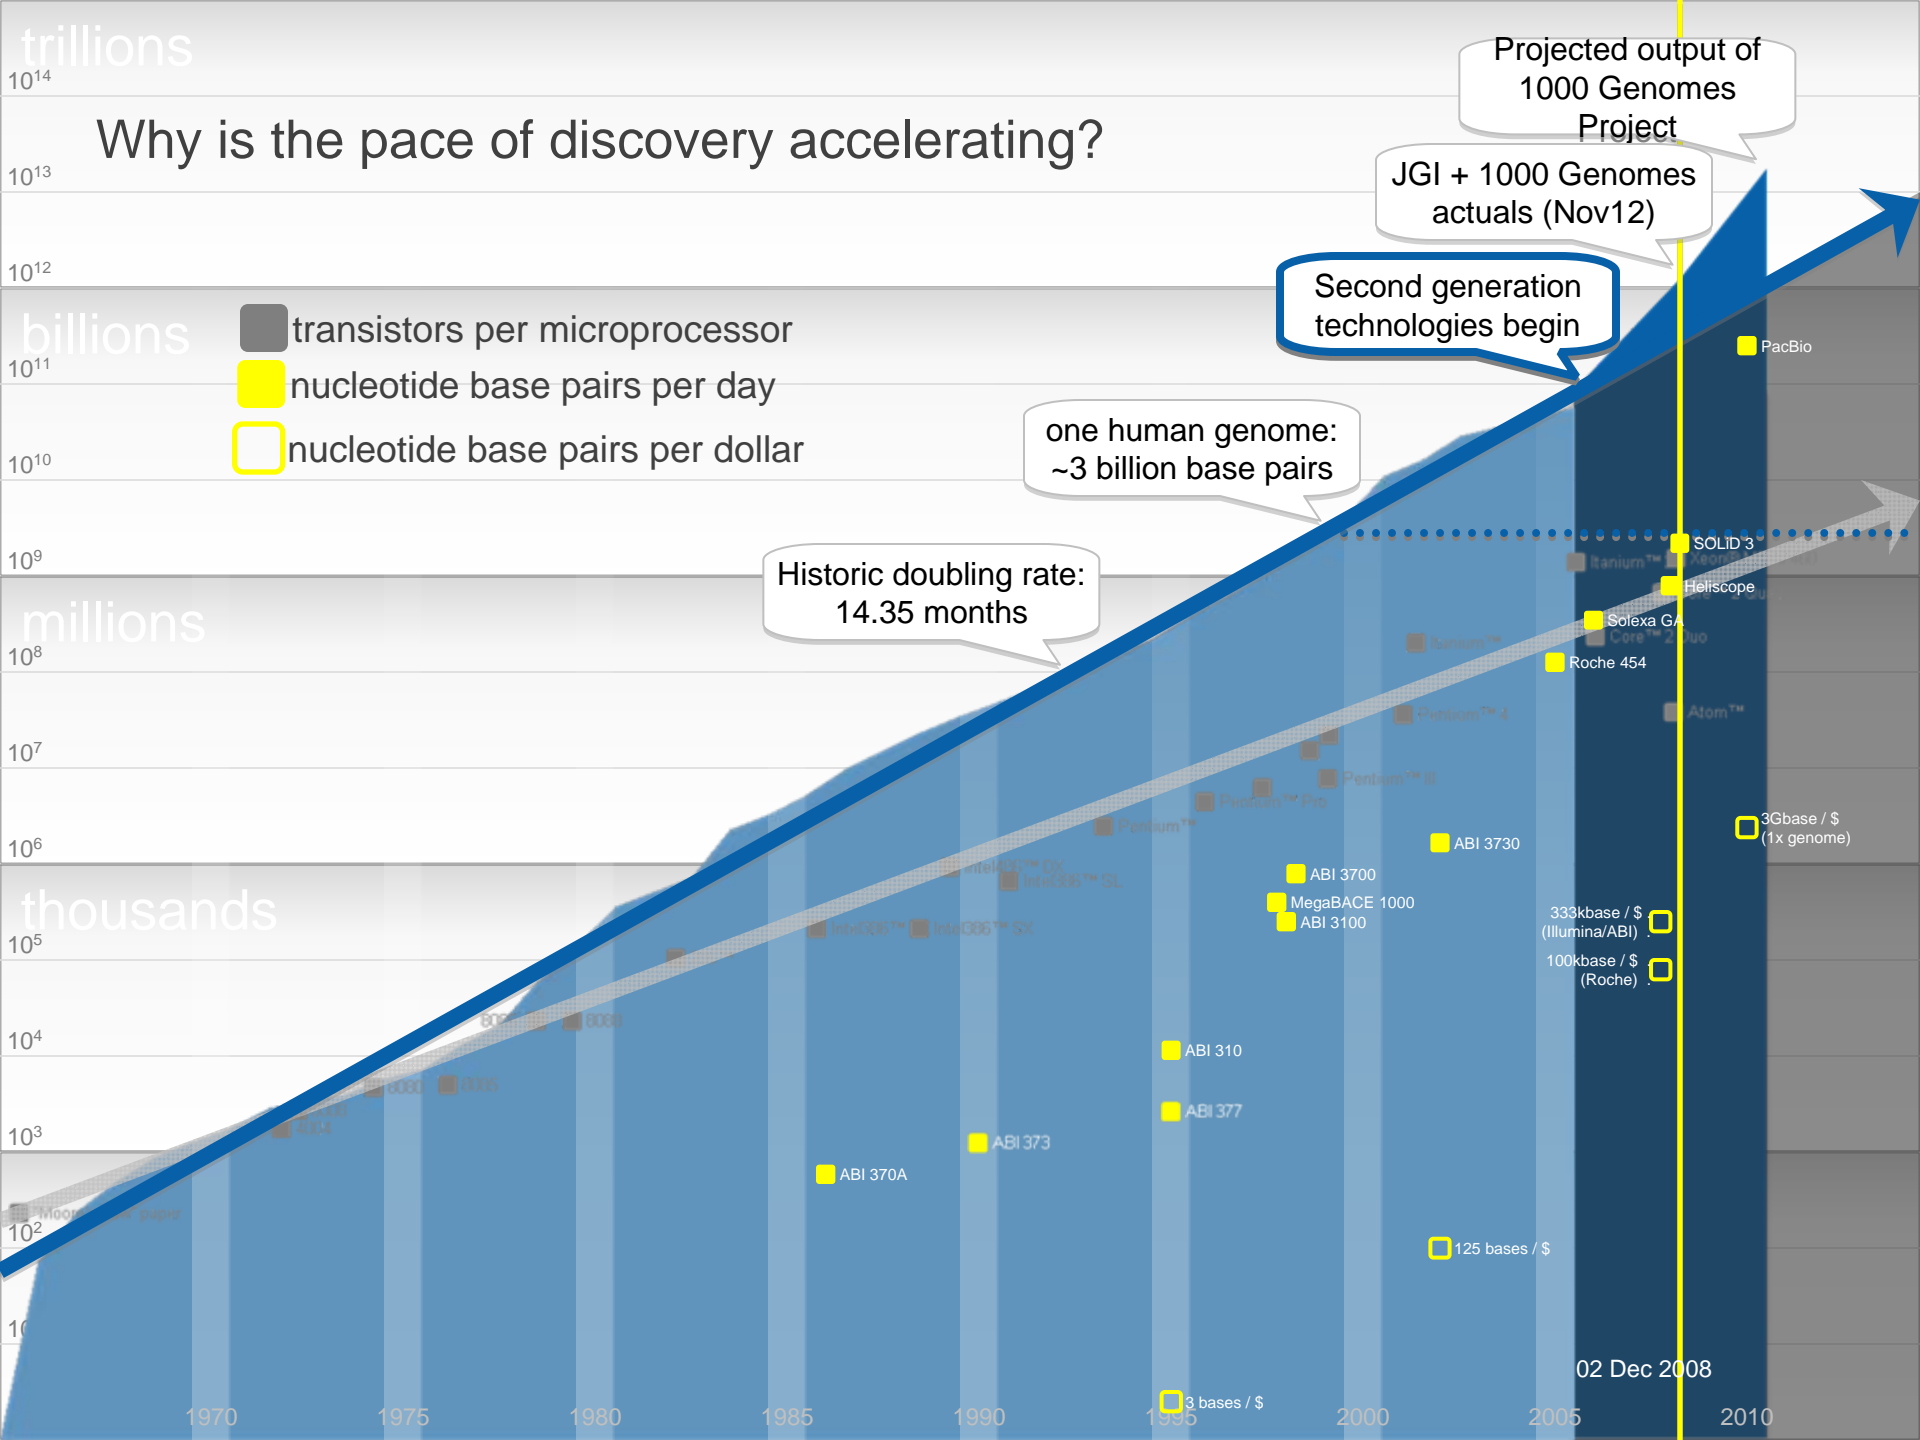

Looking to the future of PCHR, beyond data

- Need for consumer utility, small wins
- Higher rates of Compliance to treatment regiments
- Enable new tools in public health
- Radically transform the economics of clinical research
- Accelerate the pace of pharmacovigilance
- Allow direct participation in medical discoveries to the individual

Rates of discovery are
accelerating

The P

New paradigms in Genomics research

Problems with current approach In Genomic Research

- Focus on monogenic diseases (i.e., just a few diseases)
- Does not leverage new biomedical informatics and genomic technologies
- **Excludes patients from immediate benefit**
 - One-way interaction with participants
 - Knowledge not communicated back to patients in timely fashion
 - Patients are not partners in the research enterprise
- Discovery cycle is slowed
- Utilizes few patients and for a limited time

Gene Partnership Program Approach

- Radically transform the economics of research
- Accelerate the pace of discovery and cure
- Focus on polygenic diseases (i.e., most diseases)
- Leverage leading edge biomedical informatics and genomics technologies
- Reestablish the link between researchers and research subjects, using the “informed cohort” model Engage every patient in the research enterprise, empowering them with cutting edge tools from biomedical informatics and genomics

Monogenic or multigenic

Current research protocols

Effective for those rare diseases caused by a *single gene* defect (monogenic)

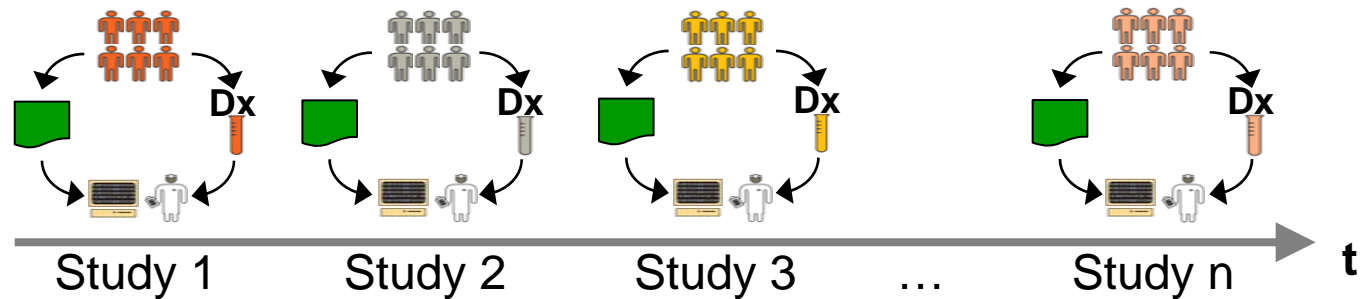

... Decoding genetic—environmental interactions is the next step

Most diseases caused when *multiple genes* (multigenic) interact with multiple triggering factors

Current Research Model

Small number of patients over *limited* duration studies

- Researchers able to get *some* data on *some* of their patients
 - Data is siloed and difficult to share
 - Patient population is too small to correlate genetic data with risk factors

New Paradigm in Research

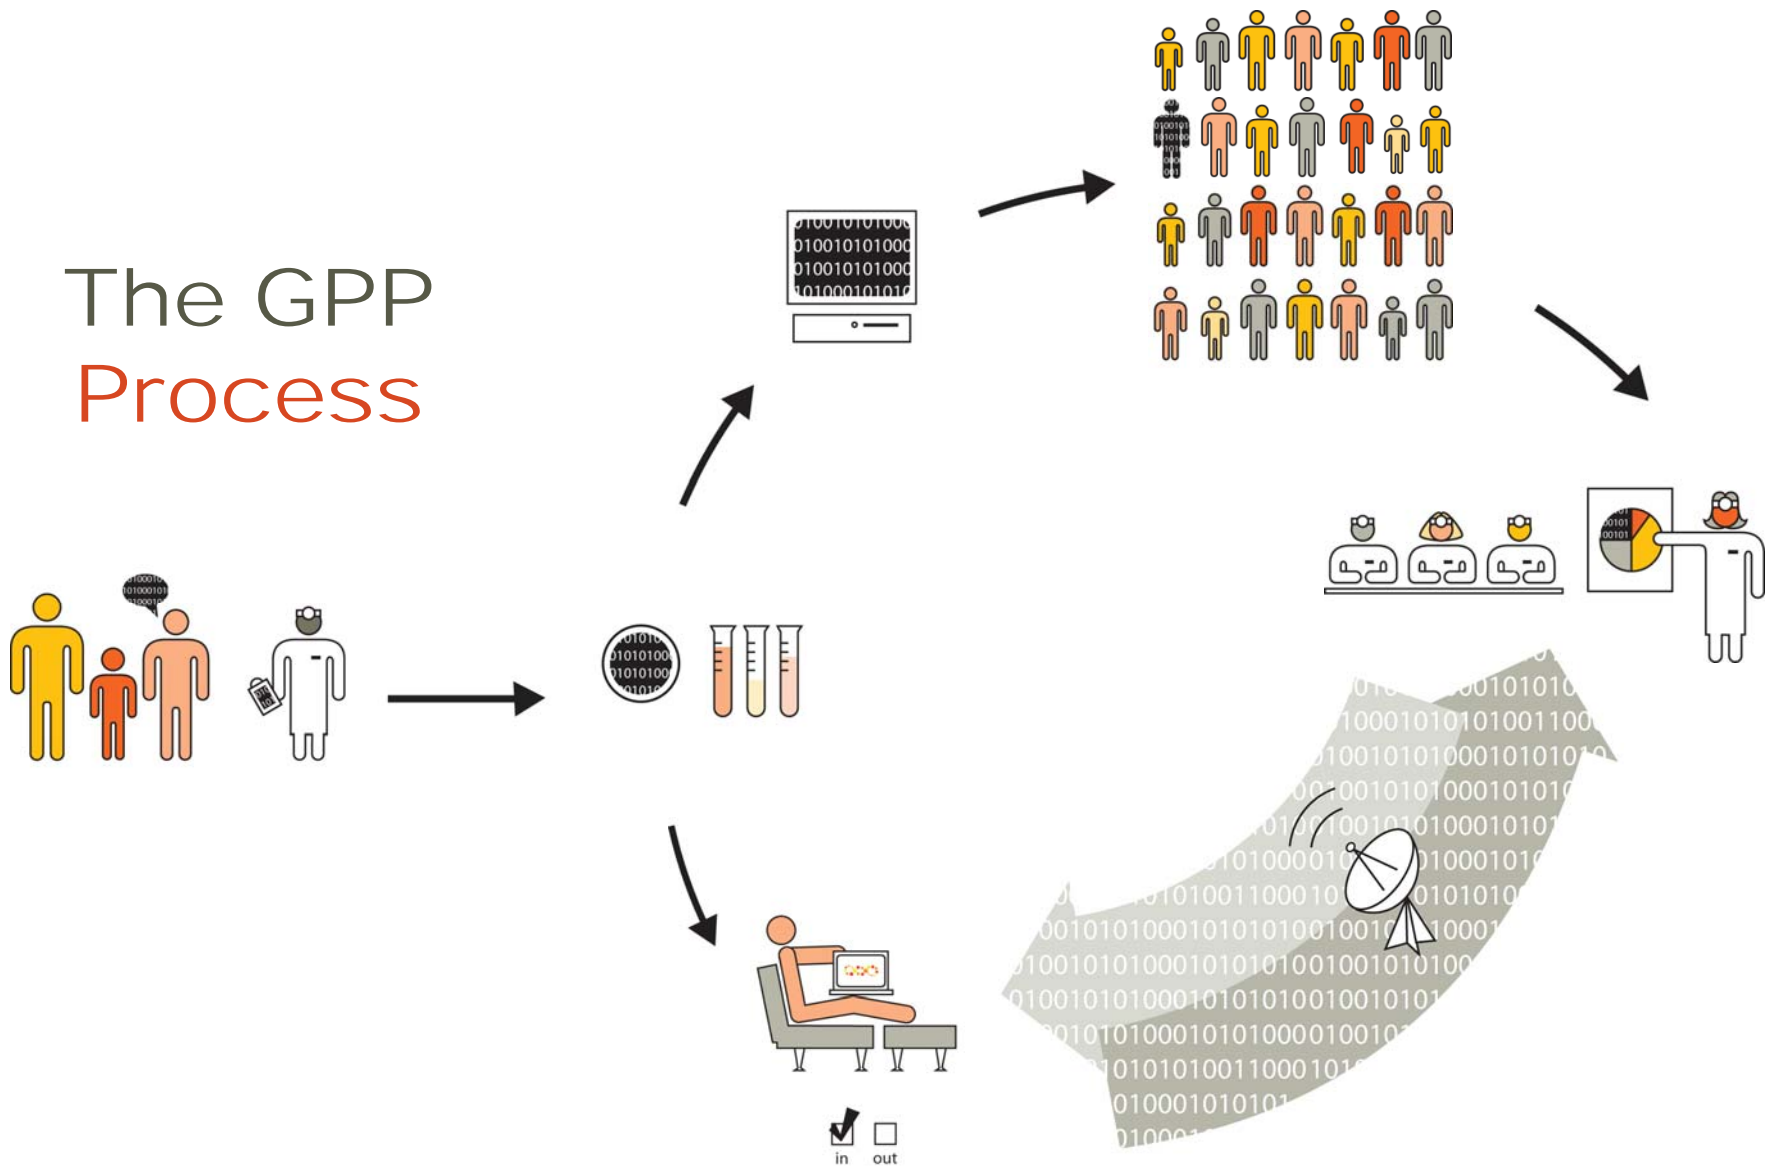

In traditional medical studies concerns over privacy has broken the doctor-patient link, disallowing subsequent communication

- As a result, participants are passive and can't be informed of medically relevant findings

GPP employs a collaborative clinical research regime, the Informed Cohort (IC), establishing a true partnership with patients

- Participants and their families are actively engaged; participants can:
 - receive timely notice of beneficial discoveries – tailored and targeted information relevant to their disease
 - control level of involvement and communication
- Added benefits increase willingness of patients to join the study

The GPP Process

The GPP Approach

Patient meets with a genetic counselor,
decides to enroll

Patients provide blood or saliva specimens for
genetic analysis, and clinical information

Genomic and clinical information is stored in
the patients' PCHR

- Germane study data are stored in an
anonymized research database

When discoveries or important clinical
information becomes available, Children's
Hospital can communicate privately and
anonymously to patients through the PCHR

- Informed Cohort Oversight Board provides
ethical oversight

Patients are linked to clinical care and research
with a PCHR

Children as
the perfect
cohort

Why Kids?

Studying childhood diseases
presents a unique opportunity to:

- Clearly identify phenotypic manifestations of genetic traits
- *Before* environmental impacts overwhelm

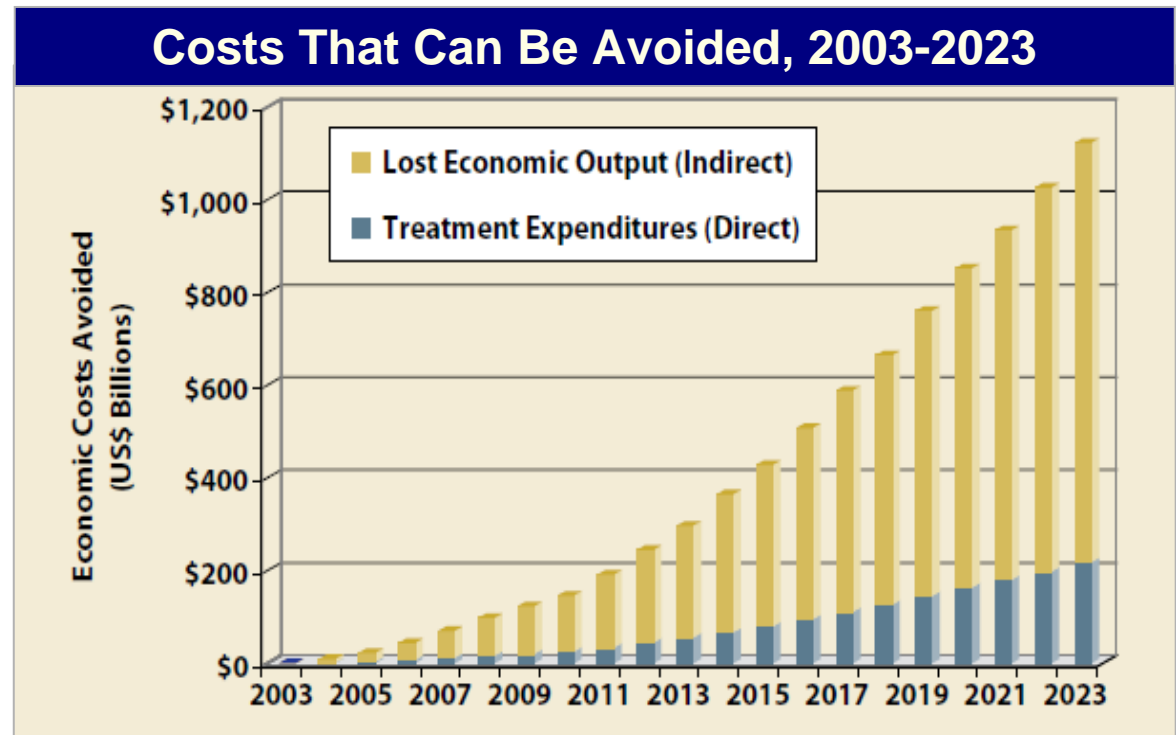

Many adult diseases have highly
predictive childhood antecedents

The Ultimate Prize

Personalized Medicine

A matter of economics

Source: DeVol, R, Bedroussian, A, et al. An Unhealthy America: The Economic Burden of Chronic Disease. The Milken Institute. October 2007.

Personalized Medicine Strategy

Apply a **chronic disease-centric approach** to public health burdens: cardiovascular disease, cancers, neurological disease, metabolic disorders, and pediatrics.

Use molecular scanning technologies to identify at-risk individuals prior to disease symptoms, and to **develop and test therapies** (with **companion diagnostics**, as feasible).

Partner with researchers, clinicians, and companies to accelerate the **translation of new discoveries into product development and then clinical practice**, to prevent or mitigate the onset of disease.

Apply the latest therapies, through an integrated health system, to benefit patients and **speed availability of new, targeted therapies**.

Integrate **health information technology** to enable broad-based clinical decision support for individualized patient management.

Share knowledge that helps to **alleviate or delay the onset of chronic disease** and decrease the time individuals are sick at the end of life.

Example: Alzheimer's

In 'Boomer' Diseases, such as Alzheimer's, Impact and Costs Will Escalate Dramatically Without New Interventions

Adapted from The Lewin Group Report, June 2004, "Saving Lives. Saving Money: Dividends for Americans Investing in Alzheimer Research," The Alzheimer's Association (http://www.alz.org/Resources/FactSheets/Lewin_FullReport1.pdf)

Average cost: USD 230 million

Time to market: 14.8 Years

Current Drug Discovery Methodology

Starting point is about

10,000 compounds

1000 in vitro trial

20 in vivo trial

10 human clinical trials

Genomics information is suppose to be the short cut in this process

Millennium Pharmaceuticals was a case in point, it did not quite work that well

New Process from end to end

identify genes that classify the population into
“high” and “low” risk

built a broad-based genetic testing infrastructure
to classify individuals using repositories of
PCHR

incorporate pointers to recruit “high” risk
individuals into clinical trial

run a series of small trials drawing to develop
primary prevention drugs for AD in the next
decade

educate the authorities (such as FDA in the US)
that targets are robust enough for approval of
drugs without a 30 year prospective trial where
we lose a generation in the process

Role of HCIT

Embed the genome into the HER/PCHR

Allow HIPAA-compliant messaging and interventional distributed trials

Secure and authenticate transactions and data flow

Link clinical information system with a research database that can connect to other HIT systems

Build a flexible clinical decision support module that allows physicians to understand molecularly-guided strategies

Enable a “learning” CDS that constantly refines itself with the data flows to optimize clinical care
