

2019 Book of Accepted Abstracts

ACSP Annual Conference

October 24-27, 2019

Greenville, South Carolina

*This book includes only the abstracts accepted for presentation at the
2019 Annual Conference in Greenville, South Carolina.*

About Our Local Host

By uniting the humanities with the disciplines of design and building and the arts, [Clemson University's College of Architecture, Arts & Humanities](#) (CAAH) offers unique opportunities for exploration and achievement – opportunities that are rigorous and imaginative, classical and innovative.

Our students and faculty see their ideas expressed in many forms – as buildings and landscapes; as the written word; as music and drama; as paintings, pottery, prints and photographs. We work in the very oldest media to the very newest. We work alone, and we work together, seeking not only the visionary answers, but also the enduring questions.

Professors and instructors are directly engaged with students in the classrooms, studios, labs, practice rooms and Creative Inquiry research projects. We value critical and synthetic thinking, creativity, diversity and the life-changing opportunity to achieve one's full potential. Our campus is fluid – encompassing the real and the virtual, off-campus and on, classical and contemporary.

The CAAH Advising Center provides services to help you assess your skills and interests and can assist you in making an informed decision about an academic major.

Find your passion. Find your voice.

Local Host Committee

Chairs

- Caitlin Dyckman, Co-chair, Associate Professor of City and Regional Planning, Clemson University
- Eric Morris, Co-chair, Associate Professor of City and Regional Planning, Clemson University

Members

- James Spencer, Associate Dean for Research, College of Arts, Architecture and Humanities, Clemson University
- John Gaber, Chair of the Department of City Planning and Real Estate Development, Clemson University

Notes about this Book

This book includes only the abstracts accepted for presentation at the 2019 Annual Conference in Greenville, S.C. This book was completed and posted to www.acsp.org on June 18, 2019.

Abstract ID

When submitted to the abstract management system, each abstract was assigned an abstract submission ID number for administrative search/find purposes. This is the number that authors should reference to staff with any questions regarding their abstract, their presentation, or their final paper submission. This number stays with the abstract throughout the process and becomes the ID of the presentation of the research at the conference.

Proposal

Organizers of groups of authors intending to submit as a pre-organized session used the abstract submission system to provide an overview or intent of the session, the name of a proposed discussant, and the authors and paper titles of those confirmed to be part of the session. The system assigned a proposal number to the grouping of these abstracts. This number stays with the session throughout the conference. When scrolling through this book and through each track, you'll find the pre-organized session *proposals*. Each proposal will indicate which of the abstracts in the track belong to that session. After the pre-organized session proposals are all of the numerically ordered accepted abstracts within that track. The abstract will also indicate if it is related to a pre-organized session.

Indexes Available

Separate indexes for Author Name and Keywords reference the Abstract ID #. These indexes can be found at the end of this book.

Order of Abstracts within Each Track

Abstracts are first ordered by the type of abstract.

- 1) Pre-organized Session Summaries – the overview describes the intent of the session and lists the abstract ID numbers for the included abstracts.
- 2) Abstracts for all roundtables, papers and posters sorted numerically by abstract ID.

Order of Authors

The abstract management system used by ACSP allows for author role declaration.

- **For paper and poster abstracts** - Authors of abstracts in this book and in the final program will be indicated as presenting, primary, or co-authors of the paper. The presenting author is always listed first. No more than eight authors for one paper are included.
- **Roundtables** will have a moderator. The remaining names listed are confirmed participants of the discussion. Anyone in the audience can also participate in the discussion. There is a maximum of eight names listed for each roundtable.
- **Pre-organized sessions** will have an organizer and some at the publishing of this book will have a proposed discussant. This proposed discussant has yet to be confirmed, and their participation will be verified prior to the schedule of presentations being created.

Multiple Program Placement Policy

Multiple abstract submissions on behalf of one author will be reviewed and may possibly be accepted and included in this book. However, more than one presentation of a paper and more than one appearance as a roundtable participant during the conference will not be allowed on the final schedule of presentations. It is, however, possible to present both a poster and a paper, if both proposals are accepted.

Participants on the final program will be limited to:

- one presentation of a paper whether in a formed paper session, or involved in a pre-organized paper session;
- one placement on a roundtable;
- one placement as a discussant of a paper session; and
- one placement in the poster session.

These roles are not interchangeable. If you have more than one submitted paper abstract accepted and are invited to participate on more than one accepted roundtable, in fairness to everyone, we will ask you to limit your participation.

Requests for Edits

All abstracts in this book are unedited and published as submitted by the author(s) for peer review. It is the policy of the ACSP that the abstracts will not be edited. This book is edited only for formatting consistency.

If information is missing about an author, it may not have been provided when submitting the abstract. We do understand the importance of names; that paper titles change as time goes on; and authors are added or dropped. In these instances, any necessary changes for the final program should be sent to abstracts@acsp.org. Updates to this book are not made immediately.

Searching this PDF

This document is over 1375 pages long including the Author Index and Key Word Index. In order to find something quickly, copy and paste the titles below in the search box, or use the indexes to search for abstract ID numbers or authors by last name.

To access the search box, use your keyboard Ctrl F.

- Search by Abstract ID: Type the words “Abstract ID: with one space followed by the number. If you try to search for just the number, you’ll likely find it in many of the bibliographical references provided by authors. Sample: Abstract ID: 12
- To scan an entire track, use the word Track followed by a track number 1-15. Sample: Track 14
- To get to the Author Index, search for Author Index
- To search by key word, search for Key Word and then scroll alphabetically.

TRACK 1 – ANALYTICAL METHODS, TECHNOLOGY AND SOCIETY

TRACK 1 – PRE-ORGANIZED SESSION SUMMARIES AND ABSTRACTS FOR THE SESSIONS

PRE-ORGANIZED SESSION - SCENARIOS AND URBAN FUTURES IN PROFESSIONAL PRACTICE

ID: 9

Pre-Organized Session Summary

Session will includes abstracts: 158, 159, 160, 161, 162

Is planning scholarship avoiding the future? Concern with the future has long been an important intellectual focus within the planning field. Although techniques such as forecasting, visioning, and scenarios are widely used by practitioners (Hopkins and Zapata, 2007), recently they have attracted only meager interest among planning researchers and educators. This pre-organized session is one of two sessions featuring scholarship on the problem of engaging the future in planning. Although long-range planning is only one component of professional practice, it carries disproportionate importance to the field's identity and leadership in civic affairs. Collectively the papers in this session speak to how practitioners engage the future, drawing connections to diverse theories of planning education and practice.

Objectives:

- Analyze the relationship between short- and long-term perspectives in planning practice
- Discuss the methods professionals use to engage the future in planning practice

EVALUATING THE PERFORMANCE OF SCENARIO PLANNING METHODS: A COMPARATIVE CASE STUDY

Abstract ID: 158

Group Submission: Scenarios and Urban Futures in Professional Practice

GOODSPEED, Robert [University of Michigan] rgoodspe@umich.edu, presenting author

The proponents of scenario planning have argued the method has many different types of benefits for practitioners, including better decision-making, enhanced collaboration, and improved planning performance (Hopkins and Zapata, 2007). There is a wealth of research, especially in other fields, about the small-scale benefits of scenario planning—especially learning outcomes among project participants (e.g., Knapp et al., 2017). However, there are few studies examining the benefits of scenarios at the scale that matters most to planning practitioners: that of planning processes resulting in plans. Furthermore, empirical studies of the use of scenarios in planning processes have often focused on projects that are relatively atypical of broader professional planning practice, such as complex regional visioning projects (Allred and Chakraborty, 2015). As a result, it is unclear how scenario methods are adapted for different

typical planning contexts. In addition to documenting the benefits, there is a need to clarify which of the many different types of benefits are most relevant to different types of practice. As a result, this paper addresses two research questions: (1) How is scenario planning adapted to different types of plans? and (2) What are the specific benefits of adopting scenario planning to create different types of plans?

Since this research is not yet complete, this abstract will describe the research design but not the specific empirical results that the final paper will contain. One challenge for conducting research on this topic is the need to combine a detailed analysis of processes with the consideration of the many different contextual factors that influence any particular plan, such as the number and types of participants, specific issues or problems to be addressed, and the type of plan being prepared. Consequently, this project will adopt a comparative case study design that compares planning projects that use scenario methodology with otherwise similar projects that do not. Pairs will be selected in three categories of professional practice: long-range transportation plan in a medium-sized MPO region, medium-sized city comprehensive plan, and corridor or district plan. This design is inspired by Ulibarri's (2015) analysis of collaboration in hydropower licensing. The scenario cases are tentatively the Miami Valley (OH) Regional Planning Commission Going Places Initiative, Imagine Madison Comprehensive Plan, and Honolulu TOD Scenarios.

The empirical analysis will be guided by a theoretical framework with two major components. First, collaborative planning theory will provide key process variables, such as the diversity of participants, interdependence of interest and authentic dialog central to the Booher and Innes' DIAD model (Booher and Innes, 2002), complemented by more recent theories of collaborative governance and the use of digital tools. Second, the literature on planning evaluation will guide the exploration of project outcomes. These may include outcomes described by both the performance and conformance paradigms in planning evaluation.

Given the growing nature of uncertainties in planning, scenario planning is attracting growing interest among practitioners. However, adopting the methodology requires translating it to particular planning settings, and the potential benefits of using scenarios remain vaguely defined. Using paired case studies, this paper hope to highlight both the diversity—and benefits—of scenario planning in professional planning practice

ENGAGING FUTURES BY PLANNING PRESENTS: HOW LONG-RANGE PLANNING CAN MATTER TO MARGINALIZED COMMUNITIES

Abstract ID: 159

Group Submission: Scenarios and Urban Futures in Professional Practice

ZAPATA, Marisa [Portland State University] mazapata@pdx.edu, presenting author

Long range planning envisions ways futures could unfold decades later. Such planning, often done through comprehensive planning processes, brings together a range of data analyses and forecasts with community knowledge to identify preferred futures and priorities. Yet our futures planning efforts include many failures to meaningfully predict the future. Which city planner foresaw the great recession, forecasted a significant housing market down turn, or foretold a growing homelessness crisis across the west coast?

While planning scholars have emphasized the importance of relying on multiple forecasts (Moore 2007), scenario planning with multiple futures (Zapata & Kaza 2015), and building adaptive management and governance (Hetz & Bruns 2014) to address our less than ideal record in predictive power, I argue our futures planning failures point out our unrootedness in the most pronounced and entrenched present-day issues in our communities – racism and poverty. Planning struggles to engage our futures not because we lack future imagination or technical savvy, but because we continue to ignore how poverty and economic inequity along with structural, institutional, and interpersonal racism will forever drive our futures until we directly, and dramatically, intervene in them. Should planners want to be relevant in long range futures planning for our communities, I argue that we must better root our imagined futures in the reality of our presents.

In this paper I critically reflection (Knapp 2018) on my experiences as a community based researcher and advocate (Siemiatycki 2012). Starting my research career as a long-range planner, I now find myself as a co-founder to and the founding director of a university-wide homelessness research center in Portland, Oregon. Homelessness functions as the inverse of futures planning as one of the least preferred situations we envision in for our future utopias, and one of the most dramatic indicators of present day societal failure. I lead research on many of the issues that serve as chapters for comprehensive plans: community participation, infrastructure, natural resource management, economic development, community health, etc. But our center's research agenda focuses on what we can do today, tomorrow, and five years from now.

At the same time, we do not believe in incrementalism, and are guided by future visions that we can have a society that no longer produces or perpetuates such dramatic rates of homelessness. To do this, we are identifying core policies and programs that must be adopted, repealed, or modified in our local and state policy environment. We center on the unique way that race functions within homelessness, and are building a long range plan for 20 years out that focuses on addressing structural and institutional barriers that limit futures for people of color and people from low income background. Long range planner means I see the vast network of interconnected wicked problems touching homelessness. Bringing that thinking and rooting it to the deep understanding that social service providers, short-term policy makers, and people who have experienced as homeless have about yesterday and today, brings the present to future and future to the present. This approach to long-range planning rejects an emphasis on future uncertainty, and instead embraces the known reality that as long as we continue to weakly engage social justice, our plans will fail to achieve the radicalness necessary for real change. I believe this work demonstrates that by focusing on marginalized communities, and building towards the futures that matter to them, we can engage futures in the ways that planners once envisioned.

TEACHING ABOUT THE FUTURE OF CITIES

Abstract ID: 160

Group Submission: Scenarios and Urban Futures in Professional Practice

SANCHEZ, Thomas [Virginia Tech] tom.sanchez@vt.edu, presenting author

GEBSSELASSIE, Mahtot [Virginia Tech] gmahtot@vt.edu, co-author

The lack of scholarship regarding the future extends into planning curricula. Oddly enough, urban planning schools rarely offer courses explicitly about the future of urbanization and city form even though the essence of planning is future-oriented. In the past year while developing such a course at Virginia Tech, we found very few examples of university level courses on this topic. In fact, most of the examples we found in our search were from disciplines outside of urban planning, none of which having a focus on planning activities or perspectives. We posit that one of the ways in which the planning field at the present moment can engage the future is through the education of the next generation of planners. Such a course provides a platform for the young generation to be part of the conversation about the future, in essence their future. Incorporating in their education how the future is thought of prioritizes their voices and gives them the rights and responsibilities to conceive a better one. It also equips them with perspectives to influence it and inspires them to develop critical approaches to trends, such as technology, that are on a trajectory of shaping it. Our paper discusses our experience with both developing and offering the course for the first time at our university in Spring 2019. The first part of the paper focuses on the process of developing the course. We review course syllabi that we collected to identify topics that were included most often in the content, readings, and student activities. We also examined the course reference list to understand whether there were formats (e.g. books, films) and authors that recurred in the collected syllabi. The second part of our paper discusses how we approached the structure and content of our course in a way that relates the past, present, and future in social, economic, environmental, technological, and global dimensions. We also share the novel methods used in collecting a reference list, and present the various technology platforms used for the course which we believe will be part of the future classroom. In this part of the paper, we summarize feedback received from students both during and after the course; we also highlight lessons learned. The course addresses theoretical questions on the

conceptions of the future of cities. We believe that our experience is useful for other planning academics that are considering offering a course about the future of cities.

ASSUMPTIONS IN/OF PLANNING ABOUT URBAN FUTURES IN A MEDIATIZED WORLD

Abstract ID: 161

Group Submission: Scenarios and Urban Futures in Professional Practice

MENNATULLAH, Hendawy [TU-Berlin] mennatullah.hendawy@campus.tu-berlin.de, presenting author

In countries with authoritarian top-down planning and state-owned media, the popular media's image of the city hardly represents the majority of citizens' everyday city experiences or perceptions of their future. This misrepresentation of urban conditions in media on one side creates processes of visibility and invisibility for the city, and on the other, effects and facilitates marginalization, disablement as well as socio-spatial injustices and the exclusion of vulnerable groups from services and infrastructure. In Egypt, these vulnerable groups form the majority of the population.

In the current time of "post-normal science" (Funtowicz and Ravetz (1994)) that is highly mediatized (Hjarvard, 2008) (Krotz, 2007), the position of media and visualizations in constructing and communicating planning as well as in structuring power is questioned. Using Egypt as the empirical setting for this investigation, this paper focuses on how planners are educated/reinforced to visualize (certain) urban futures in order to keep (certain) political and economic agendas and ruling bodies in operation. This is done in an attempt to understand how are conversations about the future, affect and are affected by the utopian and dystopian themes in current cultural narratives. Accordingly, this paper aims to identify the assumptions of/in planning about urban futures.

This is investigated through a qualitative research methodology involving interviews with planning professors and practitioners. In addition, content analysis of planning education curriculum as a medium which constructs the theatrical and conceptual background of future planners.

A LONG GROUNDWORK FOR RECONFIGURING THE FUTURE: TELECOMMUTING ADVOCACY AS A CASE OF STRATEGIC NICHE MANAGEMENT

Abstract ID: 162

Group Submission: Scenarios and Urban Futures in Professional Practice

STILES, Jonathan [Rutgers University] jonathan.stiles@rutgers.edu, presenting author

The questions of how societal practices change over time in relation to technology, and the extent to which our actions can guide this change towards more beneficial outcomes are fundamental to the discipline of planning. Broadly defined, the aim of planning is to “relate scientific and technical knowledge to actions in the public domain” (Friedmann 1987). Yet the technical knowledge that planners apply does not simply consist of tools for analyzing, mapping, or modeling. It also includes judgments about new technologies in the context of society, be it new forms of transportation, communication, energy production, coastal resilience and others. Planners well understand that notions of simple substitution of one technology for a more sustainable or just alternative belie the complexity of the comingling of politics, technologies, and nature they confront on a daily basis. Furthermore, planners don’t just consider technologies in the present; they also guide them towards alternative futures, such as convincing through storytelling (Throgmorton 1992). In this paper I present an historical case study of three decades of telecommuting advocacy in which planning sought to guide society towards an alternative future of transportation. In doing so, I adopt a theoretical framework of sociotechnical transition wherein the management of change within complex sociotechnical systems is realized by the application of long-term thinking to guide short-term decisions (Rotmans et al. 2001). Planners are sociotechnical natives, and I argue that a sociotechnical system perspective is appropriate for considering the future orientation of planning in regards to technological change.

To explore telecommuting advocacy I conduct an historical analysis of primary and secondary sources. The notion of “telecommuting” emerged in the early 1970s as a strategy to confront societal problems related to the journey between home and workplace (Nilles et al. 1976). Automobile traffic and its relationship with land use had become a central concern of regional planning in the United States by 1970, particularly in its connection to challenges of roads congestion and air quality. This paper frames the decades-long efforts of its advocates to advance the notion of telecommuting as an example of strategic niche management, in which technological innovations are managed in the long term to help engender a beneficial change within a sociotechnical system. This promotion of telecommuting in its first three decades shows fundamental elements of strategic niche management as defined by Schot and Geels (2008): a vision and expectations, learning processes, and social networks among advocates, while providing protected spaces for the practice of telecommuting.

After an introduction of strategic niche management and the multi-level perspective on system change, I describe the origins of the notion of telecommuting in Los Angeles, California. The next sections review how trip reduction and travel demand management policies opened up protected spaces for telecommuting and other related innovations, and how public agencies were early experimenters with telecommuting. A subsequent section looks at how the evaluation of pilot programs formed a shared learning process that informed telecommuting advocacy, and gives examples of advocacy in the 1990s, such as guides and events used to promote the wider adoption of telecommuting among firms. Finally, in the conclusion I consider the outcomes of telecommuting advocacy as strategic niche management, using four pathways of sociotechnical system change, finding that it laid a groundwork for a reconfiguration, but in part due to a weakening of the environmental vision of telecommuting, its sustainability benefits are limited, and the ultimate outcome depends on factors beyond the control of its advocates.

STORYTELLING, VISIONS, AND IMAGINARIES OF FUTURITY

ID: 13

Pre-Organized Session Summary

Includes abstracts: 165, 166, 167,

One could argue that the fortunes of communities depend on the co-creation of shared visions of the future. Yet, shared visions are hard to achieve and could be undesirable. Globally, slick visions of progress remake the image of the city into one that embraces technology to become ‘smart’ (Watson, 2015). Scholars in the social sciences and the humanities have documented how people think about the future as a key dimension of culture and also of the exercise of power (Appandurai, 2013). The development of rival futures can challenge essentializing and technocratic narratives. Dobraszczyk (2017) has argued that climate change adaptation requires the application of utopian and dystopian imagery in fiction, visual art, and renderings. He proposes that these open up “ways of thinking through the range of possibilities... in a world radically transformed (Dobraszczyk, 2017, p 868).” How does one draw the line between creativity and manipulation? This session, one of two focused on engaging the future, opens a dialog about the craft of urban imaginaries and planning practice and scholarship.

Objectives:

- This session seeks to open a critical dialog about orientations toward the future and the meaning of these orientations for social equity.
- Participants will learn about theories from Critical Indigenous Studies, Queer and Black urban theories, among other theories of futurity.
- Participants will learn about the importance of storytelling and urban imaginaries to planning scholarship, practice, and pedagogy.

CONSTELLATING WITH KIN AND URBAN FUTURITY: ASKING THE RIGHT QUESTIONS

Abstract ID: 165

Group Submission: Storytelling, Visions, and Imaginaries of Futurity

HARJO, Laura [The University of New Mexico] harjo@unm.edu, presenting author

Indigenous people make up 370 million of the world's population, yet still do not have the platform to articulate their formidable knowledge in shaping the future of the city. (Worldbank, 2018) The prevailing literature is the so-called expert outsider looking in, at what is best for Indigenous peoples, and is not sufficient for including Indigenous peoples in shaping Urban Futures. However, Indigenous planning scholars have grappled with community and temporality, for example, seven generation planning, walking backwards into the future, speculating futures (Harjo, 2012, Jojola, 2013, Matunga, 2013, Dorries, 2016) We need approaches theorized from Indigenous peoples' lived experiences by Indigenous peoples but even before taking that step, we need to ask the right questions about futures, time and the gaps that planners can detail and solve.

While there is a dearth of research on futurity in the planning field, Critical Indigenous Studies is rife with futurist inquiry and scholars, such as Grace Dillon, Elizabeth LaPensée, Eve Tuck, and Goodyear-Ka'ōpua are addressing futurity in literature, technology, and community engagement. By expanding on these initial inquiries, I discuss the role of futurist thinking but consider it within the context of kin-space-time. (Harjo, 2019) I move away from a linear order of past/present/future and train its focus on our kinship relationships. In this way, I move toward a framework for understanding how community operates socially, spatially, temporally, and cast this as kin-space-time. We are always in a present temporality, held in the interstice between past, and future; however, we are guided by ethical, and cultural responsibilities to kin who inhabit many temporalities. Inch argues that communities lament that they sit and plan and are told "not yet," the contribution of my work is to show how communities are living out the unactivated possibilities of their ancestors right now—they are living out old futures—which is a form of futurity. (Inch and Crookes, 2016; Lothian, 2018; Harjo, 2019)

LOCATING URBAN IMAGINARIES ON A JUST CITY

Abstract ID: 166

Group Submission: Storytelling, Visions, and Imaginaries of Futurity

TARU, Taru [University of Michigan, Ann Arbor] tarutaru@umich.edu, presenting author
BORSELLINO, Michael [Taubman College, The University of Michigan] mborsel@umich.edu, co-author

Planning practitioners are constantly reimagining our urban futures. Their images depict advancing technological processes, capital investment, and visions of affluence. This process of technocratic visioning creates narrative roles that shape belief and desire. The priority placed on and represented by aspirational aesthetics subordinates issues of justice and citizenship amongst existing residents. Representations function as agents with verdictive authority. Wielding that authority, they are directive signals to a network of decentralized actors to build and design uniform “ideal” cities with whatever means necessary. Critical examination of planning tools that imagine futurities may allow us to rethink questions of equity and diversity in planning practice. We focus on the homogeneity of the produced “future” aesthetic, broadly acceptable and non-confrontational. This aesthetic reflects middle- and upper-class sensibilities derived from a cosmopolitan framework. Planning theorists must be engaged with these processes of image creation. They must understand the problems created by imagining monolithic future cities. Images are imbued with power and knowledge, force and implication; they are inherently political.

This paper examines image production and its impacts in two bifurcated cities that have been actively and aggressively reinventing themselves over the past decade. Detroit and Delhi publish their aspirational futures as worlding cities, aiming to attract capital in an effort to erase their histories of degradation. As Delhi prepared itself for the Commonwealth Games, the emphasis was placed on become a world-class city. This was reflected in the city’s Master Plan and its urgent desire to become “slum-free”. The political and media narratives influenced the everyday image and understanding of the city on a world stage, causing citizens to understand themselves within this new paradigm. Once a pro-poor city, Delhi reclassified slums as a “nuisance”, actively seeking to erase or displace them. Detroit has taken an alternative approach, abandoning some areas while indiscriminately leveraging federal funds to demolish vacant housing in “savable” neighborhoods. Signaling that it is ripe for investment and development, new infrastructure was created to support the growing Downtown Detroit and Woodward Corridor while the rest of the city remains isolated from these new networks. This all happened in the wake of Detroit’s 2013 municipal bankruptcy stemming from the mortgage collapse. Both cities employ aesthetic to criminalize and subordinate “the other.”

Appadurai invokes a hopeful futurity, emphasizing on a need for multiple visions of future, integrating culture and voice to the capacity to aspire. Using the conjunctural cases of Delhi and Detroit, this paper examines the effects of non-critical imagery of futurity on the urban present. Further, it seeks alternatives to this limited way of exploring urban futurities. Further, it seeks inspiration from the imagery used by the grassroots counter-narratives from these two cities to imagine alternative futurities, embracing multiple ways of being and a varied cultural ethos.

STORYTELLING, CITY CRAFTING, AND THE FUTURE OF AMERICAN CITIES

Abstract ID: 167

Group Submission: Storytelling, Visions, and Imaginaries of Futurity

THROGMORTON, James [The University of Iowa] james-throgmorton@uiowa.edu, presenting author

In *Inventing Future Cities*, Michael Batty (2018) claims the future of cities cannot be predicted or formally planned; their futures will be invented and evolve from the present. I agree. However, Batty disregards or dramatically understates the ways in which diverse political actors can influence how cities evolve, the social dimension of cities, and the potential effects of climate change and mass extinction. Drawing partly upon my past ~8 years as an elected member of the City Council of Iowa City, Iowa (USA), ~4 of them as mayor, I argue in this paper that cities are “problems in organized complexity” (Jacobs 1961) which unfold (Alexander 2002-2004), and that the unfolding can be, and is being, invented step-by-step by through a process of co-crafting. Multiple actors (elected officials, professional staff, business people, nongovernmental organizations, and others) inter-act on a complexly interwoven mix of topics, and their actions take place step by step in an ever-shifting context, with each actor’s steps affecting other actors who respond in terms of their own interests, values, and stories. All of these actions produce effects that bleed across territorial and functional boundaries, escape the control of the initiating actors, and ultimately cause the city itself to unfold. Hurricanes, tornadoes, floods, droughts, flu viruses, earthquakes, forest fires, and other “actants” (Latour 2004) also play crucial roles in shaping this unfolding. The extraordinary complexity of cities and city crafting inevitably means that actions generate unpredictable consequences, which in turn produce what Rittel and Webber (1973) termed “wicked problems.” If this is the case, then planning theorists need to know a lot more about how elected officials affect that unfolding and about how stories and storytelling work. First, stories emerge to an important degree from action itself; when something happens, people tell stories about it, and these stories circulate in webs of relationships which involve both face-to-face interactions (which are deeply influenced by the spatial distribution of people by race, class and other key socioeconomic markers) and virtual interactions at the global scale via the Internet and social media. Second, many tales coalesce into and express locally-grounded versions of “common urban narratives” (Finnegan 1998). Shaped by their “situated imaginations” (Andrews 2015), tellers of common urban narratives are inclined to imagine futures that are consistent with their pasts, and they expect others to act in the future as they think those others have acted before. Third, one can craft stories that are intended to persuade. I distinguish between naïve, intentionally manipulative, and ethically sound forms of persuasive storytelling. In brief, specific actors – who change over time as individuals come and go – use stories and storytelling to influence the action of others and thereby co-craft a city’s unfolding future, with some storytellers getting prime-time attention and others being marginalized or trivialized or worse.

FUTURE-DISORIENTED AND PUNK PLACEMAKING

Abstract ID: 284

Group Submission: Storytelling, Visions, and Imaginaries of Futurity

GELBARD, Sarah [McGill School of Urban Planning] sarah@gelbard.ca, presenting author

“We shall define planning as future-oriented, public decision-making directed toward attaining specific goals.” (Fainstein & Fainstein 1971)

For decades, marxist, feminist, indigenous, and black scholars have offered critical deconstruction of the different expressions of democracy and rationality in planning and the ways they privilege capitalist, patriarchal, settler-colonial, Western interests. They have challenged the desire for justice, order, and efficiency—recognizing that these are hegemonic constructs supported by institutions that have historically and continue to exclude and burden marginalized groups. Far less attention has been focused on targeting and challenging the third defining criteria of planning, its future-orientation. When pursued uncritically, this future-orientation similarly risks reproducing hegemonic forms of oppression and exclusion. One potential dimension through which to consider why and how marginalized groups are excluded from planning is through their alternative temporalities, including the negation of future. What is the future planning plans for and who is the public planning plans for? What power does planning have to shape the public by planning towards a specific future? How do non-conforming and marginalized groups resist the normalizing forces of the future public and of a public future?

This paper draws on other theories of futurity, including queer and black futurities (Edelman 2004, Munoz 2006), and applies them to a critical auto-ethnography of the Ottawa punk scene. Punk is one of the many excluded marginalized and alternative urban groups who struggle to “make do” and make space for spatio-cultural codes that do not conform to mainstream normative values and expectations. Among its many subversions, transgressions, and denials, punk refuses to conform to normative future-oriented imperatives of life and death; and therefore refuses to conform to the ways in which future influences the social constructs of home, family, culture, and identity. I argue that this “radical negativity” of punk as sub/counterculture also has profound implications on how and why punks make place for themselves. Furthermore, punk is a subculture that arguably emerged from, and was shaped by and against, modernist utopian dreams of urban renewal and the “nameless housing estates” turned “slums-in-the-abstract” (Hebdige 1979), i.e. from a particular planning future. Hebdige argues that the generation of disenfranchised youth raised in this imaginary-future-made-present, that offered them no real future, were denied a sense of place. In return, punks were simultaneously able to deny and re-construct mainstream narrative of place and belonging in their own image.

This paper seeks to critically theorize future as a fractured and contested social construct. It further warns against imagined progressively ideal future that are disconnected from the actually existing day-to-day realities of the present, and deny continuity with the past. For planning to engage critically with the future, it must acknowledge the multiplicities of past, present, and future. This temporal rather than spatial dimension of exclusion might force planning to confront its privileging of future and those who position themselves relative to its particular future imaginary—a future which almost always reproduces the status quo. Building on the argument of Chantal Mouffe (2013), I argue that “radical negativity,” such as that expressed in punk placemaking, is able to de-code and re-code the desirability of space and may provide spaces of at least temporary resistance to forces such as gentrification, and challenge ideas of development and/as progress. Radical negativity of future-orientation might lead planning to better consider radically different futures.

BAILEY, Allison [University of North Georgia] allison.bailey@ung.edu

DRUMMOND, William [Georgia Institute of Technology] bill.drummond@design.gatech.edu

The geo-spatial sciences, including geographic information science, cartography, remote sensing, spatial analysis, and the emergent discipline of urban informatics carry with them a distinctive set of academic and professional demands. Each discipline can be computationally intensive; rely on digital technologies to allow users to organize information, analyze data, and reach conclusions; and require some degree of spatial cognitive skills and an understanding of geographical perspectives to be able to structure problems and interpret the results.

All planning scholars and educators who specialize in the geo-spatial sciences as a primary area of specialization face significant challenges as they advance their career – often, their work is seen as technical or methodological, requiring them to specialize in a recognizable substantive disciplinary area, in addition to their own area of research specialization. These and other challenges are compounded for women in academia. The academic community of women geo-spatial scientists is much smaller when compared to other STEM disciplines and there are fewer opportunities for mentoring and leadership development. Additionally, the concerns of female geo-spatial scientists has not been the subject of research, nor has substantial attention been paid towards their professional development, when compared with other STEM fields. In this roundtable, we will discuss the opportunities and challenges that female geo-spatial scientists face while pursuing research/academic careers. We will report out results of our on-

going research (the TRELIS project) funded by the National Science Foundation. We will describe examples and case studies of best practices to develop leadership and mentoring networks to support female scientists. We will also explore future needs, the role of professional associations like the ACSP to support these cohorts, and to discuss the collective impacts on planning research, education, and practice.

SPATIAL PLANNING AND FISCAL IMPACT ANALYSIS: A TOOLKIT FOR EXISTING AND PROPOSED LAND USE

Abstract ID: 20

Individual Paper Submission

TOMASELLI, Linda [NWFSC] Ltomaselli@earthlink.net, presenting author

This presentation will summarize the process of developing and using a detailed parcel level database for spatial planning and fiscal impact analysis, as laid out in the book *Spatial Planning and Fiscal Impact Analysis: A Toolkit for Existing and Proposed Land Use*, by Dr. Linda Tomaselli. The book was published in February, 2019 by Routledge, a division of Taylor and Francis (London).

1. The spatial concept: all revenues and expenditures are a function of land use at the parcel level.
2. Previous non-spatial methods can be very inaccurate.
3. The analysis is based on actual revenues and expenditures for the most recent fiscal year.
4. Multipliers are developed by identifying measurable factors at the parcel level of things like police and fire/EMS calls, locally maintained road frontage, population, employment, assessed and building market value.

5. Each parcel's revenues and expenditures are calculated, and then summarized by detailed land use categories and/or neighborhoods that can in turn be used to project future fiscal impacts, or identify areas of the city that are in need of redevelopment, and can be the basis for establishing tax increment financing (TIF) districts.

6. Detailed appendices describe:

- A. Establishing a database for address matching to parcels.
- B. Address matching police and fire calls to parcels and allocating street calls to adjacent parcels.
- C. Reconciling census block data and assessor's housing unit counts.
- D. Estimating total as well as adult and school age population at the parcel level.
- E. Using ArcGIS Model Builder to automate and document the calculations.

The book provides detailed results of projects that have been conducted in Minnesota and Illinois, and also demonstrates how the method is easily transferable to other cities in the US. The project for Bloomington, Illinois, conducted in 2015, and the book provides the step by step description of how the method was applied. To see the final report for Bloomington, visit www.Bloomington-Fiscal-Impact.com.

The method requires substantial time and resources to apply, but much of the work involves creating what can be described as "information infrastructure" that will be usable for ongoing analysis in future years. Therefore, it outlines how planners, economic development directors, finance directors, and decision-makers can build upon the parcel level data. To see the final report for Bloomington, visit www.Bloomington-Fiscal-Impact.com.

This method was identified in the 1980's, and supported by a substantial grant from the National Science Foundation (NSF). The author wrote her PhD dissertation on the subject. However, the method was before it's time because cities did not have the data, trained staff or computer software to efficiently use it. By the late 2000's, things had changed, and several successful projects have been conducted.

IMPLICATIONS FOR THE GEOGRAPHY OF URBAN FOOD RETAIL WITH INCREASES IN E-GROCERY SERVICE ADOPTION

Abstract ID: 37

Individual Paper Submission

WIDENER, Michael [University of Toronto] michael.widener@utoronto.ca, presenting author
STURROCK, Shelby [University of Toronto] shelby.sturrock@mail.utoronto.ca, co-author
FARBER, Steven [University of Toronto] steven.farber@utoronto.ca, co-author
SHARECK, Martine [University of Toronto] martine.shareck@utoronto.ca, co-author

For much of the past century in western countries, the basic procedure for acquiring groceries remained unchanged. While there are many differences in the frequency of shopping trips, product preferences and diets, and food retail design and geography, a majority of grocery shoppers make a specific trip to one or more food retailers, pick out food items on their own, purchase these items, and return home. In August of 2017, the internet commerce giant Amazon.com, Inc. acquired the supermarket chain Whole Foods Market, signalling the potential for dramatic changes in the food retailing industry (Baskin and Olszyk, 2018). While grocery deliver services have been around in urban regions for decades (Newcomer and Perkins, 1939), and various grocery delivery internet start-ups have appeared after wide-scale adoption of the world wide web, Amazon's distribution network and widely used online retail portal have many media outlets reporting that online ordering and home delivery of groceries (known as e-groceries) could be commonplace in the near future.

There have been numerous studies and reports exploring the distribution and transportation logistics of implementing an effective and profitable e-grocery service (Punakivi and Saranen, 2001). These challenges are non-trivial, and range from shifting consumer preferences and trust to ensuring groceries are delivered in a timely manner, to a potentially massive consumer base (after all, we all have to eat). Despite this attention, to this point the authors have not identified any research examining the impact of a large scale shift to e-grocery shopping on the geography of the food retail environment. If demand for supermarkets and other food retailers decreases, especially amongst populations more willing to adopt e-grocery shopping early, there could be important implications for spatial access to food retail in urban regions in the short to medium term, as markets adjust to this disruptive shift.

In this study, a model is presented that explores what impact various levels of adoption of e-grocery services will have on brick and mortar grocery retailers, and how this shift will affect the access to food retailers for those not using e-grocers. Given the current higher costs of using e-grocery services, adoption of e-grocery services is assumed to be higher amongst high-income populations. Using data provided by a consumer research company and an iterative modelling approach, changes in spatial access to food retailers is measured for all populations in the large city of Toronto, Canada. Special attention is paid to lower-income populations, which are more price-sensitive when it comes to purchasing food.

Autonomous vehicle (AV) technologies are expected to reshape travel behavior by enabling various uses of travel time. Interests regarding how AVs will impact mobility and the subsequent broader social impacts are growing. However, few studies have investigated individuals' likely in-vehicle activities during AV travel and how this may impact welfare gains for different social groups. To address this gap, researchers designed a stated choice experiment to explore potential in-vehicle activities by individuals of different socioeconomic status. The experiment collected 19,921 in-vehicle activity choices from 1,881 respondents in small and medium-sized metropolitan areas of the United States. This paper begins with a summary of the overall in-vehicle activity preferences. Next, researchers examine various in-vehicle activity preferences based on respondents' socioeconomic status, commuting trip characteristics, and residential locations. Then, researchers use discrete choice models to reveal respondents' utilities from activity engagement. The paper highlights how in-vehicle activity engagement affects welfare gains due to improved utility/productivity of in-vehicle travel time, and discusses equity implications of the autonomous vehicles deployment.

HARTT, Maxwell [Cardiff University] HarttM1@cardiff.ac.uk, co-author

POTTS, Ruth [Cardiff University] pottsr1@cardiff.ac.uk, co-author

Social media has changed the way in which people engage with urban issues by providing a digital landscape in which citizens can share their opinions on decision-making in real-time, ask questions, and actively participate in discussions around key areas of interest. With the rapid growth and massive uptake of social media into the broader population, there has been a surge in public interest in using such websites to engage with others around key place-based issues. Due to the low cost and high potential engagement, planners and policymakers have been quick to open electronic channels of participation to inform the decision-making process. In doing so, they have also created an opportunity for subversion from groups with alternate and possibly nefarious interests. While public opposition to planning projects or “NIMBY-ism” (Not In My Backyard) is not a new concept, social media has created an additional avenue for such expression. Automated social media accounts could be used to further inflate the voice, and therefore influence, of subversive groups in the participatory planning process.

Urban scholars have looked to internet-enabled communities to foster better discussions and debates around community visioning and planning (Mitchell 1995; Cowley and Hollander 2010). Research has focused around ways that the political processes of shaping places can benefit from online community engagement and dialogue, extending the work of communicative planning scholars like Forrester (1999) and Innes and Booher (2010). While the movement of community planning processes onto online platforms has largely occurred as prophesized, the risks of such a move have largely overlooked the influence of social media manipulation, NIMBY movements and discourse around local planning issues. Instead, concerns have focused around the digital divide, lack of human touch with online exchanges (Hollander, et al. 2016). In this project, we propose a study that employs deception to test the effect of a group of Twitter bots on the activities and conversations of real Twitter users. While scholars have begun to examine how tech-savvy social media users are manipulating political discourse through the medium of Facebook and Twitter, no research has yet sought to examine the potential harm that such manipulation could cause at the local level. This project seeks to study the risks that social media manipulation poses to online community discourse around urban policy and planning topics.

Using professional trade publications like the Urban Land Institute’s Urban Land magazine and the American Planning Association’s Planning magazine, we identified 20 current large-scale development projects in the USA. The sample was devised so as to select a diverse set of projects, across the following dimensions: 1) type of development (e.g. residential, mixed-use, sporting facility, etc.), 2) size (e.g. square feet and/or acreage), and 3) region of the USA. Only projects that generated three or more social media groups, blogs, or websites by non-developer entities were included in the study. For each project, we closely monitored Twitter account activity around the project by searching for project-related hashtags and keywords and attempt to identify whether any bots are actively attempting to distort or thwart real-world community debate and decision-making. For any bots that appear to be doing so, we monitored their activity and the extent to which their posts, likes, and re-posts appear to be shaping real world conversations. We constructed social network maps to assess how influential each follower is, allowing us to project the possible influence each bot is generating.

In the past ten years, Airbnb has rapidly grown from a small, online bed and breakfast product to a leading peer-to-peer hospitality magnate which operates in 34,000 cities globally. It now offers rooms-for-rent, entire houses for rent, and even allows people to book “experiences” through the platform. In general, a property owner (i.e. houses, apartments, condos, cabins, etc.) can list their property on the platform with some introductory information. Airbnb users will select properties to rent based on the host’s information and reviews left by previous guests. The “live like local” marketing strategy and cheaper price have made Airbnb popular among tourists, especially young generations who are more open and mobile.

Since the outburst of Airbnb in 2014, it has drawn so much attention from public sectors, its commercial competitors, and the academia who would like to understand the business more aiming to warrant a benign concurrence between existing local industries and new inventions from the platform economy. Besides, the popularity of Airbnb provides a great opportunity for planning scholars and practitioners to recognize the overall patterns of individual economic activity in our cities systematically via sufficient data support. However, the overall patterns are somewhat inconsistent. For example, researchers in Barcelona used Geographic Information System (GIS) to map out the spatial distribution of both hotels and Airbnb listings in Barcelona and concluded that not only did Airbnb have different spatial patterns from traditional hotels, but the explanatory factors to the location of Airbnb listings were also different from those for traditional hotels. (Gutierrez et. al, 2017). A similar study of Airbnb in Barcelona found that Airbnb served a very distinct market segment of foreigners in Barcelona with German, Italian and Portuguese speakers overrepresented in the market (Sans & Quaglieri, 2016). It is arguable that Airbnb is serving a niche market in these cities. Wegmann and Jiao used web-scraped Airbnb data in five US cities to analyze the spatial distributions of listings and found that Airbnb listings were mainly concentrated in certain neighborhoods with good transportation, more storefronts, and more college-educated young people (Wegmann & Jiao, Jiao & Wegmann, 2017). This finding implied that the ability to use Airbnb realistically (i.e. to list your property on the site and generate worthwhile income) may not be evenly distributed.

Although previous case studies have covered a lot of cities with flourishing local markets, the gap between listing location patterns and their discrepancy among different cities still persists. The objective of the paper is to answer the following two research questions: (1) what is the relationship between Airbnb concentration and its external indicators? (2) how does the relationship vary among different city sizes?

To answer the questions above, the paper chose six US cities based on their population sizes (large, medium, small, two cities per category) and performed correlation analyses between Airbnb concentration (i.e. the number of listings per 10,000 households) and eleven variables representing socioeconomic status (SES) and urban form condition. Further, the paper fit an OLS regression model for each city and compared the outputs. Results showed that the distance to the city center negatively correlated with Airbnb distribution among all cities; tourist sites and food access were significantly positively associated, and the distance to transit stops was negatively related to Airbnb concentration only in Chicago. The results contribute to planning scholarship and practice by indicating that the prevalent expansion of sharing economy like Airbnb is context-dependent and by proposing prudent previews on the local status quo before joining the party.

TOWARDS RESPONSIVE & RESILIENT CITIES: BETERMS FOR CROWDSOURCING PERCEIVED BUILT ENVIRONMENT

Abstract ID: 74

Individual Paper Submission

WANG, Yan [University of Florida] yanw@ufl.edu, presenting author

The built environment is at the transformative stage towards being smart, sustainable, healthy and resilient. Cities, as the most populated areas of the world, are facing complex grand challenges including rapid population, environmental issues (e.g., pollution, inadequate waste management, noise, ecological disruptions), aging infrastructure, disasters, and diseases, blighted vacant or abandoned land (ASCE 2017; Branas et al. 2018). These constant stressors of cities require more responsive, transparent, inclusive and creative urban planning and governance, especially in the digital era with the emerging Internet of Things. In light of this, communicative planning has been encouraged among citizens, planners, and decision makers (Seltzer & Mahmoudi 2013).

Crowdsourcing - an approach to produce data collectively on particular issues - can help urban managers produce more effective and targeted services at lower cost and place citizens' needs at the center of thinking and planning for future cities (Klein et al. 2017; Caprotti 2018). Crowdsourcing can also fully consider place-specific characteristics of distinct urban areas, which were poorly addressed in traditional research and management due to limited data and approaches. Although some platforms with specific focuses have been designed, few have been proposed for citizens' perception of their built environment

from a multidisciplinary perspective. Such a comprehensive crowdsourcing platform is important because urban problems are always complex and multi-dimensional, and they require integrated knowledge and analysis from various research communities, e.g., hydrology, health science, criminology, human geography, and urban planning.

This research will develop a built environment (BE)-specific automatic term extraction system and create a terminological resource specifically for BE: BETerms, and use the BETerms as the keywords query to consistently crowdsource citizens' opinions, sentiments and comments on their perceived environment from an open-sourced social media platform (i.e. Twitter) in real time. The BETerms will be a comprehensive, specific and accurate lexical and terminological resource that has the potential to retrieve data from online communities and other short blogs. The BETerms will also have different categories that address the most critical topics and challenges faced by cities. Specifically, the terms can be related to the perceived poor-condition infrastructure (ranging from aviation, bridges, coastal areas, ports, roads, schools, or transit), urban conservations, blighted vacant or abandoned land, and other physical components of urban environments.

The generated BE-specific terms will provide the terminology basis for crowdsourcing opinions in the context of responsive and resilient cities. The collected data can be used to evaluate citizens' sentiment towards different physical environments and infrastructures with supervised sentiment analysis, and to model the topics related to BE across cities of different cultures and spatial scales with Latent Dirichlet Allocation (LDA) topic modeling. These findings will also inspire future research on creating place-specific BETerms for local planning purposes. Additionally, the developed methodology for constructing a terminological resource will also provide a new paradigm for data collection as a supplementary to traditional surveys (e.g., questionnaire survey and interviews). Case studies of different cities using text mining technique can be incorporated in a new course of urban analytics. The collected social media data using the BETerms can inform smart, sustainable, healthy and resilient urban planning with the bottom-up approach.

EVALUATION OF LIVING CENTERS IN CHONGQING CENTRAL CITY USING MOBILE PHONE DATA

Abstract ID: 75

Individual Paper Submission

YIN, Zhenxuan [Shanghai Tongji Urban Planning and Design Institute] yinzx1990@gmail.com, presenting author
WANG, De [Tongji University] dewang@tongji.edu.cn, primary author
ZHAO, Bicheng [Chongqing Transport Planning and Research Institute] bicheng.zhao@qq.com, co-author

Living centers, the agglomeration of shopping, leisure, education, healthcare, and other urban activities, are an important component of the urban spatial structure, reflecting the physical, social, political, economic and technological conditions (Dadashpoor & Yousefi, 2019). As a result, evaluation and monitoring of the living centers are prerequisites for urban planning. There has been a long tradition in evaluating living centers from attractiveness perspective (Huff, 1962; Reinartz & Kumar, 1999; Teller & Reutterer, 2008). Some studies have argued that amount of functions and how they are mixed are the most important issues (Teller, Reutterer & Schnedlitz, 2008). In addition, traffic condition, population size, and shopping environment, can all influence attractiveness of living centers (Reimers, Clulow, 2004). However, the indicators, influencing attractiveness, of existing research are complex and are not able to figure out the actual number of visitors.

With the increasing pervasiveness of new technologies, individual-level and activity-travel data from mobile phones became available, which may provide new opportunities to move beyond indicators of attractiveness, enabling accurate evaluation of living centers (Xiao, Wang & Fang, 2019). Using mobile phone data to detect consumers' behavior and open data to analyze living centers' physical conditions, this study compares the actual development of living centers as well as the theoretical development potential to evaluate the spatial performance of the high ranking living centers. Specifically, three factors were included in the evaluation of consumers' behavior: volume of visitors, residence time, as well as service area, and three factors were included in the evaluation of physical conditions: number of POIs, service distance and population size.

The result indicates that Chongqing central city is marked by the polycentric urban spatial structure, but the trend of agglomeration is still obvious. Living centers are mainly located in the built-up areas between Zhongliang Mountain and Tongluo Mountain. Besides, rail transit has a huge impact on the distribution of living centers. According to spatial performance, the high ranking living centers in Chongqing central city can be divided into five categories. Guanyinqiao, Jiefangbei, Nanping and Sanxia Square, the most famous living centers, with good physical conditions and active consumers' behaviors, developed well. Shiqiaopu, Baotong Road, Yudong Wharf, Baguocheng and Jiandingpo have good physical conditions, while their consumption behaviors are inactive. Lianglukou, Jiangbei Airport, Xinshan Village, Beibei and Dushihuayuan Road developed generally. Daping, Yangjiaping, Jinyu, Zhuangyuanbei and Jinzhou Avenue developed well with poor physical conditions. Garden Expo garden, Renhe Interchange and Jiangbeizui, which were not well developed, should change their functions to format their specific advantages. This study is helpful for planning and building living centers.

TRACKING URBAN LANDSCAPE CHANGE PROGRAMS THROUGH AERIAL IMAGERY: CHALLENGES AND OPPORTUNITIES

Abstract ID: 100

Individual Paper Submission

LASSITER, Allison [University of Pennsylvania] alass@design.upenn.edu, presenting author

Many water agencies are implementing landscape programs to manage water consumption or stormwater flows. Programs often target both public and private lands, subsidizing or creating incentives for installing green infrastructure, removing impervious surfaces, or replacing turf grass. There are many questions that could be asked of program implementation, such as: how are programs changing the urban landscape over space and time? What are the interactions between public investments and private investments? What is the relationship between a household's participation in a landscape program and subsequent neighborhood-level landscape changes? How is the landscape maintained? There is little empirical evaluation of the dynamics of most urban landscape programs, however, largely due to challenges in data quality and attribution.

One of the questions fundamental to evaluating landscape programs is parcel and sub-parcel level mapping of urban vegetation. At present, there are no affordable, scaleable methods to do this well. Landsat (30-meter resolution) has been used to evaluate urban landscape change, but is coarse relative to most urban parcels (Brelsford & Shepherd, 2014; Brent, 2016; Zhou and Wang, 2011). Higher resolution, parcel and sub-parcel studies of vegetation tend to use commercial imagery that can be expensive to scale over space and time (Brenner, Hey, Boettcher, & Tate, 2018; Mathieu, Freeman, & Aryal, 2007).

This paper presents two methods for evaluating urban vegetation at the parcel and sub-parcel scale with publicly available, high resolution aerial imagery. First, I examine changes in parcel spectral signatures associated with a lawn replacement program. Then, I discuss classifying vegetation, comparing three unsupervised learning methods. The paper concludes with ongoing challenges and opportunities for urban landscape change evaluation through aerial imagery.

A SYSTEMATIC REVIEW OF URBAN LAND CHANGE MODELING: DRIVING FACTORS, TOPICS, AND SCENARIOS

Abstract ID: 114

Individual Paper Submission

KIM, Youjung [Texas A&M University] yk2247@tamu.edu, presenting author
 NEWMAN, Galen [Texas A&M University] gnewman@arch.tamu.edu, co-author
 GÜNERALP, Burak [Texas A&M University] bguneralp@tamu.edu, co-author

As urban environments and societies rapidly change, uncertainty in future conditions calls for more technologically driven planning approaches. People continually transform the earth's surface for their own uses primarily through land use change (NRC, 2014), the result of interaction between human activity and land-related biophysical constraints (Agarwal et al., 2002). Understanding historic land development processes in order to better predict future circumstances through land change models (LCMs) helps support planning for potential future impact. LCM enables the ability to describe current and predict potential land use and land cover change (NRC, 2014). Over the past few decades, LCMs have been significantly developed in regards to modeling tools, predicting performance, and impact analysis (Güneralp, 2011). These advances allow the capability address the challenges of urbanization with better representation and can be used as a planning support system to supply future land prediction to the land use planning process (Berke et al., 2006). LCMs create the opportunity to mold an uncertain future into a determined condition with plausible future urban growth scenarios. These urban growth scenarios have been examined with several subsequent topics (e.g. hydrology, ecology) and their impact evaluation to determine the most desirable future.

Several reviews on land change models and drivers/processes of land change provide valuable and extensive insights for LCMs. Though some studies have reviewed driving factors for urban growth, the understanding of these factors remains unclear due to the distribution across multiple disciplines and the difference in temporal and geographic condition in study areas (ESF, 2010). Furthermore, as future uncertainty increases, urbanization impacts and capabilities for scenario making using LCMs have become more important, but no study has integrated drivers with subsequent impacts and scenarios. To fill the gap, this study reviews the driving factors behind predicting future urban growth scenarios and subsequent topics in LCM studies. The research asks: 1) What driving forces have been applied to urban growth?, 2) How/what kind of urban growth scenarios have been created using these drivers?, and 3) What are the purposes of these prediction studies? This research used SCOPUS as main search database using both backward and forward search capabilities, and reviewed 144 LCM related articles.

Results show that variable amounts for urban prediction range from only 3 to up to 20. Natural and built-environmental variables are normally applied as primary driving factors behind urban growth; these include distance to roads, slope, distance to existing urban area, and distance to water. The popular socio-

economic variables tend to be population density, gross domestic product, property value, employment, and income. Some studies consider disaster impacts as land change determinants and include floodplain, tsunamis, and seismicity. The primary topics of urban prediction studies are: to forecast future urban growth (70), to introduce a new model (31), to compare tools (4), and to examine urban growth-related impacts (39). In the impact analyses (39 articles in total), ecological impact analysis (13) is the most popular, followed by hydrologic impact (9) and flooding (7). Fifty-five articles out of the 144 use urban growth scenarios. Popularly applied future growth options include 'business as usual,' 'compact development,' and 'environmental protection.' To create urban growth scenarios, articles use three general methods: pixel number control for density (compact or loosen), location control by exclusionary layers, and driving factor influence control by using different driving factors or weighting driving factors. This study contributes to the understanding of LCM studies. It provides a comprehensive list of driving factors and their locations/disciplines, and topics. It also separates them according to scenario type. The results help researchers to identify trends in LCM studies to better predict for urban growth and differing scenarios.

USE OF DRONES IN BEHAVIOR MAPPING: A CASE STUDY OF NEIGHBORHOOD PARKS

Abstract ID: 119

Individual Paper Submission

PARK, Keunhyun [Utah State University] keunhyun.park@usu.edu, presenting author

CHRISTENSEN, Keith [Utah State University] keith.christensen@usu.edu, co-author

LEE, Doohong [Utah State University] doohong.lee@usu.edu, co-author

Behavior mapping may be an effective tool when exploring the interaction between people and place (Bechte et al., 1987; Goličnik, & Thompson, 2010; Ittelson et al., 1970). The behavior map is developed to uncover whether a location is used or not, at what time, by which type of people, and what activities are performed in different areas. Using behavior mapping, a researcher can collect both quantitative and qualitative information, which allows for more nuanced understanding of design and its consequences.

While various digital tools are now being used in behavior mapping, there is still some degree of error regarding recording the location of observed activities. The use of unmanned aerial vehicles (UAVs; drones) may be used in behavior mapping to address this issue, but this has not been studied. The use of UAVs in behavior mapping could be more efficient as it covers a larger area in a shorter amount of time. Using video recording, it could provide the exact location of individuals as well as more accurate attribute

information; thus, it could be reliable and informative. This makes UAVs appropriate to study micro-scale design implications. This study explores the applicability of UAVs in the behavior mapping of neighborhood park use.

In place-centered behavior mapping, it is necessary to clearly define the area of observation (behavior settings), the types of activities (affordances), and a system for recording and coding. Refining the Ittelson et al. (1970)'s elements of behavior mapping, this study developed a protocol of UAV-based behavior mapping: 1) creating a base map in GIS, 2) defining behavioral categories and developing a system of coding, 3) defining a schedule of observation, 4) establishing an observation procedure, and 5) data extracting and analysis.

We then explored the interaction between people and place using the behavior maps and quantitative information collected using UAVs from 30 neighborhood parks in Salt Lake County, UT, USA. The results showed that the use of UAVs can enhance our understanding of park-based behaviors through behavior mappings. The locations of park users were geocoded in GIS, which can be verified later by analyzing the video files. UAV-based behavior maps can provide both quantitative and qualitative data. Summary statistics, along with digital maps, provided accurate patterns of park use. For instance, this study showed disproportional usage of neighborhood parks by gender, more males than females, a gap which becomes larger in children and adolescent groups, and age where the percentage of seniors out of all park users is 3.5%, a much lower value than the 8.7% County population average. User density was higher in picnic areas and playgrounds and lower in lawn, baseball fields, and water features. In addition, we showed that park occupancy was different by sex, age group, and activity type across different times.

Practical implications of the use of UAVs toward evidence-based design and planning are discussed. For scholarship, the spatial data may be used to relate human behaviors to environmental attributes and model and predict those behaviors. Field experiments, or quasi-experimental strategies, can also benefit from the accurately geocoded data from UAV observation (e.g., post-occupancy evaluation; Cooper Marcus & Francis, 1998). As a reliable and effective tool for the observation of behavior, UAVs can also support practitioners' data-informed and responsive design and management efforts. The visualization of a behavior map may help designers understand the outcomes of their design practice more intuitively and meaningfully. We hope that design professionals will see UAV-based behavior mapping, supplemented by other data collection techniques, as an aid for developing evidence-based practice and for applying their creative skills for the best possible solutions.

LONG-TERM PROSPECTS FOR LAND VALUE CAPTURE OF PLANNED URBAN SUB-CENTERS

Abstract ID: 128

Individual Paper Submission

YANG, Tianren [University of Cambridge] tianren.yang@hotmail.com, presenting author

Despite a century-long effort in promoting planned new urban centers, most of these developments fail to materialize particularly in developing countries. Empirical evidence surrounding effective land value capture (LVC) is desperately needed in the face of rapidly polarizing urbanization. The unprecedented release of online administrative data on land market transactions and infrastructure construction by local governments, together with the proliferation of online social media and digital trace data on consumer activities, has created significant new potential for policy-makers and practitioners in developing countries to better understand, monitor and analyze what works and what does not regarding the development of new urban centres and any associated LVC schemes.

Can infrastructure-induced land value increments be better captured and the positive externalities (i.e., socio-economic benefits) be capitalized upon in planned new urban centers? This paper aims to develop a novel method for developing countries to measure the effects of the subcenter policy interventions, to understand the causal relationships regarding the influences of their successes and failures through building and empirically validating a theoretical model, and to apply this model in predicting the impacts of existing and new LVC options that may become necessary for funding infrastructure and social programs going forward.

Through assembling, corroborating, and validating multi-source urban datasets in a new spatial equilibrium framework, this study takes a new perspective of integrated policy dimensions by simultaneously considering infrastructure, business activities, residents, social networks, and local identities. The model is applied to Greater Shanghai in China, where there have been persistent efforts in creating new city centres and a vigorous interest in land value capture.

Robust land value appraisal and spatially explicit evidence derived from the analytics will underpin the identification of key influences on property value uplift over specified time horizons. Such an approach will plug a gap in current decision making regarding planning and development in low- and middle-income countries. Furthermore, this paper would materially improve local governments' ability to explore LVC options not only as a financing instrument but also as a wider policy apparatus to promote social equity, economic competitiveness, and environmental sustainability.

The exploratory scenario planning tool developed in this paper can (1) monetize the uplift in land values resulting from new center development, (2) interpret the complex causal relationships across boundaries, over long-time spans, and under conditions of uncertainty, (3) quantify the effectiveness of policy interventions on capitalization of land and other externalities, and (4) provide new evidence for

stimulating the successful establishment of planned new centers that mitigate and forestall the climate change induced by urban sprawl.

MEDIAN CALIBRATION OF SINGLE-PARAMETER SPATIAL INTERACTION MODELS

Abstract ID: 139

Individual Paper Submission

MERLIN, Louis [Florida Atlantic University] lmerlin@fau.edu, presenting author

Spatial interaction models help planners and geographers understand how the choice of activity location is mediated by distance, travel time, or travel cost. They are useful for understanding travel behavior, migration, property values, physical activity, as well as for making accessibility calculations to ascertain the benefits of changes to transportation infrastructure or land use patterns. In order to be useful and accurate, spatial interaction models have to be calibrated correctly based on observed interaction data. This paper proposes a fast-converging method that allows spatial interaction models to be calibrated with small samples, allowing the specific calibration of spatial interaction models for less-frequent travel purposes, travel modes, and/or population groups. For example, a spatial interaction model could be calibrated for senior walk trips to recreation facilities because of the minimal data requirements and rapid convergence of this method.

First this paper reviews the challenges in correct calibration of spatial interaction models. These include establishing the zonal structure, dealing with small samples and zero flows, handling self-potential or intrazonal trips, deciding upon an appropriate functional form, and calibrating the model parameters. For model calibration, this paper explores the interdependency of zone-specific balancing factors and model impedance parameters, and reviews various “fast” methods for calibrating model impedance parameters.

Then I present a new proposed method for calibrating the impedance parameter of a single-parameter spatial interaction model using only the median travel time from observed traveler behavior. Using computer-simulated square cities with 400 (20 x 20) zones and a total population and employment of 400,000, I attempt to recover the true (a priori known) impedance value using this method for a range of true impedance values between 0.003 and 0.300. The proposed method proves to be fairly accurate, with a mean percent error of 10.6%, but lower errors for values in the middle of the impedance range and higher values towards the extremes. Accessibility calculations using these estimated impedance parameters are highly correlated with accessibility calculations using the true impedance parameter values ($\rho \geq 0.970$).

The proposed method has three main advantages over existing methods. First, it is possible to identify the impedance parameter without previously determining the balancing factors. This makes the calibration

process faster and more accurate. Second, it is possible to accurately calibrate spatial interaction models without sophisticated statistical software necessary for maximum likelihood methods; in theory the proposed method could be accomplished with standard spreadsheet software. Third, because only the median value is necessary for calibration, it is possible to calibrate spatial interaction models with small samples of travel data, which allows for proper calibration for small population segments and specialized trip types. In summary, the proposed method offers several benefits over established methods for calibrating spatial interaction models.

EXPLORING THE SPATIOTEMPORAL RELATIONSHIP BETWEEN CHICAGO’S LARGE LOT PROGRAM AND NEIGHBORHOOD RATES OF CRIME

Abstract ID: 151

Individual Paper Submission

YOO, Sanglim [Ball State University] syoo@bsu.edu, presenting author

While crime rates nationally are lower than at any point in recent American history, criminal activity remains a challenge for cities across the country. It is particularly true in the city of Chicago, Illinois where gun violence and homicides have reached record levels this decade where the South Side neighborhoods accounted for 45% of the increased homicides across the city (University of Chicago Crime Lab, 2017). Yet as violence has increased this decade, in some South Side neighborhoods where the city launched Large Lot program, some differences were observed. Established in 2014, Chicago’s Large Lot program, which sells city-owned vacant parcels to nearby homeowners for \$1 each, was a city of Chicago neighborhood stabilization initiative to help property owners, block curbs, and non-profit groups in selected Chicago neighborhoods. As of late November 2017, shootings were down 44% and homicides were down 45% over 2016 (Sweeney, 2017).

Numerous recent empirical studies have found a statistically significant relationship between the remediation of vacant lots and decreasing incidents of crime in the local area (e.g., Philadelphia, PA (Branas et al., 2012; Branas et al., 2016); Youngstown, OH (Kondo et al., 2016); Flint, MI (Sadler et al., 2017)). Those studies all considered the remediation of blighted city lots as transforming these lots into greenspace for the community and/or private reuse. To the best of our knowledge, however, there is the

limited study that has examined whether the transfer and remediation of vacant lots from absent, public ownership into local, private ownership, without consideration of the lots' post-sale land uses, in and of itself has a statistically significant impact on local crime. This study tries to fill this gap.

With the application of spatial-statistical approaches, this study examines the impact of the city of Chicago's Large Lot Program on the incidents of local crime. Using the location of 440 parcels sold in 2014 and crime data reported between the year 2013 and 2017, emerging hot spot analysis tool and geographically weighted regression (GWR) were applied to test the impact of the Large Lot Program on local incidences of crime. As emerging hot spot analysis examines clustering of crime reports over time, this analysis method was used to investigate the changing trends in crime patterns from 2013, a year before the program launched, to 2017, the last full year with available crime data. This study also applied the GWR to explain the causal relationship between the Large Lot Program and the local crime density. This analysis was able to show test crime incidents within each of the five years studied so that it could be apparent in how the crime was changing between the year 2013 and 2017. The result of this study shows a statistically significant reduction in property and drug crimes within 500 feet of sold 2014 Large Lots but not for violent crime. This result is encouraging in terms of policy implication. A detailed discussion regarding the positive relationship between blight remediation and changes in crime rate and the policy implication of this phenomenon will be provided in detail.

HOW ARE URBAN PLANNING ACADEMICS USING TWITTER?

Abstract ID: 177

Individual Paper Submission

SANCHEZ, Thomas [Virginia Polytechnic Institute and State University] tom.sanchez@vt.edu, presenting author

Academics have increased their uses of Twitter to share information, media, and other resources related to their profession. This includes sharing their own scholarship and that of others with similar disciplinary interests. And like other professionals, academics use Twitter for connecting and networking, requesting assistance and offering suggestions. Some academics have used Twitter to expand “learning opportunities beyond the confines of the classroom” (Veletsianos, 2001, p.342). Urban planning academics are active

Twitter users, but as of yet there have been no empirical analyses of how and why they use Twitter. This paper presents a descriptive analysis of Twitter use by urban planning faculty, reporting characteristics of users, the topics of Tweets, purposes of Tweets, and Twitter influencers within urban planning as well as those outside academic circles. The analysis uses data retrieved from the Twitter API for all active accounts for urban planning faculty in the U.S. and Canada. Only accounts identified as being used for professional purposes are included. Professional accounts are those that mention institutional affiliation or professionals titles. It is expected that patters of usage among planning faculty do not vary significantly from those of other academics, other than the specific topics that are most frequently mentioned.

MULTITASK LEARNING DEEP NEURAL NETWORK TO COMBINE REVEALED AND STATED PREFERENCE DATA FOR ANALYZING THE ADOPTION OF AUTONOMOUS VEHICLES

Abstract ID: 201

Individual Paper Submission

WANG, Shenhao [DUSP & CSAIL MIT] shenhao@mit.edu, presenting author

ZHAO, Jinhua [Massachusetts Institute of Technology] jinhua@mit.edu, co-author

It has been an enduring question how to predict the demand of a new technology. One classical method is to combine revealed preference (RP) and stated preference (SP) data by using a nested logit model. RP data are commonly thought as more reliable because they represent the real behavior, and SP data are necessary when researchers seek to understand the effects of new attributes, new value ranges, or new alternatives. The nested logit approach was developed by Ben-Akiva and Morikawa (1990); more precisely, this is a method of pooled estimation with heteroscedasticity across RP and SP (Helveston et al., 2018).

This study presents a new approach of using multitask learning deep neural network (MTLDNN) to combine RP and SP data, incorporating the traditional nest logit approach as one special case. The architecture of MTLDNN starts with shared layers and ends with domain-specific layers, based on the insight that shared layers reflect the similarity across RP and SP domains and domain-specific layers represent RP and SP information separately. We have designed the hyper-parameter space of MTLDNN models with seven dimensions, among which the most important one is whether proportional parameter constraint is imposed. This constraint is derived from the nested logit approach, which assumes the

proportional scales of random utility terms between RP and SP data. The nested logit approach is only one special case with the sparsest structure and the weakest regularization of all the MTLDNN architectures.

Based on a combined RP and SP survey collected in Singapore, we designed, estimated and compared one hundred MTLDNN architectures for analyzing the adoption of autonomous vehicles, with two major empirical findings. First, the model with the highest prediction accuracy is the one with one shared layer, five domain-specific layers, and weak regularization. Some transformation of the raw inputs indeed helps prediction, which is in line with our intuition and the traditional approach of engineering features before feeding into the models. But somewhat surprisingly, the traditional nested logit approach also performs very well. Its prediction accuracy ranks as the second out of the 100 models. These results suggest that the traditional nested logit approach is still a viable alternative in combining RP and SP, particularly when the sample size is not very large. Second, the behavioral constraint of the nested logit approach effectively differentiates between the MTLDNN models with high and low prediction accuracy. This constraint is too restrictive in the deep architectures. However, this distinction does not exist when the architecture is very shallow.

This study makes two contributions. First, it is the first research of using the MTLDNN framework to combine RP and SP data for travel demand analysis. The MTLDNN framework is more general than the nested logit approach and is flexible with a great number of possible architecture designs. Second, we point out that the behavioral insights such as proportional scales of random utility terms can function as one hyper-parameter in MTLDNN framework. While this study only used MTLDNN to combine two domains RP and SP, it can be extended to scenarios in which the number of domains is larger than two. Researchers could also use this MTLDNN framework for other types of applications, such as jointly analyzing choices from different regions, different time periods, or data elicited from different procedures. With the flexibility and the extraordinary power of deep MTLDNN architectures, we believe that this new framework can improve demand prediction and provide new insights into travel behavioral analysis.

WHAT ARE THE CHALLENGES IN MAKING THE “SMART” INCLUSIVE? A CASE STUDY OF TRANSPORT APPS FOR PERSONS WITH DISABILITIES

Abstract ID: 216

Individual Paper Submission

GEBRESSELASSIE, Mahtot [Virginia Polytechnic Institute and State University] gmahtot@vt.edu, presenting author

SANCHEZ, Thomas [Virginia Polytechnic Institute and State University] sanchez@vt.edu, co-author

The term “smart cities” has become overused while being applied to an overly broad range of issues. While Fistola (2013, p.47) says urban planning is its “natural site of theoretical development” the topic has percolated into various disciplines with no one particular field claiming sole ownership of the concept. Variations in smart city definitions abound as a result, with a common theme highlighting the integration of technology with infrastructure. This is partly responsible, in addition to the role technology companies play, for the technology-focused approaches to “smart cities” that is dominating current debate. The emphasis on technology in the conception of “smart cities” fosters narrow points of view of “smart” initiatives and the technologies that support them, without regard to the dynamics between technology and social, cultural, and economic systems. One of the pitfalls of such outlooks is the disregard to matters of social inclusion. The lack of focus on social dimensions and equity in the “smart city” has been well-documented in academic literature (e.g. Hollands, 2008; Batty, 2012; Trencher, 2018). The broad concern of the study is to bring attention to this blind-spot of the “smart city” paradigm in order to make the “smart” inclusive. Accomplishing that goal requires an in-depth understanding of the challenges faced in achieving social inclusion as well as integrating solutions into practices and policies. This perspective is explored by examining smartphone applications (apps) used for urban transport in relation to the needs of persons with disabilities. Smartphone apps have a marked presence in transport-related systems. As technology becomes more integrated into transport networks, they will be indispensable for transport service in their current or advanced iterations. Do they create inclusive transport experiences? Gebresselassie and Sanchez (2018) found that the app technology may have the potential to encourage inclusion of transport-disadvantaged communities. However, the study states that there are socio-economic and cultural factors required for that to materialize, implying that the “smart” is not inclusive by default. Building on the study, our research investigates what hinders the “smart” from being inclusive in the case of transport apps in relation to persons with disabilities. The research will answer the following question. What challenges exist in the availability and usability of transport apps for persons with disabilities? Our research method includes a) interviews with users with disabilities, app developers, transit authorities, and regulatory bodies and b) document analysis of transit authority websites, legal documents, and regulations pertaining to disability. The preliminary findings of our primary and secondary data show that a) existing business models of the app industry are nonviable for these apps, b) some transit authority practices are not advancing inclusive goals in the apps with which they work, and c) there are no clear governmental regulatory frameworks. The purpose of the paper is to draw attention to the interplay between technology and social, economic, and cultural systems in the conception of “smart” to ensure inclusion, especially of groups historically marginalized from urban processes and services.

URBAN EPISTEME: SEEING LIKE A SMART URBAN ENTREPRENEUR?

ABBOTT, Martin [Cornell University] mja273@cornell.edu, presenting author

Step back through time and it is evident that the figure of the male entrepreneur has played an outsized and problematic role innovating the future for more than 150 years. The male urban entrepreneur has performatively leveraged their purported mastery of science and technology to aggrandize their place in and influence over society. They have courted investment, hype, and public interest with the promise of making cities and their material infrastructures smarter. Thomas Edison's incandescent light bulb revolutionized the working day and the nocturnal urban landscape at the end of the nineteenth century as his modern electricity system gained momentum across urban USA (Hughes, 1983). With similar celebrity, much has been written about the "brilliant" Mr. Musk and his (mis/)(ad)ventures, which as Fortune Magazine put it, have made him "the one-man embodiment of the future." He is the entrepreneurial face of a string of Silicon Valley companies, such as Tesla, SpaceX, and SolarCity with ambitions to reinvent urban transportation and energy use. Other men of tech like Steve Jobs, Peter Thiel, and Travis Kalanick have built networks of power embedded with their own values and politics.

The epistemic culture of the male urban entrepreneur induces a particular way of seeing the city, which values and prioritizes certain categories, methods, and subjects, over others (Knorr-Cetina, 1999). Seldom, however, does the male technoliberal gaze extend to questions of how class, gender and race are subjugated by their technologies of transformation (Atanasoski and Vora, 2019). The city futures resident within this technoliberal order paper over, apolitically, and in contradiction to, the uneven urban geographies of difference and diversity they promise to rectify. Scrutiny of "Tech's Enduring Great-Man Myth" reveals the obfuscation of the technoscience that is to be found not only in their smart city rhetoric but embedded within the relational hinterlands of the things they make (Schaffer, 2015). Urban Epistemics is a call to move toward a more cosmopolitan view of smart city paradigms.

This paper, drawing on a systematic content analysis of North American and British media sources, shows how the disproportionately male leaders of tech see and seek to reconfigure the city. Studying the male urban entrepreneur tells us much about smart city categories and reveals that their tech industry culture is influential in the conceptualization of urban futures. The study also speaks to the reification of inequitable and uneven roles that class, gender and race play in shaping the futures of urban citizens the world over (and this paper). The growth and continued expansion of the dense and diverse urban landscapes that nourish and provide the impetus for the production of knowledge, in the first instance, are antithetical to the techno-fixes that shoehorn the colorful but dark art of city planning into universalizing and remote centers of command and control. There is a stark choice between the universalizing abstractions of a reincarnated modernity as smart cityness and the situated knowledge of local and timely political interventions (Sandercock, 1998). How these technoliberal figures relate to and reconfigure the city via new networks of power may render an increasingly urban future that is not so urbane.

OFF THE GRID: THE EVOLUTION OF AMERICAN STREET NETWORK PLANNING AND DESIGN

Abstract ID: 269

Individual Paper Submission

BOEING, Geoff [Northeastern University] g.boeing@northeastern.edu, presenting author

Street networks provide a substrate and connective tissue that organize a city's human dynamics. The pattern, texture, and grain of a street network reflect prevailing technologies, design paradigms, politics, expressions of power, underlying terrain, and local culture and economic conditions. The classic street grid's geometry and topology have been used for millennia to express human order over the landscape, to make travel more efficient, to organize the city around spaces of power, and to make land amenable to real estate speculation and development. The grid has a long history in the US; however, scholars have noted its decline over the past century, and the attendant declines in intersection density and connectivity, as well as increases in city block size and the urban fabric's grain. Much of this literature relies on case study research, but less is known about recent trends across the entire US. Barrington-Leigh and Millard-Ball, however, recently examined a subset of US counties, focusing on how street connectivity patterns changed over the 20th century.

This study expands on this work, using new computational network science and big data methods to examine the street networks of every census tract in the US (approximately 74,000 study sites), collectively comprising nearly 19 million network nodes and 24 million network edges. It builds models of each of these tract networks from OpenStreetMap data then calculates dozens of measures of the urban form and street network including street circuitry, the proportion of four-way intersections and dead-ends, average block lengths, street orientation entropy, and a composite grid index. It algorithmically tags each network with an estimated "initially-built" decade using the statistical distribution of structures-built dates and a sensitivity analysis to contrast multiple competing algorithms. Finally, it estimates spatial regression models identifying planning trends in each decade while controlling for other regional and urbanization factors, including topography.

It finds that griddedness declined steadily nationwide between 1940–2000 as street orientation entropy increased, circuitry increased, and the proportion of 4-way intersections decreased. Similarly, dead-end proportions and average block lengths increased while average intersection densities decreased. Most interestingly, however, all of these variables' trends have reversed over the past two decades, returning to levels not seen since the middle of the 20th century. Average griddedness is 38% higher in tracts built in the 2010s than it is in 1990s tracts, while four-way intersection proportions are 74% higher and dead-end proportions are 42% lower. Intersection densities are 60% higher in 2010s tracts than they are in 1990s tracts, while the average street segment length is 10% shorter. Controlling for covariates in a spatial regression model, every post-war decade predicts lower grid index values than the pre-1940 base class.

This study makes several contributions. No previous study has fully unpacked these relationships between topography and street network form, examined this rich basket of street network indicators by vintage, or comprehensively studied the patterns and structure of the circulation networks of every tract in the US. It also reveals an important facet of recent US planning history: how, over the past two decades, US transportation planning and urban design reversed their 20th century trends of increasing sprawl and disconnectivity. This paper explores these histories, considers reasons why they have occurred, and presents a reproducible big data methodology for urban form and transportation network analysis.

Based on the LBS data of mobile phones, the commuting data of mobile phone users in Wuhan should be recognized. Then, the paper judges the commuting spatial structure of the central Wuhan, and analyzes the intrinsic relationship between the commuting spatial structure and urban land use. Firstly, the commuting data of the central area are screened to identify the comprehensive commuting circle of the central area; secondly, based on the density of commuting intensity in the comprehensive commuting circle, the high-value clustering area is selected as the commuting center by using a method called local spatial autocorrelation analysis; on the basis of these analysis, the commuting spatial distribution of the commuting center can be analyzed, and the commuting life circle is classified according to commuting intensity between different regions. Finally, the paper analyzes the relationship between commuting life circle and land use characteristics. The study found that: (1) the internal commuting proportion of the comprehensive commuting circle has reached 95.7%; (2) the commuting center was a relatively

centralized multi-center structure; (3) the internal spatial distribution of the commuting life circle was circle-by-circle diffusion, and it's obvious that there are many enclave and cross-area commuting; (4) Because of the hierarchical location, land use and transportation facilities of each commuting center, the structure of each commuting life circle is significantly different. (5) There is a strong correlation between commuter life circle and land use pattern, such as land use constitution, the degree of land mixing, road transport and other influencing factors. This paper analyses the correlation between commuting space and land use characteristics from the perspective of urban spatial structure, and puts forward that the spatial unit of "commuting center-commuting life circle" should be used to readjust urban spatial structure. In order to improve commuting spatial structure, shorten commuting time and distance and improve urban spatial performance, urban planners should make rational use of land and transportation facilities and strengthen the relationship between public transport system and commuting spatial structure.

LI, Xiaojiang [Massachusetts Institute of Technology] lixiaojiang.gis@gmail.com, co-author

It has long been difficult to measure the quality of streets in an effective way. Prior research suggests that the enclosure, the human scale, the diversity of a street is directly related to a person's appreciation of that place (Ewing & Clemente, 2013). Classical investigation of an urban street's design quality relies on the actual measures with massive comprehensive metrics, ranging from calculating the height-to-width ratio to counting the number of pedestrians. It requires extensive spatial data and observations for both buildings and streets. However, with the advance of the autonomous vehicle industry, nowadays computer vision and artificial intelligence have been widely applied to monitor road conditions. This study takes Shanghai as an example and applies those state-of-the-art technologies to identify street space quality in Pudong District. First, this study develops a method to apply semantic and instance segmentation to consistently quantify more than 30 dimensions of street environments from street view images based on a classical framework established by Ewing and Clemente (2013). The method is then applied to a training sample of 5000 street view images across Shanghai region from Baidu. This study then collects the public's preferences upon these 5000 photos by an online investigation with residences from local communities. These preferences are translated to ranking scores and the scores become the labels of our

training data. Based on the machine learning model, we predict scores for more than 40,000 unseen street view photos across the Pudong region to evaluate the human-perceived street quality. In order to justify our result, we also incorporate external datasets from point of interests (POI) and Dazhongdianping for the robust check. We find a significant correlation between the diversity score and the Dazhongdianping data. We also apply our method to evaluate other 5 cities across the world to set up benchmarks for Shanghai. This study advocates an efficient way of mapping street scores in urban and regional scale with reliable accuracy. While this method may not immediately replace the long-existing techniques in urban planning and urban design, it offers many merits, for example, being closely related to the pedestrians' perspective, low-cost, requesting nothing from proprietary software or methods, and is commonly applied any city as long as the city has a complete series of street view images. It provides a reliable alternative for planners and policymakers to assess the quality of the built environment.

The historical park, as a kind of significant green resource in the current high-density central city, is attracting more and more attention worldwide on its protection and renewal (Zhang et al, 2016; Daniel and Yang, 2009). In the context of the current rapid urbanization, several historical parks have begun to implement preservation and regeneration. However, due to the lack of specific protection measures and the insufficient understanding of landscape value, several problems have emerged, such as excessive reconstruction and disorderly expansion (Zhou and Liu, 2014). Nowadays, historical parks' heritage value evaluation has become the focus of historical park conservation (Zhou and Liu, 2014). Besides the top-down value evaluation led by the government, planning agencies, experts and scholars, it's extremely necessary to investigate the public's landscape value perception of historical parks from the perspective of bottom-up. Zhongshan Park is a cultural relic conservation unit in Tianjin, China, and it's also the first public garden in Tianjin. This park, which combines traditional Chinese garden art with western

architectural characteristics, is not only the materialization carrier of memorial discourse and state power, but also a public place for public recreation daily. Therefore, this paper will take Zhongshan Park in Tianjin as a case to explore the landscape value perception of visitors and the influence mechanism, in order to provide indispensable reference to the protection and development of historical parks.

In addition to the traditional research methods such as questionnaire and in-depth interview, this paper also uses Structural Equation Model (SEM) as the main quantitative analysis method to further explore the influence mechanism of landscape value perception. The Structural Equation Model contains both directly measurable variables and latent variables that cannot be directly observed (Yi, 2008). The landscape value perception is a kind of variable that cannot be directly measured, so it is an effective method to analyze the mechanism of landscape value perception based on Structural Equation Model. AMOS 22.0 software will be used in this paper for model construction, parameter estimation, model correction and other links, so as to complete model construction.

The research content includes three aspects: (1) Through literature review, this paper summaries the construction process and current situation of Zhongshan Park in Tianjin. (2) Through questionnaires and in-depth interviews, this paper explores visitors' landscape value perception of Zhongshan Park. The content of the questionnaire mainly includes four parts: personal characteristics, socio-economic attributes, landscape elements and landscape value. Based on the classification of landscape value by European landscape ecologist (Antrop et al, 2000) and the actual situation of Zhongshan Park, this paper divides landscape value into six categories: historical and cultural value, spiritual value, aesthetic value, ecological and environmental value, recreational value and characteristic value. (3) The influence mechanism of landscape value perception is analyzed by constructing SEM. On the one hand, this paper explores whether these influence factors (personal characteristics, socio-economic factors and landscape elements) have direct or indirect influence on the landscape value perception; On the other hand, this paper calculates the magnitude of the impact.

The result shows that: (1) Visitors believe that Zhongshan Park has a high spiritual value, followed by history, aesthetics and ecological value. (2) In terms of influence mechanism, socio-economic factors and landscape elements directly affect landscape value perception, while individual characteristics indirectly affect landscape value perception. Age, place of residence, purpose of visiting, education, occupation, architectures, plants, accessorial building, rockeries are the key influence factors for landscape value perception.

With the increase of online shopping and globalization in recent years, small and independent retail businesses have struggled, despite providing benefits to local communities and contributing to the vitality of street life. In order to revitalize the small businesses in commercial districts, it is necessary to investigate how pedestrian activity along the commercial district streets where the small businesses are located. Currently, conventional methods such as count pedestrians is extensively applied in this field, but it requires considerable manual labor for monitoring and is limited by factors of cost, time, data accuracy, and subjectivity. In addition, other measurements such as trajectories of the pedestrians in real-time are needed to better understand the local street activity. In this context, we propose a methodology based on Wi-Fi sensing technologies, which allows to analyzing human mobility and activity patterns.

Wi-Fi sensing is one of the most useful technologies that can be employed to track the human mobility trajectories. As Wi-Fi-enabled devices send probe request frames to nearby access points, which includes the MAC address, it is possible to identify travel routes of people carrying the devices, based on multiple Wi-Fi scanners by developing an origin-destination matrix and classifying movement behavior patterns, such as those of passing directly by or remaining at a point for a while. Through such a method, the human mobility and activity patterns could be identified using Wi-Fi sensing technologies.

We design a prototype as a pilot study based on Raspberry Pi at a university campus, with the aim of capturing the Wi-Fi probe requests and uncovering student mobility trajectories. Algorithms are presented for hashing the MAC address for privacy concerns, dealing with randomized MAC address, and analyzing raw data. A combined dataset of Wi-Fi traces and GPS log from recruited participants is used to verify with a camera attached to the scanner. We further identify several differences in students' trajectory patterns between weekdays and weekends, depending on time of day and weather conditions. For example, during weekdays, students tend to pass through certain spots between classes with distinct peaks according to the university class schedule. With use of some features such as speed variance, the movement activity patterns are roughly classified into several types namely: necessary activity (i.e., attending to a class) and optional activity (i.e., sitting and resting for a while)

This research attempts to develop a methodology for analyzing human mobility and activity patterns based on Wi-Fi traces. When applied in a commercial district with public Wi-Fi networks, the trajectory and activity patterns can be used to characterize the district and evaluate the district's vitality at a street-level. Recognized patterns can subsequently be investigated with surrounded built environments and environmental factors such as temperature and noise. This work would help planners and policy makers to better understand pedestrian movement trajectories and activity patterns, and to identify potential interventions that could improve the vitality of the street, based on the real-time and high-resolution data obtained.

21ST CENTURY TOOLS FOR MEASUREMENT AND ANALYSIS OF METROPOLITAN REGIONS

Abstract ID: 370

Individual Paper Submission

RICHTER, Steven [The University of Texas at Austin] steven.richter@utexas.edu, presenting author

Since the early 20th century, rapid urban growth has led to evolving conceptions of urban systems. Conurbation (Geddes 1915) required a more regional perspective, leading to the metropolitan concept; however, measuring change in the metropolis was and still is a challenging endeavor. For example, the myriad definitions of “suburbs” (Forsyth 2012) complicate how we spatially delineate metropolitan regions. Researchers have primarily developed opportunistic techniques that apply existing statistical and spatial data, typically at the municipal or census tract scale to understand metropolitan spatial patterns of the 20th century, chief among them central city decline and outward expansion (“sprawl”). But the 21st century presents an evolving set of phenomena that require different approaches to measuring metropolitan change, especially urban environmental sustainability. Urban systems are a crucial scale for addressing global environmental problems (Sassen 2010) but applying traditional measurement strategies fail to capture many of the most important urban processes. This paper addresses the question “How can metropolitan measurement strategies evolve to better capture the complex and dynamic processes associated with urban environmental sustainability?”.

This paper first presents conceptual tools necessary for measuring metropolitan change. A researcher must first understand the difference between abstract and material findings associated with the application of spatial abstractions. The former represents findings associated only with changing spatial abstraction, such as changes in the counties that comprise a given metropolitan region. The latter are findings that represent actual changes in the region. Next, the researcher needs to define the phenomenon of interest as a relative versus absolute. Measurement of the former involves changing or dynamic spatial abstractions while the latter necessitates static abstraction. Taken together, these concepts guide researchers toward an appropriate measurement strategy. To illustrate these concepts, they are applied to a well-cited paper measuring 20th century metropolitan change (Baum-Snow 2007). The paper primarily uses a static approach to measure an absolute phenomenon, declining central city populations. However, the paper also addresses a relative phenomenon, suburbanization, which requires a dynamic approach to measurement. Failure to change the measurement strategy results in significantly different results, demonstrating the value of the conceptual tools described in this paper.

Next, a new metropolitan measurement strategy is presented that provides an improved approach to delineating metropolitan structure. This strategy uses the National Land Cover Database (NLCD), which identifies land cover at 30-meter resolution, as the foundation for a more flexible approach to measuring metropolitan change. In comparison to the commonly used census geographies, the NLCD reflects physical conditions on the ground at high resolution, allowing for fine-scale analysis of other data layers, such as census data, flood plains, building or parcel data, etc. This approach is demonstrated through a presentation of several measurement strategies that both target unique combinations of the relative-absolute and abstract-material concepts as well as demonstrate how NLCD data can be combined with additional layers to measure sustainability-related phenomenon. Applying the conceptual tools earlier in the paper using sophisticated spatial abstractions built around fine-scale land cover data further clarifies the challenges facing measurement of metropolitan sustainability and provides examples for researchers facing similar challenges.

Abstract: With the rapid development of the city, the public space in the city is increasingly unable to meet the needs of urban residents. In the new era, the planning and updating of urban public space provides a feasible path for urban spatial transformation, urban spatial quality and image enhancement. Since 2013, Huangpu River Riverside Development has promoted the development of public space environment while promoting regional functional development and industrial transformation. In 2014, the ‘Three-Year Action Plan for Public Space Construction on Both Sides of the Huangpu River (2015–2018)’ clearly proposed to concentrate on building a number of high-quality public spaces for three years. At the end of 2017, Shanghai has basically realized the opening for the Public Space of Huangpu River, which is 45 kilometers from Yangpu Bridge to Xupu Bridge. In addition, the ‘Public Questionnaire Survey Report on the Open Space of the East Bank of the Huangpu River’ shows that the Laobaidu section of the East Coast is very popular among the public. 30% of the citizens in the survey have visited this section, which is a relatively dynamic section of the East Coast.

Based on the urban development background of the two banks of the Huangpu River, Laobaidu section on the east bank of the Huangpu River was selected as the research section of vitality measurement. With a drone's 90-degree overhead shot of the 1.5-km coastal waterfront public space, we collected aerial image data at different time periods with characteristics of human's location and activity type. We use people's point density of the public space of the Huangpu River to express the intensity of population activity, which is used as a quantitative measure of public space vitality. The research mainly focuses on several questions: 1. The differential distribution of the public space vitality of different sections? 2. Citizens' activity type preferences and material space preferences? 3. What are the different characteristics of riverside vitality at different times? 4. What is the correlation between the public space vitality of riverside and the surrounding hinterland (influencing factors such as population, housing price, land use function, location, etc.)?

The research expects that the dynamics of different sections of the Laobaidu Riverside section are obvious, and most of the high-energy sections are equipped with riverside seats, basketball courts or outdoor dining chairs; the riverside runway and bicycle lanes are highly used, but the riverside Walking is still the most important type of riverside activity. In addition, picnics are also popular in the riverside activities. The riverside vitality is distinct at different times, with the highest vitality at noon and afternoon, and relatively low morning and evening vitality; The population of the surrounding settlements, housing prices, land use function mix and location have different degrees of correlation. Compared with other sections of the riverside, the vitality of the Laobaidu section is highly influenced by the surrounding settlements.

The purpose of the study is to explore the use and preference of the public space in the riverside of the citizens, and to find the positive and negative areas of the riverside region. Besides, it is to find the influencing factors affecting the level of vitality, and provide suggestions for urban design of the riverside city on the next step. At the same time, the construction and investment development of different sections of Huangpu River in the future should be adjusted with the vitality of the hinterland, which is not suitable for investment and development evenly.

USING PHOTOVOICE AND QUALITATIVE GEOVISUALIZATION TO MAP HUMAN PERCEPTIONS AND EMOTIONS RELATED TO THE BUILT ENVIRONMENT

Abstract ID: 408

Individual Paper Submission

MEENAR, Mahbubur [Rowan University] meenar@rowan.edu, presenting author

Scholars across the social science and humanities disciplines recognize the importance of understanding the impact of human emotions because, according to them, human world is constructed and lived through emotions (Smith, Davidson, and Bondi 2016). In the field of urban planning, it is critical for planners to understand the role that they might play in increasing mental and emotional health, as well as spiritual well-being (Pfeiffer and Scott 2016). In this paper, we explore how people perceive elements of the urban built environment, including how people's emotions are attached to those elements within the context of post-industrial and socio-economic-environmentally disadvantaged urban neighborhoods being subjected to the forces of gentrification. Our study is connected to an EPA-funded brownfields revitalization planning project situated in an old industrial district in Philadelphia's North Kensington area. We seek answers to the following three research questions: (1) What types of emotions do people feel about the spaces or places in changing urban landscapes? (2) How can we map those emotions? (3) How can such maps be useful in community and environmental planning?

According to psychologist Robert Plutchik's psycho-evolutionary theory, emotions are understood to be adaptations to physical and social environments (Plutchik 2001). We collected qualitative data on physical and social environments through three sources: (1) focus group discussion transcripts (n=16), (2) photo captions and descriptions—oral and written—obtained through community photovoice activities (n=13; 20-23 photos each), and (3) in-depth interview transcripts (n=13). This data was subsequently analyzed through qualitative content analysis and coding, utilizing a Word-Emotion Association Lexicon (Mohammad and Turney 2013). After isolating the emotional content data, it was categorized in accordance with Plutchik's "emotion wheel", consisting of 8 primary emotions organized in contrasting pairs: joy and sadness, anger and fear, trust and disgust, and surprise and anticipation. Next, we mapped the emotion associations of spaces using a qualitative geovisualization methodology to analyze and visualize geospatial data in a GIS environment. This mixed-methods approach to representing the experiences and emotions associated with geographic spaces provides a non-numerical, personable, and rich account of people's lived experience (Cope and Elwood 2011).

Our analysis found that most people who participated in this study identified challenging neighborhood spaces (e.g., vacant or unmanaged lots, scrap yards) as their photo subjects and associated those spaces with negative emotions or feelings; however, some participants identified the same types of spaces as sources of anticipation or hope. We present our results using three major types of maps: (1) a heat map of all positive and negative emotions throughout spaces; (2) eight maps showing eight primary emotions (as described above) and their connection to spaces; and (3) examples of parcel-level maps connecting spaces, emotions, quotes, and photos. Based on these maps, we argue the importance of understanding people's perception of existing spaces and their emotions attached to those spaces before any actual planning or design processes take place. Finally, we discuss how maps such as those created in our analysis can be useful in community planning and how this methodology can be applied in other similar cities.

MALECHA, Matthew [Texas A&M University] malecha915@tamu.edu, co-author

A notable result of climate change is that the frequency and costs of weather-related hazards and disasters continues to increase. 2017 was the costliest year on record for US disasters, with flooding alone accounting for over \$3 billion in damages. Costs continue to rise in large part due to a lack of coordination among decision makers and continued development in hazardous areas. The lack of coordination of hazard mitigation and land use planning, as well as community policies and plans may result in an increase of people, homes, and infrastructure exposed to flooding and climate change impacts. In Harris County, TX more than 7,000 homes were constructed in the 100-year floodplain since 2010, many of which suffered damage during Hurricane Harvey. Scholars and policymakers have pointed to the need for better coordination of plans that guide development as well as better integration of hazard mitigation throughout a community's network of plans. To address this dilemma, our research examines the interconnected network of governance structures that lead to integrated planning efforts and collaboration among stakeholders in extreme events.

We examine two sets of data, a stakeholder network and a network of plans. The purpose in examining these two sets of data is to more fully understand the individual actors and organizations involved in the planning process, as well as physical efforts around flood mitigation. By identifying who is listed in plans and who is responding to flood mitigation needs, we are able to more fully synthesize these distinct aspects of involvement in flood mitigation and hazard planning. This process allows us to answer a number of important questions, such as: Who are the actors in the hazard mitigation and planning networks? Are organizations listed in plans well connected in the hazard mitigation social network? And, what are the implications of the overlapping relationships in the two networks for hazard mitigation?

This analysis proceeds in two main steps. The first includes collecting and analyzing a comprehensive set of plans from the greater Houston region. We then create a network of plans that examines the organizational overlap and involvement in various aspects of the individual plans. The second includes the stakeholder survey which asked about levels of collaboration with other organizations on resilience mitigation. Both sets of data are analyzed using social network analysis techniques which examines the underlying structure of interaction among a set of social actors. We then compare and contrast the planning network and the stakeholder social network to identify overlaps, inconsistencies, and gaps in the two networks. Preliminary results suggest that there is overlap in those organizations involved in the

planning and flood mitigation processes. In other words, organizations listed in a plan in the greater Houston region are also likely to be collaborating with other organizations on flood mitigation efforts. There are some inconsistencies with the networks as well. Most notable, the stakeholder networks involves numerous nongovernmental organizations (NGOs) such as nonprofit organizations and private companies, that go nearly completely omitted from the planning networks. We conclude with comments about how an improved understanding of the relationship between these parallel networks may help to better coordinate approaches to planning, disaster recovery, and long-term risk reduction.

BOTCHWEY, Nisha [Georgia Institute of Technology] nisha.botchwey@design.gatech.edu, co-author

Many of the existing walkability indices do not include street-level streetscape characteristics in their calculation due to the lack of a scalable way to measure them. In a previous study, we demonstrated the effectiveness of measuring walkable streetscapes as measured at eye-level using over 44,000 Google Street View (GSV) images and a computer vision technique. Although this study showed that our method of measuring walkability outperforms Walk Score in explaining walking mode choice, it was limited in that the factor analysis approach for summarizing the image characteristics made inter-city comparisons difficult and that the generalizability of the finding to cities other than Atlanta was unknown. In this study, we extend our previous study through two innovations. First, we develop an intuitive ratio-based index converting GSV images into a single score that allows intuitive intra- and inter-city comparisons and test its effectiveness relative Walk Score as well as the factor analysis-based approach. Second, we expand the study area from Atlanta to multiple cities across the United States to examine the generalizability of the index construction.

Based on various descriptive and exploratory analyses, we formulated two ratio-based indices, each of which represents distinctive dimensions of the streetscape. They were then combined to create one composite index which is comparable across different cities. We found that the composite index provides

model fit measures that are as good as those provided by three factor scores from the previous study while being parsimonious. The multicity evaluation of the composite index can reveal the degree to which the effectiveness of the index found in Atlanta can be generalized to cities that have different characteristics and how the uniqueness of each city's built environment affects the association between the index and walking mode choice. The results can play an essential role in developing and refining a walkability index that measures the visual aspect of the built environment.

ENGAGING STUDENTS IN STUDIOS THROUGH GEODESIGN: A HYBRID APPROACH FOR AN INTERNATIONAL GEODESIGN COLLABORATION PROJECT

Abstract ID: 465

Individual Paper Submission

SMITH, Alison [University of Georgia] alisonls@uga.edu, presenting author
RIVERO, Rosanna [University of Georgia] rrivero@uga.edu, primary author
VICK, Robert [University of Georgia] ravick@uga.edu, co-author

This research is part of an International Geodesign Collaboration project (www.geodesigncollab.org), intended to answer a common question to more than 50 universities worldwide: can we improve our global infrastructure using the Geodesign Collaboration approach? We established a local collaboration at the College of Environment and Design, University of Georgia. This collaboration was a partnership between graduate-level Landscape Architecture and Environmental Planning studios that involved three professor and 24 students. Our secondary research question was: can we engage and promote better-negotiated designs among students using a collaborative online design environment?

Geodesign is a collaborative planning and design environment with evaluation, sketching, visualization, and negotiation capabilities that allows participants from a variety of backgrounds to design future scenarios on a region. Geodesign is also a framework for improving decision-making in collaborative planning projects that integrates analysis, evaluation, design, and decision support techniques, generally using enabling technologies for planning for built and natural environments (Campagna et al. 2016). Several frameworks have been developed to implement and optimize the geodesign workflow. One of the most used in a variety of projects around the world is the one proposed by Carl Steinitz (Steinitz 2012) and implemented as an online tool by Hrishikesh Ballal. This framework is inspired by systems thinking and suitability overlay ideas first developed by Ian McHarg (1969) in his book *Design by Nature*.

Methods

To answer this question, the semester-long studio focused on the 10-county coastal region of Georgia, in collaboration with several local and regional stakeholders and institutions. The geodesign process for the

studio involved defining criteria for 10 systems pre-defined by the IGC, the creation of a set of evaluation maps for the 10 systems and the use of Geodesignhub (geodesignhub.com), an online geodesign workflow platform, to facilitate the mapping, visualization, and negotiation of future scenarios for the 10-county region (Rivero et al. 2015).

From the results of the geodesign process, we identified 3 target areas (Savannah, Hinesville, and Darien), where design strategies were applied to propose solutions, and expand policies and projects proposed during the first phase of geodesign.

The innovative aspect of this Studio is that we used a hybrid approach (traditional and geodesign Studio), allowing students to produce alternative design scenarios, that integrate the learning from a traditional inventory and design approach (inventory, review of plans, studies and other documents, synthesis and evaluation maps), with the evaluation, visualization and negotiation capabilities that geodesign offers. By doing this, students were deeply engaged throughout the process, and develop a more in-depth understanding.

Findings

- Projects and policies identified through the geodesign process, and local projects developed during the site design process, addressed some of the most important priorities identified for the region, consistent also with the systems established initially by the IGC project. Therefore, this hybrid approach proved the validity of the method.
- Priorities addressed through the proposed designs included: increasing the region's resilience to sea level rise, flooding, and storms; protection of water recharge areas and need for green infrastructure and water conservation projects and policies; addressing socio-economic needs; creating new job opportunities for a region with high levels of poverty; and increased infrastructure development associated with ports and transportation.
- Representing stakeholders' perspectives through the negotiation phase, proved to be an excellent approach to teach students about the importance of collaborative planning and negotiation. Therefore, the relevance of this work to planning scholarship, practice, or education
- There is still room for improvement in the tools and in the process, for effective implementation of these methods in the classroom.

An end-chain accessibility assessment, commonly referred to as the ‘last mile problem’ refers to an analysis of the bottlenecks incurred in the final leg of a network delivery system, typically the product delivery to end-users. In urban transit parlance this is the final leg of a commute. Some research suggests that the last mile problem (LMP) can play an important role in how public transit systems are perceived and used (Zellner et.al., 2016). Prior LMP studies have typically focused on walking/biking strategies for improving the last mile experience (Tight et.al., 2016). Missing however, has been an analysis on the potential destinations of public transit users and a standardized way for identifying the areas that warrant last mile strategic or design intervention on a large scale. The ability to do this would enable designers to focus specific strategic intervention to specific places.

This paper describes a machine learning approach for identifying residential areas that have the characteristics of LMP. We use the cities of Chicago, IL and Stockholm, SE to test and evaluate the performance of an LMP identification model. We compare outcomes in our two test cities in order to explore the differences between each condition, the potential differences in benchmarks for interpreting the issue, and potential localization problems that might be incurred in applying the model to two geographically disparate conditions.

Transit, transportation, land use and social media data are used to identify potential public transit based, travel routes to popular destinations for each residential parcel in each city. An easy to navigate, user interface is used to help visualize the assessment scores and collect public feedback. By considering transit destinations and not just potential walking distances, we begin help discern the link between destination, travel time, and the approach to the transit stop. We utilize user feedback and a Support Vector Machine algorithm to find an objective and locally recognized benchmark for score interpretation and weighting (Semanjski et al., 2017). These benchmark scores represent the local interpretation of public transit end-chain accessibility service levels. Exploring how the urban contexts and facilities impact last mile scores in the two cities can help to understand the differences in physical and socio-economic contexts between our test cases. This study will use a geographic weighted regression model to find the statistical relationship between context attributes such as road network density, public transit density, land use mix, amenity access, and the interpreted last mile scores in the two cities.

A comparative approach is increasingly important as new forms of urbanization unfold around the world, challenging inherited conceptions of cities as bounded and universally generalizable (McFarlane and Robinson, 2012; Brenner and Schmid, 2015). A common trap in comparative urban analysis however, is that the end result is a parallel description of the differences between cities without providing any contextual insights related to potential policy effectiveness. To address this, we extend comparative urban methods by developing a comparative modeling framework around the last mile issue. The process of constructing our model, data collection, data manipulation, and model calibration can reveal deep-rooted behavioral preferences, socioeconomic functions, urban structure, and core development patterns. The

inclusion of comparative analysis can help address the typical, overly context-specific shortcoming of typical spatial model applications (Pan et al., 2019), which prevents useful and easy application to different sites.

This research represents a potential approach to help reveal some of the complexity in urban transit system planning, and can also (at least) partly uncover causal relationships and feedbacks between system components (Pan et al., 2018b). We suggest the process is important for planning and urban design related planning support systems.

ANALYSIS OF THE SERVICE CHARACTERISTIC OF METRO STATIONS USING MOBILE PHONE DATA: A CASE STUDY OF HANGZHOU CITY IN CHINA

Abstract ID: 534

Individual Paper Submission

WANG, zexia [College of Architecture and Urban Planning, Tongji University] 18840852351@163.com, presenting author

NIU, Xinyi [College of Architecture and Urban Planning, Tongji University] 18840852351@163.com, co-author

Over the past few years, big data is widely used to explore metro passengers' mobility pattern and evaluate the performance of the metro system. And with the rapid development of metro systems in big cities in China, recognizing and identifying the service characteristics of metro stations and passengers' spatial-temporal behaviors seems very important for TOD strategy and metro systems planning. Many scholars defined the linear distance of 500m or 1/4miles as the size of the catchment area of metro stations (Cervero, R. et al., 2008). However, the deficiency of this scope is that all the metro stations are the same, without considering the difference of metro stations, while in fact, the catchment area is largely affected by the built environment around stations. Therefore, the radius of 1/4 miles cannot accurately describe the actual service scope of metro stations (Li Chen et al., 2017; Lauren Alexander et al., 2015).

This article aims to clarify (1) The actual catchment area of each metro station and (2) The spatial-temporal distribution patterns of metro passengers' traveling before boarding and after alighting the metro

stations. (3) The influence factors of the catchment area.

In this paper, we identified the travel trajectory of metro passengers using mobile phones data and analyzed the catchment area of metro stations in Hangzhou, China. The advantage of mobile phone signaling data is that it has larger sample size compares to other data, and as long as the user turns on the phone, the moving track can be recorded continuously, and we can identify all the moving tracks of the user (Ding Liang et al., 2017). After cleaning data, totally 18,836,798 OD trips are calculated from a dataset of 1.3 billion anonymous mobile phones positioning records. And based on the underground base station code in the mobile telecommunication network, 584,632 trips using the metro system are identified and 348,587 mobile phone users who identified as metro passengers. Using the trajectories of passengers from mobile phones positioning records, their places of residence and places of work can be identified, as well as their trip OD of before and after they enter or exit the metro station.

Results show that the catchment area of many stations are not within the theoretical 1/4 mile radius, and stations can be divided into different categories according to their size of catchment area (Ma Xiaolei et al., 2017). Moreover, significant differences exist in spatial-temporal distribution patterns of passengers' traveling of different stations. The actual catchment area of stations located in the central area of the city is larger than that of the non-central area. Furthermore, passengers who alight terminal stations travel further than those alight from non-terminal stations. For the time-varying pattern of passenger flow, it shows that many stations have a bimodal distribution pattern, and most of the passengers use subway during rush hour. It also shows that the distribution of passengers after they take off train and exit station is influenced by many factors like road network structure and bus connection around the station, which means a good road network and bus connection can effectively extend the service distance of the metro station. Moreover, the land use around the stations has a significant influence on the time-varying pattern of passenger flow. The mixture of land use around stations is beneficial to alleviate the imbalance of passenger flow.

MEASURING LIFE QUALITY AND RETAIL VITALITY BASE ON BIG DATA REVEALED STREET CHARACTERISTICS

Abstract ID: 544

Individual Paper Submission

WANG, Sen [China Academy of Urban Planning and Design] senwang2016@gmail.com, presenting author
ZHANG, Chun [Beijing Jiaotong University] zici0723@126.com, co-author

The roles of street design and network characteristics on urban vitality have been discussed for a long time. But the conclusion is still unclear. Using the points of interest data and navigation data extrapolated from Baidu Maps, we investigate the relationship between road characteristics and retail distributions – an indicator of urban vitality. Our research applies K-means to cluster retails in light of three continuous factors of roads, including network density within $\frac{3}{4}$ miles, total network capacity within $\frac{3}{4}$ miles, and the Euclidean Distance to the nearest Central Business District. Incorporating the clustered categories of retails, we implement a logit regression model to estimate the determinants of retail categories in the context of their commercial definitions, e.g. café, restaurant, bookstore, etc. Results indicate that there are three types of retails. The first-tier retails cluster near the center of CBDs with high requirements of network density and relatively low network capacity; the second-tier retails are more widely distributed but still sensitive to network density and network capacity; the third-tier retails locate centerless with no connection to network density and network capacity. The logit regression model is non-significant. Only the distance to the nearest CBD exerts diminutive negative effects on the commercial definition of retail categories. This indicates that location strategies are different within each retail category.

The results contribute to the relevant fields in that it provides an empirical analysis of the relationship between basic elements of road design and retails. Urban road networks support the location strategy of retails. The policy implications of the research are in two folds. On the one hand, retailers could evaluate the match of retail locations with road networks and guide their location decisions. On the other hand, planners could leverage urban land use through dedicated road design. Further research might dig in the POI types beyond retail and reveal a more comprehensive influence of road networks on cities. In addition, researchers may develop thresholds/matrixes for certain type of roads to sustain urban vitality.

CALIBRATING TRAVEL DEMAND MODELS USING DATA ANALYTICS

Abstract ID: 556

Individual Paper Submission

QAISRANI, Muhammad Arif [University of Texas at Arlington] muhammad.khan10@mavs.uta.edu, presenting author
HAMIDI, Shima [University of Texas at Arlington] shima.hamidi@uta.edu, co-author
TAYARANI, Mohammad [Cornell University] mt789@cornell.edu, co-author
GAO, H. Oliver [Cornell University] hg55@cornell.edu, co-author

Transportation and land use planning heavily rely on travel demand models to predict how future cities will look like. The accuracy of these models, therefore, are important regarding the rapid change in urban infrastructure and mobility. Calibration and validation are critical tasks in increasing the reliability of the models. Traditionally, the models have been calibrated using observation data which are costly and unreliable since they do not take into account the real-time congestion, road conditions and peak hour traffic (Bedogni et al., 2015).

Advancement in information and communication technology (ICT) and the influx of smartphones provide a new venue for travel data collection. Google maps calculate travel times between origins and destinations using complex algorithms through anonymously recording travels data from the users who turn on their GPS location. Google Maps data for travel time is relatively accurate, up to date, easy to acquire and take into account the real-time conditions (Dumbliauskas, Grigonis, & Barauskas, 2017; Wang & Xu, 2011). The large penetration of smartphone usage in the USA provides a big dataset of real-time travel data including detailed information on congestion, road condition and peak hours (Cottrill & Derrible, 2015).

In this paper, we aim to provide a framework for validating and calibrating the regional travel demand models with real-time data obtained through Google Maps Distance Matrix Application Program Interface (API). This API is a service by Google that provides travel distance and time for a matrix of origins and destinations based on recommended routes between the two points (“Distance Matrix API,” 2019). We intend to use this novel technique to collect travel time data for each Origin-Destination (OD) pair for the 1075 Traffic Analysis Zones (TAZs) in the City of Dallas and use them to validate the travel times predicted by the regional travel demand model. Python will be used to automate the process of data extraction and create travel time (skim) matrices for the OD pairs.

The findings will be used to develop a new generation of low cost, time effective and highly accurate traffic forecasting methods using the emerging field of data analytics. This technique will help improve the forecasting capabilities of travel demands models which would assist the transportation agencies and stakeholders in making right decisions for infrastructure financing based on real-time demands.

URBAN PLANNING & OPERATIONS RESEARCH: A REVIEW AND CRITIQUE TO SUPPORT DECISION ANALYTICS FOR URBAN PLANNING AND COMMUNITY-BUILDING

Abstract ID: 581

Individual Paper Submission

FABUSUYI, Tayo [University of Michigan] fabusuyi@umich.edu, presenting author

JOHNSON, Michael [University of Massachusetts, Boston] michael.johnson@umb.edu, co-author

Operations research (OR) is a multi-disciplinary field devoted to the science and practice of improved decision-making through modeling and analytics. While inquiry in OR modeling of urban planning processes is long-standing (Rosenhead 1981), on the whole the OR discipline has not influenced urban planning practice, teaching and scholarship at a level of other domains such as public policy and information technology. Could an OR approach which focuses on the complex, emergent nature of cities and the institutional environment in which these urban planning models are implemented enable urban planning to better meet challenges that are complex, multi-stakeholder, data-intensive and stochastic in nature?

Given demographic shifts towards cities and urban areas, and with an eye towards the future, we identify nascent innovations and developing challenges within the urban planning space. Based on a review of research and practice in OR and urban planning, we argue that a prospective and prescriptive approach to planning that embraces mixed-methods can help researchers and practitioners develop interventions that are equitable and which reflect community concerns. Examples of these approaches are community operational research (Johnson, Midgley and Chichirau 2018), geodesign (Goodchild 2010) and complex adaptive systems (Holland 2006). We show that trends and developments within urban planning highlight the benefits of embracing an OR modeling approach both in the framing of the model and in its implementation, while emphasizing two cautionary themes. First, a mechanistic application of decision modeling principles rooted in stylized representations of institutions and systems using mathematics and computational methods may not adequately capture the central role that human actors play in developing neighborhoods and communities. Second, as innovations such as the mass adoption of automobiles decades ago led to auto-centric city design show, technological innovations can have unanticipated negative social impacts. Therefore, we emphasize the important role of critical approaches, community engagement and diversity, equity and inclusion in planning approaches that incorporate decision modeling.

We use “smart cities” programs as examples in illustrating our approach – documenting how many improvements from these programs have been incremental at best; in large part due to the inability to properly reflect the contextual realities and institutional environments in which they are implemented (Goodspeed 2015). We create an OR modeling framework robust enough to conceptualize and design smart cities solutions that make explicit consideration of the context in which the innovation will be implemented. Specifically, we make the case on the need to push back against the observed “off the shelf” mentality that has plagued most OR models applied to urban planning in the past, and instead argue for the need to subscribe to context-specific approaches that place the residents and the stakeholders at the center of the planning process.

ASSESSMENT OF CITIZEN’S ‘AFFECT’ FROM TWEETS IN DIFFERENT URBAN SETTING: COMPARING ATLANTA AND BOSTON

Abstract ID: 584

Individual Paper Submission

DUTT, Florina [Georgia Institute of Technology] florina.design@gatech.edu, presenting author
GUHATHAKURTA, Subhrajit [Georgia Institute of Technology] subhro.guha@design.gatech.edu, co-author

Urban design of a city, characterized by its land use pattern, block sizes, building density, etc. are critical in generating urban vitality and encourage civic activities. Studies show that certain urban spaces have taken a crucial role in generating urban activities and in upholding the liveliness of urban areas while others have failed to do so. In this study, the key assumption is: the emotions felt by individuals engaged in different types of urban activities often differ in diverse urban settings. The situational emotion is often the result of the individual’s interaction with the environmental stimuli, and it is termed as ‘affect’ [1]. To conduct an extensive study and unravel how urban settings impact citizen’s affect and overall mental health two cities are chosen: Atlanta and Boston. The reason for the choice of these two cities (Atlanta and Boston) is the inherent difference in their urban characteristics. While, Boston has a dense urban fabric with smaller block sizes, providing a diverse land use choices to individuals; Atlanta is known for its sprawled development, larger block sizes, and less diverse land use.

This study looks at Tweets from both cities for a year period and uses applied machine learning [2][3] to gauge the urban activities [4][5] and identify the ‘affective measures’ associated with each of these tweets. The tweets are first classified to identify the associated urban activity [6]. Next, linguistic analysis is conducted to assess the ‘affect’ value associated with each urban activity identified. The result of the study intends to explain how the ‘affective measure’ associated with the urban activities differ in different areas of the city (characterized by the land use pattern, block sizes, and building density, etc.). Also, the study highlights the differences in ‘affective measures’ for urban activities between Atlanta and Boston. The results primarily show that land use is the crucial factor in determining the ‘affective measure’ of Tweets in both Atlanta and Boston. Building density, block sizes, and street network density also has the explanatory power in determining the frequency of reported urban activities on Twitter. Finally, the results reveal, Tweets in Boston and Atlanta has significant differences in the ‘affective measures’ for certain land use categories and associated urban activities.

IS POLYCENTRIC SPATIAL STRUCTURE CONDUCTIVE TO JOBS-HOUSING MATCHING? A STUDY ON URBAN EMPLOYMENT CENTERS IN HANGZHOU USING MOBILE PHONE SIGNALING DATA

Abstract ID: 603

Individual Paper Submission

JUAN, Zhu [College of Architectue and Urban Planning, Tongji University] 39976970@qq.com,
presenting author

NIU, Xinyi [College of Architectue and Urban Planning, Tongji University] niuxinyi@tongji.edu.cn,

Current studies show that since the reform and opening up, due to the constant diffusion of the housing and employment, an emerging polycentric spatial structure in Chinese mega cities has been confirmed in literature, but few empirical studies has payed attention to whether polycentric spatial structure is more conducive to jobs-housing matching, that is, people will choose jobs in the employment center close to their place of residence to reduce the commuting distance (co-location hypothesis). Taking Hangzhou as an example, this paper proposes two research hypotheses, namely (1) whether Hangzhou is a polycentric city; (2) whether the polycentric spatial structure of employment is conducive to jobs-housing matching.

Based on the location of the base station, mobile signaling data can identify the user's residence and work place, which is similar to the journey-to-work survey data with a large sample size. The paper uses the mobile phone user's residence and work place data to identify employment center and analysis its jobs-housing characteristics. Firstly, from the perspective of TAZ unit in the central urban area of Hangzhou, employment centers are identified by the method of the threshold value of employment density and employment to residence ratio. Secondly, the average distance from the boundary of the employment center is used as the buffer zone, and the commuting rate within the average commuting distance of the employees in employment center is taken as the index of jobs-housing matching rate. Finally, stepwise multiple regression analysis is adopted to study how the industry type, industry diversification level, industry specialization level, land mixed use level and supporting infrastructure affect the jobs-housing matching rate of the employment center.

The study found that Hangzhou identifies 42 employment centers, which are divided into six types: comprehensive, business-office, commercial-entertainment, commercial-logistics, R&D, and industrial manufacturing. Among them, the suburban agglomeration characteristics of commercial, R&D and industrial manufacturing employment centers are significant, indicating that Hangzhou has the characteristics of polycentric spatial structure. The Jobs-housing matching rate index of employment

centers shows that under the polycentric spatial structure, there are still a few employment centers with serious jobs-housing mismatch. The polycentric spatial structure may not guarantee the Jobs-housing matching of all the employment centers, but it can promote the Jobs-housing matching in whole city. Factors such as the type of industry, urban renewal mode, spatial location, functional mixing degree, traffic and natural barriers are important factors affecting the matching relationships. Multiple regression analysis found that the location entropy of finance and business service and industrial diversification level in the employment center had a negative impact on the jobs-housing matching rate, while the mixed use of land and industrial specialization level had a positive impact on the jobs-housing matching rate. Therefore, the employment center should avoid excessive agglomeration of multiple functions in urban planning, in particular, the financial, business and other high-level service industry agglomeration center should pay much more attention and relevant residential facilities must be provided surrounding such employment centers. In urban renewal and new town employment center planning, special attention should be paid to Jobs-housing mismatch, and we suggest to establish a policy zoning system based on employment centers and the Jobs-housing matching index in urban renewal and new city planning should be taken into consideration.

How can we identify functional regions using alternative but more widely available data sources? For local economic and policy analysis, researchers often need to redefine urban or regional boundaries reflecting functional connectivity and complementarity, which do not necessarily respect administrative boundaries (Cörvers et al., 2009). Conventional methods employed for this purpose are based on detailed cross-municipality traffic and trade flows data, but application of the methods is highly constrained by data availability (Duranton, 2015). In the context of developing countries, lacking quality subnational data sets makes it hard for the application, although rapid urbanization and the imminent need for policy intervention increase demand for urban analysis (Glaeser and Henderson, 2017).

This study is motivated to fill the gap, and we introduce an alternative method subject to low data requirement, taking South Korea as an example. Our case selection is for the validation of our analysis results (vs. the results from conventional methods), although South Korea is far from a developing country in any standard. The method we employ is a percolation model in physics, which has also been applied for urban analysis (Arcaute et al., 2016; Batty, 2018). The only data input required for our model is national level road network data, which is widely available through various official and open sources. In this model, we focus on road junctions for connectivity, and convert the network data into an extensive origin-destination table. Then, we test a wide range of cross-junction distance thresholds to analyze system-level hierarchies and connectivity. From this analysis, we ultimately aim to demonstrate road network data can substitute for subnational flows data in drawing functional urban and regional boundaries.

Our results show that distance thresholds of 740 meter (~0.46 mile), 1.64 to 1.66 km (~1.02 miles), and 3.08 to 3.12 km (~1.93 miles) have particular importance in defining functional urban areas in Korea's context (Figure 1). When a distance threshold of 740 meter is tested, the model detects major cities and core urban areas. Applying a threshold of 1.64 to 1.66 km identifies Korea's major urban agglomerations or metropolitan regions, which are functionally well connected. Finally, a threshold of 3.08 to 3.12 km helps distinguish a few areas presenting exceptionally weak connectivity (and thus highly isolated) from other parts of the national urban system, which then can be considered with priority for publicly initiated transport infrastructure projects.

Figure 1. Urban Agglomeration Patterns Identified with Different Distance Thresholds.

Mianyang city suffered huge losses in “5.12 Wenchuan earthquake” in 2008, which mirrored the lack of capacity of urban disaster prevention and mitigation. According to literature review, 17 times earthquake whose magnitude was larger than 5 occurred in Mianyang between 1579 and 1978, including 5 times earthquake whose magnitude was larger than 6. Mianyang is located at the junction of three tectonic domains, and Longmenshan fault zone across north Mianyang. Both geological condition and seismic belt make Mianyang to be one of the zones with higher disaster risk level in Sichuan province. Percent of area threatened by earthquake accounted for about 86% of total area of Mianyang. It is essential and typical to take Mianyang as an example in this research. Previous researches mainly used straight-line distance in space as threshold value to calculate the buffer area of facilities. However, there is a big discrepancy between results calculated by straight-line distance in space and results calculated by actual walking or driving path. In order to improve the accuracy of results, network analysis of GIS should be adopted in this research. Urban road distance would be used as threshold value to study on mapping of disaster prevention and mitigation of Mianyang city (take second ring road as research range). Capacity of urban disaster prevention and mitigation are mainly reflected on refuge and rescue, namely disaster response capacity. Six factors have been chosen in this research, including density of population, service area of emergency shelter, service area of police station, service area of hospital, service area of fire station and explosion range of hazardous products warehouse. All of these factors are directly related to disaster response capacity. Result of explosion range of hazardous products warehouse could be analysed by using buffer analysis of GIS and results of another 5 factors could be analysed by using network analysis of GIS. Data and visual image of urban disaster response capacity of Mianyang were analysed by using GIS overlay analysis which could get comprehensive result considering these 6 factors. Outcomes can be listed as follows: 1. Total area of research area is about 200.02km²(100%). Area with high capacity of disaster response is about 79.45 km² (39.72%), area with medium capacity of disaster response is about 91.68 km² (45.84%) and area with low capacity of disaster response is about 28.88 km² (14.44%). Area with medium and low capacity of disaster response accounted for 60.28%, which means more than half of research area is in a comparatively high risk level of urban disaster prevention and mitigation from the overall perspective. 2. From the visual image, districts with comparatively low capacity of disaster response are Yuanyishan district, Nanhe district, Science City district, Xiaojian district, west section of second ring road and east section of second ring road. Nanhe district and Science City district are old towns, and the main cause of low capacity of disaster response is high population density. Yuanyishan district and Xiaojian district are new districts, and the main cause of low capacity of disaster response is lack of capacity of urban disaster prevention and mitigation, including lack of urban disaster prevention planning and facilities such as emergency shelter, hospital, police station, fire station, etc. Main causes of west and east section of second ring road with low capacity of disaster response are lack of urban roads, number of facilities. This GIS-supported mapping research on urban disaster response capacity of Mianyang city could provide precise and intuitionistic guidance and suggestion for urban disaster prevention planning. Furthermore, research could provide the fundamental basic for further visualization research on urban disaster prevention and mitigation.

MAPPING THE LANDSCAPE OF BEHAVIOURAL THEORIES: SYSTEMATIC LITERATURE REVIEW

Abstract ID: 610

Individual Paper Submission

KWON, Heeseo Rain [University of Cambridge] hk394@cam.ac.uk, presenting author
SILVA, Elisabete A. [University of Cambridge] es424@cam.ac.uk, co-author

The “behavioural” approach is receiving increasing attention in many disciplines including planning, attracting many academics and practitioners to apply various behavioural theories. However, there is yet limited understanding of the available theories and how they can be applied. This paper addresses the following research question: Can we create a more transparent list and classification of behavioural theories?

This paper argues that a “behavioural theory” explains some aspects of the process where a stimulus or situation gets imposed on a person, leading to an intention or motivation and a response or decision. It takes an approach of a systematic literature review of 963 publications that contain the word “behavio(u)ral theor(ies)” in the title between 2000 and 2017 and filters the key papers based on times cited and the scope of general human behaviour. As a result, 62 behavioural theories are identified and are classified into four groups. The first group explains the factors that affect behaviour such as attitudes, norms, risks, heuristics, institutions and rationality explained in theories like the theory of planned behaviour, prospect theory, collective action theory, and the theory of bounded rationality. The second group focuses on the strategies to influence behaviour and gets used in public policy and business management such as nudge theory and diffusion of innovation theory. The third group includes learning and conditioning theories such as reinforcement conditioning theory that can modify the response and is largely applied in topics like artificial intelligence and machine learning. Finally, the fourth group focuses on the modelling of behaviour such as neural networks theory, game theory, complexity theory and fuzzy theory, and gets mostly used in computer science and neuroscience as the basis of techniques such as dynamic network analysis, agent-based modelling and microsimulation.

Based on the literature review, the paper discusses the following five points. First, there needs to be a further clarification of what theories can be classified as “behavioural theory”, and in what fields behavioural approaches are applied to transfer models and compare results. Second, further classification of the types of behaviour is important because different behaviour gets affected by different variables. There is also a need to identify the hierarchy, family trees, and overlapping concepts of theories. Third, more guidance on the selection and use of appropriate behavioural theory is needed by building a portfolio of theories linked with variables, type of behaviour, and research methods. Fourth, behavioural theories can be more included in data-driven research and agent-based modelling. Computer science, artificial intelligence, and big data analytics are very important in the behavioural research at present, all part of the bigger effort towards the development of data science which is closely related to planning in the era of smart cities. Behavioural theories can play a critical role in bridging the traditional theory-

based, aggregate, quantitative and equation-based approaches with the new data-based, disaggregate, qualitative and language-based approaches such as agent-based modelling (Parunak, Savit, and Riolo, 1998; Ahmed and Klischewski, 2017). Finally, behavioural theories are ever more important because they can answer “how and why”, provide rationale for the rules, variables, assumptions and parameters of models, and help researchers generalize results (Wise and Shaffer, 2015). Furthermore, this paper proposes complexity theory as the overall theoretical concept (de Roo and Silva, 2010) and suggests that behavioural theories can play an important role in spatial planning in the bigger picture of integrating spatial and a-spatial approaches of modelling human behaviour. This paper is greatly relevant to planning research and practice because it helps navigate behavioural theories and highlights the importance of them in the era of big data analytics where data seem to speak for themselves.

SHI, Linda [Cornell University] lindashi@cornell.edu, co-author

MINNER, Jennifer [Cornell University] j.minner@cornell.edu, co-author

Municipalities have many incentives to maximize property values, even when they know they are developing in areas that will increasingly be prone to hazards. If we want cities to conform their land use planning practices “with nature” (Burby, 1998) – instead of relying solely on disaster preparedness or building stronger infrastructure – then they need to be able to evaluate the fiscal implications of land use alternatives. Sea level rise (SLR) is an increasing challenge for coastal cities in terms of fiscal sustainability as it claims land, devalues and damages property that local governments have to repair. However, it is not clear the extent to which current planning support software facilitates assessment of vulnerability to SLR. To address this gap, we conducted a systematic review of existing scenario planning software for their ability to assess SLR scenarios. Because fiscal considerations often drive land use policy, including common strategies for SLR adaptation, like open space acquisition and down zoning (Schmidt, 2008), we focus our assessment on assessment of fiscal impacts.

First, we conducted a systematic review of software packages for their capabilities to assess fiscal vulnerability and tested three of them. We tested Envision Tomorrow, Urban Footprint, and Geodesignhub to calculate fiscal impacts of multiple SLR and adaptation scenarios. Our criteria for assessment include the ability to (1) compare fiscal impacts of multiple land use changes; (2) present results in multiple time periods to allow planning phased responses in step with projections that SLR will

accelerate, (3) and integrate development pathways and multiple jurisdictions. We found that the three tested packages facilitate some part of a fiscal impact assessment and require use of a general GIS to complete the assessment. None of the software packages create scenarios in multiple time periods; instead scenarios allow comparison between one baseline and one or more future states. Finally, each combination of policy responses must be treated as a separate scenario, posing challenges to incorporating contingencies in SLR adaptation planning.

Second, we share our experience assessing fiscal vulnerability under multiple scenarios for three municipalities in Boston's regional planning area. The research was conducted alongside a student workshop and land use planning class with three South Shore municipalities (Cohasset, Hingham, and Hull) and the regional planning authority, MAPC. Hull is one of the densest and most built-out coastal peninsulas in New England and will be a series of islands in 2100. Cohasset and Hingham are more inland and less developed, with more opportunities to adapt to changing coastlines. Each of these municipalities is pursuing strategies to secure their own future, though the strategies will also impact the other municipalities. To coordinate multiple local responses along with climate uncertainty results in hundreds of scenarios; a simplified model is necessary to be useful for planning (Kirchhoff, Lemos, & Engle, 2013; Kirshen, Merrill, Slovisky, & Richardson, 2012). Due to issues with scenario planning tools discussed above we found it challenging to articulate the breadth of possibilities and explore the interactions among them. Instead, we developed and evaluated a subset of likely scenarios selected with input from local elected officials, local and regional planners, and consultants familiar with the region.

Our assessment of scenario planning tools suggests a need for tool development that (1) integrates fiscal policy and sea level rise; (2) takes a spatially explicit approach to account for interaction of multiple local government strategies; and (3) includes multiple time periods, for example by incorporating discount rates. Finally, this research contributes practical guidance for fiscal and land use planning practitioners to mainstream sea level rise information and contributes more broadly into research on drivers of climate change adaptation planning.

DETECTING ABANDONED FARMLAND USING TIME-SERIES AND MACHINE LEARNING ANALYSIS OF REMOTE-SENSING IMAGERY - A CASE STUDY OF GWANYANG CITY, SOUTH KOREA

Abstract ID: 631

Individual Paper Submission

YOON, Heeyeun [Seoul National University] hyyoon@snu.ac.kr, presenting author

Farmland abandonment has been an increasing worldwide concern. Diversified reasons would explain this phenomenon, while main anthropogenic ones include aging rural population, the shortage of agricultural labors, restructuring industrial sectors and excess urbanization. Farmland abandonment have divergent effects. On the negative side, the invasion of native plant species on an abandoned land parcel would be likely to spread to nearby parcels that are still actively used for agricultural production. Some of such abandoned farmlands have been converted to a building site and accommodated haphazard property developments, which further ruined rural communities. Also, the removal of crops would increase the possibility of soil erosion, desertification, and the occurrence of wildfires.

Detecting abandoned farmland has been a challenging task. First, it requires a tremendous level of manual works, involving site visits and investigations to confirm the abandonment. Considering that those sites have inconvenient accessibility in general, precisely inventorying those might not be possible in most of the cases. Remote-sensing techniques have supplemented the manual efforts, however, limitations still exist. First, it is not easy to identify common and representative characteristics of abandoned farmlands in general, since the current status of those widely varies. The presence and types of vegetation are heterogeneous by the local contexts, and the reasons for and the length of abandonment; some of those sites experienced ecological succession and turned to a piece of naturalistic ecosystem, such as forests/thickets, while others remained barren or were cleared for human uses. And second, because the abandonment is determined after a certain period of time without agricultural productions on it, a cross-sectional analysis is not appropriate for detecting, classifying or mapping those conditions.

Against this backdrop, this study aims to detect abandoned farmlands from active croplands, through discerning the phenological trajectories, fully utilizing parameters derived from harmonic analysis of vegetation index, one of the time-series analyses for periodic cycle, and support vector machine, one of the machine learning classification techniques. In the first step, using harmonic analysis on the reference data, the characteristics of each land-cover type is derived from the remote-sensing imagery, and second, using the test set, classification is conducted using support vector machine. This study is the first attempt to utilize only the raw form of harmonic coefficients for the classification of abandoned farmlands, rather than using composited amplitudes and phases of vegetation index trajectory or estimated phenology matrix. Unlike other studies, the coefficients of the higher-order harmonic components enable more accurate detection of the differences in vegetation index trajectory of abandoned farmlands in case only short-term observation is available.

The study site is Gwangyang, in South Korea, one of the cities experiencing increasing farmland abandonment. The study period is from Jan. 2016 to Oct. 2017. The definition of the abandoned farmland varies by countries as well as government authorities in a country, and we follow one of the widely used ones in Korea defined by Korea Rural Community Corporation.

This study will shed light on land and resource planning literature, emphasizing the new analytical techniques, and will provide a useful reference to urban and rural planners on a mission of effective land management and revitalization of rural communities.

Individual's social networks can be formed by their social activities in the physical and cyber environments. Although previous empirical studies on social network and activity travel behavior provide useful insights, they are also constrained by data limitations in terms of spatial and temporal coverage and sample size. In this study, we investigate the relationship between social hotspots and individuals' social networks, taking advantage of a unique mobile phone dataset of millions of anonymous subscribers. Our main objectives include 1) exploring new determination technics for social hotspots and social connectivity using mobile phone data, 2) documenting empirical features of social hotspots and social connectivity, and 3) analyzing the relationships between individuals' social network structure, their activity travel patterns and social hotspots, and identifying empirical features that need new theories and explanations.

In conventional studies, social hotspots are often identified based on static geographic features such as point of interest, which is unable to capture the dynamic nature of these social spots. Our datasets allow us to characterize social hotspots in terms of land use characteristics and time characteristics (working hours, night time and holidays), and participant characteristics (neighborhood residents, national residents, and foreign visitors). We are able to analyze the interactions between individuals and the physical environment and the interactions among individuals in the cyber and physical environments to provide a complete plot of linkage between social connectivity and social hotspots.

In this study, the mobile phone data consists of millions of anonymous subscribers' detailed call records including the location and time stamp of each connection from March 2011 to May 2011 in Singapore. Firstly, we combine static geographic data such as points of interests, land use and infrastructure with dynamic population distribution derived from mobile phone data to characterize social hotspots, taking their activeness and service radius into account. We also develop algorithms to infer individuals' home location, work location and the spatiotemporal patterns of their visits to social spots. For social connectivity, we measure the number of contacts, connection frequency as well as spatial features of individuals' social networks, such as the distance from an individual's home to their contacts' home. With these features, we apply quantile regression models to conduct association analysis among individual social network, social hotspots, and their activity mobility patterns.

Our preliminary findings suggest that active social hotspots during after-work hours are close to active social hotspot during the working hours which implies that social activities after work are more likely to happen near people's working places. Besides, the increase in the distance of individuals' home/work

locations to downtown is associated with a decrease in their social network size at different extents. Regarding the spatial feature of their social network, people who live distant from downtown have contacts who appear to live far from them. While for people who work near downtown, their contacts tend to live close to them. Moreover, the results also indicate that the diversity of their social activities is positively related to the size as well as the spatial attributes of their social networks. In terms of the effectiveness of hotspots, the contribution of active social hotspots and non-active social hotspots to individuals' social connectivity varies.

The unique mobile phone data enable us to examine the complicated interactions among social network, social activities and social hotspots. This study demonstrates an innovative big-data-based approach in social behavior research. The findings could contribute to the planning practice in multiple ways, for example, to assist land use planning to improve the spatial distribution and efficiency of social hotspots to better meet neighborhood's demand for social interactions.

BEJLERI, Ilir [University of Florida] ilir@ufl.edu, presenting author

ZHOU, Ruchen [University of Florida] ruchen.zhou@ufl.edu, co-author

NOH, Soowoong [University of Florida] nswscott@ufl.edu, co-author

Background:

To enhance livability of our cities, planners and urban designers make efforts to improve the design of streets to accommodate all transportation modes and road users. Successful designs in the addition to the street proper should encompass other aspects of built environment such as buildings, streetscape, and sidewalks. Recent developments in rule-based parametric modeling inherently integrated into a geospatial framework, offer opportunities to support visual design of complete streets by blurring the lines between CAD, GIS, BIM and 3D modeling and visualization. The objective of this study is to apply such technology integration to explore parametric street design.

Study Design:

More specifically in this study we explore the application of complete streets rules to interactively develop several street design scenarios in a geospatial parametric environment. To support our methodology, we use several city blocks in need of redevelopment in Gainesville, Florida. We model the fundamental street and block morphology using Sketchup and 3D ArcGIS Pro and import the model into City Engine where we apply the ESRI's Complete Street Rules to develop several scenarios by parametrically manipulating numerous variables including physical layout, mode, on-street parking, street lighting, street trees, medians and sidewalks to name a few. The model includes additional parameters to redesign building size, roof types and façade textures to create a complete parametric environment for exploratory planning and design. Next, we import the model in a VR environment and simulate various design scenarios using walking, bicycling and driving modes of travel. Finally, we conduct a comparative analysis of traditional 3D modeling and visualization methods applied to street design with the rule-based approach taken in this study.

Results:

The use of 3d modeling and visualization, animation and even interactive visual simulation is not uncommon for street design. The difference in this study is in the use of the rule-based visual design which allows for development and exploration of scenarios interactively by dynamic manipulation of input variables. In addition, we publish various scenarios as web scenes for interactive exploration, especially to garner public input on the proposed designs, a typical requirement for plan approval by most planning agencies. Our comparative analysis shows clear advantages of the rule-based methodology. Such advantages include (a) rapid generation of scenarios leading to major reduction in modeling and visualization time; (b) modeling and visualization on a geospatial framework makes it possible to evaluate scenarios in the real-world context including buildings, streetscape, and zoning regulations; (c) enabling of opportunities for innovative public engagement by using web-scene interactive environment for exploration of planning and design scenarios; (d) future opportunities to expand this framework toward a more complete civil integrated management environment.

Conclusion/Contribution:

In conclusion, we find that 3D rule-based complete streets geospatial parametric modeling is a promising and effective integrated framework for street planning, design and evaluation.

HISTORIAN FOR A DAY: A USE CASE OF AUGMENTED REALITY IN COMMUNITY DEVELOPMENT AND CIVIC ENGAGEMENT

Abstract ID: 711

Individual Paper Submission

LEE, Ming-Chun [University of North Carolina at Charlotte] ming-chun.lee@uncc.edu, presenting author

History offers lessons and insights for any effort or attempt to make a neighborhood a better place to live, work, and play. It builds a foundation for the connections between people and people as well as between people and the place to be formed (Billig, 2005; Borer 2006). To reveal the history of any place in a city, proper tools are needed (Devisch, et al., 2016). This collaborative project demonstrates a new way to combine data visualizations, Augmented Reality (AR), and story-telling with narratives to engage community members in an effort to revisit the history of their neighborhood and in turn to re-create a common ground for mutual understanding and consensus-building necessary for meaningful community engagement and development.

Levine Museum of the New South is currently developing a new project, called #HomeCLT. It is imagined as an urban autobiography, peeling back the layers of time to show the city in new ways through a wide variety of voices and perspectives. The collection of stories, past and present, is the cornerstone of these exhibits. Levine Museum has built two proof-of-concept prototype models as a pilot version that were installed temporarily at two different locations in a pop-up style. The Augmented Reality Team (ART) at UNCC has been working with Levine Museum to organize two community events for two Charlotte neighborhoods of Eastland and Hidden Valley to include these indoor pop-up exhibits at two branch libraries. In addition, a neighborhood walking tour was conducted to accompany the indoor exhibit and allow visitors to go around the surrounding area and learn about the history of the neighborhood. To enrich visitors' experience with these pop-up exhibits, ART developed an experimental AR app, which works with the physical displays to offer visitors additional visual contents associated with the theme of the pop-up exhibits. These contents combine historical photographs, video clips, and illustrative figures of quantitative information in 3D. The underlying principle behind this AR app and these community events is the belief that innovative digital tools for information-sharing and broad-based public engagement can help build inclusive, healthy, and livable communities.

The goals of this project include: 1) to explore the potential of AR in community development and civic engagement; 2) to introduce AR to the general public through the use of mobile AR apps developed by ART in a series of community events; 3) to build partnership with local organizations, such as Charlotte-Mecklenburg Library and Levine Museum of the New South to develop and conduct community events as a platform to achieve these goals; 4) to develop AR mobile apps using Niantic's AR platform and other open-source software programs and assets and explore potential use cases in the field of community development and public participation.

The surveys conducted during the events provide initial findings as the following: 1) event participants learned about AR and gained first-hand experience about its potential in promoting civic engagement and public education; 2) participants were able to get involved in community affairs and learn more about

their own places and people through the exhibits and the AR app; 3) event organizers got hands-on experience about how the mobile app can be a fun way to engage community members.

UNCERTAINTY IN FLOOD MITIGATION PRACTICES: ASSESSING THE ECONOMIC BENEFITS OF PROPERTY BUYOUTS AND FREEBOARD ELEVATION IN FLOOD PRONE COMMUNITIES

Abstract ID: 714

Individual Paper Submission

MOBLEY, William [Texas A&M] wmobley@tamu.edu, presenting author
ATOBA, Kayode [Texas A&M University] kayodeatoba@tamu.edu, co-author
HIGHFIELD, Wes [Texas A&M Galveston] highfiew@tamug.edu, co-author

In the aftermath of repetitive flood events in the United States and their associated impacts on property damages, adopting effective flood mitigation practices continues to play a prominent role in preventing future damages and fostering resilience to residential flooding. Two common mitigation practices for reducing residential flood risk from both inland and storm surge-induced flooding are raising an existing structure to or above base flood elevation (Montgomery & Kunreuther, 2018), and acquiring chronically damaged properties in flood prone areas, restoring them back to serve their natural functions as green open spaces (Tate et al, 2016). However, among decision-makers and planners there is a discrepancy between where mitigation is implemented and an approach that is financially optimal from a flood-risk perspective. This discrepancy is due in part to data accuracy and limitations. We address this problem through the following research questions: What does the optimal allocation of flood mitigation resources look like under data uncertainty, and what are the optimal methods to combining mitigation measures with consideration for the best economic benefits? Using the Exploratory Modelling and Analysis (EMA) uncertainty workbook (Kwakkel, 2017), we assess how uncertainty in property values, construction and demolition costs, as well as policy implementation options such as structure selection and budget allocation influence the final benefit to cost ratio. Results suggest that clustered buyouts, the amount budgeted for mitigation, and how those funds are allocated directly influence the selection of the most economically viable mitigation practices. These findings highlight the importance of evaluating parcel-level mitigation strategies at the community scale (Highfield et al, 2014) and shed light on the opportunity that strategic buyout selection and post-construction elevation provides planners in channeling scarce monetary resources to locations that are both economically viable and benefit open space restoration. Our research also contributes to the growing need for evaluating specific flood mitigation strategies which can be applied in congruence with other non-structural approaches of flood risk reduction (Brody et al., 2009).

MEASURING HOUSEHOLDS' AWARENESS AND UTILITY VALUE OF SMART CITY IN SONGDO, KOREA

Abstract ID: 722

Individual Paper Submission

SOHN, Jun Ik [University of Florida] juniksohn@ufl.edu, presenting author

ALAKSHENDRA, Abhinav [University of Florida] alakshendra@dcp.ufl.edu, co-author

Smart cities are expected to improve people's quality of life by using state-of-the-art urban management technologies in service delivery. Although, there is no consensus on the definition of the smart city yet (Caragliu et al., 2011; Albino et al., 2015). The concept of smart cities has become a popular urban planning strategy, and in recent times, many countries both developed and developing have announced various smart city-led development models. In this paper, we critically evaluate South Korean's smart city of Songdo International Business District (Songdo IBD).

Songdo IBD is one of the first smart city in the world that has been constructed from scratch in a city of Incheon, Korea. Songdo has invested heavily in cutting edge sensing technologies and networks which helps make transportation, and other public service deliveries smarter. However, although the utilization of smart technologies may improve the quality of life for most, it can also exacerbate the inequalities of the city (Odendaal, 2003). We analyzed 2017 Korea Housing Survey and found housing and living costs in Songdo higher than surrounding areas, and widespread differences in the households' characteristics, leading to inequality, between Songdo and neighboring urban areas in Incheon City. In addition, Songdo is currently in danger of being underpopulation and has a high vacancy rate. According to Statistics Korea, the current population of Songdo, which is 131,309 in 2018, is only about half of the projected population, which is 265,611. The vacancy rate of office spaces in Songdo is about 40 percent, while the national rate is only about 13 percent which raises an important question of financial sustainability.

Meanwhile, the regional government is promoting to invest additional smart infrastructure to make Songdo more attractive to residents and businesses. However, there is no universal solution for the success of a city in its path towards smartness, and smart city project requires taking account of different aspects (Pellicer et al., 2013). In the case of Songdo, people-centric policies can be key factors to lower

the inequality and improve the sustainability and livability of the city, instead of advanced technologies.

Encouraged by the secondary data analysis, we plan to undertake primary household survey (100 surveys) of Songdo residents along with semi-structured interview (18-20) of business owners, policy makers, and residents to understand the level of awareness about smart cities and the technologies implemented, their residential satisfaction, and willingness to pay (WTP) for smart services. We will calculate WTP by contingent value method (CVM) and will analyze the impact of households' characteristics on WTP.

This research has huge policy implication as it is important to understand the effectiveness of smart city initiatives as a new planning strategy.

SENSITIVITY ANALYSIS OF HOUSING MARKET SIMULATIONS

Abstract ID: 790

Individual Paper Submission

ZHANG, Xiaohu [MIT] xiaohu.zhang.cn@gmail.com, presenting author

FERREIRA, Joseph [Massachusetts Institute of Technology] jf@mit.edu, co-author

Advances in technology have made it computationally feasible to simulate travel decisions and household relocation at individual scale (Hunt, 2007). Modelling daily housing market behavior becomes more desirable than annual or even monthly aggregate adjustment to supply and demand in order to avoid ecological fallacy concerns and to capture the impact of market shocks. However, as the models become more disaggregate, the variability increases, and the simulations are more prone to stochastic variation and parameter sensitivity (Raftery, 2007). More research is needed to determine whether the increased variability outweigh their operational usefulness. This paper addresses these questions by examining the sensitivity of the land use portion of one microsimulation platform—SimMobility (Zhu, 2018), which uses a daily bidding model to simulate household relocation decisions.

First, we test model stability and sensitivity to initial conditions with five-year 'dynamic equilibrium' runs that have no new units developed or demolished, and no changes in population. The results demonstrate that, with plausible parameter choices, stable market behavior can be simulated. Using Singapore data and econometrically estimated supply and demand submodels, the model can be calibrated

to approximate observed market behavior during 2012 with parameter choices that also approach dynamic equilibrium conditions after five years and are relatively insensitive to initial conditions.

In addition, we evaluate uncertainties arising from submodels that ‘awaken’ households who then search actively, and that construct each household’s housing ‘choice set’ from the available supply. We know that all households are not equally likely to move during the next period and to examine all vacancies. The SimMobility Long-term model uses targeted awakening and choice set submodels to simulate a more realistic search process. We conducted ten simulations for each of the three cases: a base model with targeted awakening and targeted choice sets, and two other cases with either random awakening or random choice set construction. The coefficients of variation (CoV) were calculated for the number of bidders and sales. The base model has the largest variability because the targeted awakening and choice sets induce more competition, which leads to higher volatility. Nevertheless, the higher CoV is still reasonably small (1-5%) suggesting that ten Monte Carlo simulations of each case are adequate to distinguish significant differences across cases.

Lastly, we analyze the effect of varying supply and demand. The number of sales and average prices can be sensitive to the ratio of actively-searching households (the demand) and available-for-sale housing units (the supply). Model calibrations appeared to be most realistic when this ratio was in the range of 2-7%. In these cases, housing units that receive bids on any particular day tended to average 1.2 – 2.0 bids. Lower averages resulted in too little competition for the available housing, and higher averages yielded too much competition whereby housing prices escalated rapidly. Across 35 planning areas, we observed spatial heterogeneity because supply and demand are uneven. However, the volatility across sub-markets was still low enough to allow meaningful scenario comparisons of 10-run averages. To illustrate this point, we compared one-year simulations of housing market behavior with and without that year’s supply of new public housing, and with/without the introduction of a ‘car-lite’ neighborhood that improved first/last mile accessibility.

This paper demonstrates the feasibility of using an agent-based urban simulation platform (SimMobility) to study housing market behavior through daily bidding at disaggregated scales. The results identify key parameters that could be estimated from survey data and the calibrated model is used to examine the market effect of new public housing and of accessibility improvements within a study area. The methodology could also be applied to analyze the sensitivity of other urban simulation platforms.

EXPLORING SCENARIOS OF PLANNING/POLICY INTERVENTION IN REGIONAL EMPLOYMENT LOCATION: AN AGENT-BASED MODEL

KAUFMAN, Sanda [Cleveland State University] s.kaufman@csuohio.edu, presenting author
KAUFMAN, Miron [Cleveland State University] m.kaufman@csuohio.edu, co-author
SALLING, Mark [Cleveland State University] m.salling@csuohio.edu, co-author

The complex social-ecological systems for which we plan change, whether or not we intervene through policies. This is partly due to the numerous individual and organizational actors who make self-interested, unilateral decisions in the regional space. Their joint outcomes at any point in time are difficult, if not impossible to predict. Nevertheless, we expect planners and public decision makers to act in the public interest and to be accountable to constituents. They need the ability to explore alternatives, select ones that benefit the public, and reduce the likelihood of negative outcomes. Predicting decision outcomes in the context of complex systems is risky, because mistakes can be costly and/or irreversible. One alternative to relying on predictions is to switch to anticipation, which consists of generating a range of scenarios—possible system responses to specific decisions—instead of attempting to predict the response that will actually prevail. Then planners can select decisions that are robust—wise for a broad range of possible futures (Avin 2007, Chakraborty & McMillan 2015).

We propose a dynamic, agent-based spatial model for generating scenarios that allow anticipation of employment location in an economic region in response to various policies. The model (Kaufman et al. 2018) is based on Krugman's (1996) market potential characterizing localities, such that employment flows from places with lower-than-average market potential to places with higher-than-average market potential. The model has four parameters, estimated using the first two years of an employment time series for all localities in a region. The model can then be used to generate employment in time at each location in the region.

To test the model and its potential use as a scenario-generating tool, we selected two regions that differ from each other in terms of their economies. Northeast Ohio is a legacy region, relatively stagnant and trying to revive its economy; it is mature, with its 241 localities ranging from very large to very small. The Dallas-Fort Worth region has a growing economy and a younger structure, whose 358 localities consist of two major cities and much smaller places surrounding them. We asked whether the model we propose performs well in such different circumstances, in terms of actual versus predicted employment values.

First, we used 2001-20015 number and location of jobs in each of the two regions (Longitudinal Employer-Household Dynamics, U.S. Census Bureau [<https://lehd.ces.census.gov/>]), to estimate region-specific parameters, and to validate results against the actual data. The model performed well for both regions: the correlations between actual and predicted employment at of the 241 localities in Northeast Ohio was .988 in year 2015, while for Dallas-Fort-Worth the corresponding correlation was .996 for the 358 localities. Thus the model performed very well in predicting actual values over a 15-year span, in regions with very different economic characteristics. This validation gave us confidence in using the model as a scenario-generating tool to anticipate outcomes of decisions that affect employment location in a regional space.

Next, we show how planners can use the model: we generated illustrative scenarios of spatial outcomes of policies intended to either attract employment at specific locations or discourage growth in environmentally sensitive parts of the region. Results revealed some interesting and surprising region-wide consequences of both tax incentives at some locations and conservation set-asides in environmentally sensitive areas. These region-wide consequences are difficult to foresee by other means.

The results of the policy scenarios allow planners to debate the wisdom of alternatives and share the information with regional stakeholders. Thus the model can be used to generate alternatives in participatory settings.

RESEARCH ON THE SPATIAL CHARACTERS AND PLANNING STRATEGY FOR THIRD PLACE BASED ON THE NETWORK DATA

Abstract ID: 845

Individual Paper Submission

ZHANG, XINYI [College of Architecture and Urban Planning, Tongji University]
15221373783@163.com, presenting author

With the advance of globalization and network technology, the flexibility of time and space is increasing, and the concept of third place arises. In the process of building a smart city, the third place plays an important role in promoting the communication between innovative people and attracting the science and technology enterprises.

This paper introduces the concept, origin and research progress of the third place. It proposes a method for identifying the third place based on semantic analysis. Through the use of network data, this paper analyzes the spatial distribution characteristics and mechanisms of the third place. And some planning strategies to guide the healthy and orderly development of the third place are put forward.

Firstly, this paper obtains the user's evaluation information on the recreational and leisure sites by analyzing the data of crowd-sourced reviews websites. According to the definition of the third place, this paper sets the accessibility, social interaction, information intensive, and sharing as keywords through which the user evaluation information is semantically analyzed to identify the public places that meet the third place characteristics. Then the paper obtains the spatial location information of these public places through open source map data, and uses ArcGIS software to perform nuclear density analysis on these public places. At the same time, the public service level was evaluated by the user's reviews. Based on these analyses, the spatial distribution characteristics of the third place in the city is revealed.

The result shows that the third place tends to concentrated in urban centers and scattered in urban peripheral areas. In terms of location selection, it tends to be close to business centers and research intelligence centers, and it is integrated with various types of urban spaces. The paper considers that the

third place, as a platform for information exchange and social interaction, needs to highlight the flow, agglomeration and sharing of innovation elements. They are more dependent on intellectual and information resources, have more demand for funds and services, and have higher requirements for environmental quality. Therefore, gathering around the business centers will help the third place to enjoy good transportation and communication services, rich information resources, perfect surrounding environment and high-quality professional services. And close to the intelligence centers, the third place can attract more creative people, and use their advantages to provide a good display and practice platform. In conclusion, the article argues that the distribution of the third place tends to form a community that integrates resources, saves costs, and promotes innovation. The third space is deeply integrated with the urban space in a flexible way which promotes the formation of urban innovation networks, the renewal and utilization of urban stock space, and the growth of public social space.

Based on the distribution characteristics and mechanism of the third place, this paper proposes some planning strategies to guide the healthy and orderly development of the third place. In the urban comprehensive planning, the strategic orientation of encouraging the sharing of the third space should be established. In the regulatory detailed planning, the third space should be provided with more compatible land use regulations. And urban design should provide flexible design guidelines for the third place, encouraging the integration and sharing of the third place with other functional spaces in the city.

This paper proposes a third place recognition method based on semantic analysis, reveals the spatial distribution characteristics and mechanism of the third place, and puts forward some planning strategies to guide the development of the third place which is of great significance for activating social interaction, promoting information sharing, and building innovative cities.

FROM HERE TO WHERE? THE ROLE OF SCALE IN THE MEASUREMENT OF SPATIAL MISMATCH

Abstract ID: 855

Individual Paper Submission

WANG, Weijing [Michigan State University] wangwe92@msu.edu, presenting author

DURST, Noah [Michigan State University] durstnoa@msu.edu, co-author

A substantial body of research has examined spatial mismatches between housing and employment, though there is considerable variation in the metrics with which (Wu, Zhang, and Yang, 2015) and the spatial scales at which (Benner & Karner, 2016, Wang, 2000) such housing/employment imbalances are measured. This paper examines the issue of scale in detail with the purpose of evaluating the impact of research design decisions on the estimation of housing and employment imbalance.

Building off the prior literature, we hypothesize that the suitable commute distance at which to measure spatial mismatch may vary by local context. To test this hypothesis, we use data from the Longitudinal Employer-Household Dynamics Origin Destination Employment Statistics data set, published by the U.S. Census Bureau, and detailed road network data from Open Street Map to measure jobs-housing imbalances in the Detroit and Grand Rapids, Michigan, metro areas. We use network analyst in ArcGIS to create commute sheds of varying distances (.5, 1, 2.5, 5, and 10 miles) from the population-weighted centroid of each census block. We then use descriptive statistics and regression analysis to examine how estimates of jobs-housing imbalance vary based on the selection of commute shed distance thresholds and characteristics of the local urban form (housing and road density). Our analysis illustrates that measures of spatial mismatch are highly sensitive methodological decisions regarding the appropriate unit of analysis and to variations in urban form. Our paper suggests the need for robust testing of and justifications for the units of analysis in examinations of spatial mismatch.

URBAN-GANS: A GENERATIVE ADVERSARIAL NETWORKS MODEL FOR URBAN DESIGN COMPUTATION

Abstract ID: 922

Individual Paper Submission

QUAN, Steven Jige [Seoul National University] stevenchuan6656@gmail.com, presenting author

In recent years, increasing applications of machine learning techniques and big data enrich our understandings of cities greatly. However, there are limited discussions on how to apply those technological advances to facilitate urban design process by enhancing current design computation methods as “Design in Science” (Batty, 2013). Design computation has two parts: representation and process (Knight and Stiny, 2001). Both parts could have their current struggles better addressed by applying machine learning techniques. On one hand, current urban form representations in design computation are mostly symbolic, which are analyzed and predefined by designers as schemata (Rowe, 1987). Such symbolic representation is often too simplified comparing to actual urban form, which leads to design generation results that mostly seem rigid and unrealistic. On the other hand, the process in design computation deals with the design generation and selection, which can be viewed as searching toward certain objectives in a design space (Rowe, 1987). Advanced studies follow the optimization-oriented process, integrating scientific modeling and optimization techniques to guide the design generation (Knight and Stiny, 2001). However, such integration is sophisticated, and the modeling is often limited in its accuracy and capability to deal with qualitative performance such as human perception.

The strength of machine learning techniques to identify complex patterns in a huge dataset provides new solutions for design computation. For the representation, techniques such as Convolutional Neural Networks (CNN) widely used in spatial data learning allow analysis with the sub-symbol representation of urban form as raster, which preserves more spatial information. For the process, the emerging Generative Adversarial Networks (GANs) model provides a coherent framework to integrate neural networks models that can connect urban form with various performance observations including those hard to quantify, into design generation. The GANs is a generative model that uses two adversarial neural networks, a generator (G) and a discriminator (D), to engage in a two-player minimax game to find an equilibrium (Goodfellow et al., 2014). Such a technique has been widely and successfully used in producing photorealistic images.

This study aims to develop an Urban-GANs model that uses both techniques of CNN and GANs, to enhance urban design computation by generating more realistic and creative design solutions with certain performance criteria, based on real urban form datasets. This model has five stages. In the preparation stage, the urban form dataset is sampled and represented as raster images with the same size and labels. In the training stage, sample batches are used to train a GANs model, resulting in generator weights. In the generation stage, the trained generator is used to synthesize design solutions from random noise inputs with objective labels. The generated designs are further processed and transformed into 3D models in the post-processing stage. This Urban-GANs model will be applied to a hypothetical urban design case based on urban form datasets including building, street and vegetation in three megacities: New York, Seoul and Shanghai. Over 100,000 training samples with the size of 500m x 500m will be drawn from the datasets, labeled with city names and different types of percepts such as safe and beautiful, acquired from crowdsourcing datasets including geo-tagged tweets and the MIT Place Pulse dataset (Zhang et al., 2018). As a demonstration, designs will be generated with certain label combinations such as “New York + safe”, which are supposed to share same complex patterns as real urban forms of that kind. The Urban-GANs model can provide urban designers a more powerful design computation tool to generate realistic and creative designs with certain performance criteria, and similar methods can be applied to other planning fields for scenario generation to better inform decision-making.

A PLANNING SUPPORT TOOLKIT

Abstract ID: 934

Individual Paper Submission

KLOSTERMAN, Dick [University of Akron] dick.klosterman@gmail.com, presenting author
BROOKS, Kerry [Eastern Washington University] kbrooks@ewu.edu, co-author

An impressive array of planning support systems has been developed and employed around the world as described in several edited volumes including Brail and Klosterman (2001) and Brail (2008).

Unfortunately, these systems have not been widely used in planning practice for several reasons identified in the literature. Experience suggests that most PSS provide sophisticated analysis and spatial modeling systems that do not meet user's needs (Vonk, Geertman, and Schot 2007). Partially as a result, there is little awareness of, and practical experience, with PSS among planning practitioners (Von, Geertman and Schot (2005).

This paper illustrates a different approach to PSS development. It describes a collection of planning support tools that abandon the attempt to develop sophisticated, complex and expensive models for simple, easy-to-use urban and regional analysis and projection methods at the core of planning education and practice. It similarly avoids sophisticated "cutting edge" technologies by employing only the ubiquitous Microsoft Excel and freely available open source QGIS.

Methods provided in the tool set include: (1) demographic and economic analysis tools such as location quotients, Gini coefficients and population pyramids; (2) trend, share, and cohort component projection methods; and (3) and vector land suitability analysis. The methods are thoroughly described and applied to a real community in a recently published text (Klosterman et al, 2018), which identifies data sources for applying the methods in the United States. The paper describes and illustrates the analysis and projection tools and considers their advantages and limitations for planning education and practice.

A METHOD TO ASSESS ALGORITHMS FROM THE PERSPECTIVE OF JUSTICE

Abstract ID: 935

Individual Paper Submission

POKHAREL, Atul [New York University] pokharel@nyu.edu, presenting author

With new algorithms being developed constantly, city governments worldwide are encountering novel automated decision-making systems. Policymakers and planners are consequently faced with assessing systems that they and their agency staff do not adequately understand. These systems' range extends from

traffic management to deciding benefits eligibility to school assignments to parole and sentencing decisions. In each of these applications, algorithms promise practical benefits for urban governance such as efficient and consistent decision-making, among others. At the same time, governing-by-algorithm raises serious concerns about justice—though policymakers currently lack an adequate method for assessing algorithms from the perspective of justice. We propose such a method.

First, we draw on the emerging literature on algorithms and justice to describe how our understanding of a sector's justice concerns are systematically altered when seen through the lens of algorithms. In particular, the algorithmic lens has tended to focus attention on justice concerns that are readily operationalized in statistical terms. These concerns are typically only a subset of long-standing justice concerns in a sector. For example, the literature on criminal justice algorithms has focused heavily on discrimination, thereby drawing attention away from other long standing criminal justice concerns such as proportional punishment and due process. Then, we describe a differential method to assess how a domain's justice concerns are altered by seeing them through the lens of an algorithm.

To illustrate, we apply our method to several algorithms in use in New York City. In each of these cases, we argue that policymakers' knowledge of key justice concerns and performance targets be the starting point for evaluations of these automated decision-making systems. This approach forces us to consider the full range of justice concerns and standards of justice existing in a sector, ignoring whether they are easily operationalized or not. As a consequence, we take a critical view toward the current tendency to assess algorithms primarily using measures derived from easily operationalized concerns of justice.

SOCIAL MEDIA AND DIGITAL PUBLIC DISCOURSE: EXAMINING THE ROLE OF CROWDCULTURE IN PORTRAYING PLACE BRANDING AND STIGMA IN DALLAS, TX

Abstract ID: 968

Individual Paper Submission

AUDIRAC, Ivonne [University of Texas, Arlington] audirac@uta.edu, presenting author
BONAKDAR, Ahmad [the University of Texas at Arlington] ahmad.bonakdar@mavs.uta.edu, co-author
GRANPAYEHVAGHEI, Tahereh [the University of Texas at Arlington]
tahereh.granpayehvaghei@mavs.uta.edu, co-author

A central feature of the digital age and the network society is the emergence of social media as a game changer in the landscapes of networked power of mass-self communication (Castells, 2013) and crowd cultures (Holt 2016). Social media has become a powerful wheel of social change, shaping the urban experience (Zukin, 2009) and augmenting or leveling the asymmetries in symbolic power of actors

(Fuchs, 2017). Aided by the Internet and social media, cities and places may bask in their positive urban imaginaries as promoted through place brands or endure negative territorial stigmas associated with their past or most vulnerable distressed places (Audirac, 2018).

This study uses tweet data to decipher positive and negative urban and social imaginaries associated with the City of Dallas. Drawing on the concept of “crowdculture” via social media, as framed by Douglas Holt (2016), this research examines the link between urban imaginaries and places in the city identified as racially/ethnically concentrated area of poverty (R/ECAPs). Holt suggests that crowdculture involves diverse spontaneous sub-cultures seemingly isolated, but that collectively can forge powerful challenges to traditional branding campaigns and ultimately to place marketing regimes. Despite the place branding efforts to create a “geography of buzz” (Currid & Williams, 2010) led by Dallas’ municipal planners and city leaders, social media crowdcultures as manifest in tweets, while raising challenges to these efforts, may uplift traditionally stigmatized areas or inspire more community-based action. This posits the possibility of new forms of digitally produced public spheres (Fuchs, 2017). This research aims to identify the leading digital public-sphere discourses associated with Dallas’ “elite” and “distressed” places and to provide insights into the crowdcultures behind these urban and social imaginaries. To accomplish this, the authors draw on the classification and sentiment analysis of tweeted data. These data profiles are compared with the urban imaginary promoted by the city’s official Tweeter outlets.

Preliminary findings suggest that tweeting subcultures relate positively to Dallas “elite” places regarding sports events, and negatively around social issues, and economic malaise. Following Schweitzer (2014), social media has the ability to influence decision-making in planning processes, with the potential to tap into the digital-public-sphere discourses of specific crowdcultures. Thus, big data sentiment analysis by local planning agencies may contribute to identifying what residents think of the city and to help improve policy making in practice.

CAN ADVANCED TIME SERIES MODELS ACCURATELY PREDICT FUTURE POPULATION AND INCORPORATE UNCERTAINTY THROUGH THE PROVISION OF REASONABLE PREDICTION INTERVALS?

Abstract ID: 999

Individual Paper Submission

DRUMMOND, William [Georgia Institute of Technology] bill.drummond@design.gatech.edu,
presenting author

Planners often rely on forecasts of future population when working in a broad range of activities, from estimating global impacts of climate change to the development of local land use, infrastructure, and transportation plans. These forecasts are typically single point values around which the full plan is then crafted. This approach, however, ignores the inherent uncertainty in any prediction about the future. This has led one of planning's most prominent methods academics to conclude, "I agree with a growing number of scholars who suggest that planners abandon the futile effort to predict what the future will be" (Klosterman 2013, p. 164).

However, what if forecast future values of variables such as population could be bracketed with the high and low values of a reliable prediction interval? Any plan dependent on the projection could then be designed to be as robust as possible over the likely range of future population values. This paper explores the question of whether a suite of advanced time series (or "ATS") models can provide both reasonably accurate 20-year population forecasts and reasonably valid statistically-based prediction intervals for those forecasts.

The suite consists of three ARIMA models, two exponential smoothing models, and two damped trend models. Also calculated are three models using different combinations of the seven individual models: an average of all seven, a maximum-and-minimum trimmed average of the five remaining models, and a trimmed average of the three remaining models after discarding the two highest and two lowest projections.

To test this hypothesis I use a dataset of Census Bureau annual U.S. state population estimates covering the years from 1900 to 2018. Using R open-source statistical software and the R forecast package, I adopt a 25-year base period to fit the models and a 20-year forecast period to produce retrospective forecasts for every fifth year from 1945 to 2015. I then compare actual population to forecast population and calculate several common error measures.

To establish a set of baseline forecasts I construct and apply a similar suite of well-researched traditional extrapolation (or "TEX") models. The (preliminary) overall findings are that individual ARIMA models and combinations of all the advanced statistical models are more accurate than any of the competing traditional extrapolation models, although the magnitude of the difference(s) is not large. I also compare both suites of models to a historic set of Census Bureau cohort component state projections and discover that models from both the ATS and TEX suites have lower errors than the Census Bureau models.

The R forecast package can also produce statistically-based prediction intervals for each individual model in the ATS suite. For the three ATS combination models, I calculate the prediction intervals of the model combinations by applying the same process used to calculate the point forecasts. I then ask whether the proper percentage of actual values falls within prediction intervals ranging from 5% (which should encompass 5% of actual values) to 95% (which should contain 95% of actual values). The preliminary results from the full dataset of projections (forecast years from 1945 to 2015) are disappointing. For example, for most models only 25% of the actual values fall within the 50% prediction interval. However, when I calculate separate results for the most recent period of projection years (1995-2015), the combination models have projection intervals that work well or are even slightly too narrow over the 5% to 80% range of intervals.

In conclusion, advanced time series models show substantial promise. They enable planners to project population more accurately, but their real benefit is their ability to directly incorporate future uncertainty through research-verified prediction intervals.

THE PURSUIT OF HAPPINESS: RE-THINKING NEIGHBORHOOD SATISFACTION USING GEO-SOCIAL MEDIA DATA AND GIS IN TURIN, ITALY

Abstract ID: 1012

Individual Paper Submission

RYBARCZYK, Greg [University of Michigan-Flint] grybar@gmail.com, presenting author

Central theme

Assessing life satisfaction at the neighborhood scale has long been a focus area for researchers (Jokela, Bleidorn, Lamb, Gosling, & Rentfrow, 2015). The major weaknesses of previous studies have been the use of untimely and aggregated data that is tangentially linked to mental health. This fault likely due to traditional assessment techniques, such as survey instruments (Mitchell, Frank, Harris, Dodds, & Danforth, 2013). The advent of geosocial-media (GSM) data, however, have opened-up new channels of exploring links between place and human satisfaction (Frank, Mitchell, Dodds, & Danforth, 2013). The data, and approach, contains three attributes which sets it apart from other data: a timestamp, location, and syntax. These can collectively reveal previously unknown psychosocial relations to one's environment. Our main goal was to harness this information and answer the question: can we more re-imagine and consider how neighborhood composition, environment, transportation, and time affect life satisfaction using GSM?

Approach and methods

The GSM data was obtained from the Twitter open-source API. The database was filtered and used to derive a valance (i.e. sentiment) index. Compositional and contextual information for each statistical zone were then collected from government sources and then linked to the Twitter database using GIS. The zonal indicators included in this research consisted of: public health, infrastructure, travel safety, incivilities, accessibility, socioeconomic standing, and density. Exploratory spatial data analysis (ESDA), GIS, and spatial regression modeling were implemented to investigate the spatial patterning of sentiments, and highlight important explanatory factors associated with increased or decreased values.

Results

The ESDA results showed that the spatial patterning of Tweets clustered near the central portion of the city. Unsurprisingly, it was also found that sentiment values differed depending on time-indicating the importance of temporality on life satisfaction when neighborhood effects are controlled for. The regression model's diagnostics were marginal ($R^2 = .03$) though revealed statistically significant relations ($p\text{-value} < 0.05$) to sentiments. Most notably, urban density, mortality rates, and disturbances negatively affected values, while pedestrian infrastructure had the opposite influence. The results validate a growing body of work on how urban stressors affect life satisfaction spatially and within neighborhoods.

Conclusions

The research has provided valuable evidence on the nuanced relationships among mental health, neighborhood, time, and space. Our results show how GSM may potentially be used to estimate neighborhood life satisfaction, when neighborhood effects are controlled for. We expect the results of this research to be valuable for practitioners and researchers on two fronts. First, the models' displayed several noteworthy coefficients indicating the importance of time, space, and neighborhood effects on life satisfaction. Second, we showed that the combination of GSM data and GIS is valid approach that could be used to examine mental health in neighborhoods in other cities.

COMPACT AND GREEN URBAN DEVELOPMENT – TOWARDS A FRAMEWORK TO ASSESS URBAN DEVELOPMENT FOR HIGH-DENSITY METROPOLIS

Abstract ID: 1015

Individual Paper Submission

FAN, Peilei [Michigan State University] fanpeilei@msu.edu, presenting author

As we are entering the urban age, urbanization has been identified as one of the most development challenges in the 21st century by the United Nations. While cities worldwide have manifested a diverse range of spatial patterns, from the typical suburban sprawl to densely developed urban core or new towns

at the urban fringes, compact and green urban development has been gradually gained attraction in recent years, considered as one of the most viable solutions to this development challenge. Despite the numerous literature on topics of compact or sprawl urban development, there is lack of consensus on concepts or measurements for either urban compactness or urban sprawl (Bhatta, 2010; Ewing et al., 2002). In a comprehensive literature review, Bhatta (2010) found that various dimensions and associated indicators have been suggested to identify urban sprawl or compact development. For example, Galster et al. (2001) enlisted 8 such dimensions for sprawl, including continuity, concentration, clustering, centrality, nuclearity, mixed uses, and proximity. Meanwhile, public urban green space has been increasingly recognized as an important dimension for sustainable urban development and assessing accessibility of urban green space to local residents is therefore essential to ensuring quality of city life (Artmann et al., 2019; Fan et al., 2017).

This paper proposes a concept of Asian urbanism and a framework for measuring compactness and green urban development in high-density transit-oriented metropolis by looking at density, diversity, connectivity, and accessibility (centers, transit, and Green Infrastructure/Blue Infrastructure). It focuses on the conceptual development and proposes a general framework of measurements of the above-mentioned dimensions, emphasizing dense, mix-used, connected, polycentric, accessible, and green urban format. It then uses a high density Asian metropolis, Taipei, as a case to illustrate the concept and the measurement framework. A comprehensive index, urban compact-green index (UCGI) is developed to integrate six aspects of a sustainable urban built environment in the context of high-density metropolis, including density of residents and commercial activities, land use mix, street connectivity, access to center/subcenters, access to transit stops, and access to public urban green spaces. We found that while great spatial variations exist among different parts of Taipei Metropolitan Area, the metropolitan area had a distinguished polycentric pattern of UCGI index with several clusters around the center and sub-centers illustrating higher index values. Using the outcomes of our assessment, we further compare them with the planning maps of Taipei and discussed major factors contributed to planning-led or non planning-led compact-green urban development in Taipei Metropolitan Area. Our framework can be applied and used to assess other cities and is particularly useful for high-density metropolis in Asia and Europe. It can provide insights and policy recommendations to urban planners to address different dimensions of compact and green urban development.

URBAN AIR MOBILITY: ASSESSING VIABILITY AND EQUITY WITH AN URBAN PLANNING LENS

WOODBURN MCNAIR, Amber [The Ohio State University] woodburn.26@osu.edu, presenting author

Connected, autonomous vehicles (CAV) on the ground and Unmanned Aerial Systems (UAS) in the sky are among a suite of smart mobility technologies that have captured the attention of planning practice, planning scholarship, and the broader public. In the barest description, all of these smart mobility technologies function as machines equipped with sensors to detect real-time information about the vehicle-operating environment, internal computation capabilities to optimize routing decisions across a variety of constraints, and wireless networks to share information with other machines. Specifically, urban air mobility (UAM) leverages UAS to impose an urban model of air service to transport passengers and cargo (in contrast to the more familiar global model of air service). As the engineering and computational sciences continue to advance toward a world where smart mobility is possible both on the ground and in the air, urban and regional planners have the difficult position of guiding implementation across uncertain futures of technology ownership, policy, and markets.

In the context of America's urban history, there is cause for reflection and caution to ensure that the business plans, land uses, and travel behaviors stemming from smart mobility systems do not further exacerbate existing spatial patterns of social isolation or exclusion. My intent in this research is to assist practitioners and theorists with a treatise for framing the social impacts of implementation, with the goal to broaden the conversation surrounding this technology beyond traffic operations and towards urban outcomes. Thus, I propose the following research question: If we prioritize social inclusion and equity, how might a transportation planner conceptualize and define effective integration of urban air mobility into the built environment? Alternatively, and perhaps more optimistically, if urban air mobility provides the opportunity to re-imagine transport services, what service characteristics would improve accessibility for those who have been historically excluded or marginalized?

To address the question, I reviewed the planning literature to contextualize prevailing theories on the socio-technical interface, frameworks for assessing viability of speculative smart mobility technologies, and frameworks for assessing equity outcomes. After evaluating the existing theories and framework, I summarize three perspectives familiar to the transportation planning profession. First, system design with an emphasis on physical, digital, human, and social components. Second, travel behavior with an emphasis on demand, utility, consumer surplus, and travel costs. Third, spatial design with an emphasis on the scale of the body, the building, the neighborhood, and the city region. Within each of these perspectives, I develop examples of service characteristics that may appear as part of proposed business models and implementation scenarios.

As part of the exploratory findings, I evaluate and reflect on whether those service characteristics would likely exacerbate social exclusion or promote social inclusion. Ultimately, the three perspectives are repackaged to represent inclusive principles: system design relates to fair and equitable opportunities regarding the choice to participate in the new mode of mobility; travel behavior relates to willingness to pay and the balance of incentives to participate in the new mode of mobility; and spatial design relates to the intentional design of the built environment in response to the new mode of mobility.

The contribution of this work is to use prevailing urban theories to unpack the significance of changes to space, place, and social inclusion in urban landscapes that deploy smart mobility services, particularly in the context of urban air mobility. Machine platoons alone will not bring us closer to social inclusion, rather our human spirit as exercised through our socio-technical-spatial design intentions must be at the center of the narrative if we are to hope to construct more equitable, just, and inclusive societies.

EFFECTS OF MORE ADVANCED FAST CHARGING INFRASTRUCTURE ON ELECTRIC VEHICLE PREFERENCES

Abstract ID: 1037

Individual Paper Submission

ZOU, Tianqi [University of Washington] tz237@uw.edu, presenting author

MACKENZIE, Don [University of Washington] dwhm@uw.edu, primary author

With lower operation cost and reduced greenhouse gas emissions, alternative fuel vehicles, such as electric vehicles (EVs), have a great potential to drive us to a sustainable future. It is generally accepted that the relative attractiveness of EVs and other alternative fuel vehicles depends on several factors. In the case of EVs, many of these factors are determined by the characteristics of the charging infrastructure, i.e. the number, type, locations, and pricing of charging stations. Since charging infrastructure has a significant effect on the adoption of electric vehicles, prior research generally indicates that to make EVs more attractive to consumers, we should make charging opportunities ubiquitous, fast, and inexpensive. However, in a world with budget constraints, tradeoffs must be made between these goals. Fortunately, many charging needs can be satisfied through relatively inexpensive infrastructure such as home-based Level 1 charging (< 2 kW), workplace and other intracity charging provided mostly by less costly Level 2 charging (> 2 kW and < 10 kW) (TRB & NRC, 2015). Although they serve relatively few charging events, expensive, high power direct current fast charging (DCFC) (> 20 kW and < 120 kW) and extreme fast charging (XFC) (> 350 kW) are a key to making EVs feasible for longer, interurban trips, which is necessary if EVs are to attract mainstream consumers (Botsford & Szczepanek, 2009; Fontaine, 2008). However, the findings of previous research on the effects of attributes of fast charging stations on EV adoption are inconsistent, resulting in a lack of reliable guidance and strategy on new vehicle technology development and sustainable transportation infrastructure planning.

To fill in the gap, this study conducted a stated preference experiment by collecting data via an online survey to investigate the effects of fast charging characteristics on EV purchase preference. Previous studies show that up-front cost, operating costs including fuel (electricity) and maintenance, range, refueling/recharging time, the availability of refueling infrastructure, environmental impacts, and government incentives, as well as those factors that affect any vehicle purchase decision, such as vehicle size, performance, and features, affect the attractiveness of EVs (Hoen & Koetse, 2014; Tanaka et al., 2014). Based on the previous findings, targeting at potential car buyers, the survey presented respondents

a combination of conventional gasoline car, battery electric car, and plug-in hybrid electric car purchase choices with the attributes of purchase price, energy cost, and driving range. In addition, for the choice of battery electric car, the charging facility availability such as distance to home and the spacing along highways, and charging features including price and charging time are also provided. Since previous studies seldom investigated the impact of a shorter charging time with a lower bound of 10 minutes of full charge, this study explores ways to enable a more reliable inference of the effects of reduced charging time on EV preferences, as well as to envision the benefits of more advanced fast charging technologies.

This study applied a discrete choice model to examine the impacts of all the factors on consumer preference, where the interaction between EV battery range and recharging time is also investigated. The results reveal car buyer preferences on vehicle-specific attributes and how their preferences change according to the availability of fast charging infrastructure for electric cars. Additionally, the results identify that the impacts of the vehicle-specific and infrastructure-specific factor differ for consumers with different socio-economic background. With the findings, the study provides implications on sustainable transportation infrastructure planning in terms of addressing and discussing how to direct investments in order to get the greatest public benefit from new charging infrastructure.

DATA SCARCITY IN THE ERA OF BIG DATA

Abstract ID: 1040

Individual Paper Submission

WILLIAMS, Sarah [Massachusetts Institute of Technology] sew.williams@gmail.com, presenting author

A recent report by the World Bank, *Data Deprivation: Another Deprivation to End*, discusses the fact that data is so scarce in developing countries that it makes it hard to track simple, sustainable development goals, including poverty reduction. According to the report, fifty-seven countries have only one or no poverty estimate; this roughly amounts to a third of the world's developing or middle-income countries missing essential data to track poverty. One of the main reasons these countries lack such data is that they do not have the means, either technological or financial, to collect it. Some believe that data scarcity amounts to a new societal divide: the needs of those not counted are forgotten. The United Nations Report, *A World That Counts*, argues that a lack of data can lead to a “denial of basic rights.”

Indeed the development of population data, then, is not only essential because everyone must be counted, but also because data regarding population distribution and urban infrastructure mapping are essential for governments and NGOs to develop and improve both infrastructures and social services. At the same time, data does exist locked in the databases of corporations such as Facebook, Google, LinkedIn and Telecoms who hold vast quantities of human interaction data in these countries. Analyzing this data can provide insights on everything from mobility to internet access should it be anonymized and released to governments and intuitions for planning. Recently there have been examples of private organizations collaborating with governments and institutions to share this data. This research project set out to understand the benefits, barriers, and limitations of these partnerships. Illustrating lessons from these unique partnerships provides a framework for how private data can be used for policy change. Looking at three cases studies including Facebook's openly available population data set, Orange's Data for Good Challenge, and the World Bank's collaboration with Grab Taxi, the research highlights the challenges of working with private institutions to use data for civic change. Data licensing issues was found to be one of the biggest barriers, sometimes taking years for agreements to be made, making the data outdated. Having pre-negotiated license terms could help these partnerships. Finding mutual interests in planning outcomes helps data sharing partnerships. For example, upgrading infrastructure might be beneficial to both parties and using data to help develop those plans provide a benefit to both the government and the private agency. Governments need to provide more incentives for private companies to share the data – perhaps even regulating the data. This may include mandatory data sharing agreements in return for allowing them to operate in their territory. Ultimately this research illustrates pathways for how planners and policy experts can work with private companies to use their data for as a public good and answer questions important to society.

DIGITAL REDLINING? EVIDENCE FROM LOS ANGELES COUNTY 2014-2016

Abstract ID: 1055

Individual Paper Submission

LE, Thai [University of Southern California] thaivle@usc.edu, presenting author

DAUM, Kurt [University of Southern California] kdaum@usc.edu, co-author

GALPERIN, Hernan [University of Southern California] hgalperi@usc.edu, co-author

Broadband is the lifeblood of some of the most vibrant and innovative industries. It is also a vital tool for individuals and families that enhances economic, educational and civic engagement opportunities (Chang et al. 2004; DiMaggio & Hargittai 2001; Prieger & Hu 2008). However, broadband infrastructure investments in many cities and regions are not keeping pace with the growing demand for high-quality, affordable Internet connectivity from households and businesses. Further, there is evidence that investments in next-generation technologies (such as fiber and 5G) are bypassing low-income and minority communities (Strain et al. 2017; Tomer et al. 2017). These market failures are compounding preexisting socioeconomic differences, thus exacerbating inequality by skewing digital opportunities in favor of wealthy residents.

Using Internet service deployment data from the California Public Utilities Commission (CPUC) and sociodemographic data from the American Community Survey (ACS), this study explores the statistical and spatial links between broadband competition and neighborhood characteristics in Los Angeles County. In particular, it seeks to determine the relationship between broadband investments and the share of low-income residents at the census block group level for the 2014-16 period.

Our preliminary results (limited to DSL, cable Internet, and fiber-based services) find that broadband competition remains weak throughout Los Angeles County. While the share of residents able to choose between two or more broadband ISPs increased in the study period, about half of the county residents still lacked choice in broadband provision at year-end 2016. In addition, increased competition mostly benefited higher-income areas, and largely bypassed block groups with higher shares of Latino residents. Our multivariate regression model shows a statistically significant negative association between broadband investments and the share of poor households in a census block. However the link between investments and race is less conclusive, and we explore how spatial autocorrelation may be affecting these results.

While our results are preliminary and require further investigation, they suggest that incumbent ISPs are bypassing areas that need digital infrastructure investments the most. Further, they suggest that efforts by local policymakers concerned with the inequality effects of the digital divide should focus on actions that address market failures in infrastructure investments in low-income areas.

EXPLORING THE NEXUS BETWEEN KNOWLEDGE CAPITAL AND SOCIAL VULNERABILITY: A COMPARATIVE STUDY ON THE U.S. AND AUSTRALIAN CITIES

Abstract ID: 1057

Individual Paper Submission

TULI, Sajeda [Department of Urban Planning, University of Illinois at Urbana-Champaign]

sajeda.tuli@canberra.edu.au, presenting author

KASHEM, Shakil Bin [University of Illinois at Urbana-Champaign] kashem1@illinois.edu, co-author

This paper investigates the interactions between knowledge capital and social vulnerability through a comparative study on the U.S. and Australian cities. Based on the theoretical framing of knowledge city and social vulnerability, it explores how knowledge city opportunities interact with social vulnerability, and how cities should be prepared for the dual challenges of technological shift and social vulnerability to natural hazards. Frey and Osborne's (2013) study on the future of work in US cities found that 47 per cent of all extant jobs were susceptible to automation or could otherwise be made redundant by the advancement of various technologies. Study on 25 Australian cities (Pratchett, et.al, 2017) found that some Australian cities are well positioned to grow and advance in the emerging technology-driven and knowledge-based economy, but others lack the infrastructure and capacity to resist and survive the impacts of technological redundancy. However, this dichotomy of decline and resilience is not equally distributed across the geography of the U.S. and Australian cities. The theoretical framework of Social Vulnerability can help us to study this unequal geography of knowledge capital. Studies on social vulnerability have widely documented how vulnerability to natural hazards vary by socioeconomic characteristics like age, race, income, etc. (Fothergill, 2004; Peacock et al., 1997). While prior studies have highlighted the importance of considering the changing dimensions of social vulnerability in the adaptation plans of cities (Kashem et al., 2016), a very few studies have looked at the causalities behind such differential outcomes and how the changing nature of work may improve or exacerbate existing social vulnerability in our cities. To explore this question, we apply a quantitative approach using the Census data of selected Australian and U.S. cities. Extending the previous work on Australian cities (Pratchett, et.al, 2017), we created a knowledge cities index for cities in the U.S. and applied it to explore the spatial variation of knowledge capital at the census tract level of three cities. In addition to knowledge cities index, a parallel social vulnerability index is also developed to measure how the level of social vulnerability interacts with knowledge cities index. Our analysis shows that in both Australian and US cities, there are significant overlaps between high social vulnerability and low knowledge capital. It indicates that while cities are planning for climate adaptation, they should also consider how technological shift may exacerbate the prevailing social vulnerability within the cities. This paper gives an understanding of the extent to which the U.S. and Australian cities have the capacity to respond to the complex challenges of technological change, and how they should address the dynamics of social vulnerability.

Background and Purpose: Walking and bicycling are common types of physical activity (PA) and widely promoted as ways to promote healthy living that can also bring many environmental benefits as carbon-free modes of transportation. The roles of community environments in promoting or hindering such physical activities are increasingly recognized with the growing evidence establishing the link between the two. However, the challenges related to obtaining precise, objective, and quantitative measures of PA (and also the environment) still remain as barriers to advancing research on this topic. Recent development of wearable technologies has contributed to improving accuracy in measuring PA intensity and duration. However, detecting the specific types of PA from these devices has not been as easy or accurate. Studies in computer science, public health, and transportation/planning have each explored ways to recognize PA using accelerometer or GPS data. Most previous studies focused on detecting a small number of target activity types in controlled test settings.

Objectives: This study presents a machine learning approach to detect a wide range of PA and sedentary behavior based on the GPS and accelerometer data collected in community settings. It also incorporates a hyper-parameter optimization algorithm to reduce noises/errors prevalent in this type of data/approach.

Methods: Accelerometer and GPS data were collected from 25 participants who performed eight target activities in community settings: driving, biking, walking, strolling, standing, sitting, jogging, and running. Data from 15 participants served as the training data and 10 participants as the test data. The two-phase algorithm first employed a standard machine learning approach to classify windows of data as one of the eight activities in Phase 1, based on 17 features calculated from the data. Phase 2 involved a novel smoothing algorithm to remove errors/noises produced in Phase 1. To determine the optimal parameters, we performed hyper-parameter tuning using a Tree-structured Parzen Estimator (TPE) approach, which considers previous parameters during the testing often producing better results than other methods.

Findings: The optimum parameters of our algorithm were 13-second Phase 1 windows, Random Forest as the Phase 1 classifier, 6 neighbors for Phase 2, and the logarithmic scoring function. This algorithm assigns weights to the six neighbors of each target window based on their proximity to the target window

using a logarithmic scoring function, to determine whether the target window has been correctly classified or should be adjusted to one of the neighbor classes.

Tuning on the training data, we achieved an accuracy of 96.7% using 10-fold cross-validation. The optimized model achieved an overall accuracy of 77.3% based on the test data. It is worth noting that our data were self-collected in free-living community settings, which tend to contain significant noises. The two main outputs from the algorithm are a master table populated with a wide range of variables (e.g. average frequency of walking trips per week day, % of all walking performed within the target community) that can be used for statistical analyses, and a bar-chart graphic that visually presents PA types, intensities and locations for each day.

Conclusions: Our method is a promising approach to improve PA recognition, facilitating future research efforts on environment-PA relationships and allowing for reducing participant burdens by removing the labor-intensive travel/activity log requirement.

Implications for Practice and Policy: With its web-based user interface currently under development, our method can serve to facilitate future population studies and intervention efforts aimed at promoting PA and active transportation.

Note: An earlier version of this work has been presented as a poster at the 2019 Active Living Research conference.

TOWARDS A FORM DATA-BASED DEFINITION OF INFORMAL SETTLEMENTS: FINDINGS ON THE GLOBAL PATTERNS FROM THE ATLAS OF INFORMALITY.

Abstract ID: 1129

Individual Paper Submission

SAMPER, Jota [University of Colorado Boulder] jota@colorado.edu, presenting author

A discussion is happening today regarding the growth of informal areas globally, despite an apparent decrease in the percentual proportion of the population “the absolute number of urban residents who live in slums continued to grow”. Surprisingly, despite the scale of the phenomena of informality, we lack a comprehensive, database that presents these cases globally. Scholars map informal urban development at two scales: the national scale and the neighborhood scale. At the national level, based on data collected by

states or international agencies, these entities use national indexes that can be compared across region. These studies focus on indexes have little reliability at the city scale. The second group of studies focuses on case studies at the neighborhood scale. While these exercises present fabulous detail, the single case selection presents problems of generalization of findings. These two scales of measurement create blindness of informality at an urban scale and its relationship with global trends. The Atlas of Informality is an attempt to broaden understanding of such overlooked phenomena.

The primary goal of this research is first creating a database that breaches the data gap between measurements of informality at national level and those single case at the local scale for neighborhoods comparison of informal settlements across geographies. And second to critically answer, how such geographies of informality change at the neighborhood scale globally? And, how does this compare to current informal area growth indexes?

This research uses a robust definition of informal settlement, incorporating global database cases designated as informal settlements in any of its diverse interpretations to include the broad spectrum of informal settlement urban form. A defining characteristic of informal settlements as an urban form is their constant state of change due to the piecemeal additive process of construction. This persistent state of change complicates the study of these urban forms. However, it is necessary to study the variation of the change of settlements over time to further understand their urban processes. This research collects standardized measurements of 420 informal settlements to provide a tool to geolocate, at the neighborhood scale, each one of these places. It then focuses on the mapping of urban growth. For the mapping of informal settlements, the Atlas uses a combination of remote sensing and direct mapping with readily available satellite photography. For this project, we use manual digitization from high-resolution satellite data over fifteen years to construct all cases. The direct measure is a more labor-intensive process but provides more accurate and standardized data.

The survey of growth corroborates the idea of informality as expanding geography. Since the cases selected are the most known in the literature, the expectation is that old cases will consolidate and stop expanding. This mapping revealed the contrary: the entire sample continued expanding. The average increase in the sample is .005 percent per year, meaning that approximately 81,000 hectares of informal settlements are added per year globally, just in already existing informal areas. The data made evident that there are significant differences between regions. Latin America, as expected, presents a less accelerated growth whereas Africa exhibits a more substantial number of entries with an increase between .7 and 1.9 percentage area expansion per year.

Findings of measuring informal areas at neighborhood scale contradict current data on informality that show a deacceleration in the rate of growth of such places. However, this finding raises important questions about the value multi-scale measurements of informal settlements across the world. The discrepancies presented here are crucial to clarify since global measurements of the scale and change of the problematic of informality guide global urban policy.

Urban parks provide both physical and mental health benefits to visitors and residents nearby and, therefore, are an important element of city planning. While the catchment area of a park, how a wide area is served by a park, needs to be investigated and measured for more reasonable and systemic park planning, in many cases it is simply assumed without much empirical evidence. One main reason for this lack of evidence is that actual service areas are difficult to measure with previous survey methods such as individual travel-activity data.

Since the turn of the millennium, the emergence of big data provides inspiring potentials to examine urban mobility at low cost and a large scale such as social media and crowdsourcing data. (Yuan et al., 2012; Liang and Zhang, 2018; Zhai et al., 2018) This study aims to propose and exemplify a new way to understand actual park catchment areas based on these newly available data, particularly mobile phone GPS location records.

The study area of this study is the 23 special wards of Tokyo, or tokubetsu-ku, the core of the capital of Japan. Sample urban parks were selected through stratified random sampling based on park size. We divided urban parks into five groups (A to E) and sampled six parks from each group. To minimize the bias due to seasonal variation, we included visitors during March, June, September, and December to the visitor sample. We roughly estimated park visitors' home locations based on the mobile GPS data, while all other information of visitors is anonymized.

We proposed a method using density distance gradients to delineate and visualize park catchment area, instead of the conventional distance-based buffers, mapping and counting cells (100m by 100m) based on the park visitor density of each cell. Using kernel density functions, we interpolated overall density distribution within the mapping areas. For mapping and counting, we used six density levels, of which thresholds are 0.001, 0.01, 0.1, 1, 10, and 100 GPS points per km². We introduced three spatial scales of searching radius for the kernel density mapping, 5,000 m for the city scale, 10,000 m for the metropolitan scale, and 20,000 m for the regional scale, and compared how each scale works well for different park size groups.

The mapping showed that there were striking differences in terms of park visitor distribution pattern. Maps of some parks exhibited concentric circles, as often assumed in many existing studies, while those of other parks showed linear expansions, irregular shapes, and even discontinued hot spots around the city. These various typologies require further discussions connecting park characteristics and other urban

infrastructure. In addition, the spatial scales of visitor density distribution mapping and cell-counting should be chosen according to the park size. For example, park catchment areas investigated and quantified on the city scale can explain almost all visiting activities for the category A parks (0.5-1ha) and most of the visiting activities for the category B parks (1-3ha). However, for the category D or E parks (10-50ha and larger than 50 ha, respectively), the city scale can only explain a small portion of activities and the metropolitan and regional scales should be examined.

This paper explains why cities are optimal sites of experimentation for emerging technologies such as robotics, and argues that city planners should play a pivotal role in regulating these technologies for the public good. The paper begins with an introduction to the nature and current state of robotics technologies being tested in cities, and the institutional economics and potential hazards for cities that open their public rights of way to experimentation with new technologies. There are numerous unintended consequences of urban robotics, and this paper includes a discussion of the privacy impacts of robots for cities, and local government's role in reshaping concepts of privacy in public space. To give shape to the existing institutional environment for cities, the paper clarifies the legal authority of cities to regulate urban robots within the complicated schema of federal and state laws that touch this technology. Lastly, it situates planning as a profession at the intersection of the governance of public space, the advocacy of public interests, and the emergence of urban robotics in the marketplace of cities, and provides a framework for their evaluation. Co-authored by a legal scholar, a designer of robots, and a planning academic, the purpose of this work is to further planners' understanding of the beneficial yet disruptive forces of technology--from autonomous vehicles to follow-me drones and security bots--that are seek purchase in the city.

MASS EVACUATION MODELLING: A MULTIDISCIPLINARY ANALYSIS OF TRANSPORTATION PLANNING FOR COASTAL FLOODING

Abstract ID: 1189

Individual Paper Submission

HABIB, Ahsan [Dalhousie University] ahsan.habib@dal.ca, presenting author
ALAM, MD Jahed [Dalhousie University] jahed.alam@dal.ca, co-author
WALKER, Katie [Dalhousie University] Kathryn.Walker@dal.ca, co-author
QUIGLEY, Kevin [Dalhousie University] Kevin.Quigley@dal.ca, co-author

This study contributes to a growing discussion of how planners should prepare for a mass evacuation event. The literature in this field is limited when it comes to multidisciplinary analysis and training to evacuation from coastal floods. Transportation modeling centers on traffic simulations and road network performance, whereas evacuation planning focuses on vulnerability assessments and policy development. There is a gap in developing a holistic and robust understanding of how transportation models inform evacuation decision-making. The purpose of this research is to utilize a simulation study and mixed method approach to determine planning parameters to help inform evacuation plans.

The study first developed a large scale, sequential modeling framework that utilizes a flood risk model, a transportation network model and a traffic micro-simulation model. The flood risk model generates the extent of the flooding scenarios and their associated disruptions in the road network. The model results in four flood level scenarios, which includes flood levels at 0 m, 2.9 m, 3.9 m and 7.9 m. The network connectivity is disrupted by 0%, 23.3%, 27.3% and 31.2% respectively (Alam and Habib, 2019). Then, the study develops a transportation network model that generates evacuation demand for auto and transit users. The origin and destination matrices were extracted from the transportation network model to feed into the traffic micro-simulation model. This micro-simulation model builds upon dynamic traffic assignment procedures. The Halifax Peninsula, the urban core of Nova Scotia's capital was used to develop the traffic simulation model. This simulation model identified that it would take 22 hours to evacuate the Peninsula for the first two scenarios and this would increase to 23 hours for scenario 3 (3.9 m) and 4 (7.9 m). However, only 87% of evacuation can be achieved in scenario 4 because the network capacity is significantly reduced.

The study also utilizes a mixed method approach for a vulnerability assessment, the evaluation of evacuation routes, siting shelter locations and counter measures to improve evacuation planning. The study involved a stakeholder workshop, which saw 46 attendees from many sectors including government and non-government agencies. The workshop included focus discussions and participatory activities that inquired, for instance, what are the major considerations in selecting areas to evacuate? and how would stakeholders prioritize areas for a mass evacuation? Experts who attended the workshop identified potential locations for evacuation shelters and vulnerability weighting schemes. The lessons learned from

the workshop and the results of the traffic micro-simulation model inform developing operational plans for The Halifax Peninsula, which includes delineations of evacuation routes and potential shelter locations. A multiple-criteria analysis was used to validate emergency shelter locations choices. The study also proposed a framework for assessing vulnerability that accounts for long-term neighborhood changes, socio-demographic characteristics, residential locations and vehicle ownership (Alam, Habib, Quigley, and Webster, 2018). They found that clearance time was the key determinant of mobility vulnerability and the ‘presence of female’ and the ‘presence of seniors’ were found to be the two primary contributors to social vulnerability. Additionally, several peripheral zones were found to be at a higher risk due to their proximity to the flood source.

This multi-disciplinary research results in alternative scenarios which will be utilized within the traffic micro-simulation models to examine alternative strategies. A graphical user interface for scenario building will aid decision-makers to review alternative counter measures. The study will assist to identify alternative ways to improve mass evacuation operations in the event of coastal flooding. This research illustrates the importance of enabling a multidisciplinary approach in transportation planning and modeling to prepare for mass evacuations.

EFFECTS OF URBAN GROWTH BOUNDARIES ON STREETSCAPE URBAN FORM IN 50 U.S CITIES

Abstract ID: 1199

Individual Paper Submission

CHEN, Yan [University of North Carolina at Chapel Hill] waholulu@gmail.com, presenting author
SONG, Yan [University of North Carolina at Chapel Hill] ys@email.unc.edu, co-author

In the U.S, Urban growth boundary has become one of the most popular adopted development management policies to promote growth and control urban sprawl. Although the literature on growth management is extensive, few researchers have explored policy-oriented evaluation methodologies.

This article applied a new methodology to measure urban forms at streetscape level via deep learning in order to evaluate the geographical effects of urban growth boundaries in 50 cities in the U.S, selected from Oregon, Washington, California Virginia, and Florida State. The methodology utilizes google

streetview data from 2009 to 2018 that were further analyzed by the deep learning image segmentation model to extract the proportion of built environment factors in each streetview images, including building, sky, tree, grass, road, sidewalk. After joining with some traditional GIS urban form measures, we will compare how the urban streetscape forms shifted within and outside the urban growth boundary from 2009 to 2018. Then using the coarsened exact matching method, the selected 50 cities will be matched with another 50 U.S cities with similar urban form attributes to compare the effect of UBG on urban form from city level scale.

The results of our study are expected to be that urban growth boundaries would lead to a substantial change the streetscapes, increase building density, sidewalks and decrease the sky view inside those boundaries. The implications of these findings are important for planning practitioners and the evaluation of growth management policies throughout the United States and elsewhere.

Background:

In the past decades, decreased level of physical activity (PA) has significantly contributed to the obesity epidemic in the U.S. (Flegal et al., 2012). Physical environment plays an important role in people's PA (Zimring et al., 2005). In the active living literature, many methods have been introduced to measure the physical environment objectively and subjectively (Brownson et al., 2009). Objective measures include GIS and environmental audit; subjective measure can be achieved via interview and survey. Moreover, travel diary and drawing on a map are useful to identify participants' PA routes and places, especially in complex environments. Yet, it is difficult to administer and the results are often not reliable. This study

proposes a multi-method approach that integrates a survey, an online interactive map (i.e., WikiMapping), and an environmental audit to measure the physical features of routes chosen for walking, running and biking. WikiMapping is an online tool originally developed for urban planners to obtain public inputs, allowing participants to provide route and place information by directly drawing lines or dots on an interactive GIS map and answering related questions (e.g., frequency of use and comments).

This study aims to better understand how specific routes/places and their features influence people's choices of routes/places for PAs, and to test the WikiMapping tool for a larger-scale study.

Methods:

Settings: This study was conducted in the Mueller Community in Austin, Texas. Mueller is a mixed-use, healthy community with a 711-acre land, 140-acre green spaces and 13-mile walking/biking trails.

Participants: Mueller residents who were 18 years or older, and able to read and write English.

Measurement instruments: (1) A survey was administered to inquire participants' socio-demographic status, PA frequency and duration, and their perceptions of the built environment; (2) an environmental audit tool was used to objectively record conditions of all the streets in Mueller, including land use, street characteristics, sidewalk conditions, pollution, buildings and overall perceptions; (3) the WikiMapping collected GIS/visual information of the PA routes and up to six PA places, frequency/purposes/types of PAs and reasons for route/place selection. A unique ID was used to link a participant's WikiMapping results to his/her survey responses. **Analysis:** The unit of analysis was the street segment. There were a total of 151 street segments audited during the time the WikiMapping was conducted. GIS, descriptive statistics and multivariate regression model were used for data analysis.

Results

Seventy-two of 395 survey participants participated in the WikiMapping exercise. 111 routes were identified for walking, 66 for running, 34 for biking, and 207 places for various PAs. A large percentage of PA places were located in neighborhood parks and community green areas. Multivariate analysis indicated: (1) Walking route choice ($R^2=.494$) was significantly associated with 'distance from home' (-), 'number of recreational land uses' (+), 'average building height' (+), 'tree/vegetation conditions' (+), and 'number of park land uses' (+); (2) Biking route choice was associated with 'distance from home' (-), 'speed limit' (-), 'visual quality of tree/vegetation' (+), 'number of bicycle facilities' (+), 'number of recreational facilities' (+), 'presence of education/office land use' (-), and 'presence of residential land use' (-); (3) Running route choice was related to 'distance from home' (-), 'type of recreational land uses' (+), 'average building height' (+), visual quality of street' (+), and and 'presence of residential land use' (-).

Discussion/conclusion

WikiMapping helps visualize the PA routes and link PA with specific street characteristics. However, the response rate was low due to the learning curve and the difficulty for participants to manipulate/modify the routes.

ABSTRACT: THE PAN-ARAB CORRIDOR: GEOSPATIAL ANALYSIS CASE STUDY.

Abstract ID: 1223

Individual Paper Submission

ABDOUNI, Lynn [The University of Georgia] lynn.abdouni@uga.edu, presenting author

The 'Pan-Arab Highway', conceived in the early 1950's, was designed to connect the Mediterranean Sea to the Persian Gulf by way of Lebanon, Syria, Iraq, Saudi Arabia, and Kuwait (Manasseh, 1958). Plans for its construction folded in the wake of armed conflict that started in the region in the late 1950's. Lebanon proceeded to construct its section of the highway outside of this regional framework and is expecting to complete the highway segment within the next 10 years. The slow and interrupted construction process spurred land use responses to materialize along the highway. These responses serve as built-in pilots that are telling of how land use will change as the highway construction continues.

My paper discusses geospatial methods in land use classification and techniques in forecasting land change by borrowing concepts from urban ecology to address what is traditionally reserved for land-use – transportation interaction models. This framework has the potential to overcome challenges in acquiring data and in representing the diversity of the mixed-use land classes exhibited by this case study.

The paper will first discuss the progression of creating a land use classification schema unique to the Pan-Arab Corridor (combining satellite imagery analysis to ancillary datasets and ground proofing), then proceed to use the classification dataset's applicability in populating landscape ecological assessment frameworks, in an effort to contribute to their growing impact on urban planning research by addressing the specificities of the case study area. Contemporary examples of ecology applications to urban planning are the use of graph theory to assess a transportation network's impact on habitat fragmentation (Girardet, Foltête, & Clauzel, 2013) and the use of fractal theory to understand and simulate land use contagion (Carrizosa Umaña, 2014). Applying urban ecology will serve the premise that the urban form itself behaves much like a living organism, and exhibits its reaction to changes by displaying fragmentation, boundary shifts, and landscape pattern changes (Forman, 1995) (Batty, 2013).

The research, joining a case-specific land use classification set to a geospatial analysis process entrenched in ecology, will a) present geospatial analysis methods that overcome data shortage, b) accurately represent the case study's cities in relationship with their transportation network, and c) lay the ground work for later, higher resolution analyses for urban planning research.

Keywords: land use, transportation planning, urban ecology, remote sensing, geospatial analysis, Lebanon, Middle East, Pan-Arab Highway.

CEMETERY PRESERVATION: USING TECHNOLOGY TO PROMOTE SOCIAL INCLUSION

Abstract ID: 1231

Individual Paper Submission

THOMPSON, Michelle [University of New Orleans] mmthomp1@uno.edu, presenting author

GARCIA, Jennie [City of Hammond] garcia_ja@hammond.org, co-author

Cemeteries are not necessarily considered a tourist destination but increasingly they have become a place for education, discussions about community development and social inequality. Using new technologies such as ground penetrating radar (GPR), we can learn about the location and number of internments. This becomes increasingly important as the demarcation of grave boundaries could impact future development especially if a cemetery is located within a neighborhood and bounded by residential housing. In both Historic Preservation and Planning, information about cemeteries is being used to complement other data which evaluates social class, quality of life and ethnography of place.

In Louisiana, the City of Hammond holds two small African American cemeteries: a municipal city cemetery, and another small cemetery that contains Peter Hammond. Peter Hammond was one of the founders of Hammond, LA, Mr. Hammond, his family, and an enslaved person are located in a small neighborhood cemetery. The Greater St. James AME cemetery contains a notable founder of Hammond's African American community, Charles Daggs. The latter cemetery was a designated African American Cemetery founded in 1870. The history of these Hammond prominent figures needs to be preserved and shared in the future. However, the preservation of the cemeteries, and their history, remains incomplete. This study explores the physical placement of the sites, their current condition and questions the difference in maintenance and historical significance of these equally important sites. Along with understanding the technology that is needed to conduct the physical research and using sound methods for accurately evaluating cemetery history, GIS is used to provide accurate site information and ultimately add to local tour and educational material for Hammond residents and visitors alike.

A COMPARISON OF STATISTICAL AND MACHINE LEARNING ALGORITHMS FOR PREDICTING RENTS IN THE SAN FRANCISCO BAY AREA

Abstract ID: 1264

Individual Paper Submission

BESHARATI-ZADEH, Arezoo [University of California Berkeley] arezoo.bz@berkeley.edu, presenting author

WADDELL, Paul [University of California Berkeley] waddell@Berkeley.edu, primary author

Urban transportation and land use models have used theory and statistical modeling methods to develop model systems that are useful in planning applications. Machine learning methods have been considered too 'black box', lacking interpretability, and their use has been limited within the land use and transportation modeling literature. We present a use case in which predictive accuracy is of primary importance and compare the use of random forest regression to multiple regression using ordinary least squares, to predict rents per square foot in the San Francisco Bay Area using a large volume of rental listings scraped from the Craigslist website. We find that we are able to obtain useful predictions from both models using almost exclusively local accessibility variables, though the predictive accuracy of the random forest model is substantially higher.

PREDICTING PEDESTRIAN FLOWS: AN EMPIRICAL ANALYSIS OF GPS WALKING TRACES IN SAN FRANCISCO.

Abstract ID: 1290

Individual Paper Submission

SEVTSUK, Andres [Harvard University] asevtsuk@gsd.harvard.edu, presenting author

A widely held belief among planners and transportation scholars commends that street attributes play an important role in influencing pedestrian route choice. Faced with alternative options, we typically expect a pedestrian to choose a faster, safer, more comfortable, more interesting or a more beautiful route. A robust literature on pedestrian route choice has provided methods for assessing the likelihood of such

options using discrete choice models. However, route choice estimation, which is data intensive and computationally challenging, is infrequently performed in planning practice. Furthermore, even when coefficients and odds ratios from previous studies tell us how different route attributes affect route choice, operationalizing them in footfall predictions in newly planned places is rare because detailed information about sidewalk quality, aesthetic attributes or experiential factors themselves are difficult to collect. In this paper we use a unique dataset of over a 100,000 anonymous GPS routes from pedestrians in San Francisco to test how important route characteristics really are to pedestrian route choice. We compare two route choice predictions: first using detailed route quality coefficients calibrated on half of our dataset and tested on the other half; second, a significantly simpler model that assigns equal probability to all routes that are up to 15% longer than the shortest route. Our findings show that while route attributes do have a significant impact on pedestrian route choice, using the much simpler assumption of random distribution with pre-specified detours offers a reasonably accurate prediction of actual walking behavior. This implies that instead of investing significant efforts to model route choice according to specific route qualities and parameters, considerably simplified assumptions can be used to predict pedestrian flow in practice with existing software, opening walkability analyses to a much wider range of planning projects.

WU, Yiwen [University of Kansas] yiwen@ku.edu, presenting author

JOHNSON, Bonnie [University of Kansas] bojohjohnson@ku.edu, primary author

LYLES, Ward [University of Kansas] wardlyles@ku.edu, co-author

As social media becomes increasingly popular in people's lives, governments and nonprofit organizations are realizing the importance of using it to enhance public relations and promote public engagement. In the context of natural hazards/disasters, social media use by organizations has been found to be crucial in many regards, such as the rescue process, resource navigation, and status reports (Murphy and Gross, 2016). After a disaster, victims' mental health is as vitally important along with their physical safety. Planning scholars have pioneered innovative ways to understand public opinions on social media for

public transportation (Schweitzer, 2014). Nevertheless, only a handful of studies have shown how governments and nonprofit organizations' online responses answer the public's emotional demands in the disaster context. An understanding of the rapid development of social media platforms and social media adoption by various government agencies and nonprofit organizations is needed. An exceptional opportunity is offered for planners to evaluate how governments and nonprofits react online to mitigate emotional trauma in the climate-change era.

My research will build off of previous research on considering compassion as a key element to promote public health and well-being in the planning profession (Lyles, 2017), by accessing a large amount of data from Twitter in order to measure empathetic expressions by organizational accounts. The use of social media in dealing with public affairs and emergency management has been adopted by a number of government agencies and practitioners to various extents (Eyrich et al., 2008; Waters et al., 2009; Mossberger et al., 2013; Kavanaugh et al., 2011; Picazo-Vela et al., 2013). Hurricane Florence, a category four hurricane, is chosen as the study target for its long duration and impactful damage characteristics. Regarding tweets related to Florence, the research focuses on three questions: 1) Which local planning agencies, organizations and government agencies play important roles in facilitating the communication environment on Twitter? 2) What themes can be used to categorize tweeted data? For instance, do tweets belong to disaster information, rescue guidance, or empathetic expressions? 3) How does one accurately catch empathetic tweets and find their patterns?

This study employs the open-source tweet collection method by using R software. The content analysis will be applied to several sets of tweets that are categorized by users (accounts), content (hashtags), and themes. Specifically, the study will identify a set of government agencies, including any planning departments/agencies, and nonprofit organizations that responded and worked through the recovery of Hurricane Florence. Then two local emergency management agencies and two charitable organizations will be chosen for further analysis to compare government and nonprofit responses.

Adoption of social media certainly brings enormous possibilities to promote public health, even mental health, and strengthen an equitable online environment. Social media is changing from simply a tool for information exchange to a dynamic networked community including individuals, governments, and nonprofits. From a scan of 14 Florence related tweets by the national office of the American Red Cross during and right after Florence, preliminary results demonstrate six tweets are resources information, one is appreciation notes to donors or supporters, four are disaster status reports, two are empathetic or emotional expressions, and one falls outside of the four preceding categories. One of the two emotion related tweet is: "I'm going to stay positive because that's the only thing I can do.' We are helping those impacted by #HurricaneFlorence and will be there to support them in the weeks and months to come. How you can help: <https://rdcrss.org/2QaWVeU>" – Red Cross, Sep. 26th, 2018. Next steps will be conducting the same analysis with local organizations and Florence related tweets.

A WAY TO LIBERATE FROM POVERTY FOR SMALL SCATTERED VILLAGES IN CHINA: GIS-BASED MULTI-FACTOR SCREENING OF RECHARGING POINTS ALONG RURAL HIKING LINE

Abstract ID: 546

Poster

WEN, JUN [College of Architecture and Urban Planning, Tongji University, Shanghai, China]
1015063466@qq.com, presenting author

Question

When urbanization encroaches on rural land, urban resources also flow into rural area, like tourists, capital and ideas. How to use them to realize the rural regeneration has become a heated issue in China, especially for the small and poor scattered hilly villages with certain historical cultural value. A planning methodology that connects scattered villages by a rural hiking line could address the question to some extent. Specifically, as recharging point, the villages along the line provide accommodation, rest spots and emergency rescue to make the most of the urban resources, develop the economy and escape poverty. However, what kind of village can bear the function of recharging point?

Methodology

In the theoretical stage, oriented by the question, a GIS-based screening method with spatial overlay analysis on multiple impact factors is proposed. Assisted by literature research, the essential impact factors are summarized by taking the characteristics of an existing rural hiking line in Zhejiang Province as a reference. Consequently, per capita income, population, historical cultural resources, river system, roads are summarized as the five key factors of potential villages. Then those factors are segmented and assigned values differently according to the local policy, actual situation and requirements of hiking line. After adding up factor values, the possible recharging points are displayed.

In the practical stage, two neighboring poor towns with 77 villages in Zhejiang Province are taken as research objects.

Firstly, screen the potential starting points. Two starting points are supposed to be the core attractive points with a range of high requirements: 1) village committees set up; 2) residential area larger than 5000 m²; 3) population larger than 600; 4) per capita annual income higher than 6000 yuan; 5) no more than 200 m away from 5-m roads. As a result, 10 villages are selected.

Secondly, screen the potential recharging points. Spatially via GIS, the values of internal factors, per capita income, population, historical cultural resources, are assigned respectively to the 500-m buffer of residential areas larger than 5000 m². The values of external factors, rivers and roads, are assigned to their 200-m buffers. Overlay each spatial buffer.

Thirdly, screen reasonable line and points. As centers, the 10 potential starting points are buffered with a radius of comfortable hiking line length 5000 m. Based on the analysis of its intersection with overlay result, appropriate lines become visible in the end.

Findings and Relevance

1) A larger-scale study across town is conducive to discovering more favorable starting point that can drive the development of poor villages. 2) Factor segmentation and assignment of villages from other districts should be adjusted according to actual conditions to ensure optimization. Sometimes it is possible to add 1-2 non-poor villages in the line for economic promotion. 3) Though still with 7 options after analysis, the optimal rural hiking line can be chosen by local policy, actual terrain condition and the function of enhancing towns connection. 4) The methodology research makes the rural hiking line more generalizable and implementable in rural planning. However, policy maker and urban planner also should consider the endowment of each village, and find other ways for those inappropriate villages.

PRIORITIZING SUSTAINABLE DEVELOPMENT GOALS (SDGS) BY ANALYZING THEIR INTERLINKAGES

Abstract ID: 601

Poster

JANG, Chang-Ho [University of Seoul] ckdgh501@naver.com, presenting author

SONG, Jaemin [University of Seoul] jmsong@uos.ac.kr, co-author

In 2015, the United Nations adopted the Sustainable Development Goals (SDGs) urging comprehensive changes to move toward sustainable development at the global level. SDGs serve as a guideline for 193 UN member countries in introducing and implementing policies in their cities and countries. However, understanding interlinkages between the goals should be preceded prior to establishing sustainable development policies or a implementation plan, since they are interlinked each other. SDGs consist of various goals and targets; thus, implementation of one goal can facilitate to achieve another goal while pursuing one goal can conflict with another goal. Therefore, it is important to identify complex and close interlinkages between SDGs. Although recent studies have attempted to identify their interlinkages, most of the studies describe the linkages in a rather qualitative way on the basis of researchers' arbitrary decisions. Against this backdrop, the objective of our study is two-folds: to find interlinkages between the

targets of SDGs using a text mining and Word2vec machine learning technique and to prioritize targets given their importance based on their relative centrality using a network analysis. In this research, we extracted 676 academic papers on SDGs by web crawling in Google Scholar and conducted text preprocessing. Each SDG target was represented by their keywords and cosine similarity between the keywords using Word2vec were calculated, which were used as weight for the network analysis. The preliminary results show that 22.6% of the targets are linked with more than one target while the rest do not show any relationship with other targets. For example, SDG5.c “endeavor for gender equity” is highly related to SDG1.3 “implement social protection system”, SDG1.4 “access to basic service”, SDG4.3 “access equal education”, and SDG10.3, 10.4 “eliminating discriminatory laws and policies”. The results of this research are expected to contribute to prioritizing policies and developing synergic policy for sustainable development considering interlinkages between SDGs.

This poster uses participatory scenario planning to assess the environmental, physical, and social implications of recasting Brazil’s mass housing program Minha Casa Minha Vida (MCMV) as a densification strategy along São Paulo’s Tamanduateí industrial corridor. As is currently common across Latin America, the MCMV program is divesting public resources from the upgrading of existing informal settlements, and promoting peripheral sprawl and sociospatial segregation by constructing mass housing enclaves at the urban margins (Rolnik, 2015; Stiphany and Ward, 2019). Located 10 kilometers east of Centro, the Tamanduateí industrial corridor provides a key site for calibrating MCMV to centralized locations, because it is occupied by vacant industrial land tracts, informal settlements, and a series of

historical preservation sites. Although a plan Operação Urbana Consorciado Bairros do Tamanduateí (OUCBT) was approved to develop the Tamanduateí, first in 2008, and again in 2015, no proposals have been implemented and Brazil's economic downturn has impeded forward movement. The use of scenario planning is one way to use a local research infrastructure to guide broader development decision-making processes (Goodspeed, 2019).

Drawing on a large-scale study about housing and technology was undertaken between 2015 – 2017 within Heliópolis, an informal settlement located within the Tamanduatei Corridor, this poster unites methods that include a household survey (n = 1,032), the GIS-based webmapping tool ComuniDADOS (www.chapa.io/comunidados), and Envision Tomorrow to generate three scenarios that draw into discourse: (1) environmental management strategies based on the Tamanduateí's geography of flooding (Perez, 2013); (2) development types that include mixed income housing, recreation, and commercial programs; (3) housing typologies with meterage aligns with MCMV parameters, but whose form is guided by incremental housing typologies found in Heliópolis; (4) outcomes of a workshop that presents scenarios to residents of the Heliópolis favela, who have been engaged since 2015.

Our analysis reveals that there is room for densification within the Tamanduateí Corridor, and that benefits include locating MCMV units in areas that optimize existing social and infrastructural networks; build upon the real demands for housing, which recent research has found to be in rental (Stiphany, 2019); and co-manage the range of biophysical and technical infrastructures that currently concentrate along the corridor for enhanced urban livability. This scenario planning methodology can be adapted to peer-contexts.

TRACK 2 - COMMUNITY DEVELOPMENT

TRACK 2 - PRE-ORGANIZED SESSION SUMMARY & ABSTRACTS FOR THE SESSION

HISTORIC PRESERVATION AND SOCIAL INCLUSION

ID: 3

Pre-Organized Session Summary

Includes abstracts: 32, 33, 34, 35, 36

This session explores the social dimensions of historic preservation. The papers analyze the synergies and tensions between historic preservation and underrepresented populations and communities. Within the field of preservation, there are increasing calls for a more inclusive practices. Yet, the concept of inclusion, as it pertains to preservation, is ill-defined and the field has been slow to address fundamental issues of power and barriers to inclusion. The papers in this session explore the ways in which preservationists are seeking out diverse narratives, opportunities for inclusive participation, and ways to generate equitable community benefits from preservation strategies. The authors also shine a critical light on the past and current practices within the field and offer ideas for a more equitable and inclusive preservation profession.

Objectives:

- Synergies and tensions between preservation and social inclusion
- Methods of increasing inclusion within historic preservation practice
- Strategies for engaging diverse communities with regards to historic preservation

THE PATH TOWARDS INCLUSIVE PRESERVATION: LESSONS FROM CLEVELAND, OHIO

Abstract ID: 32

Group Submission: Historic Preservation and Social Inclusion

RYBERG-WEBSTER, Stephanie [Cleveland State University] s.ryberg@csuohio.edu, presenting author

Preservation has long-struggled to mesh the ideals of diversity, equity and inclusion with barriers inherent in the field's methods, policies, and regulations. Using two case studies from Cleveland, Ohio, this paper explores preservation practice within African American neighborhoods. Both Buckeye and Lee-Harvard are located on the city's far east side. Both are predominantly African American neighborhoods, with vastly different development and preservation histories. Buckeye developed in the early 1900s as the nation's largest Hungarian enclave, experiencing rapid racial turnover in the 1970s. Preservationists in the 1970s struggled to navigate the disconnect between Buckeye's architectural heritage and its current residents. In recent years, a renewed interest in Buckeye as a historic neighborhood sheds light on

preservation's longstanding bias towards "origins" stories and architecture and the ways in which these narratives erase the significance of lived experience for African American residents. In contrast, Lee-Harvard developed in the post-WWII era, largely by and for middle-class African Americans seeking a suburban lifestyle outside of the urban core. The neighborhood retains many of its original, now aging, residents. Deeply flawed past efforts to survey, document, and preserve the city's African American heritage, eventually led to a more engaged approach in Lee-Harvard. In recent years, the Cleveland Restoration Society, a prominent non-profit preservation organization, embarked on a multi-year effort to document and preserve Lee-Harvard. In doing so, preservationists have slowly moved from architectural-based windshield surveys to deeper community engagement, oral histories, personal stories and archives (i.e. family photographs). Using archival research, interviews, and participant observation, the research compares these two case studies to draw lessons for preservation research and practice. The comparative analysis illustrates key factors in making progress towards an inclusive preservation practice, highlighting the particular importance of political will and funding. The paper also addresses ongoing constraints, including the value placed on architecture and material integrity, the prominence of professional expertise, and power structures within the profession.

PRESERVING COMMUNITY: COMMUNITY LAND TRUSTS AND HISTORIC PRESERVATION

Abstract ID: 33

Group Submission: Historic Preservation and Social Inclusion

CHEONG, Caroline [University of Central Florida] caroline.cheong@ucf.edu, presenting author

This presentation presents findings from an ongoing investigation focused on if and how historic preservation and affordable housing goals can be jointly met and combined through the use of community land trusts (CLTs). The purpose of the project is to expand and deepen our understanding of historic preservation's ability to address, or contribute to solutions, to contemporary problems of housing affordability and the creation of equitable, sustainable cities. Similarly, it is hoped that those researching and working in the affordable housing sector will consider historic structures as viable options for CLT or other affordable housing initiatives.

Research regarding the symbiosis between historic preservation and affordable housing is in its beginning stages, with the majority of publications coming from graduate students and professional organizations or think tanks – such as the National Housing Institute (Ceraso 1999) and The Advisory Council on Historic

Preservation (2005). This project contributes to the growing body of research on the relationship between these two fields. Its interdisciplinary approach contributes to a variety of fields in the humanities and allied fields, reaching scholars and practitioners in public history, historic preservation, and city planning.

Within the affordable housing sphere, community land trusts (CLTs) are particularly promising for their potential to preserve both housing affordability and historic structures. CLTs that utilize historic structures within their management portfolio represent unique opportunities to investigate how the twin goals of housing affordability and historic preservation can be achieved. A review of CLTs belonging to the National Community Land Trust Network demonstrated that organizations using historic buildings run along the spectrum of those that do so begrudgingly – perhaps as a means of necessity because their housing stock is aged – and those that do so explicitly and with historic preservation principles in mind at the outset.

This study investigates how shared equity models like CLTs can be applied to historically and culturally significant low-income neighborhoods, such that the existing residents maintain ownership, management and affordability for their homes while simultaneously preserving the history and culture entrenched within the structures and community. By providing avenues for homeownership and wealth building, these models not only preserve a neighborhood's physical assets but also the social and cultural resources embedded within its residents. This presentation presents findings from a literature review focused on historic preservation and community land trusts, a national scan of CLTs that combine both and a preliminary assessment of case studies that combine historic preservation and affordable housing, but differ in process and outcome. Case studies include the Champlain Housing Trust in Burlington, Vermont, Flagstaff Townsite Historic Properties Community Land Trust in Flagstaff, Arizona and others. All represent varying ideological and practical approaches to historic preservation. It is likely that, pending outcomes from the literature review and national scan, two to three case studies will be added.

THE RIGHT TO WORK TOWARDS THE PRESERVATION OF PHILADELPHIA'S CIVIL RIGHTS HERITAGE

Abstract ID: 34

Group Submission: Historic Preservation and Social Inclusion

AIDOO, Fallon [University of New Orleans] faidoo@uno.edu, presenting author

The Civil Rights Acts of 1954, 1964 and 1968—landmarks in a century-long civil rights movement—granted racial minorities the right to work, live and travel throughout America. Yet, urban scholars increasingly find informal metrics of inclusion and insidious mechanisms of exclusion have regulated access to public spaces of the American metropolis in the post-civil rights era. Amongst many meters and managers of blackness in once white-only spaces, philanthropic “friends of” privately owned public spaces such as pocket parks and commercial plaza receive little scholarly attention outside case studies of neighborhood preservation (Ryberg 2014; Kinder 2016; Lawson 2005). This paper highlights how one friends group mobilized its peers, public partners and philanthropic sponsors to preserve historic places of black access to white privilege: commuter rail stations and surrounding parkland.

This paper follows Friends of Allen Lane Station (FALS, a committee of Philadelphia’s West Mount Airy Neighbors Association) in its quest to create a metropolis-wide consortium of communities and contractors capable of rehabilitating and maintaining rail stations facing disinvestment since their racial integration. Rising to the helm of the U.S. Department of Transportation and the halls of the U.S Public Utilities Commission, FALS founders and funders successfully brought their international acclaim in fair housing litigation, regulation and advocacy (Perkins 2014) to bear on the transportation sector. These resourceful “fixers” of deregulation, degradation and desegregation eschewed the black politics of budding community development corporations (Goldstein 2017; Hill and Rabig 2012), even though they engaged in color commentary to compete for local control of labor and land not desired by Conrail, a federal corporation formed from bankrupt railroad companies in 1976. Archival research of FALS’s communications and contracts in the 1970s and 1980s reveals Friends of Allen Lane Station instead waded into labor rights, aiding the unhoused, unemployable and uneducated to acquire a right to re-work underutilized historic stations into homes, workplaces and schools.

The so-called “post-racial” labor politics of FALS, and its parent organization and peers, undergo close examination in this paper. By linking workforce development, homesteading and historic preservation, I argue, the Friends of Allen Lane Station not only built a local network of community foundations and community development corporations of Greater Philadelphia that supported its consensus politics. Their right to work campaigns conscripted federal corporations and conservancies such as CONRAIL and the National Endowment for the Arts into the contentious politics of black power and white empowerment organizations that pledged to preserve FALS’s rail stations long after friends of them disbanded. Friends of the Rail Park in Philadelphia, now funded by these same corporations and foundations (Rigolon and Nemeth 2018), is indebted, I conclude, to preceding rail preservationists that fought for their right to work on America’s civil rights heritage.

CURATING FREEDOM: MAKING TEXAS' HIDDEN BLACK PUBLICS VISIBLE IN PRESERVATION PLANNING AND RESEARCH

Abstract ID: 35

Group Submission: Historic Preservation and Social Inclusion

ROBERTS, Andrea [Texas A&M University] aroberts318@tamu.edu, presenting author

While support for safeguarding African American historic sites has increased in recent years, state and local “authorized heritage discourse” (Smith) inhibits interpretation and commemoration of Black agency (slavery resistance, sovereignty, self-governance, and intentional placemaking.) This essay exposes the deliberate forgetting (Connerton, 2008) and disremembering (Gillman 2010; 112) of Black agency (Nieves and Alexander 2008; Gutman 2008; A. R. Roberts 2017) in Texas public history. The article argues that this disremembering reinforces narratives supporting decisionmaking, which undermines socially inclusive preservation planning and interpretation in Texas. The ways in which various groups collude to obscure historic and current Black agency and instead privilege community origin stories centering settlerism and white benevolence are discussed.

This paper will provoke a reconsideration of seemingly innocuous encounters with disremembering Black agency during visits to a public park, public archives (state historical marker applications), and stays with Deep East Texas freedom colony descendants (historic Black communities founded 1865-1920). Reflections elucidate mainstream preservationists’ collusion with Anglo settler narratives, in which the voices of benevolent whites, conciliatory black leaders, and “bootstraps” ideologues are valorized, and those of black resistance and contestation are obscured or ignored. Cases include that of the contestation over the discovery of 95 bodies in Sugar Land, Texas, the interpretation of Black history in Jasper, Texas, and the lack of diversity of leadership in preservation organizations.

Conceptually, curation is introduced as a way to think of new ways to approach preservation and interpretation so that these processes are inclusive of a variety of constructions of place, identity, and state history including those centering Black agency. Curation then, of space, a landscape, or a moment, should then be a process of investigating the absences of the formerly enslaved (Jessica Marie Johnson). These absences are forms of fugitivity signifying what is missing from the archive especially regarding the positionality of those silenced, enslaved peoples.

I extend this to curating what is missing more broadly from our curation (stewardship, interpretation, advocacy, collecting) of African American landscapes or black geographies, which McKittrick refers to as often being rendered legally ungeographic. Public narratives, which proscribe white socio-legal constructions of place and negate Black epistemologies of planning and preservation obscure hidden black agency in the past and current descendant communities. Therefore, to curate freedom is to collect and interpret what Leonie Sandercock called foundational stories or origin stories of place, which center the storyteller’s periodization and meaning of spaces, actors, and events.

The article explores ways that practitioners can exercise allyship with fugitivity, defined as freedom-seeking from socio-spatial constraints of the past and of the present. The article then explores the ways scholars and practitioners can act as curators or keepers of place, custodians of black geographies of freedom. The article provides some avenues to inhibiting collusion with a persistent narrative of disremembering black agency or complicated statuses betwixt and between freedoms. Then, the paper concludes with suggestions for how to leverage Black counternarratives to foster socially inclusive

conservation practice. The author shares preliminary findings from recent workshops (R. Johnston and Marwood 2017, 816) in which counternarrative writing exercises were employed to foster “safe” confrontations with persistent white sociospatial imaginaries dominating Texas’ public history. Findings suggest that recording and publically sharing complicated counternarratives in interracial groups are constitutive of a social justice based approach to inclusive heritage conservation because these activities force communities to confront persistent interlocking spatial injustices privileging some voices and places while silencing others (Baird 2014, 142).

CRITICAL HISTORIC PRESERVATION IN PRACTICE: CASE STUDY OF ASIAN AND PACIFIC ISLANDER AMERICANS IN HISTORIC PRESERVATION.

Abstract ID: 36

Group Submission: Historic Preservation and Social Inclusion

MAGALONG, Michelle [University of Maryland, College Park] michelle.magalong@gmail.com, presenting author

The rich histories of the diverse and multifaceted Asian American and Pacific Islander (AAPI) communities can be found in the varied places where AAPI communities have made their homes across the nation. Few sites associated with AAPI history and cultures have been recognized as landmarks on municipal, state, and federal levels. As historic AAPI neighborhoods continue to deal with changing economic and sociocultural dynamics and threats of redevelopment and gentrification, many community residents, small businesses, and local nonprofits turn to planning and policy approaches, including historic preservation, for help. However, marginalized groups, like AAPIs, still perceive the preservation movement as not representing their interests, particularly as discussion moves into the politics of race and place in historic preservation. With these challenges in gaining recognition in the field of historic preservation has emerged grassroots efforts to elevate the importance of having more inclusive, diverse, and relevant approaches in historic preservation.

This paper explores critical race theory as it may be applied to underrepresented groups informing and potentially transforming the field of historic preservation. Despite evidence of growing ethnic/racial diversity of historic preservation efforts, the issue of racial equality in the field remains marginal to mainstream historic preservation activity. It is important to examine the margins, and from those underrepresented groups themselves, from a critical race theory perspective on how changes have been made in recent years in terms of preservation policy and practice. Utilizing a critical race theory approach

to history preservation, this paper explores how community-based participation challenges traditional approaches to issues of diversity and inclusion.

With the case study of Asian and Pacific Islander Americans in Historic Preservation, a national nonprofit organization, critical historic preservation theory is positioned to be informing (and transforming) the field from the ground up. Through this lens, historic preservation education, practice, and policy must include a focus on the centrality and persistence of racist ideologies and challenge dominant practices and understandings that have historically discriminated and silenced underrepresented communities. This paper utilizes in-depth interviews and participant-observation with Asian and Pacific Islander American historic preservationists that have been involved with local, state, and/or federal efforts focused on Asian and Pacific Islander American historic preservation, particularly through their work with Asian and Pacific Islander Americans in Historic Preservation (APIAHiP), a national non-profit organization. Data will explore how they provide culturally competent, ground-up alternative approaches to dominant historic preservation practices and understandings.

Findings explore the importance of structural change, organizational change, and individual empowerment that help shape alternative approaches to historic preservation that are centered on critical theories and approaches to participatory practices. In developing a framework that centers marginalized voices in underrepresented communities, this approach focuses on elevating the issues and needs in preserving historic sites and cultural resources associated with AAPIs while fostering more inclusive and relevant approaches in historic preservation.

REBUILDING RESILIENT COMMUNITIES AFTER A DISASTER STRIKES: ON HOUSING, COMMUNITY DEVELOPMENT, AND INTER-ORGANIZATIONAL NETWORKING

ID: 17

Pre-Organized Session Summary

Includes abstracts: 206, 207, 208, 209, 210

Natural disasters reveal the deficiencies of infrastructure and essential services. In particular, it highlights the lack of an institutional framework for effective community participation, development, and governance with clearly defined goals of how to provide respond, relocate, and reconstruct after a natural catastrophe. One of the priorities of communities is to generate disaster and climate resilience—that is, to strengthen the capacity to adapt and recover from the effects of natural disasters. Unfortunately, most governance models are characterized by bureaucratic structures that are fragmented into different sectors

and whose actors do not have much interaction between them. With technical assistance from organizations and networking, stakeholders are learning how to develop plans that encouraged the collaboration of multiple sectors (e.g., transportation, economic development, housing, etc.) and improves the working relationships between various institutions (e.g. local associations, NGOs, private and public organizations).

Objectives:

- Investigate and propose innovative policies and other government and community-led actions or initiatives that foster sustainable infrastructure and socio-economic development in communities affected by disasters in particular individuals that have been marginalized (e.g. low-income or disabled) and households in under resourced neighborhoods.
- Understand how guidance from community actors is important to assess vulnerabilities (e.g., landslides, flooding-based relocations, etc.)
- Present strategies for optimizing streams of funding for recovery efforts in rural and urban communities

HOUSING RECOVERY IN SENDAI, JAPAN AFTER 3.11

Abstract ID: 206

Group Submission: Rebuilding Resilient Communities After A Disaster Strikes: On Housing, Community Development, and Inter-organizational Networking

MUKHERJI, Anuradha [East Carolina University] mukherjia@ecu.edu, presenting author

Urban housing recovery in Kobe, the largest city in Hanshin, after the 1995 Great Hanshin earthquake widened socio-economic inequities and created spatial polarization (Hirayama 2000). Hirayama (2000, p.118) argued that the “two tiered system” in Japanese housing policy created the conditions for the polarization. The policy concentrates resources on moderate- to high-income groups to expand owner-occupied housing. For those who cannot obtain housing in the market, public housing units are rented to low-income households (Hirayama 2000). More than 20 years later, housing recovery after the 2011 Great East Japan Earthquake and Tsunami (also called the 3.11 disaster) has also created socio-economic polarization in urban areas, albeit amidst different conditions and context. Based on in-depth informant interviews conducted between 2012 and 2017, and review of planning documents and maps, recovery plans and policy briefs, this paper examines the reasons for such polarization in Sendai, the largest metropolitan in the disaster impacted Tohoku region. Tsunami waters during the 3.11 disaster inundated 8,110 coastal households in the City of Sendai, with 30,000 buildings completely collapsed and more than 250,000 buildings impacted (City of Sendai 2015). Eager to use nationally funded reconstruction programs, the city applied municipal planning power through a local ordinance to cast coastal lands as a high-risk zone, and to relocate households’ inland close to the city center. The ensuing movement of communities away from the coast to inland locations has created a more compact city, a long-term planning goal of the city with deep anxieties over an aging and shrinking population. It has also driven a largely elderly population, with financial limitations and the inability to afford a second mortgage, to high-rise public housing apartment complexes. Those with financial means have chosen to rebuild single-family homes at city designated relocation sites. The resulting socio-economic segregation has fragmented previously close-knit coastal communities and isolated low-income and/or elderly households in urban high-rise apartment complexes. While Japan’s housing policy has remained unchanged since Kobe, starting in 1999, Japan enacted a series of decentralization reforms that give greater powers to municipalities over local land use and decision-making (Wataru 2013). The outcomes in Sendai are examined within the context of Japan’s decentralization of planning powers. The study argues that in

large urban areas, the decentralization of planning power has not translated to decision-making based on local community needs, creating the conditions for the current wave of socio-economic segregation.

GEORGIA TECH PUERTO RICO STUDIO: PLANNING FOR EL CAÑO MARTIN PENA

Abstract ID: 207

Group Submission: Rebuilding Resilient Communities After A Disaster Strikes: On Housing, Community Development, and Inter-organizational Networking

ROSS, Catherine [Georgia Tech] cr15@gatech.edu, presenting author

Since Category 4 Hurricane Maria touched down on September 20th, 2017 with wind gusts of up to 147 mph (FEMA Hazus Report, 2017), Puerto Rico has struggled for stability amidst an ongoing humanitarian crisis affecting government functions and economic activity. In response, Georgia Tech students and allied faculty from the School of City and Regional Planning (SCaRP) interested in Global Development proposed a pilot joint studio with the University of Puerto Rico's Graduate School of Planning (EGP). With funding from the American Planning Association (APA), faculty in both institutions developed parallel courses, an exchange program for the Spring of 2019 and a planned multi-year collaboration, with the goal of contributing to long-term recovery and development.

The pilot studio focused on the eight communities – originally developed as informal settlements – adjacent to the Caño Martín Peña (CMP), a severely degraded 3.75 mile-long tidal channel connecting two important water bodies in San Juan (EPA, 2015). In these communities, the joint studio primarily engaged with two local organizations: the Land Trust which owns much of the community land; and ENLACE, an independent government organization, which advances efforts to alleviate poverty and improve the quality of life for local residents. ENLACE served as the joint studio's client.

In addressing ENLACE's needs, the pilot studio's most prominent objective was to develop a transferable model to channel planning assistance to other vulnerable communities – one which captured local and international institutional resources and talent. Consistent with Professor Cecilio Ortiz Garcia's (of UPR Mayaguez) emphasis on identifying gaps articulated by local communities as the greatest need (NCSE ,2018), this objective built on David Godschalk's concept of a "hazard mitigation corps," whereby state universities partner with local communities to provide hazard information and mitigation assistance (Texas A&M, 2019). Other studio objectives included educating next-generation planners and devising

transferable tools and analytics to strengthen the planning capability of communities and local organizations.

To achieve these objectives, the joint studio began with a 1-credit hour course in the Fall semester to better understand the Puerto Rican context. A 5-credit hour course in the Spring semester followed, in which UPR and GA Tech students – who communicated through bi-weekly calls – divided into small teams addressing project management, revenue streams, data, and parcel analysis. Over Spring Break, Georgia Tech students traveled to Puerto Rico for intensive workshops, fieldwork, and presentations. Site visits and in-depth interviews revealed the complexity of issues, and opportunities, facing ENLACE and the eight communities, including the need to secure funding and leverage the Land Trust's potential.

Studio deliverables included an in-depth evaluation of 15 project management tools, a review of over 60 government grants and alternative funding streams, a methodology for interactive data management in Tableau, and process recommendations for a tree inventory. Through interactive presentations in Spanish, students received feedback from clients and partners on the deliverables. As such, the joint pilot studio has proven relevant to planning scholarship, education, and practice, offering a broadly replicable model for disaster mitigation planning.

HOUSING AND DISABILITY IN EMERGENCY RESPONSE

Abstract ID: 208

Group Submission: Rebuilding Resilient Communities After A Disaster Strikes: On Housing, Community Development, and Inter-organizational Networking

VANIK, Leonor [University of Illinois at Chicago] leonor.vanik@me.com, presenting author
BETANCUR, John [University of Illinois at Chicago] betancur@uic.edu, co-author

Hurricanes Katrina and Rita revealed the inequitable social and political landscape marginalized populations (e.g., low income, Black, Hispanic and disabled) faced in the aftermath of recovery; since then, with each natural and manmade disaster, planners and governing bodies continue to learn how to effectively service devastated community residents with emergency essential services and post-recovery programs. Of the marginalized populations rarely cited in the literature are people with disabilities and

when cited, they are lumped into a singular category. By lumping them, the service needs of the visual, sensory, and hearing impaired are interjected with individuals who have mobile limitations thus not adequately acknowledging the unique challenges and circumstances of people with disabilities when providing a solution framework. This paper is part of a larger research agenda, using the mixed methods approach of grounded critical visualization, on marginalized populations and the responses governmentality has to emergencies where evacuation and relocation is necessary for the wellbeing of community members. Using the substantive theoretical framework on the social production of disability space(s) to guide the analysis, this paper traces the evolution of US policies addressing natural disasters and the mitigating solutions thru Hurricane Maria, for providing temporary and permanent accessible housing for people with disabilities (across the disability spectrum). Concentrating on the life experiences of Hurricane Maria stakeholders (specifically housing providers, government partners, and displaced residents) in the Chicagoland area, through in-depth interviews, we broach the continuing struggle of providing and accessing affordable housing and access to governmental community amenities. We identify and detail the extent of the barriers and facilitators people with disabilities and actors continue to face concluding with recommendations on ways policies and responses can be better framed for future disasters.

NETWORKING AMONG NON-PROFITS IN PUERTO RICO TO BUILD DISASTER RECOVERY CAPACITY.

Abstract ID: 209

Group Submission: Rebuilding Resilient Communities After A Disaster Strikes: On Housing, Community Development, and Inter-organizational Networking

CHANDRASEKHAR, Divya [University of Utah] chandrasedkhar@arch.utah.edu, presenting author
GARCIA ZAMBRANA, Ivis [University of Utah] ivis.garcia@utah.edu, co-author

Nonprofit organizations can play a critical role in disaster recovery owing to their ability to motivate volunteerism, assess local needs and distribute goods and aid [1]. But few such organizations have the capacity to successfully navigate the dynamism and uncertainty of disaster recovery. This is particularly true of locally-embedded, community-based organizations which typically have smaller staff, less resources, fewer extra-local connections, and much less experience in disaster recovery matters. But they are also the ones with the highest stake in long-term community recovery.

Research has indicated that networking and communication can provide nonprofit organizations with new avenues of information and action [2], boost their diminished capacities , provide better means of community representation [3], and improve “cognition” of “emerging risk to which a community is exposed and to act on that information”[4]. Social networking can also help these organizations by facilitating information exchange, collective action, and access to new resources for recovery [5]. Despite these preliminary insights, few studies have systematically examined how inter-organizational networking between community-based and nonprofit organizations improves their recovery actions. The knowledge of what makes some networks more effective than others can directly contribute to more targeted capacity building initiatives for this critical recovery stakeholder group.

In this study, we use a mixed methods approach to examine the ways and means in which inter-organizational networking improves post-disaster recovery efforts of community-based organizations. We focus particularly on the ‘Common Idea,’ a new emergent network of local community-based and nonprofit organizations in San Juan, Puerto Rico. Data is collected through online and face-to-face surveys of participating and non-participating organizations, and through semi-structured, key informant interviews of nonprofit representatives. We conclude on the impact of participation and non-participation on individual operations of these organizations, their knowledge seeking behavior, ability to resolve disputes, undertake negotiations, build trust, create new collaborations and access resources in the post-disaster context.

THE LOCAL PARADOX - COMMUNITY RECOVERY AND MUNICIPAL ADAPTATION IN STATE POLITICS FOR STRATEGIC RETREAT

Abstract ID: 210

Group Submission: Rebuilding Resilient Communities After A Disaster Strikes: On Housing, Community Development, and Inter-organizational Networking

ENRIQUEZ, Jared [Cornell University] jre92@cornell.edu, presenting author

Large-scale residential relocation will become increasingly necessary to adapt to the complex challenges of flooding and climate change (Adger et. al 2018). Evolving environmental philosophies are calling for policymakers to govern climate risks through climate adaptation approaches (Mazmanian et. al, 2013), but political acts of avoidance (Koslov, 2019) and preemption have prevented climate adaptation practices from receiving primacy in federal climate mitigation policies. In response, local governments must increasingly exercise greater autonomy to converge climate resilience and adaptation goals with other

policy agendas. Local innovations, however, greatly challenge communities with limited institutional resources. This paper evaluates multiple cases of buyout sites in the State of New York to examine how rural and limited-capacity governments can stimulate adaptation efforts and flood risk reduction without policy integration. Through its coordination-driven policy design and financial and technical support, the NY Rising Community Reconstruction (NYRCR) Program facilitated the multi-scalar recovery planning process for local governments facing capacity and resource constraints. Drawing from field work completed for my dissertation, including interviews with planners, spatial data, and a review of policy documents, I found that hazard mitigation and fiscal divestment continue to drive municipal decisions for retreat. Since federal eligibility criteria both incentivizes and discourages participation for households in neighborhoods undergoing processes of marginalization, both pre-event planning and inter-municipal networking were critical factors in local abilities to administer buyouts. I conclude with recommendations on ways that state policies can preserve local autonomy while formalizing more roles and structures for regional-scaled, intergovernmental coordination.

FROM URBAN-RURAL DUALISM TO STRUCTURAL INTEGRATION: STRATEGIES FOR THE RESILIENT AND SUSTAINABLE DEVELOPMENT OF BOTH URBAN AND RURAL COMMUNITIES IN CHINA

ID: 16

Pre-Organized Session Summary

Includes abstracts: 230, 231, 232, 745

China's dualistic urban-rural structure results from policies focused on urban development whereby urbanization and industrialization are given precedence over traditional agriculture and rural culture. The results are abandoned villages, overcrowd cities, loss of prime farm land, and the degradation of air, land and water resources. While urbanization has increased incomes for some, the quality of life in both urban and rural areas has been degraded for many. This dualistic pattern is neither sustainable nor resilient for either type of community, and there is a need to identify approaches that balance urban rural development. This is especially needed as cities and rural villages prepare for climate change with its uncertainty and extreme weather. If cities are to become sustainable and resilient, they must be supported by sustainable and resilient rural areas, and visa-versa. This session will begin with a presentation that defines and documents the patterns and outcomes of dualistic development in China, followed by presentations of case studies of successful integrated urban-rural development, two in Beijing, one in Jilin Province and one in the US.

Objectives:

- Attendees will better understand the origins and impacts of China's dualistic urban-rural structure.
- Attendees will learn about case studies of successful integrated urban-rural development on the fringe of large urban areas.
- Attendees will learn about a case study of successful integrated urban-rural development in rural Jilin province.

REUSE THE ABANDONED RAILWAY LEAD COMMUNITY REGENERATION-CASE OF ZHANGJIAKOU THE WINTER OLYMPIC CITY

Abstract ID: 230

Group Submission: From urban-rural dualism to structural integration: Strategies for the resilient and sustainable development of both urban and rural communities in China

ZHANG, Chun [Beijing Jiaotong University] zici0723@126.com, presenting author

LIN, Chunxiang [Beijing Jiaotong University] lcxiang0224@163.com, co-author

Abandoned railway is another side of coin under the rapid development of high speed rail in middle and small cities in China. The changes are not only limited on transportation mode and speed, but also promote urban space transition and sustainable regeneration. Speed changes bring spatial responding, and also bring a serious of urban economic and social problems. By case study of Zhangjiakou, the winter Olympic city in 2022, this paper demonstrates how to reuse the abandoned railway to promote community regeneration. This paper focuses on reuse of the old railway as urban metro system, and its impact on spatial changes of the nearby urban space. It includes experiences and practices from both international countries and China. It tries to approach from the transportation changes to urban space and daily life of residents, especially how they revitalize the old factory community near the railway. It brings new opportunities and new driven forces on urban growth, by providing new ways of daily commuting and adopt suitable planning tools. This paper shed light on how to promote sustainable transition of old factory community near the abandoned railway.

URBAN REGENERATION IN COLD REGION: LEARNING FROM THE ANCIENT ORIENTAL SOCIO-ECOLOGICAL WISDOM OF A TRADITIONAL VILLAGE IN NORTHEAST CHINA

Abstract ID: 231

Group Submission: From urban-rural dualism to structural integration: Strategies for the resilient and sustainable development of both urban and rural communities in China

ZHAO, Hongyu [Jilin Jianzhu University] marthewzhao@126.com, presenting author

WANG, Xinhao [University of Cincinnati] wangxo@ucmail.uc.edu, primary author

Many villages in China, which still function well after hundreds of years, are the living carrier of ancient oriental socio-ecological wisdom. Traditional villages in the cold region in northeast China face multiple threats such as drought, floods, snow and various other types of extreme weather disasters. While some ancient cities and towns with plenty slaves and workers could carry out large-scale engineering projects and challenge mother nature, the small ancient traditional villages have developed a unique water management knowledge system to deal with the multi-disasters by applying principles such as ‘fully respect nature’ and ‘let nature work’. Comparing the principles and solutions for water management between ancient traditional villages and the modern sponge cities, we can easily notice that, ancient traditional villages developed features such as low technology, low cost, low impact, low maintenance, adaptable, and multi-functional, which are precisely the goals of contemporary urban regeneration. This paper uses Jinjiang Muwu (chalet) village as an example to illustrate the lessons and experiences new urban regeneration can learn from ancient traditional villages. The settlement layout of Jinjiang Muwu (chalet) village fully combines the landscape resources to form a unique human settlement environment where the humanities and nature of the cold region blend together, a reflection of the unique ecological wisdom. We build the traditional village’s 3D morphology by drone photography with multispectral imaging technologies and analyze multi-attribute data to demonstrate the socio-ecological wisdom of ‘let nature work’ at the macro, meso and micro scales. We analyze the external settlement selection, internal space environment, unique woodcut shingle construction rules and the folk culture of Jinjiang Muwu (chalet) village to reveal the unique and ingenious ecological wisdom in coping with the cold climate. We find that maintaining convenient access to resources is the primary objective for village site selection, the principle of avoiding threats and making the best use of everything is the basic guarantee for the village’s continuous development, and the regional culture is the fundamental reason for the formation of its environmental characteristics. Those lessons can serve well as the inspiration for urban regeneration in the cold region.

URBAN VILLAGE: A NEW SOCIO-ECOLOGICAL HUMAN SETTLEMENT LIFESTYLE BUILT UPON TRADITIONAL WISDOM AND TECHNOLOGY

Abstract ID: 232

Group Submission: From urban-rural dualism to structural integration: Strategies for the resilient and sustainable development of both urban and rural communities in China

CHEN, Yongquan [Beijing Jiaotong University] yongqucn@ucmail.uc.edu, presenting author
WANG, Xinhao [University of Cincinnati] wangxo@ucmail.uc.edu, co-author

Abstract: China is in an accelerated phase of urbanization. Cities attract a large number of rural laborers so that many farmers no longer rely on agriculture to obtain the basis for survival, life, and self-development. Differences in lifestyles and job opportunities are making more young people prefer to staying in cities. With this change, new social problems occur from hollow villages and villages with only left-behind children and elderlies, etc. The disappearance of rural areas seems to be an inevitable trend. To address this problem, the Chinese government has proposed to revitalize the countryside and to carry out new village construction for improving the quality of life and living standards of rural residents. The situations in rural areas vary widely and it is impossible to solve the problem through unified strategies. Then, in the context of urbanization and the promotion of new village construction policies, what should the future of the countryside be like? Should rural villages be developed similar to existing city communities?

This paper jumps out of the dualistic research model of urban and rural areas and returns to the perspective of human settlements. We propose a new concept of urban village which learns from the traditional villages' ecological wisdom of living with the nature and the attractive contemporary lifestyle in cities, and at the same time, addresses different issues and challenges faced by current rural and urban communities. A new urban village will develop infrastructure with advanced technology that supports a new lifestyle that fulfills human needs with minimizes human impacts on the environment. We will use an innovative sewer system as an example to illustrate the new urban village concept.

SOCIO-ECOLOGICAL PRACTICE IN THE CONTEXT OF URBANIZATION

Abstract ID: 745

Group Submission: From urban-rural dualism to structural integration: Strategies for the resilient and sustainable development of both urban and rural communities in China

WANG, Xinhao [University of Cincinnati] xinhao.wang@uc.edu, presenting author

XIANG, Wei-Ning [University of North Carolina at Charlotte] wxiang@uncc.edu, co-author

The presentation starts with a description and explanation of the importance of socio-ecological practice. Socio-ecological practice is the human action and social process that take place in specific socio-ecological context to bring about a secure, harmonious, and sustainable socio-ecological condition serving human beings' need for survival, development, and flourishing. It is the most fundamental and arguably

primordial social practice Homo sapiens has been involuntarily engaging in over thousands of years of co-evolution with nature. Socio-ecological practice, which includes six distinct yet intertwining classes—planning, design, construction, restoration, conservation, and management (Xiang 2019). The process of urbanization brings urban and rural areas closer in one socio-ecological system. Activities happening in cities and villages will affect other parts of the system, which may in turn affect the cities and villages. The current urbanization is not sustainable because of the increased use of automobiles and energy, air and water pollutions, and loss of farm land (Daniels 2001). To build sustainable and resilient human settlements calls for innovations (Wong et al. 2018) and socio-ecological practices that follows the precautionary principle to pursue benefits and avoid problems (Wang 2019). This presentation sets the stage for other presentations in this session that demonstrate socio-ecological practice from cases in China and USA. Chen’s presentation uses an innovative sewer system as an example to develop a new type of urban communities that follows traditional wisdom and takes advantages of the latest technology. Zhao’s presentation calls for a socio-ecological practice to coordinate urban and rural development. Instead of demolishing rural villages or converting them to ones similar to existing urban communities, we should learn to retain the socio-ecological wisdom exhibited in rural villages when we plan, design, construct, restore, conserve, and manage rural and urban communities. Zhang’s presentation demonstrates how to reuse the abandoned railway to promote community regeneration. Auffrey’s presentation assesses two areas that initially developed as rural villages and were transformed into the American version of “urban villages”.

PRE-ORGANIZED SESSION - ENGAGEMENT PRACTICES FOR REGENERATIVE DEVELOPMENT: BUILDING COLLECTIVE POWER FOR CLIMATE JUSTICE AND RESILIENCE

ID: 22

Pre-Organized Session Summary

Includes abstracts: 274, 275, 276, 277, 876

What methods and practices of community engagement help practitioners plan in an era of climate volatility for climate justice and resilience? How can the planning profession shift its paradigm to better disrupt inequitable systems and create structures to enable equitable, thriving communities? Much has been written about methods available to participatory planners and many authors have documented community engagement processes and measured outcomes. Yet, despite the importance of self-awareness and ecological awareness in supporting personal, social, and ecological resilience, such awareness-based practices are rarely discussed or documented. This session presents practitioner stories, case studies, and historical/theoretical perspectives on the intra-personal, interpersonal, and place-based practices of

engagement that are necessary to support regenerative community development that advances climate justice and resilience.

Objectives:

- Explore how the inner practices of community change agents under differing circumstances across the world have helped them attune to, flow with, and foster the emergent potential of communities in which they are engaged.
- Explore methods of community engagement that practitioners can critically and creatively employ to build the knowledge and power needed to advance climate justice and resilience.
- Explore place-based, ecologically-grounded, radically-rooted methods of participatory design and development that can unleash the power of individuals, communities, and ecosystems to heal and create the world anew.

THE HEART OF COMMUNITY ENGAGEMENT: REGENERATIVE PATTERNS FOR PRACTICE

Abstract ID: 274

Group Submission: Engagement practices for regenerative development: Building collective power for climate justice and resilience

WILSON, Patricia [University of Texas at Austin] patriciawilson@utexas.edu, presenting author

The author addresses a blind spot in community engagement practice that is identified in the principles of regenerative change: the practitioner's awareness of self and system.

To elucidate this awareness-based practice of regenerative change, the author draws upon reflective practitioner stories from across the globe. In each of the stories the community engagement practitioner is facing issues of economic, social, or environmental justice: rural communities in post-civil war El Salvador, an immigrant colonia on the Texas-Mexico border, embattled peasant farmers in Colombia's Cauca Valley, the Khayelitsha township of shack dwellers in post-apartheid South Africa, a cluster of poor farming villages in Uttar Pradesh, India, and informal settlements in an imperiled watershed on the outskirts of metropolitan Mexico City. The stories chronicle the path from self-awareness to "ensemble awareness"--a sense of the living social field and its emergent regenerative edge.

The 10 patterns of regenerative practice that the author identifies deepen the understanding of triple-loop learning for action research and contribute to the historic shift toward a quantum view of interconnectedness and dynamic complexity.

LEARNING FROM ARNSTEIN, MEADOWS, LORDE AND BOGGS: BUILDING A SPECTRUM OF COLLECTIVE POWER FOR CLIMATE JUSTICE AND RESILIENCE

Abstract ID: 275

Group Submission: Engagement practices for regenerative development: Building collective power for climate justice and resilience

WALSH, Elizabeth [University of Colorado - Denver, College of Architecture and Planning]
elizabeth.walsh@ucdenver.edu, presenting author

In the 50 years since the publication of Sherry Arnstein's "Ladder of Participation," what have we learned about community engagement that can help us plan in an era of climate volatility for climate justice and resilience? How can the planning profession shift its paradigm to better disrupt inequitable systems and create structures to enable equitable, thriving communities? This paper reviews lessons for practice from four female scholars (Sherry Arnstein, Donella Meadows, Audre Lorde, and Grace Lee Boggs) whose work responded to the social and ecological crises of the late 1960s (and all published significant works in the five years between 1969 and 1974). Although these four thought leaders did not appear to have been in dialogue with one another at the time, their work (1) named different aspects of the complex, interrelated social and ecological crises that contribute to climate injustice today, and (2) called on planners and community members to disrupt the systemic structures that threatened life on earth and to create new structures that redress the harm of past inequities. Drawing on their combined legacies, we propose a "Spectrum of Collective Power" that can be used to complement Arnstein's "Ladder of Citizen Participation." We posit that the Ladder will continue to help planners name, expose, and oppose the noir side of citizen participation, including abuses of power and entrenchment of status quo. Used in tandem, we imagine the Spectrum of Collective Power will support planners in facilitating processes that build collective capacity to advance climate justice and resilience. In describing this proposed Spectrum, we identify eight forms of collective power categorized into three sub-spectrums: the spectrum of grounding (including the powers to heal and disrupt), the spectrum of learning (including the powers to sense, appreciate, and integrate), and the spectrum of action (including the powers to redistribute, co-create, and regenerate). For each sub-spectrum, we point to contemporary planning engagement methods/practices that have been used to cultivate corresponding collective powers to advance climate justice and resilience. In identifying these methods of engagement, we draw significantly from literature in environmental justice, regenerative design and development, public interest design, asset-based community development, appreciative inquiry, critical participatory action research, community-based participatory research, feminist epistemology, and black feminist theory. We also draw from lessons from thought leaders engaged in contemporary social movements including the Movement for Black Lives and climate justice movement. These methods support an approach to praxis that is radically rooted and regenerative. Using Arnstein's "Ladder" and the Spectrum of Collective Power, practitioners can critically and creatively engage communities to disrupt structures of oppression and co-create structures that support resilient communities for all in an era of climate volatility.

BUILDING LOCAL LEADERSHIP CAPACITY FOR CLIMATE RESILIENCE IN BUFFALO-NIAGARA

Abstract ID: 276

Group Submission: Engagement practices for regenerative development: Building collective power for climate justice and resilience

WHITE, Julia [University at Buffalo - SUNY] jwhite25@buffalo.edu, presenting author

This paper documents leadership practices via the Citizen Planning School Champions for Change program curriculum as well as methods in action (Walsh et al, 2017). It offers insight on the following key points of inquiry: 1. Confronted by the challenges of climate volatility, how can planners support regional community leaders in expanding collective capacity to advance social and ecological well-being and climate justice?; 2. How can leadership efforts be both place-based and historically based, both honoring and learning from local heritage in ways that support regional regenerative development?; and 3. How can universities, as anchor institutions, best support civic infrastructure and facilitate the work of leaders who can implement regional action towards climate justice, both within the university and in the broader community?

The paper specifically explores the University at Buffalo's Champion for Change course, a program based off of other citizen planning academies in the country (Mandarano, 2015), that partners students with community leaders seeking to make change in their communities. Leadership practices employed by the program are analogous to practices of planning and design innovation in other places, yet this program grounds them in local heritage in ways that honor the diversity and depth of experience and wisdom of those in our region, specifically the Haudenosaunee or Six Nations of the Iroquois. The Haudenosaunee participatory practices and Great Law of Peace, which centers community and harmony, have in many ways laid the groundwork for our present-day democracy (Lyons & Mohawk, 1998).

At the heart of the curriculum are the four practices of regenerative development as practiced and learned from the Haudenosaunee: Thanksgiving Practice, Law of Regeneration, 7th Generation Principle, and Great Law of Peace. As these practices are built into many aspects of the coursework, the research will assess the effectiveness of centering these principles and practices within a group setting and developing a deeper analysis and dialogue around whether the curriculum can be replicated elsewhere.

The research will offer insight into how universities, as anchor institutions, can best support civic infrastructure and the development of leaders who can positively impact regional actions towards a more just and flourishing future, both within the university and the broader community. While it is expected that the results will highlight the importance of civic infrastructure, it is also expected that the process will provide insight into the real challenges that can make civic infrastructure so difficult to implement.

The research methods involve process-based assessment, participatory action research, and developmental evaluation. The program curriculum has a built-in assessment via an assortment of activities that examine student-community leaders' progress towards the completion of their project plans. Preliminary findings suggest the complexity of university/community partnerships, requiring trust as a core ingredient. Students and residents are half way through the program, and the most productive project plans are those student-resident partnerships that meet weekly to not only move their projects forward, but to develop their relationship with one another.

This work is relevant to the planning field, as it explores how planners can extend themselves beyond the confines of traditional planning techniques to be leaders in fostering authentic relationships and strong communities. Urban planning as a field tends to frame itself as a technocratic discipline in which neutral, objective planners apply techniques to help elected leaders achieve outcomes they believe to be in the public interest. Planning education rarely trains planners to be leaders, yet leadership by people trained to understand complex systems is essential in an age of climate change. This research explores the possibilities of actively supporting the collective power necessary ensure communities are resilient, just and equitable.

CONSTRUCTION DOCUMENTS FOR EMERGENCY HEARTS: DEMOCRATIC DESIGN PROCESS AS A TOOL FOR CLIMATE RESILIENCE

Abstract ID: 277

Group Submission: Engagement practices for regenerative development: Building collective power for climate justice and resilience

SLABAUGH, Danielle [California State Polytechnic University - Pomona] yard2table@gmail.com, presenting author

In *A Paradise Built in Hell: The Extraordinary Communities That Arise in Disaster*, Rebecca Solnit describes the phenomenon she calls “Emergency Heart”, the almost universal inter-community support that individuals extend to each other in times of catastrophe (2010). Social science research confirms that strong social capital correlates highly with community scale and individual resilience. Indicators such as

strength of social networks, local ecological knowledge and degree of place attachment have been tied directly to adaptation capacity related to natural disasters such as avalanches (Hovelsrud, Karlsson, & Olsen, 2018) and wildfires (Prior & Eriksen, 2013).

While assertions have been made regarding the value of participatory processes and their capacity to improve social inequalities (Arnstein, 1969), and increase place attachment (Melcher, 2013). Little or no research has been done to quantify and qualify the impacts of democratic design of neighborhood places on indicators of social capital, and thus climate resilience. Through a case study of one such democratic design process in a low-income, Latinx community in South East Los Angeles led by a parks and open space non-profit, this study will investigate how and to what extent design processes at the top of Arnstein's Ladder may influence social networks, place attachment, and local knowledge in marginalized communities. Semi-structured interviews will provide insight into the impacts of deep community engagement in the design process from the perspectives of residents, landscape architects, and community organizers.

Planning and designing cities for climate resilience presents major challenges, the least of which is the simple fact that future patterns of extreme weather are unknown. The implications of this research for climate resilience and adaptation efforts underline the critical function of process, not just product. By engaging in bottom-up planning and design processes professionals may be able to support the critical social infrastructure of climate resilience, an infrastructure that is far more adaptable to what is still unknown about climate futures than physical form. Preliminary results will be presented at the 2019 ACSP conference.

RECIPROCITY, REFLECTION, REGENERATION: LESSONS ON LEADERSHIP FOR RESILIENCE FROM THE HIGH ANDEAN RUNA COMMUNITIES OF PARQUE DE LA PAPA.

Abstract ID: 876

Group Submission: Engagement practices for regenerative development: Building collective power for climate justice and resilience

BUSH, Alan [University of South Florida] resonance.resilience@gmail.com, presenting author

This research employs a new leadership framework in ethnographic analysis with the intention of drawing practical lessons about resilient leadership. In specific, field research used Complexity Leadership Theory

(CLT) to assess resilient leadership practices in Parque de la Papa, a set of Runa communities in high Andean Peru.

We have conceptualized, organized & practiced leadership in particular ways in the global North/West. Leadership comes from individuals: leaders. Authority is granted by structure, often hierarchy. Social patterns of selection into positions of authority introduces systematic bias. Individual-led hierarchical leadership is fragile in conditions of increased uncertainty & complexity (Boisot et al 2008).

This is relevant now, as the background conditions to civilization are changing. Research in socio-ecological systems anticipates the next 75 years will not be as stable as the past 75 (IPCC 2018). This is driven by the twin ecological & energy crises; if we address our ecological crisis, we drive a disruptive energy transition. If we fail to engage with the energy transition, it will drive a cataclysmic ecological crisis. Both will drive increased uncertainty for human communities generally, requiring greater adaptability. As a result the leadership that has been effective (or at least passable) in the past may encounter the edges of its operational effectiveness.

All of this has set up a quest for new ways to conceptualize leadership. Complexity leadership theory (CLT) is an approach to conceptualizing leadership as distributed phenomena that emerge from relationships rather than people (Hazy & Uhl-Bien 2015). Previous work has employed CLT to assess the degree to which leadership practices accounted for resilience in urban systems (Bush 2016). Cases that exhibit "positive deviance" can be rich places for learning and theorizing in complex systems (Anderson 2005). An ethnographic analysis of positively deviant cases in other cultures may be useful in identifying practices for resilient leadership.

The high Andean communities of the Runa people may hold lessons for us. The inheritors of the cultural legacy of the Inca, these communities have navigated successive waves of uncertainty, as brought by Spanish colonization, the Peruvian civil war, and globalization. Throughout these they have maintained a degree of autonomy and self-determination, as well as sustainable relationship with their supporting ecosystems.

Through thick description, we illustrate three of the cultural elements that lead to resilient leadership in Parque de la Papa. First is the principle of reciprocity. Second are the specific practices of multi-scalar reflection. Third is the approach or mindset of regeneration. Taken collectively, the three contribute to an emergent leadership consciousness they have developed an approach leadership that has led to resilient communities over long timescales. We close with some thoughts about how to adapt the practices and lessons from these communities into an American planning context.

FROM PRESENCE TO MAKING IT THEIR OWN: STRATEGIES OF YOUTH AND OLDER ADULT PLACE-MAKING IN LOS ANGELES AND BEIJING

ID: 30

Pre-Organized Session Summary

Includes abstracts: 377, 378, 379

In this session, practicing and academic planners from Los Angeles will present research on how youth and older people, groups that are sometimes considered “socially vulnerable” empower themselves with the resources available to them by reimagining spaces in cities and communities to fit their needs. Papers from this session will examine: how youth from disinvested communities, homeless youth, and older adults with limited social support devised ways to find belonging through their work, social circles, and beloved pastimes. The ability to persevere, survive and thrive is the overarching theme of this session. Identifying how youth and older adults reuse and reinvent public spaces that were not planned with them in mind can help planners to further support the active use of those spaces, and to design more inclusive and equitable policies in a city for all ages.

Objectives:

- To discuss how homeless youth find community in Los Angeles.
- To discuss how older adults maintain social ties and health through urban dance in Beijing.
- To discuss how youth from disinvested communities assert their ownership of place by working with researchers to conduct community needs assessments in Watts.

DESIGNING THE DANCEABLE CITY: HOW RESIDENTS IN BEIJING CULTIVATE HEALTH AND COMMUNITY TIES THROUGH URBAN DANCE

Abstract ID: 377

Group Submission: From Presence to Making It Their Own: Strategies of Youth and Older Adult Place-Making in Los Angeles and Beijing

CHEN, Caroline [Independent Researcher] carolinechen06@berkeley.edu, presenting author

Kevin Lynch envisions the city as a place that supports health, survival, social contact, and vitality. Urban dance is how many residents who live in Beijing, China achieve these goals. A popular activity for an estimated 100 million older residents who live in China, urban dance happens primarily in parks and leftover spaces in the city transportation infrastructure. Dance groups often face challenges finding appropriate places for dancing and are forced to move multiple times because of conflicting demands for open space.

In this study, I ask four research questions: (1) Why are people dancing in Beijing? (2) Where does urban dance happen? (3) Why does dance happen in some places but not in others? And (4) Why may urban dance be relevant to American planning? I used open-ended interviews and two surveys to evaluate these issues, finding that urban dancers are mostly older women who dance to keep healthy, to feel happy, and to cultivate a sense of community. Urban dance in Beijing happens primarily in parks and spaces in the transportation infrastructure, although dancers prefer parks because of the clean air and natural environment.

Dancing space is a coveted resource in a city of 21 million residents, however, and dance groups are often forced to move multiple times because of competition with other groups for the right to use limited space. They often move to spaces in transportation infrastructure such as freeway underpasses and parking lots, where it is noisy and polluted. Complaints from neighbors who are disturbed by dance music and conflicting demands for open space have led the central and municipal governments in China to attempt to ban or restrict urban dance. Urban dance continues to persist, however, bringing health, community, and vitality to Beijing's open spaces. This case study offers an attractive, alternative vision to American planners and urban designers who work in a context where space is relatively plentiful, but dancing in public is not the social norm: can we make it happen here?

A PLACE TO BELONG: WHERE HOMELESS YOUTH FIND COMMUNITY IN LOS ANGELES

Abstract ID: 378

Group Submission: From Presence to Making It Their Own: Strategies of Youth and Older Adult Place-Making in Los Angeles and Beijing

ORNELAS JR, Norman [Independent Researcher] n.ornelasjr@gmail.com, presenting author

Homeless youth are vulnerable to social and legal regulations of the built environment in spaces such as parks, streets and sidewalks. Forms of surveillance, scrutiny and suspicion within public spaces impact their lives, due to lack of access to private space, making them a frequent target for policing. Understanding these impacts and identifying strategies employed by youth may lead to solutions for more effective policy and programs.

Much research has been conducted on homeless populations, mostly through survey and quantitative data methods, though more qualitative insight may lead to a more nuanced understanding of the lived homeless experience. This paper will examine the spatial distribution of homeless transition age youth (ages 18-24) living in urban environments in Los Angeles through mapping. Maps will be gathered from homeless youth to explore the niches in the city where they congregate and will describe their patterns of movement as they seek opportunities for survival, through formal and informal work and social networks. In the absence of sources of security and acceptance from the traditional family and home, they find a sense of belonging and community in alternative spaces. This research uses participatory mapping methods and in-depth interviews to reveal where the places of support and sources of sustenance are found from the perspective of homeless youth in Los Angeles.

By better understanding how homeless youth negotiate their needs in the spaces available to them, this research aims to contribute to more inclusive planning policy discussions and frameworks.

CENTERING YOUTH IN NEEDS ASSESSMENTS: WHEN PARTICIPANTS BECOME COMMUNITY RESEARCHERS

Abstract ID: 379

Group Submission: From Presence to Making It Their Own: Strategies of Youth and Older Adult Place-Making in Los Angeles and Beijing

ANDERSON, Heather [Independent Researcher] hna2106@caa.columbia.edu, presenting author

This paper presents a case study of a participatory community needs assessment (the first phase of a project titled Watts Community Studio, or WCS), in which youth residents of Watts were employed through the City of Los Angeles's Summer Youth Employment Program to administer surveys, enter data, and develop a policy recommendation with guidance from adult researchers. The youth researchers achieved 800 resident surveys and 50 business surveys. Most significantly, centering youth also provided a significant foundation of qualitative data for the needs assessment.

In disinvested communities, youth often have limited options in terms of education and employment opportunities, amenities, commercial base and resources. Efforts by residents to assert control, create predictability and stability, or establish community ownership sometimes takes the form of gang boundaries. These boundaries further constrict the movement of youth through the community. In Watts, this is compounded by a history of negative media portrayal that impacts youth perception of their own community.

After identifying the disconnect between youth and the physical/built environment of Watts, several of the WCS needs assessment recommendations involved supporting the grassroots and organizational efforts to create space for youth. Additionally, the adult researchers aimed to use the assessment as a tool to re-connect youth to their physical environment, and discovered that prioritizing youth in the assessment had potential outcomes beyond the policy document.

The paper grounds the case study in the history of youth engagement, and provides an update of youth engagement since the first phase of WCS in 2013, aiming to contribute to more inclusive planning in disinvested communities. Shifting youth from participants to community researchers is a critical first step.

EXPECTATION, LOSS AND CHANGE IN URBAN HISTORIC DISTRICTS

ID: 33

Pre-Organized Session Summary

Includes abstracts: 522, 523, 524, 525

Communities living in neighborhoods with older housing stock can use historic district designation to prevent demolition, attract new investment, and establish local oversight on new development. But who is making decisions about historic district designation in communities? What kinds of communities use historic preservation as a redevelopment tool? What are the expected neighborhood outcomes associated with district designation and how do these expected outcomes influence planning and decision-making with the community? This panel brings together four emerging scholars to examine the dynamics of neighborhood change in historic districts. Their papers examine: 1) the relationship between demolition and preservation as redevelopment strategies, 2) how communities use historic district designation as a way of preventing unwanted development and mitigating gentrification, 3) the politics of historic district designation and expectation of change in gentrified neighborhoods, and 4) the relationship of same-sex households with historic districts.

Objectives:

- Better understand the dynamics of neighborhood change, particularly gentrification, in historic districts
- Understand how communities use historic districts as a tool of local control
- Understand the relationship of demolition and preservation as redevelopment strategies

THE LONG VIEW ON NEIGHBORHOOD CHANGE IN LOWER INCOME HISTORIC DISTRICTS: A COMPARATIVE CASE STUDY OF OHIO CITY, CLEVELAND AND SHAW, WASHINGTON, DC - 1970-2010

Abstract ID: 522

Group Submission: Expectation, Loss and Change in Urban Historic Districts

STANEK, David [University of Pennsylvania] dstanek@upenn.edu, presenting author

Planners, preservationists, and community development organizations have a long history of using local historic district designation as one among many tools of neighborhood revitalization. However, when neighborhood revitalization in lower-income communities designated as historic districts succeeds, the optics of well-preserved historic homes inhabited by wealthier residents suggests that historic district designation causes gentrification. This article contributes to our understanding of preservation and

planning history by examining the local politics of historic district designation and dynamics of neighborhood change between 1970 and 2010 in two gentrified neighborhoods designated as local historic districts: Ohio City in Cleveland, OH (1983) and Shaw in Washington, DC (1998). This study allows for a comparison of historic district designation and neighborhood development that resulted in similar outcomes of neighborhood change in significantly different socio-economic contexts. It contends that historic district designation should be understood as a tool of urban planning and hypothesizes that the decision about designation is based on factors internal and external to the neighborhood and that considerations of neighborhood change are central to the decision-making process.

SPATIAL PATTERNS OF DEMOLITION AND PRESERVATION IN SHRINKING AND GROWING CITIES

Abstract ID: 523

Group Submission: Expectation, Loss and Change in Urban Historic Districts

KINAHAN, Kelly [University of Louisville] kelly.kinahan@louisville.edu, presenting author
MAWHORTER, Sarah [University of Syracuse] sarah.mawhorter@gmail.com, co-author
ROHRET, Danielle [University of Louisville] danielle.rohret@louisville.edu, co-author

Demolition is a common redevelopment strategy in both shrinking and growing cities, but for different reasons. In shrinking cities, it is a response to vacancy, abandonment, and population loss (Mallach, 2011). In growing cities, the pressures of development and housing demand can trigger teardowns to rebuild at a greater density or for designs that are more modern. Preservation tools can deter demolition through financial incentives that support adaptive reuse, local policy mechanisms that protect existing buildings, or through less direct methods that highlight the social and cultural values of the built environment. Local historic district ordinances commonly preclude demolition of buildings considered contributing elements of the district through the design review process (Hamer, 1998). A National Register historic district provides honorary status for residential buildings and is a necessary first step for non-residential buildings seeking to use federal historic tax credits (Ryberg-Webster, 2015). Yet, we know very little about the relationship between the spatial patterns of demolition and historic districts. In this research, we ask - what is the relationship between historic districts and demolitions? Using local, administrative data on demolitions from 2013-2018, this exploratory analysis compares recent trends in one shrinking city (Philadelphia) and growing city (Los Angeles) through descriptive statistics and hotspot analysis. First, we examine the spatial pattern of the overall scale of building loss and the characteristics of the demolition (e.g. residential or commercial, a result of a code violation or initiated by

owner/developer). Next, we analyze the socio-economic characteristics of the types neighborhoods in which demolitions are occurring, using a national typology of neighborhoods developed by Delmelle (2017). Finally, we consider the relationship between demolition, neighborhood-level socioeconomic characteristics, and existing local and National Register historic districts boundaries to understand whether these preservation tools effectively mitigate demolition. Preliminary findings show that in shrinking cities, substantial demolition is occurring within historic district boundaries, indicating that these preservation tools are not enough to overcome the weak market context. In growing cities, the presence of local and National Register historic districts result in fewer demolitions compared to non-designated areas. We also find significant spatial clusters of demolitions just beyond the boundaries of historic districts, indicating that buildings near but not within historic districts may face a higher risk of being demolished. This research contributes to the preservation planning scholarship through its analysis of demolition patterns in relation to historic districts, an existing gap in the literature.

HISTORIC DISTRICTS AND SAME-SEX PARTNERED HOUSEHOLD

Abstract ID: 524

Group Submission: Expectation, Loss and Change in Urban Historic Districts

KINAHAN, Kelly [University of Louisville] kelly.kinahan@louisville.edu, co-author

RUTHER, Matthew [University of Louisville] matthew.ruther@louisville.edu, presenting author

The LGBT community, particularly gay men, have well-established connections to historic preservation in U.S. cities. Many celebrated queer spaces are part of designated historic districts, including Chelsea in New York City and Midtown Atlanta. The creation of queer space intersected with broader neighborhood change processes and early waves of gentrification in the 1960s and 1970s. Scholars argue that more recent waves of gentrification differ from the earlier processes in breadth and scale, including the involvement of global real estate forces and a public sector tuned to neoliberal priorities. This has triggered concerns over whether LGBT populations are now being displaced from neighborhoods that were previously tolerant queer spaces. Linkages between historic preservation initiatives and gentrification are often centered on how historic districts affect property values or socioeconomic characteristics, and the consequent displacement of existing populations. In this research, we connect these related threads by analyzing the relationship between historic district designation and change in same-sex partnered households. In particular, we evaluate whether neighborhoods with greater concentrations of same-sex households are more likely to create historic districts, and whether the presence of a historic district is associated with future growth in the number of same-sex partnered households. We use data from the 2000 Census and the 2017 American Community Survey to analyze local and National Register Historic Districts in 47 cities with a series of OLS and logistic regression models. We find significant relationships between historic district designation and same-sex populations.

An increase in the same-sex population over the study period is associated with a higher probability of a historic district being introduced during that period. Conversely, the introduction of a historic district during the study period is correlated with greater same-sex partnered population growth during that period.

NEIGHBORHOOD CHANGE AND DEFENSE OF COMMUNITY BY HISTORIC DISTRICTS

Abstract ID: 525

Group Submission: Expectation, Loss and Change in Urban Historic Districts

DUBLIN- BOC SOR, Jenna [Columbia University] jld2211@columbia.edu, presenting author

Introduction: This paper will present the survey findings of my dissertation research, which examines how and why community-based organizations utilize historic district designations to influence neighborhood change in a sample of US cities.

Recent journalism shows evidence that federal, state, and local historic district designation is a tool being utilized by lower-income, communities of color as a preventive measure against displacement-inducing development in NYC, Durham, Seattle, San Francisco, and San Diego. For example, in Seattle's Chinatown International District (CID) residents argue that the city's incentive zoning plan will lead to displacement of existing residents. Since the purpose of the CID is to protect cultural, architectural, and historic features, the existing historic district within the CID is recognized as "exempt" from the new zoning allowances. The desired outcome is for preservation restrictions to make the area disqualified for increased density.

Community-based organizations are pushing for policies that prioritize existing lower-income communities, and are looking for successful approaches. But, the reasons and outcomes of applying district designation as an anti-displacement strategy are not known. Studies examine how historic districts affect economic and racial change with mixed results. Scholars who evaluate preservation in terms of equity demonstrate its contributions to inclusive public participation suggesting an alliance with communicative planning. But, the re-adaptation of historic district policy here suggests a stronger connection to post-structuralist social movement theory that demands reform and action.

Methodology: The purpose of the survey is to collect information from historic preservation professionals in a sample of large US cities to elicit their knowledge of organizations that have either successfully or unsuccessfully achieved historic district designation for insular motivations not directly related to special architectural features and historical significance. The survey data will be presented and I will examine the

socioeconomic, political and cultural conditions that influence groups' use of designation as an anti-displacement strategy. The survey will also allow me to select organizations for case study. Historic designation may act as one of the few publicly accessible regulatory tools and an approachable entry into city politics.

Findings: The reasons to apply historic district designation as an anti-displacement strategy aren't immediately apparent, but the phenomenon suggests that community-based organizations are taking on an activist role by participating in decision-making not only in the streets and existing public-input forums of policy makers and urban planners, but by engagement through application of regulatory tools to their particular spaces, built environment, and affective connections, like heritage.

Relevance: There is no existing study that examines the range of insular motivations and contexts that inspire groups to apply for district designation and the literature would benefit from empirical examples that demonstrate how historic preservation contributes to equity and inclusion, particularly when compared with neighborhoods without preservation activity. Additionally, while urban planning literature theorizes the decision-making of planners, there are fewer studies that theorize the work of community-based groups that act as planning actors and sit between protest and participation with bureaucratic and legislative bodies to reform municipal policy.

LEARNING IN PLANNING: DESIGNING TOOLS FOR PLANNERS AS A WINDOW ON LEARNING

ID: 37

Pre-Organized Session Summary

Includes abstracts: 675, 676, 677

This session offers a close look at four programs of research at the nexus of planning and the Learning Sciences, examining the role of technological tools in planning processes in which community development, agency and empowerment are at stake. Learning scientists have a long history of using design-based research methods to create, test, and refine tools for use in real-world settings that promote learning, and to study the learning that results (e.g., Brown & Campione, 1994; Edelson, Gordin & Pea, 1999; Wilensky & Rand, 2015). The growing body of Learning Sciences work being conducted in urban and community planning contexts (e.g., Gutierrez & Jurow, 2016; Melendez & Parker, 2018) suggests a

valuable cross-pollination of concepts and methods that can expand our understanding of how people learn with tools, and the kinds of social learning processes that emerge in community development work.

Objectives:

- To learn about four programs of research at the nexus of planning and the Learning Sciences.
- To examine the role of technological tools in planning processes in which community development, agency and empowerment are at stake.
- To translate concepts, theories, and methods across disciplines.

COMPUTER SUPPORTED COLLABORATIVE PLANNING: USING VISUALIZATION TOOLS TO ENHANCE SOCIAL LEARNING AND DEMOCRATIC DELIBERATION

Abstract ID: 675

Group Submission: Learning in Planning: Designing tools for planners as a window on learning

MILZ, Daniel [University of Minnesota] dmilz@hawaii.edu, presenting author
ZELLNER, Moira [University of Illinois at Chicago] mzellner@uic.edu, co-author

How do computer technologies support social learning and enhance democratic deliberations? Research on planning support systems has been tackling this question for decades (Goodspeed, Pelzer, and Pettit, 2017), and this paper brings together two active threads in this literature to demonstrate how tools support both learning and planning outcomes. The first focuses on how participatory planning workshops promote, but also depend upon, learning among stakeholders and participants (Meléndez and Parker, 2019). The second examines how tools support group judgments and deliberation in participatory contexts (Milz, 2019). Over the last decade, our research has made technological, methodological, theoretical, and practical contributions to these parallel conversations. In this paper, we draw on empirical cases to demonstrate these contributions and to chart a path forward for research on computer-supported collaborative planning (Zellner, et al. 2012; Radinsky, et al. 2017).

Working across disciplines, we have built a simple, game-like tool to support community-level planning for flood hazard mitigation. The tool combines (1) an analog planning map, which participants use to create a green infrastructure plan for their neighborhood, (2) a process-based model of flooding, which reads the analog map and uses it to simulate a storm event, and (3) individual tablet interfaces, which participants use to report their preferences and concerns. We have also designed an approach to participatory planning workshops that embraces, not just ecological complexity, but social and political complexity, as well. By providing stakeholders with an opportunity to report and rank their concerns, our tool and process help stakeholders interpret data within planning meetings, identify opportunities for creative compromise, and to collectively generate innovative, contextually relevant responses to flooding.

We use methods adapted from the learning sciences to track the interactions between participants and facilitators throughout planning meetings. Our methods allow us to identify and dissect group judgments about flooding and green infrastructure placement to show how the groups use the tool to make plans. Moreover, by linking our study of group learning to the plans groups produce for each new simulation trial, we can track how their judgments evolve within a single workshop and across an entire planning process. Findings demonstrate how our tool and process consistently lead to better, more durable compromises and plans that are more likely to improve local environmental conditions.

CREATING OPPORTUNITIES FOR SOCIAL LEARNING USING ONLINE GAMES

Abstract ID: 676

Group Submission: Learning in Planning: Designing tools for planners as a window on learning

CAMILLE, Barchers [Georgia Institute of Technology] cbarchers3@gatech.edu, presenting author

As planners we work in small, interdisciplinary groups, to complete the tasks most commonly associated with our field: preparation of plans, community meetings, negotiation, goal formation, and review of documents (Shalinsky & Norris, 1981). We also frequently ask citizens to engage with small groups through focus groups and advisory boards. The popular and regional scale goal setting approach espoused by the Urban Land Institute, Reality Check, brings hundreds of invited stakeholders together and asks them to play a board game in small groups of 5-7 ("Reality Check - Urban Land Institute," n.d.). This game has been developed to educate stakeholders on the tradeoffs inherent in regional development challenges, and although each table of participants has a facilitator to manage game play, there are no rules for how participants should interact. In other examples, we ask citizens to develop ideas in groups, review models in groups, and develop visioning maps in groups (Desouza & Bhagwatwar, 2014; Frewer & Rowe, 2005; Kleinhans et al., 2015a; Zellner et al., 2012).

While many of these face-to-face games and planning activities are still being conducted, many more planning agencies are creating games and activities for synchronous and asynchronous play, online. When these planning activities are evaluated, we frequently attempt to select the best planning outcomes (most creative proposals, implementable strategies, etc). We have used learning science in a very limited capacity to understand the ability of the exercise to inform participants and create opportunities for social learning. Previous work on social learning has evaluated the extent to which face-to-face planning support systems (PSS) can create opportunities for learning (Goodspeed, 2015). In this work, we tested the ability of the role-playing game, @Stake, to improve the deliberative nature (collective intelligence) of unfacilitated planning discussion amongst small groups of students and measure the dimensions of social learning that occurred during an online game playing session. This research reveals the extent to which games can create opportunities for social learning and how learning science can inform the development and validation of post- activity surveys in community planning. Using learning science to understand

social-learning within a community planning activity can also help suggest new strategies for enhancing social capital in a planning process.

DATA VISUALIZATION TOOLS AND NARRATIVES: LEARNING AS A PROCESS OF ANIMATING DATA

Abstract ID: 677

Group Submission: Learning in Planning: Designing tools for planners as a window on learning

RADINSKY, Josh [University of Illinois at Chicago] joshuar@uic.edu, presenting author

Planners – whether professional urban planners or community groups organizing for change – are impacted by the constant churn of technological innovation in tools for data access, modeling and visualization. For example, geographic information system (GIS) tools are a mainstay of planning professionals, but there is often a technology gap between the GIS experts generating and interacting with these systems and other members of planning groups and communities (Zellner & Campbell, 2015). Some data access and visualization tools have the potential to democratize access to complex data archives like U.S. census data (National Research Council [NRC], 2006), enabling relatively unskilled users to find, download, and manipulate data in unprecedented ways – but even these supposedly easy-to-use tools can present challenging learning problems (Radinsky, Hospelhorn, Melendez, Riel & Washington, 2014) and a technical expertise gap.

The rapid evolution of these tools, and its impact on the work of planners, suggests many important research questions about learning (NRC, 2006; Radinsky, Milz, Zellner, Pudlock, Witek, Hoch & Lyons, 2017). Tools mediate our perception, communication, conceptual understandings and decision-making – all aspects of learning that are involved in planning processes. What kinds of learning occur as planners, students, or community members adjust to the changing affordances and requirements of these tools?

In this talk I will look at this issue through the lens of narrative analysis (Connelly & Clandinin, 2006; Wortham & Reyes, 2015) – specifically, the ways planning problems, situations, and solutions are narrated with the mediating use of data visualization tools. Narrative analysis enables us to go beyond thinking about the use of visualization tools in terms of learning discrete skills, and to look more holistically at the interactive nature of how professionals learn new tools (Tsatsou, 2018).

The analysis focuses on three cases of collective narration of planning problems with data visualization tools, in three different contexts:

1. Data-mediated narratives about planning problems and situations in a public health classroom, where students are being introduced to a census data mapping tool
2. Data-mediated narratives in a workshop of water resource planners and engineers using a variety of GIS mapping tools to discuss current socio-ecological problems in the region
3. Data-mediated narratives in a public policy dispute between a public school district and several advocacy organizations mobilizing against district changes, each using mapped data to support and refute claims.

In each case, the visual data and the visualization tools are deployed in narratives that construct purposes for using data, roles for the people who use them, and representations of real-world planning situations in which those people accomplish (specified or implicit) purposes with the data. Beyond illustrating particular skills, the learning implied in these narratives includes developing a particular sense of belonging in certain communities; emotional attachments to experiences; and developing relationships with tools and data – elements of a more complex conception of disciplinary learning with tools (Tsatsou, 2018). The results suggest ways we might frame learning objectives and design professional development workshops for planners, to better engage the ways people narrate planning problems, and to better facilitate discussions in which data-based claims are made and disputed.

LEARNING IN PLANNING: COMMUNITY BASED PARTNERSHIPS AS SITES OF LEARNING

ID: 38

Pre-Organized Session Summary

Includes abstracts: 696, 697, 698

In this session, three programs of research at the nexus of urban/community planning and learning sciences will be presented. This is a response to the growing interest in building a bridge between planning research and work in the field of learning sciences, which has robust theoretical and methodological tools for studying learning (e. g. MelÃ©ndez & Parker 2018; Radinsky, et al., 2016). In particular, sociocultural learning theories from the learning sciences can help researchers align behavioral changes with cognitive learning, a challenge identified frequently in the social learning planning literature

(Muro & Jeffrey, 2008). The focus on social learning moves away from more traditional research methods, where planning scholars often assess learning with pre- and post-measures of conceptual understandings, positions, interests, or beliefs (Deyle & Schively Slotterback, 2009). Such methods are valuable for documenting individual, cognitive change, but overlook social processes (Radinsky, et al., 2016). This shift highlights the need for more conceptual tools that support planners' theorizing of how learning happens in community settings.

Objectives:

- To investigate the various ways that learning manifests in community planning contexts.
- To share conceptual tools that support planners' theorizing of how learning happens in community settings.
- To describe methodological tools for studying learning.

DIFFERENTIATING PARTICIPATION: DEFINING AND IDENTIFYING LATINO IMMIGRANT'S CIVIC CAPACITIES

Abstract ID: 696

Group Submission: Learning in Planning: Community based partnerships as sites of learning

MELENDEZ, Jose [University of Oregon] jwmuic@gmail.com, presenting author

MARTINEZ-COSIO, Maria [University of Texas Arlington] mcosio@uta.edu, co-author

Understanding individual civic capacities as skills necessary for collective decision-making is important for advancing community-building strategies that support democratic participation, particularly in diverse neighborhoods (DeSipio, 2006; Ebert & Okamoto, 2013; Morenoff, Sampson, & Raudenbush, 2001). However, numerous studies have failed to differentiate between civic capacities at the individual level versus as a community resource for collective efficacy (Sampson, Morenoff, & Earls, 1999). This study sought to identify and define individual civic capacities activated by predominant Spanish-speaking Latino immigrant residents engaged in a participatory budgeting (PB) process. We sought to also determine the role of these capacities in moving participants' individual ideas into collective decision making through an ethnographic approach, using videotaped PB meetings that took place in a diverse neighborhood in Chicago, Illinois.

To identify the specific individual civic skills evident in committee meeting discussions, we conducted discourse analysis of multiple speech events over time (Wortham & Reyes, 2015). While discourse analysis is not new to the study of participatory processes, it has not been used systemically to examine talk over longer time scales that show change over time, which we characterize as learning (Meléndez, et. al., 2018). Examining three brief ethnographic accounts of interaction in a participatory planning process, Briggs (1998) demonstrated the types of insights a socio-linguistic analysis of a participatory planning enactment could provide. However, very few, if any, planning activities take place in one speech event. Thus, different time scales are needed to study how participants learn the norms and practices of participatory processes, or more specifically the "interactions that occur between citizens and government officials participating in the official work of the city" (Farkas, 2013, p. 24). This methodological gap (Forester, 2015) represents an opportunity to expand the analysis of discourse from one public speech event (e.g., a meeting) to analyses of multiple speech events over time. The aim of this study was to gain generative insights (Sannino, Engeström, & Lemos, 2016) into how individual capacities were activated over time, their dynamics, and their role in the collective decision-making of participatory planning processes. The participatory budgeting process in the Chicago's 49th ward provided a rich context for this research.

Our analysis of transcripts revealed 16 unique civic capacities that fit the definition of civic skills. These capacities aligned with or were closely related to those presented by political scientists and civic educators (e.g., Kirlin, 2005; Verba, Schlozman, & Brady, 1995) as complex skills for collective decision-making. To explore more deeply the role of these individual civic skills in fostering community action, we highlight five individual civic capacities, providing examples of their activation and interplay as Latino immigrant participants engaged others in collective decision-making.

We argue that the activation of these civic capacities is impacted by context, the engagement of participants with prior experience in the civic sphere, and that these capacities do not occur in isolation. Instead, these civic capacities are engaged in a complex interplay that has the potential to foster more expansive forms of community engagement in potentially transformative participatory partnerships, built on deep levels of trust, reciprocity, and local knowledge of practices and context (Gutiérrez & Jurow, 2016; Meléndez et. al. 2018). We seek to contribute to the literature on civic capacity by adding specificity to defining individual civic capacity, as the knowledge, skills, and dispositions necessary for collective decision-making. Our research was limited in its capacity to connect participatory design decisions with the emergence of civic capacities although our analysis suggests that creating safe spaces for residents from underserved communities to express their needs, “including their feelings of injustice and oppression” (Forester, 1998, 221) certainly impacts engagement.

LEARNING IN THE FOOD MOVEMENT

Abstract ID: 697

Group Submission: Learning in Planning: Community based partnerships as sites of learning

JUROW, Aachey [University of Colorado Boulder] susan.jurow@colorado.edu, presenting author

Community-university partnerships are often advanced as a way to develop responsive solutions to real-world problems that affect the most marginalized populations (Bang, Medin, Washinawatok, & Chapman, 2010). This claim has strong merit; however, what is typically not discussed is how such partnerships are fraught with tensions around shared goals, forms of valued engagement, and what counts as consequential forms of learning and becoming. These tensions are not peripheral issues to the partnership, but are central to how relationships of trust and commitment emerge and shape action (Teeters & Jurow, 2018).

Perspectives from the interdisciplinary field of the Learning Sciences can be particularly valuable in discussions of designing with community members towards greater justice. In particular, research in the Learning Sciences draws critical attention to the organization of consequential learning – defined as people’s changing forms of participation that allow them to be recognized as competent and valued participants in dynamic and often contentious networks of practice (Jurow & Shea, 2015). What is defined as consequential learning thus needs to be understood in relation to particular temporal, social, and spatial scales of activity. Following from this, determining what is consequential for communities requires that we examine how the social world functions to make certain ideas, practices, and identities visible and potentially valuable.

In this paper, I report on my team’s longitudinal, participatory design research project on the food justice movement in the Western United States. In the project, we worked with a community-based non-profit, which we call Impact, and their team of promotoras who were seeking social justice for their historically marginalized, largely Mexican immigrant community. The model of using promotoras to organize justice-focused social action has a long history in Latin America as an approach to public health. Key to the success of the model is that it leverages the shared cultural practices among acknowledged community leaders (the promotoras) and residents to advance desired health and community goals. Impact used promotoras to develop a garden program to facilitate the establishment of backyard vegetable gardens in the neighborhood, which had been identified as a food desert by the U.S. Department of Agriculture. Since the garden program started nearly a decade ago, it has been enormously successful and has transformed the material, social, and relational organization of the neighborhood (Hall & Jurow, 2015).

The aim of our community-university partnership, which developed over 5 years, was to develop new tools (e.g., a software application, participant structures in the non-profit) and understandings that could make learning consequential for the promotoras. While their work was integral to the success of the garden program, the work they were doing – establishing and tending gardens, developing long-term relationships of trust with residents, and advocating for their community in multiple forums – was nearly “invisible” and not sufficiently valued (Jurow, Teeters, Shea, & Van Steenis, 2016). As we found through our sustained ethnographic work with the non-profit and the promotoras, without making the differential scales of influence and values of participants’ work visible, possibilities for the promotoras’, the non-profit’s, and the community’s learning that could extend across multiple positions and perspectives would be significantly limited. Participatory design research, with a particular focus on the organization of consequential learning for community members, allowed us to consider with our community partners what practices are significant for them, how we might create pathways together on which these practices could travel, and the implications of these changes for their and our futures.

RESUSCITATING (AND REFUSING) CARTESIAN REPRESENTATIONS OF DAILY LIFE: WHEN MOBILE AND GRID EPISTEMOLOGIES OF THE CITY MEET

Abstract ID: 698

Group Submission: Learning in Planning: Community based partnerships as sites of learning

HEADRICK TAYLOR, Katie [University of Washington] kht126@uw.edu, presenting author

“Let me ask you: How do you overcome the psychological and physical barrier of an interstate highway that was carved intentionally through [our community] and isolated it from other areas of the community?”

A resident, Mr. Corey, asked this question of a planner at a participatory planning meeting. His query is representative of the issues at stake in this paper: How do you know what you know about your home, your neighborhood, your city? How is your knowledge of that place valued (or not) within different conversations and interactional structures? How would you use this knowledge to teach someone else about a place you care deeply about and would they understand? How do people from outside your home represent what they think they know about your home, and how can you refuse those representations, and at what cost? How will others interpret this refusal: as ignorance, as being uncooperative?

Drawing upon work by Jurow and Shea (2015) and Hall and Jurow (2015), my focus on consequential teaching and learning exchanges connotes the high stakes at play when people’s homes hang in the balance of a “successful” educative moment; the consequence or outcome of a failed or productive teaching and learning interaction could mean the preservation or destruction of someone’s community. According to prior work on consequential learning, that which gets deemed valuable in teaching and learning interactions is always historically contingent and shifts the nature of participation across time, space, and social relations. In Mr. Corey’s question, for example, teaching the planner about the futility of future planning without first addressing the historical and contemporary impact of the interstate highway could equate to revitalization in certain areas of the community. Planners learning from Mr. Corey could also catalyze revised professional practice whereupon similar contributions from residents are taken-up and considered in community development plans.

In analyzing video records of planning meetings, I hold two epistemic stances in tension. I use mobile epistemologies (Cresswell, 2006) to describe what people know about a geography based upon moving through it, interacting and changing the place through corporeal engagement. Mr. Corey draws upon memories of pastime mobility and his current experience of being immobilized. This epistemology produces a spatial imaginary (Lipsitz, 2007) around sociability and reparations. Grid epistemologies (Dixon & Jones, 1998) refer to how people come to understand a geography based on maps or other (usually two-dimensional) abstractions of that place. Planner maps, for instance, produce a spatial imaginary based on potential property value and land parcel homogeneity (each piece of land is used for a specific purpose). Mr. Corey refuses a grid epistemology, speaking over and beyond what is mapped of his community and visible on the tabletop; he imagines a future neighborhood that is repaired, resuscitated from urban “renewal.” Such instances of epistemic tension are especially important to the learning sciences because, unlike in classrooms (e.g., Lampert, 1990), who and what has rights to the

“most valuable” forms of knowledge are constantly under negotiation in everyday interactions. What, then, happens if we design with and for epistemic tension?

In conclusion, this paper troubles the idea of “consensus” in planning processes, providing ways of seeing and productively engaging with epistemic incommensurability to imagine more equitable, open places. Fundamentally, engaging with the tension can be a teaching and learning interaction in which residents and planners have expertise to give and gain.

TRACK 2 - ROUNDTABLES

ROUNDTABLE - IMMIGRANT URBANISM AND COMMUNITY ECONOMIC DEVELOPMENT

Abstract ID: 81

Roundtable

LEE, Kevin [Massachusetts Institute of Technology] kevinjl@mit.edu

HARWOOD, Stacy [University of Utah] harwood@arch.utah.edu

HUM, Tarry [Queens College CUNY] Tarry.Hum@qc.cuny.edu (moderator)

ISKANDER, Natasha [New York University] natasha.iskander@nyu.edu

KIM, Anna [San Diego State University] anna.kim@sdsu.edu

LIU, Cathy [Georgia State University] cyliu@gsu.edu

This proposed roundtable pursues the following research questions: How should we conceptualize community economic development of immigrant communities? Is it an issue of immigrant labor market incorporation; an issue of citizenship, belonging, and multiculturalism; some combination of the two; or are other conceptual tools necessary to capture the issues accompanying both immigrants and the communities transformed by their arrival and integration? How might we encourage dialogue between different planning approaches to immigration, to take on the complex challenges at hand?

Immigration has arguably always been an important concern of planning scholarship and practice. Broadly, scholarship at the intersection of planning and immigration seemingly views the latter in two central ways. The first way sees immigration as constitutive of economic restructuring—and thus a

problem of unregulated and precarious work, and of increasingly disposable, exploitable labor (Theodore, Valenzuela, and Meléndez 2006; DeFilippis et al. 2009; Visser 2017). Such scholars often arrive at questions of immigration through considering how informality and place shape immigrant workplace conditions and labor market outcomes. Day laborers—predominantly immigrant and/or undocumented—are central figures in a vibrant, sizeable body of literature tracking the expansion of the informal economy and low-wage work (McGrath and DeFilippis 2009). To address their exploitative labor conditions, scholars have proposed migrant civil society organizations as sites of socioeconomic integration, and as both important and effective political actors for achieving economic justice (Visser et al. 2017; Martin 2011; Doussard and Gamal 2016).

The second way sees immigration as an integral component of increasingly multicultural, transnational communities—thus a problem of the politics of recognition in placemaking and planning processes, and of the redrawing of identity boundaries for both native-born (whites) and newly-arrived foreign-born populations (Burayidi 2000; Sarmiento and Beard 2013; Steil and Ridgley 2012). Scholars interested in these questions have also studied processes of multiculturalization in non-urban areas, centering how these places are contending with new immigrant influxes and difference, given contentious histories of white supremacy and renewed anti-immigrant fervor (Miraftab and McConnell 2008; Harwood 2005; Sandoval 2013). To address these problems, they emphasize the importance of micropolitical and ethical interventions in the planning process, such as the creation and leveraging of informal planning structures to engage multiple publics, and provide opportunities for robust community engagement and participation in municipal decision-making processes, and the legal and policy reforms to accommodate new forms of political claims-making (Hum 2010; Irazábal 2009; Allen and Slotterback 2017).

Planners working with/for immigrant communities face compounded challenges today: restrictionist federal immigration policies, widespread anti-immigrant sentiment, and renewed attention on public charge mean that municipalities have a greater role to play in ensuring positive immigrant incorporation outcomes. Yet, placing greater responsibility on municipalities has its dangers: scholars have documented how the devolution of immigration policy has resulted in municipalities adopting a range of protective and restrictionist local policies (Vitiello 2014; Walker and Leitner 2011). Protective immigration policies (e.g. sanctuary ordinances) improve immigrant incorporation outcomes, while restrictionist policies (e.g. active police-ICE collaborations) worsen them (Capps et al. 2015; Lyons, Vélez, and Santoro 2013; Rhodes et al. 2015). Through it all, institutions matter: they can play critical roles in both shaping the passage of immigration policies, and in shaping incorporation outcomes in restrictionist localities (Gleeson and Gonzales 2012; Steil and Vasi 2014). Through a discussion of how planners might leverage formal and informal place-based institutions to build long-term immigrant integration infrastructure, this roundtable seeks to promote cross-fertilization between scholars of the two aforementioned areas. In doing so, it raises and engages broader questions about how planning scholars might conceive and approach the new, compounded challenges faced by both immigrant communities, and the planners that work with/for them.

ROUNDTABLE - HOMELESSNESS AND URBAN PLANNING

Abstract ID: 513

Roundtable

ZAPATA, Marisa [Portland State University] mazapata@pdx.edu (moderator)

LENS, Michael [University of California Los Angeles] mlens@ucla.edu

GARCIA ZAMBRANA, Ivis [University of Utah] ivis.garcia@gmail.com

SANTIAGO, Luis [Clemson University] luis.santiago2@ucf.edu

AZHAR, Awais [The University of Texas at Austin] awais.nca@gmail.com

NEVAREZ MARTINEZ, Deyanira [University of California Irvine] deyanira.n.martinez@gmail.com

POLSTER, Katia [UCI] kpolster@uci.edu

Homelessness continues to gain attention in media around the country, despite decreasing in the last decade. Part of this increased interest is that who, where, and how people are experiencing homelessness is changing. The West Coast is seeing growing numbers of houseless people, with CA nearing its highest numbers since 2007 and Portland having the second highest share of unsheltered people in the nation. Rising housing costs in these and other areas continue to drive people out of their homes and onto friends' couches, cars, shelters, and tents on the sides of highways.

As jurisdictions around the country look for solutions, new approaches arise and old fracture lines become apparent. Revenue is being raised by local government to address homelessness in previously unheard of amounts. Tiny home villages and small modular housing are championed by some advocates. Intensive resource expenditures for specific populations such as houseless veterans seek to demonstrate that the wicked "problem" of homelessness can be fought. Yet long term and entrenched racial disparities within homelessness continue to draw less attention, and few localities have demonstrated success in, or a commitment to, remedying those disparities. Meanwhile social service providers, used to a scarcity of funds, struggle to adjust and cooperate across competing ideologies.

Urban planning has been largely silent on homelessness in the past. Across the main US planning journals (JAPA, JPER, and JPL) fewer than 15 articles have been published with a focus on homelessness. Most planning scholars writing about homelessness publish within Housing Studies, and there the number is just 50 articles. Yet the creation of homelessness research centers at Portland State University and University of Southern California are led by or housed within urban planning faculty or units. Perhaps something is shifting? The participants of this roundtable will discuss how urban planning intersects with homelessness, and how the recent attention to homelessness is shifting the professions role in supporting these marginalized communities. We will discuss a selection of the following questions:

- How is the planning profession responding to homelessness? Is this response different than decades before? Which research topics are needed to more effectively address homelessness? How can planning scholars participate?
- Homelessness and housing have often been viewed as separate conversations. Why did that occur, and is that changing now? Where should homelessness discussions be placed in planning scholarly discussions?
- Which approaches have been effective in addressing homelessness in communities?
- How do we define who is experiencing homelessness?
- How do communities of color experience homelessness? Which governance arrangements have been effective in addressing homelessness?
- What drives members of the LGBTQIA population to experience homelessness? How do we tailor interventions for members of the LGBTQIA community, and youth in particular?
- What are some of the causes of homelessness among veteran populations and differently abled individuals? Which interventions would be effective for these groups?
- How do we address public health issues, including mental health and addiction problems, among the houseless population?
- What are some of the survival strategies adopted by the houseless population? How can local government and NGO's assist in enhancing those sources of support?
- How do contemporary approaches to alternative shelter (e.g., tiny home villages, sanctioned camping) shape homelessness discussions? Are these viable or effective ways of addressing homelessness?
- How do democratic institutions and practices respond to the vilification of people experiencing homelessness? What legal remedies do houseless people have for neighbors protesting against them?
- What policies need to be adopted, amended, or repealed at the local, state, and federal level to revert homelessness trends across the range of intersecting policy domains?

ROUNDTABLE - TRANSLATING ACROSS DISCIPLINES: PLANNING & LEARNING SCIENCES

Abstract ID: 700

Roundtable

MELLENDEZ, Jose [University of Oregon] jwmuic@gmail.com (moderator)

RADINSKY, Joshua [University of Illinois at Chicago] joshuar@uic.edu

HEADRICK TAYLOR, Katie [University of Washington] kht126@uw.edu

In recent years, there has been a good deal of interest in building a bridge between planning research and work in the field of learning sciences, which has robust theoretical and methodological tools for studying learning (e. g. Meléndez & Parker 2018; Radinsky, et al., 2016; Taylor, 2017). This is since learning is at the core of many urban planning processes (Forester 2009). The list of topics that citizens have to learn about when engaging in community development or the local knowledge that those in charge learn about by engaging with communities is endless. Nevertheless, planning as a field is always wrestling with how to attend to social learning in a variety of contexts, especially in relation to issues of power, access, and social justice. In particular, sociocultural learning theories from the learning sciences can help researchers align behavioral changes with cognitive learning, a challenge identified frequently in the social learning planning literature (Muro & Jeffrey, 2008). Additionally, learning scientists have a long history of using design-based research methods to create, test, and refine tools for use in real-world settings that promote learning, and to study the learning that results (e.g., Brown & Campione, 1994; Edelson, Gordin & Pea, 1999; Wilensky & Rand, 2015). The growing body of Learning Sciences work being conducted in urban and community planning contexts (e.g., Gutierrez & Jurow, 2016; Melendez & Parker, 2018) suggests a valuable cross-pollination of concepts and methods that can expand our understanding of how people learn with tools, and the kinds of social learning processes that emerge in community development work.

Given the need for research to build on our current knowledge of learning in planning, we have submitted two pre-organized panel proposals to bring together scholars from both Planning and the Learning Sciences at the ACSP 2019 Conference. The goal is to provide a space for conversations about expanding the framing and conceptualizations of learning in both disciplines, with implications for both practice and research – following Friedmann’s (2008) advice to translate concepts, theories, and methods across disciplines. These sessions are in part supported by a small funding initiative from the International Society of the Learning Sciences (ISLS). The goal of this small grant is to outreach and engage with other professional communities whose work can mutually benefit from engaging with Learning Scientists.

Although we expect the pre-organized panels to be engaging, we are keenly aware that panels are not the most appropriate venue to engage in conversations about what possibilities for collaborations exist between researchers across disciplines. For this reason, we propose a roundtable discussion, hosted by Drs. Meléndez, Radinsky, and Headrick Taylor. The purpose of the roundtable will be to continue the conversation from the earlier sessions, inviting participants from both, in addition to other conference participants interested in advancing interdisciplinary research in learning. Specifically, the roundtable will be geared towards germinating possibilities for future collaboration and research that can advance both disciplines’ understanding of transformative learning, especially for under-represented communities.

It is our hope that in addition to laying the initial seeds for potential cross-disciplinary research, we will also discuss the opportunity of Planning researchers joining Learning Scientists at the International Society of the Learning Sciences conference (ICLS). The plan following ACSP 2019 is to implement a similar series of sessions at ICLS in 2020, using a similar design of pre-organized panels to further both societies’/associations’ common interests in learning in planning.

JUNQUEIRA, Mariana [University of California Irvine] mjunquei@uci.edu

First, come the artists, then the cranes. As the kamikaze pilots of urban renewal, wherever the creatives go, developers will follow, rents will rise, the artists will move on, and the pre-existing community will be kicked out with them.

Such is the accepted narrative of gentrification, a term first coined more than that 50 years ago by Ruth Glass, a British urbanist who observed changing demographic and socio-economic shifts in north London. In 2019, gentrification is one of the most controversial issues in American cities. However, it also remains one of the least understood. It is one of the most slippery and most contested concepts in social science today. Few agree on how to define it or whether it is boon or curse for cities. Gentrification has changed over time and has a history dating back to the early 20th century. Historically, gentrification has had a smaller demographic impact on American cities than suburbanization or immigration. However, since the late 1970s, gentrification has dramatically reshaped cities like Seattle, San Francisco, and Boston.

Furthermore, districts such as the French Quarter in New Orleans, New York City's Greenwich Village, and Georgetown in Washington DC have had an outsized influence on the political, cultural, and architectural history of cities. Gentrification thus must be examined alongside suburbanization as one of the major historical trends shaping the 20th-century American metropolis and global urbanism.

More-and-more contemporary discussions of gentrification include issues surrounding equity and justice with environmental justice, public health, economic development, and community development all being essential components of the conversation. Specifically, for academic planning scholars, it has become imperative to grapple with how to discuss these issues with students critically and with empathy for all life experiences. Additionally, exploration is needed on how to do research in the field without further alienating and exploiting communities suffering due to displacement caused by gentrification.

We will discuss a selection of the following questions:

- How is the planning profession reacting to gentrification?
- Have urban planners been part of the problem?
- Have urban planners used gentrification as a strategy for economic development?

- What are the different ways in which urban planning scholars have examined gentrification and how can that be improved?
- How can planning scholars participate in on the ground conversations about gentrification with communities?
- Is gentrification inevitable in the life of a neighborhood?
- Is gentrification an irreversible process?
- Are there different types of gentrification? Are some better than others? (e.g., gentefication)
- Can urban communities be improved without causing gentrification? Where should the line be drawn?
- What strategies are communities using to avoid gentrification? Can these be considered compromises? Are these ethical? (e.g., green enough movement)
- What are the health concerns that stem from gentrification?
- Do planners have a role in mitigating these health concerns?
- What other fields or professionals should planners/planning scholars be engaging with to foster more just development?
- What are the parameters of work for planners in communities confronting gentrification?
- How has gentrification exacerbated existing conditions for low-income and immigrant communities?
- How do we alter teaching in the classroom to reflect the realities of gentrification to students who may be more economically and racially privileged?
- Should gentrification be structured as its own field of study? (e.g., have its own curriculum?)
- What have planning scholars been able to learn through analytical exercises?
- What are important alternatives being discussed?

TRACK 2 – INDIVIDUAL PAPERS

COLLECTIVE IMPACT AND COMMUNITY CHANGE: A SUCCESSFUL INTERVENTION FOR HOMELESS STUDENTS AND FAMILIES

Abstract ID: 46

Individual Paper Submission

WILLIAMSON, Anne [University of Missouri-Kansas City] williamsona@umkc.edu, presenting author

Complex or “wicked” social problems have long been a challenge in urban planning. These problems are especially difficult to address, because they are unstructured, involve multiple, cross-cutting policy problems, and persist despite even the most well-intentioned efforts to eliminate them (Weber and Khademian 2008). The collective impact model for community change is a specific form of action involving key actors across sectors for the purpose of solving complex social problems.

Since its introduction less than a decade ago, collective impact has gained attention among community organizations, governments, and philanthropic foundations around the world as a promising means for addressing complex social problems. It has been used to address issues such as crime, employment for public housing residents, clean water, and homelessness (Walzer and Weaver 2019). Collaboration based on the collective impact model requires a common agenda, shared measurement systems, mutually reinforcing activities, continuous communication, and a backbone support organization (Kania and Kramer 2011).

This paper examines the successful application of the collective impact model for community change to the issue of student homelessness. Student homelessness in U.S. public schools more than doubled between 2007 and 2014, with an estimated 1.3 million students in grades pre-K through 12 identified as homeless in the 2013-2014 school year (Ingram et al. 2016).

Research is based on an explanatory case study of the nationally recognized Impact KCK program, a successful community effort to address student homelessness in the poorest of 105 counties in Kansas. Launched in 2015, Impact KCK reduced student homelessness in the Kansas City Kansas Public Schools by more than 50 percent in less than three years. Collaborative service providers continue to innovate to eliminate student homelessness by 2020.

The case study provides an empirical analysis of how this group of more than 30 organizations from the public, private, and nonprofit sectors came together to address the needs of homeless students and their families in Kansas City, Kansas through the Impact KCK program. Together, members of this collaborative network provide an array of services that support not only stable housing in formerly homeless families, but also increased employment, financial literacy, healthcare access, and improved nutrition. Impact KCK's results include a 95 percent stable housing rate among families who receive a permanent housing solution.

Findings include the skillful application of collective impact principles by the backbone and partner organizations, as well as the introduction of several key social service innovations. These innovations include providing a single point of service, the application of intensive, navigator-style case management practices, and making a permanent housing solution available.

Backbone and partner organizations show a clear understanding of the multiple issues that lead to homelessness and its impact on student learning outcomes. The collective engages in continuous communication using both formal and informal methods. The program has visible support from community leaders, including the mayor and school superintendent. The program has benefitted from strong commitment by multi-sector partners, including a state agency, multiple nonprofits, and a private sector employment firm.

The backbone has shown itself to be particularly adept at fundraising and relies on multiple sources, including private philanthropy. Finally, the backbone organization and a core group of partner organizations have shown resilience and adaptability as challenges to program success arise.

This explanatory case study illustrates that a critically resource-challenged community has the capacity to come together to produce needed change. In doing so, it contributes to scholarly and practice-oriented knowledge about factors contributing to effective collaboration based on a strategic approach to community action.

WHEN EMPOWERMENT MARGINALIZES: PLACE BRANDING AND THE POLITICS OF NEIGHBORHOOD GOVERNANCE

Abstract ID: 69

Individual Paper Submission

COLLINS, Brady [Cal Poly Pomona] bjcollins@cpp.edu, presenting author

In recent years, place branding has emerged as both an interdisciplinary academic field as well as an economic development strategy employed by local, regional, national, and even international organizations. Place branding is generally considered to be a variety of practices aimed at shaping the public's perception of a particular geography, such as cities, regions, or communities, by forging emotional and psychological bonds with a place. However, despite the fact that some public agencies spend millions of dollars on such strategies, there is a severe lack of conceptual clarity as to what activities constitute branding, what actors are engaging in branding, for whom the brand is created and to what ends. This study seeks to elucidate these issues by focusing on how municipal policies for neighborhood-level governance encourage or discourage residents from engaging in practices associated with place branding. Through interviews and archival research, this paper analyzes how and why 35 US municipal governments define and create neighborhood organizations. In doing so, I demonstrate how formal and informal government processes influence neighborhood change, and how the conflation of "neighborhood" and "neighborhood organization" exacerbates power dynamics between community stakeholders. I conclude with recommendations for how city governments can engage residents and local associations without inflaming neighborhood politics.

SANDERCOCK, Leonie [University of British Columbia] leonies@mail.ubc.ca, presenting author
MORAES, Dana [GwaalagaNaay Development Corporation] dana@skidegate.ca, primary author

Hypothesis

The making of a feature film in the Haida language could serve as a catalyst for Indigenous community development on Haida Gwaii.

Context

Haida Gwaii is a remote archipelago in northwest Canada. Pre-contact, between 20,000 and 30,000 Haida people lived on Haida Gwaii. By the late 19th century, European diseases had reduced that population to 600. Government policies of assimilation further undermined the vitality and viability of Haida culture. For the past fifty years, the Haida have been resurgent, but the struggle for economic and cultural revitalization is ongoing due to the intergenerational effects of Residential Schools, and decline of the economic base (logging and fishing). The relative isolation, and lack of opportunities for youth on Haida Gwaii compounds the sustainability challenge. Haida cultural identity is linked to language and storytelling, yet their community is inundated with foreign media.

The research challenge then, from an Indigenous community planning perspective, is how to use 'homegrown' storytelling in the context of community development.

Approach and methodology

In 2014 a three-way partnership was formed between the Council of the Haida Nation, the Inuit film production company, Kingulliit, and the Indigenous Community Planning (ICP) program at UBC.

The goal of this partnership has been to contribute to the ongoing cultural and economic revitalization of the Haida Nation by (1) preserving traditional language and storytelling through a community-based story gathering process bringing together youth and Elders, and culminating in the collaborative creation of a feature film script in the Haida language, drawing on Haida myth, legend and history. (2) providing training for 40-50 Haida community members as cast and crew of the film production: skills in acting, script writing, production and management skills, and (3) contributing to knowledge among and between First Nations, government, multimedia industry, planning practitioners and planning academics about the potential of multimedia as a catalyst for Indigenous community development in other northern and remote communities.

Relevance

The theoretical framework for this project draws on various streams within planning theory (communicative, empowerment, and decolonizing theories), as well as the practice based experience of the academic partner (Sandercock and Attili 2010a; 2010b) and the Indigenous film making partners.

A major stream of influential literature examines the role of planning as a colonial practice in settler societies, serving to render Indigenous populations invisible, to deny their rights, to exacerbate their

geographical and economic marginalization, and provide them with culturally inappropriate programs and services (Porter 2010; Walker, Jojola and Natcher 2013). We seek, through our film work, to practice a decolonizing planning, and to work in partnership with Indigenous communities, supporting them in achieving their own aspirations for self-determination, economic and cultural revitalization.

Results/Findings

After completion of the film script, the project received \$2m in production funding, \$1.3m of which went directly into the Haida community in employment and training. Elders translated the script into Haida dialects: community members were hired as cast and crew; the 15 remaining fluent speakers trained the cast in a 2-week language boot camp. An interactive website was developed to support language training. The 100 minute film, *Edge of the Knife*, premiered at Toronto International Film Festival in 2018.

Evaluation of the impact of the film on language revitalization and sustainable economic development is ongoing.

QUADRUPLE BOTTOM LINE COMMUNITY DEVELOPMENT

Abstract ID: 140

Individual Paper Submission

HERRANZ JR., Joaquin [University of Washington] jherranz@uw.edu, presenting author

This paper provides a conceptual framework and empirically-based case study for clarifying and categorizing four inter-related outcomes of community development: economic development, social equity, environmental sustainability, and creative cultural vitality. This perspective extends the triple bottom line approach that focuses on developing projects that simultaneously yield economic, social, and environmental benefits. Several researchers argue that creative individuals and industries increasingly drive regional economic growth as part of global restructuring (Florida 2005; Scott 2004); cultural vitality is an under-emphasized yet measurable asset and process of community development (Jackson et al 2006); and that the impact of artistic clusters is often place-specific as well as under-estimated (Grodach et al 2014). However, few studies examine cultural creativity in the comparative context of economic, social, and environmental development. This paper contributes to existing literature by addressing the question of whether a creative cultural vitality outcome is conceptually and empirically distinct from economic, social, and environmental outcomes. The paper provides a case analysis of the quadruple bottom line framework by examining a community economic development project in Seattle. The case analyses highlights the emergence of a quadruple bottom line policy framework as well as will examine the trade-offs associated with quadruple bottom line community economic development. Case data—

collected annually between 2005 and 2018 by graduate researchers in a Community Economic Development course at the University of Washington—include field studies, key informant interviews, documents review, and photo and video documentaries. The paper discusses the implications of a quadruple bottom line approach for researchers and practitioners of community economic development.

BUILDING BEYOND THE FAÇADE: LAYERING DOWNTOWN SPILLOVER INVESTMENT

Abstract ID: 173

Individual Paper Submission

GIBSON, Huston [Kansas State University] hgibson@ksu.edu, presenting author

ZURCHER, Micky [Helena Business Improvement District] mzurcher@helenabid.com, co-author

WISEMILLER, Tash [Montana Department of Commerce] twisemiller@mt.gov, co-author

NEWMARK, Greg [Kansas State University] gnewmark@ksu.edu, co-author

In a time when funding for communities is limited, an analysis of investment strategy is critical. Façade improvement programs are thought to spur spillover of both direct and indirect investment in central business districts by leveraging built capital and harnessing a sense of placemaking. Our study asks, “do downtown façade improvement grants generate spillover effects on Main Street?” Our hypothesis is they do, and our findings support this sentiment. Furthermore, we explore the nuances of the spillover into the Community Capitals Framework (CCF) for asset-based community development (ABCD) planning initiatives.

Through case study in three designated Montana Main Street communities; Helena, Kalispell, and Anaconda, our paper empirically analyzes this phenomenon. Data was collected through face-to-face interviews with grantees and grantors in the fall of 2018 along with a qualitative observational analysis of all three communities. In addition, for Kalispell, historical property tax rolls (back to 2013, prior to the onset of the grant program) were used to determine property valuations overtime for grantees, their neighbors, and controls. A difference in difference approach was used to determine statistical trends.

Findings show that direct public-private investment through downtown façade grants, administered by downtown focused organizations, leverages positive direct and indirect spin-off via supplementary privately initiated renovations and building maintenance. This implies that strategic downtown planning and investment generates a multiplier effect; creating a larger return on investment from façade improvements on “Main Street.” Downtown façade improvement grants are hypothesized to have several tangible and intangible benefits in a community, yet they are still regularly questioned by officials and

taxpayers as to their value. While recognizing every decision has trade-offs, for discussion, we will recap and outline the major take-aways from the Montana study with recommendations for future policy and practice directed for potential adaptation by planners and community development professionals across varied US communities. This topic is relevant to community planning because it offers empirical evidence of local asset-based community development (ABCD); strengthening the local Community Capital Framework (particularly social, political, financial, and built capital).

NEIGHBORHOOD EFFECTS OF SOCIAL CAPITAL ON CHILDREN AND ITS MEANING FOR ADULTHOOD SUCCESS

Abstract ID: 204

Individual Paper Submission

YUN, Jinhee [Cleveland State University, College of Urban Affairs] jhyun321@gmail.com, presenting author

Individuals' residential location strongly affects their access to opportunity, such as obtaining sufficient public goods and services, as well as their children's' outcomes when they reach adulthood. One explanation for these neighborhood effects on children is social capital. However, the definition and operationalization of social capital vary. Robert Putnam considered social capital as largely a positive factor for individuals. He saw social capital as connections or social networks among individuals that give them mutual benefits, overlooking its exclusiveness to outsiders. French sociologist Pierre Bourdieu posited instead that social capital is the accumulation of relation-based resources that function to distinguish individuals and allow them to get ahead of others. He expressed a critical perspective on social capital because it reproduces gaps in the amount of social capital across individuals and neighborhoods, and therefore can lead to inequality. This aspect of embeddedness in Bourdieu's social capital theory refutes existing neighborhood effect studies which rely on Putnam's view of social capital.

This study categorized social capital into two forms, using Bourdieu's embeddedness of social capital: how relationships within a neighborhood (relation-based neighborhood social capital) and the neighborhood location and its resources (descriptive neighborhood social capital) affect adult outcomes. This research studied the long-term effects of these two forms of social capital in conjunction with the resources parents offer children (parental relation-based/descriptive social capital) and the attachment children have to their particular neighborhood (neighborhood attachment). It contributed to the literature in two ways, showing how the embeddedness of social capital creates unequal access to neighborhood resources and how the embeddedness of neighborhood social capital impacts adult outcomes.

This study used Structural Equation Modeling (SEM) and data from the National Longitudinal Study of Adolescent to Adult Health (Add Health) to determine the role neighborhood social capital plays in unequal access to neighborhood resources. This approach showed not only the effects of each form of neighborhood social capital on adult outcomes such as educational attainment or personal earnings but also the ways in which personal neighborhood attachment acts as a mediator of that relationship. Neighborhood effects are generally considered by scholars to influence all residents who live in the neighborhood. However, this research sought to understand more nuanced dimensions of neighborhood effects, particularly how neighborhood social capital and attachment play a role in unequal access to neighborhood resources. Even if residents have access to neighborhood resources, the impact of neighborhood social capital can vary depending on whether they experience relationships within a neighborhood or not. It also explored how parental social capital influences children and their neighborhood social capital. Thus, neighborhoods can offer children a variety of experiences they will contend with for the rest of their lives.

Many studies explain why neighborhood social capital is important, but overlook the downside of the embeddedness of social capital. In addition, few empirical studies analyze the neighborhood effects of social capital due to the difficulty of measuring social capital. My research redefined social capital to include Bourdieu's notion of embeddedness, allowing me to examine more fully several interactions that were overlooked by Putnam and his followers. An outcome of this research is evidence of the need for urban policymakers to examine carefully who may be excluded from various neighborhood resources and to find ways to introduce these resources to this ignored population.

DO QUALIFIED ALLOCATION PLANS INFLUENCE DEVELOPERS' LIHTC SITING DECISIONS? THE CASE OF ACCESS TO HIGH-PERFORMING SCHOOLS

Abstract ID: 215

Individual Paper Submission

SHANHOLTZ, Spencer [University of Virginia] sas7px@virginia.edu, presenting author
ANACKER, Katrin [George Mason University] kanacker@gmu.edu, co-author
SKUZINSKI, Thomas [Virginia Tech] skuzinski@vt.edu, co-author

This study analyzes variation among Low Income Housing Tax Credit (LIHTC) allocation policies as outlined in state qualified action plans (QAP) and their impacts on the siting patterns of LIHTC properties in proximity to high-performing schools. We focus on 37 states and control for factors relevant to the

development location decisions, using Census-based population characteristics and LIHTC property attributes. Our goal is to determine the effectiveness of LIHTC QAP allocation policies in motivating developers to site their developments near high-performing schools.

QAPs typically use points when awarding tax credits competitively. We focus on points awarded for (1) access to high quality schools, (2) access to any schools, and (3) location in areas with attributes expected to correlate strongly with high-quality schools. We use descriptive statistics and multi-level linear modeling. We find a significant and positive effect on location in catchment areas of high-performing schools. We also find that other allocation policy variables have no significant effects. We discuss the ability of current allocation policy to influence developer actions, provide policy recommendations, and the need for further research.

BUILDING THE FOUNDATION FOR ARNSTEIN'S LADDER: COMMUNITY EMPOWERMENT THROUGH A PARTICIPATORY NEIGHBORHOOD NARRATIVE PROCESS

Abstract ID: 249

Individual Paper Submission

DEDENBACH, Laura [University of Florida] laurajd@ufl.edu, presenting author
FRANK, Kathryn [University of Florida] kifrank@ufl.edu, co-author
LARSEN, Kristin [University of Florida] , co-author
REDDEN, Tyeshia [Gettysburg College] treden@ufl.edu, co-author

Meaningful citizen participation involves a redistribution of power to those excluded from political and economic processes. The development of informational, social, political, and organizational capacities is necessary for marginalized groups to overcome the institutional and organizational barriers prohibiting equal participation in the public process. Building upon Arnstein's Ladder of Citizen Participation, Rocha (1997) synthesized interdisciplinary literature to propose a "ladder of empowerment", with empowerment planning as one method for community-level capacity building. Empowerment planning is the use of participatory action research, direct action organization, and education to develop both individual and community capacity to seek beneficial outcomes (Rocha 1997, Bratt and Reardon 2013). Methods involving participation, culture, and communication, such as narratives/storytelling, participatory video, community informatics, participatory mapping, and relational public art have been found to be effective forms of community-based participation and empowerment in planning (Sandercock and Attali 2014, Goldstein et al. 2015). Our work contributes to the literature on empowerment planning methods and practices designed to engage local knowledge to build the community capacity required to fully participate in the planning process.

We began our work with the Porters neighborhood, an historically African American neighborhood in Gainesville, Florida, with the question of how to build neighborhood capacity and communicate a neighborhood's importance to the city as a whole. Our response was to build a foundation for citizen participation in the planning process through a new practice for empowerment planning at the intersection of participation and communication – the Participatory Neighborhood Narrative (PNN). PNN empowers in multiple ways, including by taking a dialogical approach to creating a narrative, which builds consensus, and by supporting existing, neighborhood-preserving values to counter the replacing rhetoric of gentrification. PNN also provides a mechanism for documenting and celebrating the cultural, social, organizational, and human assets of a neighborhood. As a method separate from traditional planning processes, PNN gives residents the space to become engaged and informed on their own terms. It also allows the neighborhood to create a narrative that represents their cultural and social values in dialogue with the larger community. We found that the Porters neighborhood was empowered through the PNN process. Evidence of empowerment included the development of informational, social, and political capacity and the use of those capacities in collective action that benefited Porters.

The PNN is grounded in three guiding principles – participatory, neighborhood, narrative – that serve as a framework for a transferable model. The methods and activities that we used to support the guiding principles were coproduced with the Porters neighborhood to address their specific needs, however many are likely vital and transferable. Based on the Porters PNN experience, we make recommendations for fundamental elements, including processes, skills, and competencies, necessary to create a PNN model that can be customized as resources, interests, and opportunities permit. PNN is a bottom-up, inclusive, and culturally sensitive practice aimed at giving voice and building neighborhood capacity for advocating for their interests in city affairs, i.e., empowerment. The PNN process draws attention to the need for planners to plan with communities, rather than for communities, in a manner that respects cultures and differences.

DISPLACEMENT RISK INDEX: A GIS-BASED ASSESSMENT OF RESIDENTIAL DISPLACEMENT RISK IN ATLANTA

Abstract ID: 322

Individual Paper Submission

WILLIAMS, Patrice [Florida State University] pcw04@my.fsu.edu, presenting author

JACKSON, April [Florida State University] ajackson5@fsu.edu, co-author

For the last 50 years, scholars have studied and debated the definitions and impacts of gentrification and displacement and its relation to individual, market, and government interventions (Freeman, 2005; Marcuse, 1985). New greening and sustainable consumption policies and/or development can increase desirability and stimulate gentrification, driving up property values and making these developments increasingly unaffordable for its low-income residents. Green gentrification is a process that is driven by green initiatives that create or restore environmental amenities that draw wealthier groups and push out lower-income residents (Gould & Lewis, 2017).

Amid discussions on the definition and outcomes of the gentrification process there is constant debate and controversy regarding the potential of gentrification to displace low-income households, communities of color, and other vulnerable populations. Residential displacement is often discussed solely as a product of the gentrification process, where there is an influx of a new demographic, along with exorbitant increases in housing costs. Researchers and practitioners often view the relationship between gentrification and displacement as linear and sequential, which is not true in all cases. Zuk and Chapple (2015) found for some of their case studies in the San Francisco Bay area where displacement preceded gentrification and the two processes have occurred simultaneously. Marcuse (1985) argues that when examining the relationship between gentrification and displacement, we must consider the disinvestment of urban neighborhoods and subsequent displacement, which creates vacant land ready for investment. Although displacement is a central concern of gentrification, it is not a phenomenon that is distinct to gentrification.

In this paper, we review the literature on how residential displacement is defined and measured. We ask the following research questions: 1) what factors impact the susceptibility of existing residents to residential displacement and 2) to what extent does green redevelopment contribute to residential displacement? We used the Atlanta BeltLine – a 25-year public-private green redevelopment project that will result in improvements to 700 acres of existing parks, addition of 1,300 acres of new and expanded green space, 33 miles of new multi-use trails, and a 22-mile loop of rail transit service – as our case study. When this project initiated in 2005 a major goal was to ensure housing equity by creating at least 5,600 affordable housing units, yet the BeltLine has only secured funding for 2,565 units. From 2011 to 2015, neighborhoods along the BeltLine saw median home sale prices increase from 40 - 68% compared to 17.7% for the City of Atlanta (Immergluck & Balan, 2017).

To answer our research questions, we present a displacement risk index that identifies neighborhoods that have a concentration of residents who are most susceptible to residential displacement, measures demographic and housing market changes over time, and classifies the neighborhood's risk from low to high risk of displacement by combining two indexes: 1) vulnerability index, which focuses on characteristics that make certain social groups more vulnerable to displacement and 2) housing market index that includes indicators that reflect affordable housing options, disinvestment, and reinvestment within the housing market. We also performed a hot spot analysis to examine the extent and variation in the spatial concentration of environmental amenities in neighborhoods classified as low to high risk of residential displacement. Combining these two approaches allows us to consider the cumulative risk of displacement – the demographic and housing market aspects as well as the concentration of “pull factors” – for socially vulnerable populations residing in neighborhoods classified as high risk of residential displacement. Planners can use this assessment to better understand the vulnerability of populations to displacement in an effort to provide policy and plan recommendations that may limit displacement for low-income households and communities of color.

A GRASSROOTS APPROACH TO INFLUENCING URBAN POLICY: A CASE STUDY ANALYSIS OF ONE DC

Abstract ID: 347

Individual Paper Submission

BAQAI, Aabiya Noman [University of Texas at Arlington] aabianoman@gmail.com, presenting author

A long-time host to racially-infused urban policies, Washington, D.C. has more recently been a victim to the second highest percentage of gentrifying neighborhoods in the country at 51.9% (Maciag, 2015). This has been caused by more affluent, national and international, dominantly young communities, moving into the more “prime”, inner parts of D.C., that neighbor major policy hubs. The reasons include an increase in job opportunities, stable economic development despite a recession, Federal oversight in local governance, and pro-growth objectives. Despite the unique contributions to gentrification in D.C., like most cities, it has faced the complete physical and cultural eradication of existing spaces with the redevelopments only serving incoming community needs. Mere odes to existing culture with insensitive and irrelevant references is what plagues most gentrified neighborhoods today. These circumstances have completely altered the urban and cultural landscape of the city, causing cyclic physical, psychological, socioeconomic and financial displacement of existing, low-income minority communities, as well as converting the once called chocolate city into “Cappuccino City” (Hyra, 2017).

With a lack of trust in the bureaucratic Federal and local system, D.C.’s long-time low-income residents have sought the assistance of grassroots nonprofits such as One DC that play an important role in preventing this displacement through advocacy for “the right to income, housing and wellness” (One DC, n.d.). Located at the heart of D.C., in the Shaw district, and principally focused on Ella Jo Baker’s ideologies, One DC aims to achieve the above through organizing, empowering and working with low-income, poor, and immigrant communities to “exercise political strength to create and preserve racial and economic equity.” (One DC, n.d.).

To fully understand One DC’s role in addressing the city’s rising gentrification-based displacement issues, this study has been conducted instrumentally with an in-depth analysis of the context of D.C. to interpret its application to other contexts and draw conclusions. This process has been facilitated by semi-structured interviews of One DC stakeholders including community organizers, low-income D.C. residents, and policy experts that have studied these issues previously. Ethnographic observations have

also been carried out during One DC's meetings and organizing efforts with local communities to detail their approaches and community reactions. Lastly, to visually and comprehensively assist in understanding the role of One DC in shaping equitable urban policies, document analysis of items such as newspaper articles, developer websites, before and after pictures of Washington D.C.'s neighborhoods, and spatial maps have also been conducted.

Based on the above methodologies, the key findings of this study include some of the major advocacy efforts and policy propositions by One DC such as:

1) Solutions within the current gentrification process:

- a) Providing tenants with a temporary place to stay during the revitalization process
- b) Inclusive redevelopment with involvement of both existing and incoming communities
- c) Affordable housing options in all neighborhoods
- d) Local business options such as co-ops and community working spaces

2) Alternatives to gentrification:

- a) Higher wages
- b) Creating platforms that allow for government accountability to the public such as a People's Congress
- c) Universal housing, healthcare, education and transportation
- d) Removing aristocracy within leadership positions at the local, state and national level

This study, therefore, helps to determine how grassroots political activism are crucial to shaping future policy-thinking and equitable urban development, concurrently overcoming insensitive hierarchical and bureaucratic oversight.

BRANCHING OUT INTO IMMIGRANT NEIGHBORHOODS: HOW PUBLIC LIBRARIES DISTRIBUTE COMMUNITY RESOURCES TO MEET IMMIGRANT NEEDS

Abstract ID: 355

Individual Paper Submission

DELGADO, Laura [Massachusetts Institute of Technology] ldelgado@mit.edu, presenting author

Local organizations play a critical role providing access to supports and opportunities for those who are low-income, socially isolated, or marginalized (Allard and Small 2013). This is especially true for immigrants in the United States, where support with social, economic, and political integration falls almost entirely on local organizations (Jiménez 2011). Yet, immigrants are accessing the social safety net less than in previous years for fear of discrimination and deportation, even though they are more likely to live in poverty than those who are native-born. Public libraries, which are viewed as safe and more trusted than other government institutions (Horrigan 2017), offer an alternative point of access for immigrant services (Koerber 2018). Furthermore, with a branch system that extends across neighborhoods, public libraries have an existing infrastructure that is designed to meet the distinct needs of diverse communities and can reach immigrants where they live.

Not all library branches, however, provide equal access to immigrant services and programs. Some branches in immigrant neighborhoods provide daily immigrant programs, whereas others provide none. If community needs alone cannot explain the uneven distribution of immigrant programs, what other factors help to explain the variation in immigrant services and programs across neighborhood branches? This research examines how the availability of community resources, such as volunteers and local organizations, shapes the distribution of immigrant services and programs. Moreover, this research addresses the socioeconomic implications of a public system that draws on community resources to meet the needs of local immigrant populations.

I approach this research through a mixed-method study of the Boston Public Library and its twenty-five neighborhood branches. I focus on Boston because it is a major-continuous gateway for immigrants (Singer 2015), and it also is home to the first large, municipal public library and neighborhood branch system in the United States. Through analysis of quantitative and archival data, I first examine how library services for immigrants vary across branches in relation to neighborhood needs and local demographics. For example, I find that branches in neighborhoods in which the foreign-born population increased by over twenty percent in the last five years were less likely to have English as a Second Language conversation groups than those in neighborhoods with slower growth in the local immigrant population. Second, I use interviews with branch librarians and participant observation to uncover the mechanisms responsible for variation in immigrant services across branches.

Through a focus on services and programs in public libraries, this research illustrates how one type of public institution designs and distributes programs to serve immigrants. As such, it contributes to scholarship on how local organizations provide access to resources for socioeconomically vulnerable populations. Finally, it sheds light on an informal, and often overlooked, component of the social safety net, the public library, and how it can supplement other more formal programs for immigrants at a time when immigrants are becoming more fearful of government services.

COASTAL COMMUNITY RECONSTRUCTION IN COMPRESSED TIME: FUNDING DISTRIBUTION IN PUERTO RICO'S SOCIALLY VULNERABLE COMMUNITIES AFTER HURRICANE MARIA

Abstract ID: 359

Individual Paper Submission

SANTIAGO, Luis [University of Central Florida] luis.santiago2@ucf.edu, presenting author

BARRETO, Maritza [University of Puerto Rico] maritza.barreto@upr.edu, co-author

DIAZ, Elizabeth [University of Puerto Rico] ediaz13@gmail.com, co-author

Hurricane Maria was the most powerful hurricane to affect Puerto Rico in more than a century. As a result, there was widespread housing and infrastructure damage, including the distribution and quality of natural infrastructure, especially in already vulnerable coastal regions. Infrastructure damage is also associated with the high death count resulting from this extreme weather event. Kishore et al. (2018) have estimated the death toll at 4,645, with one-third of the deaths attributed to delayed or interrupted health care, associated in turn to power and transportation infrastructure failures (i.e., road damage, transportation issues). Both public sector and citizen-led plans have proposed interventions for physical and natural infrastructure improvement in vulnerable coastal regions (Government of Puerto Rico, 2018; Resilient Puerto Rico Advisory Commission, 2018).

There is a history of inequitable funding outcomes among affected populations (Adams, 2013), partly due to compressed time frames imposed by hurricane relief efforts and regulatory frameworks associated with relief funding (Johnson & Olshansky, 2017). One relevant case that exemplifies inequitable funding patterns is post-Katrina New Orleans (Fussell, 2015). Have the initial post-hurricane monetary outlays in Puerto Rico been distributed in a socially equitable manner, or according to alternative criteria such as future expected financial returns based on economic development potential?

We used georeferenced data to measure the spatial association between monetary outlays in physical and natural infrastructure projects and community social vulnerability indicators in coastal regions. The paper examines spatial patterns in the distribution of infrastructure funding in coastal regions (mainly power and road networks, and natural infrastructure), mapping the location of funded projects, and measuring the gap between the location's social vulnerability indicators and corresponding funding levels. An integration of Geographic Information Systems (GIS), remote sensing and published data analysis were used to measure the spatial association between monetary outlays in physical and natural infrastructure projects and community social vulnerability indicators in coastal regions. ArcMap software was used to develop the necessary coastal geodatabase. Spatial investment and social vulnerability data was

converted to standardized indices for comparison. Preliminary data indicates initial outlays favor less socially vulnerable locations with economic development potential. Our research aims to identify patterns of inequity in infrastructure funds distribution at initial post-hurricane stages, to point out unsustainable practices that could be rectified in the long term, and inform policy on post-hurricane infrastructure reconstruction efforts.

NEW YORK CITY COMMUNITY BOARDS AND SUBSTANTIVE REPRESENTATION

Abstract ID: 387

Individual Paper Submission

BAE, Hyun Hye [Columbia University, GSAPP] hb2455@columbia.edu, presenting author

Although planning theorists have emphasized the importance of public participation in local decision making process since the second half of the twentieth century, several limitations have been pointed out when the participation theory has been applied to practice. One of the arguments is that resident representative bodies are incapable of representing their residents (Fagence 1977; Beatley, Brower, and Lucy 1994). John Stuart Mill states that “no matter the predisposition and benevolence of a representative towards the interests of those he represents he is rarely capable of an accurate degree of representation because each man knows his own interests more completely” (Fagence 1977). Theoretically, resident representative groups are created to act based on ideological views and preferences of the represented, where the act is known as substantive representation. In order to better represent their residents, the groups must continuously communicate with their residents and local government and advocate on the behalf of their residents. However, Abram (2000) argued that it is difficult for local representatives to speak for the represented as they face the dilemma of representatives; if they speak for narrow interests they will be accused of self-interest, while if they act in general views, such as opposing to major developments to conserve neighborhood, the state will take the views as ‘subversive’.

This study observes the level of substantive representation of New York City Community Boards, representative bodies composed of local residents. One of their major roles is to assess and address the needs and concerns of their neighborhoods. The mandated annual task of a Community Board is to communicate with its district residents to develop the Community District Statement of Needs for the next two fiscal years. The statement presents three most pressing issues and one main issue per policy

area. The statements from all Community Boards are to be carefully reviewed by the City officials and integrated to develop the Citywide Statement of Needs.

To observe the level of substantive representation in this process, this research conducted a resident survey of over 600 residents through a crowdsourcing platform known as Amazon Mechanical Turks and completed interviews with Community Board members in the summer and fall of 2018. Based on the needs statements, the survey asked residents to reflect on whether their neighborhood need supports in several policy areas and to choose three pressing issues about their neighborhoods. During the interviews, Community Board members were asked about the process of finding and developing the Statement of Needs, including the hardship and their personal opinions about their representation.

The research focused on finding answers to the following research questions: 1) how well do Statements of Needs describe the needs of residents? 2) which policy area shows higher similarities or dissimilarities? 3) what are the associated neighborhood and resident characteristics that make the difference among neighborhoods? 4) and, what are the differences among Community Board members that resulted in a low or relatively high level of substantive representation?

The research contributes to planning scholarship in several ways. By comparing the needs stated by the local representatives and the residents, the study results provide a better understanding about the general degree of substantive representation of local representative bodies. Comparing the policy areas and neighborhood characteristics associated with the level of representation identifies room for improvement in the official participatory system. Lastly, by speaking with actual Board members, the research points out the practical problems that Board members are facing in order to deliver the theoretically expected outcome of public participation.

GUO, YUTING [College of Architecture and Urban Planning, Tongji University] 1410896910@qq.com, presenting author

YU, YIFAN [College of Architecture and Urban Planning, Tongji University] 15316185773@163.com, co-author

Nowadays, China's overall aging situation is increasingly serious, the pension problem has aroused the concern of all sectors of society. There are three traditional pension modes in China: home-based pension, community pension and institutional pension. A long-term follow-up survey of the elderly in Shanghai (1998-2013) shows that "home-based care for the aged is always the intention of the majority of the elderly, and this trend remains unchanged even when the self-care ability declines. Over the past decade, more than 89% of the elderly have always chosen family as the "current place of care". And since 2012, the number of domestic residential development began to show a downward trend, entering a phase of slower growth. In this context, expanding the intrinsic value of existing residential areas and buildings is a potential development direction, and improving the living environment is a development trend that must be followed in the future. Therefore, it is of great significance to study how to adapt the existing residential environment to aging.

Since WHO launched the 《Global age-friendly Cities - A Guide》, many cities and countries have carried out various livability measures for the elderly, including the urban level and the community level. Many developed countries have issued relevant guidelines for local pension and formed a unified index system, such as America, Japan, Singapore and so on. China has also followed the international pace in this regard, and introduced various relevant standards. However, these standards and guidelines are only a guided-type policy document, and do not involve specific matters of age-friendly renovation to guide the subsequent community renovation. So, in this study, questionnaire survey, interview, empowerment and grounded theory were used, and self-care elderly people in a residential area of Changning District in Shanghai were selected as research samples. We tried to analyze the data of the survey results, and combined with the interview content, to understand the old people's views on the age-friendly existing residential reconstruction in Shanghai and find the elements they pay attention to. We will rank these elements, so as to form a list of age-friendly reconstruction, and finally form an evaluation system of age-friendly reconstruction of existing residential environment to guide the government and researchers to do it better in Shanghai and other cities in China in the future.

COMMUNITY ENGAGEMENT AND EMPOWERMENT: REMEMBERING & ENVISIONING GERMANTOWN AVENUE

Abstract ID: 417

Individual Paper Submission

MANDARANO, Lynn [Temple University] lynn.mandarano@temple.edu, presenting author

Community capacity building can take many forms from ad-hoc workshops to more formal training programs (Mandarano 2015). Regardless of form, these efforts share common goals from enhancing one or more community capitals, essential elements of a community's capacity to take collective action (Emory and Flora 2006). This paper presents the results of research of a community-engaged service learning project focused on enhancing residents' human capital relevant to the redevelopment of the neighborhood's commercial corridor. The Eastern North area of Philadelphia has experienced decades of disinvestment that left the neighborhood and its commercial corridor – Germantown Avenue – in a state of blight. However, residents now are struggling to defend their neighborhood from an influx of market rate development that followed the construction of an award winning LEED certified, mixed-use development in 2013 by Asociacion Puertorriquenos en Marcha, the local community development corporation. Unfortunately, most residents attending the local development review meetings do not share a collective memory of the corridor during its heyday and have limited local examples to draw upon to encourage developers to include first floor retail or other uses in development along Germantown Avenue.

The community engagement project embraced a humanistic approach to planning (Good et al 2017) and used several forms of storytelling to facilitate building a collective memory of place and capacity for envisioning a future. The engagement project, designed by seniors in a capstone community development course, was comprised of a series of activities sequenced to build residents knowledge of the past development along the commercial corridor, awareness of how the built environment impacts their lives, and vision for the future. The event started with students sharing stories about the history of iconic places and smaller businesses on the avenue using archival photos and posters as well as residents' stories of experiences on the avenue collected by video-recorded interviews. Residents then shared their memories of place on a storyline clothesline. To aid residents' understanding of how the built environment impacts their daily lives and of market leakage they mapped 'Where we go' frequently to shop for goods and services. The last station prompted participants to create another storyline clothesline highlighting businesses and services they would like to see on "Our Germantown Avenue". The use of several storytelling methods enabled residents not only to learn about the community's former assets and how the state of the corridor impacts their daily lives but also to learn from and connect with each other about the corridor's history and potential.

This project demonstrates the value of providing residents with ad hoc community building programs in the form of experiential learning and community engaged storytelling. Direct outcomes from the engagement process were discerned through interviews with community stakeholders conducted by the author after the conclusion of the capstone course. Outcomes include, for example, increased knowledge of the community's history and assets, improved sense of place, greater sense of a shared vision, and stronger neighborhood commitment. All of which are foundational elements of a community's capacity to organize, to act, and to affect change (Chaskin 2001).

CHANGES IN U.S. NEIGHBORHOOD-LEVEL INCOME SEGREGATION AND FACTORS ASSOCIATED WITH THESE SHIFTS, 1990-2010

Abstract ID: 432

Individual Paper Submission

WON, Jongho [University of California, Irvine] jonghw1@uci.edu, presenting author

Many studies of income segregation in the U.S. have explored the phenomenon based on regional-level indices which mask the local variations of segregation levels among subunits. This article, therefore, expands the literature by exploring the local dimension of income segregation among neighborhoods within U.S. metropolitan areas and by applying a political economy perspective. Using the data of census tracts, I calculate the local-level delta score, a local measure of income segregation, to explore the unique attributes and trajectories of each neighborhood from 1990 to 2010. In a six neighborhood typology based on the local-level delta score change, this article explores the longitudinal transitions of neighborhoods. Moreover, using regression analyses, I found that the existence of middle-aged housing is associated with neighborhood ascent in affluent-concentrated neighborhoods, while in poor-concentrated neighborhoods this type of housing is associated with neighborhood decline. These results indicate that affluent-concentrated neighborhoods enter the redevelopment stage earlier than poor-concentrated neighborhoods, promoting unequal redevelopment patterns and consequent neighborhood polarization. In addition, among other findings, this research shows homeownership is positively related to neighborhood ascent regardless of the neighborhood segregation status.

ENGAGING ANCHOR INSTITUTIONS TO ADVANCE LOCAL EQUITY GOALS

Abstract ID: 453
Individual Paper Submission

WINSTON, Francisca [LISC] fwinston@lisc.org, presenting author
GREENBERG, David [LISC] dgreenberg@lisc.org, co-author
VOLTOLINI, Patricia [LISC] pvoltolini@lisc.org, co-author

Investments in community development need to achieve a certain scale before they impact conditions at the neighborhood level (Pooley 2014). Unfortunately, federal funding for many community development programs has declined significantly. This has drawn policymakers to examine ways that other institutional partners can be engaged in community development, including “anchor institutions,” to make up for lost resources and to leverage their economic presence for community benefit. There is recent evidence that these partnerships can in fact be impactful at the neighborhood level (Ehlenz, 2018¹).

At the same time, anchor partnerships hold the potential for misaligned interests, including concerns that anchors will prioritize strategies that result in gentrification and displacement. Some authors have pointed to the need for on-the-ground community capacity, including political mobilization, to leverage community commitments from anchors and to implement community programs that advance equity-related priorities (Perry, Wiewel and Mendendez 2009).

Accordingly, this paper asks two related questions: 1) what factors facilitate productive engagement between community and anchor stakeholders to advance local equity objectives, 2) what are the impacts of intentionally-directed community revitalization strategies related to these partnerships.

To address these questions, the paper presents a mixed-methods case study of activity and community impacts in Minneapolis, Minnesota. Like many urban places in the 1990s, diverse neighborhoods in South Minneapolis experienced significant strains, including the highly publicized murder of a Honeywell employee in 1995. What followed was a sustained effort on the part of community organizations, the public and philanthropic sectors, and Twin Cities LISC to engage Allina, a health care organization, and other major corporations. Using an Adjusted Interrupted Time Series Analysis (see Galster, Temkin and Walker 2004), we examined home loan values in census tracts which received substantial community development investments, and interviewed long-time residents and community practitioners.

There is evidence that partnerships influenced investment activity at the broader community level: controlling for other factors, the levels and slopes of local home loan values in focal tracts reversed their decline to catch up with broader citywide trends. Qualitative findings emphasize that the active support of elected and appointed officials, general alignment and trust among high-capacity community development actors, and culturally-resonant organizing with diverse communities contributed to neighborhood outcomes.

This case adds to the literature on community mobilization for equitable neighborhood change, and in particular how to engage anchor institutions to advance local equity goals, so as to make partnerships productive over the longer term.

THE RISE AND FALL AND RISE OF CLEVELAND'S BARRIO

Abstract ID: 461

Individual Paper Submission

TIGHE, Rosie [Cleveland State University] j.l.tighe@csuohio.edu, presenting author

This work discusses the causes and consequences of white return to urban areas, and the many facets of displacement. Most discussions of displacement focus on the physical sense – people are forced to move out of rental units due to rent hikes, or even sell their property due to property tax increases. However, a large part of the pushback against gentrification is the loss of a sense of community and belonging that occurs when neighborhoods change. This can be called “cultural displacement” – the feeling that one no longer belongs in their neighborhood and that the essential character of the place you call home has changed in a way that you don't fit into anymore.

Coupled with cultural displacement is economic displacement. As reinvestment and revitalization occur, many long-standing small business may be displaced due to rent increases – corner stores, barber shops, restaurants, and clothing stores that used to cater to the older residents in a neighborhood are replaced by high-end coffee shops, boutiques, salons, and cafes. Often, these new restaurants are not only too expensive for low-income residents, they are not particularly inviting to them, either.

Focusing on the last 20 years on the West side of Cleveland, this chapter chronicles the continued displacement of Cleveland's largest Hispanic (predominately Puerto Rican) neighborhood in terms of physical, economic, and cultural displacement. This chapter presents the story of the dismantling of one of Cleveland's most unique and diverse neighborhoods – Little Puerto Rico– from the Ohio City area and how the community is trying to reconstitute itself in nearby Clark-Fulton. Relying on historical and archival materials as well as in-depth interviews and focus groups with current and previous residents of Little Puerto Rico, I analyze how the community has dealt with all three facets of gentrification – physical, economic, and cultural.

**WHERE DID HOMELESS FAMILIES LIVE BEFORE ENTERING THE SHELTER?
ANALYZING NEIGHBORHOOD CHARACTERISTICS AFFECTING THE RISK OF FAMILY
HOMELESSNESS IN SALT LAKE CITY, UTAH**

Abstract ID: 469

Individual Paper Submission

KIM, Keuntae [University of Utah] keuntae.kim@utah.edu, presenting author

GARCIA ZAMBRANA, Ivis [University of Utah] ivis.garcia@gmail.com, co-author

Although homelessness is not a permanent condition for most people, understanding the causal path of being homeless has been one of the key issues in various academic fields including urban planning. Some homelessness studies have been dedicated to identifying two major factors—individual factors such as gender, age, race, and physical barriers and structural factors such as employment, prior residential experience, and education (Culhane et al. 2007; Gould and Williams 2010; Rodriguez and Eidelman 2017). Nevertheless, only a few studies have been done to examine the relationship between the characteristics of the built environment and the risk of homelessness (Smith et al. 2005). Particularly, considering that homeless families still make up about one-third of the national homeless population in the 2017 Point-in-Time count, identifying the neighborhoods where homeless families lived before entering the shelter helps both policymakers and planners develop strategies for inclusive urban growth and policies for family homelessness prevention through targeted neighborhood development.

This study aims at identifying the neighborhoods that produce homeless families and analyzing characteristics of neighborhoods affecting an increase in the number of homeless families. To achieve the research goal, this study collects homeless individual data from the Road Home Homeless Management Information System (HMIS) database. The HMIS data used in this study cover detailed historical records of homeless individuals who had entered the Road Home shelter located in the downtown Salt Lake City between January 1, 2015, and December 31, 2017, and include the zip code information of where each homeless individual stayed before entering the Road Home shelter. From the HMIS data of 5,780 homeless individuals during the study period, 1,651 unique homeless households are identified by using the homeless family identification criteria. By combining the 2013-2017 American Community Survey (ACS) 5-year estimate data, this study traces the geographical origins of these homeless families and conducts geographically weighted regression models to understand characteristics of neighborhoods that produce homeless families.

Based on the homeless family count at the zip code level from the HMIS data and the 2013-2017 ACS 5-year data, this study first conducts exploratory data analysis of identifying Zip Code Tabulation Areas (ZCTA). As we expect, exploratory data analysis confirms the geographical concentration of neighborhoods where homeless families lived before entering the shelter. Among the 41 Zip Code Tabulation Areas in Salt Lake County, all the homeless families identified in the 2015-2017 HMIS data came from 19 different zip code areas. Choropleth maps of spatial distribution of homeless families show little geographical variation in terms of family composition or demographic backgrounds, but reveal some variations depending on the crime, education, jobs, and economic levels. To see how census characteristics of neighborhoods affect the number of homeless families within a zip code area, geographically weighted regression models are conducted, and the analysis results show that neighborhoods producing homeless families are neighborhoods that have a higher number of families below poverty level, foreign-born population, female-headed households, and families with younger children. The results also found that neighborhoods with a higher unemployment rate and the higher number of vacant housing units also tend to have homeless families within an area. Race and ethnicity

(Hispanic vs. non-Hispanic) also play a significant role in determining neighborhoods with homeless families, but as with previous studies, some structural factors such as education and housing unit structure are not associated with the number of homeless families. From these results, this study contributes to expanding the further discussion on ending family homelessness through more targeted neighborhood development strategies and planning policies for inclusive urban growth.

COMMUNITY CAPACITY BUILDING THROUGH A SELF-HELP PLANNING: LESSONS FROM SEATTLE, WASHINGTON

Abstract ID: 508

Individual Paper Submission

CHOI, Sunho [University of Washington] sunhoch@uw.edu, presenting author

CHAE, Hyein [University of Washington] hichae@uw.edu, primary author

Participation in urban design and planning has been evolved from community involvement to citizen-initiated design and planning (Hou 2011). With efforts to move beyond conventional participation rooted in deliberations and its basis on Habermasian ideal communications, community empowerment has been discussed as one of the alternative forms of participations (Rios 2008; Purcell 2009; Hou 2011). The idea of empowerment engages the process by which community members shape their lives through making their own decisions as well as build their capacities to manage their everyday living environments. Based on this perspective of community empowerment, this research aims to examine Neighborhood Matching Fund (NMF) program, a representative community building program in Seattle. Launched in 1989, NMF has served as a key resource for communities to implement self-help plans in which they figure out neighborhood issues, initiate and complete projects by themselves (Diers 2004).

This study investigates how NMF program has contributed to community capacity building based on the concept of community capacity that refers to “the interaction of human capital, organizational resources, and social capital existing within a given community that can be leveraged to solve collective problems and improve of maintain the well-being of a given community (Chaskin, 2001).” Analyzing the accumulated data of NMF projects for the past 30 years, this empirical study aims to shed light on the de

facto roles and impacts of NMF program on communities' self-managements of affairs in their everyday lives. For this purpose, this research mainly conducts a content analysis on a data-set of implemented NMF projects provided by Seattle's NMF database. Public documents such as application forms, final reports, and other administrative records, available in the Seattle Municipal Archive, are also used for a better understanding of each project.

This case study evaluates the process and outcomes of NMF program that has funded over 5,000 neighborhood-level projects from 1989 to 2018, focusing on three aspects: the resources each project utilized, leading organizations, and the benefits produced by each project. First, this study provides descriptive statistics about the budgets plans of funded projects concentrating on the community match to explore which community resources were accessed the most and the least and how the specific usages were linked to the project outcomes. Particularly among the four types of community match -- labor, professional services, materials, and cash -- the share of volunteer time indicates not only inputs of neighbors' labors but also the level of participation that local populations experience. Second, this research examines the implementing organizations of NMF projects, which aims to demonstrate NMF's effects on organizational development and collaboration. The analysis on their activities and networks evinces NMF's contribution to encouraging residents to aggregate and existing groups to continue to take actions for community improvements. Third, we categorize awarded projects according to their outcomes to illustrate types of assets built through NMF. This categorization allows us to investigate how those projects nurtured human and social capital so that communities autonomously solved their problems and enhanced wellbeing.

NMF program, utilizing community's human capital the most, has supported local organizations to be sustained around abiding desires of community building among neighbors by fostering a variety of community activities. For new organizations, the program has assisted their formations based on everyday issues with purposes to address ongoing problems in their neighborhoods. Moreover, the city government has simplified the application process and strengthened its assistance in designing a project to broaden an opportunity for citizen-initiated design and planning. These findings provide insight into policy implications for community empowerment and self-help planning

WHAT AFFECTS RESIDENTS' SATISFACTION IN NEIGHBORHOODS WITH DIFFERENT INCOME LEVELS? A STUDY USING THE IMPACT-ASYMMETRY ANALYSIS

WU, Xinyi [University of Minnesota] wuxx1088@umn.edu, presenting author

Residents living in different types of neighborhoods tend to have different needs and different levels of neighborhood satisfaction. Existing studies have examined the needs and satisfaction of residents in various types of neighborhoods. However, a limited number of studies has examined the determinants of neighborhood satisfaction in neighborhoods of differing income levels. This knowledge gap potentially reduces the effectiveness of neighborhood improvements, especially in lower-income neighborhoods, which tend to have lower social capital and higher degrees of fear of crime and racism. The social vulnerability of lower-income neighborhoods calls for the differentiation in neighborhood income levels when exploring the determinants of neighborhood satisfaction. This also helps address the equity issue in neighborhood planning.

In this paper, I aim to fill these this research gap and answer the following two research questions: What are the important neighborhood attributes to residents living in higher-income and lower-income neighborhoods? What are their patterns of influence? Based on the answers to these questions, I will provide implications for the planning and improvements in specific types of neighborhoods and discuss what these findings mean to equity planning for lower-income neighborhoods.

This study uses the data collected in the Neighborhood Environment, Daily Activities, and Well-Being Study. The survey data were collected in six neighborhoods in the Twin Cities metro area, containing both higher-income and lower-income neighborhoods. I will apply a machine learning algorithm, the gradient boosting decision tree, to answer the first research question and identify the attributes that are the most influential to residents in lower and higher-income level neighborhoods. Thereafter, I will employ the impact asymmetry analysis (IAA) to answer the second research question and illustrate the patterns of influence. Mikulić and Prebežac (2008) developed this method to better illustrate the asymmetric and non-linear relationships between service attributes and overall satisfaction. This method classifies service attributes into five categories based on their abilities to increase or decrease overall satisfaction. These five categories can be defined as follows:

- Dissatisfiers cause dissatisfaction when performing poorly, but do not lead to satisfaction when performing well.
- Frustrators are extreme cases of dissatisfiers.
- Satisfiers lead to satisfaction when performing well, but do not cause dissatisfaction when performing poorly.
- Delighters are extreme cases of satisfiers.
- Hybrids are attributes that can cause both satisfaction and dissatisfaction.

I plan to build an IAA plot where I identify improvement priorities for higher-income and lower-income neighborhoods. Every neighborhood attribute will be positioned in this plot based on its importance to neighborhood satisfaction and its classification in the five IAA categories. A typical IAA plot has two axes, where attributes are being positioned based on their overall impact on satisfaction (horizontal axis) and IAA factor classification (vertical axis). Based on the relative positions in the plot, I will be able to provide implications for planners regarding which attribute should be the focus for that specific type of neighborhood.

This paper will contribute to academic research and practice in several ways. First, it will introduce innovative methods to the field and adds to the toolkit of planning scholars. Furthermore, the result of

this paper will provide essential implications for planning practitioners regarding which attributes should be prioritized for a specific neighborhood with respect to their income level. More importantly, the findings of this paper will promote equity in neighborhood planning and benefit residents living in lower-income neighborhoods.

EFFECTIVENESS OF DEVELOPMENT CONTROL IN REGULATING ACTIVITIES OF REAL ESTATE DEVELOPMENT IN LAGOS STATE, NIGERIA

Abstract ID: 538

Individual Paper Submission

ODEKUNLE, Folasade [Bells University of Technology, Nigeria] jokotadeshade@gmail.com, presenting author

ADEDAMOLA, Wasiu [Bells University of Technology, Ota, Nigeria] jokotadeshade@gmail.com, co-author

The state of the physical environment, particularly the urban areas, is a major source of global concern in developing nations like Nigeria. Currently, Lagos State is experiencing great influx of people and uncontrollable traffic congestion as a metropolitan area. As a result of this, many unauthorized residential, commercial and industrial developments are prominent within and at the periphery of most cities in the State. The existence of such land development is often not in conformity with the Physical Development Plans (If any). Majority of real estate developers and people in Lagos fail to take cognizance of the effectiveness of development control measures and regulations. Development control is one of the measures applied by physical planning agencies, particularly, local planning authorities to ensure that developers do not deviate from approved building plans that often restrict them to their earmarked plots. Despite the importance of development control measures in physical environmental balancing, series of factors still hinder its effectiveness.

The research question of this study was, “How effective are the development control mechanisms in regulating the activities of real estate development in Lagos State with a view to achieve orderliness, and healthy aesthetic environment”? The study area was zoned into three using stratified sampling techniques: namely, Lagos Island, Victoria Island and Ikeja where many real estate developments have taken place. The research used both primary (questionnaire) and secondary data. Two sets of questionnaires were used, one was directed to real estate developers and the other one to planning authorities in each local government area of each zone. Among the 373 registered estate surveyors, valuers and developers registered in Lagos State, 100 (26.8%) participants selected from the three zones were sampled, with a total of 100 questionnaires randomly distributed in the three zone and three questionnaires for the three planning authorities. Some questions on development, causes, challenges, failures, successes and

prospects from these institutions were obtained. Other data collection method engaged includes taking of photographs. Data were analyzed using descriptive statistics and chi-square at $p < 0.05$, which was used to test the relationship of the problems of development control in the three zones.

Findings revealed that some of the developers were aware of development control measures but simply decided not to comply with them. Many of them failed to acquire proper approvals before commencing developments. Other notable findings include ignorance of developers on the application of relevant laws, compliance as a major challenge, change of use of property without permit and competition for lands. Other identified problems also included inadequate personnel, unguided and ineffective enforcement of building regulations, lack of organized public education on development control mechanism, lack of coordination between the various stakeholders of development control and lack of implementation of planning policies and regulations.

The study concludes that development control is a potent tool for city managers to ensure the continual growth and management of a city for orderliness, beauty, health and aesthetics. The researchers recommended that the urban planners should ensure that construction developers obtain all necessary planning approvals prior to any physical development or re-development,. Additional recommended measures include efficient monitoring and site inspections, public sensitization, strict enforcement of land use planning and developments laws.

CORONA PLAZA AND THE FIGHT FOR AN IMMIGRANT COMMUNITY'S LIVING ROOM

Abstract ID: 541

Individual Paper Submission

DEFILIPPIS, James [Rutgers, The State University of New Jersey] jdefilip@rutgers.edu, presenting author

GARCIA, Maria [Rutgers University] ma.garcia@rutgers.edu, co-author

For years, Corona Plaza sat as one-small block which was under-utilized. Its uses were primarily as a parking lot for trucks servicing the retail along the densely packed corridor of Roosevelt Avenue in the heart of central Queens. Beginning in the middle of the last decade, community groups, working collaboratively with the Queens Museum began to pressure the city's Department of Transportation to de-map the streets and open the plaza up to the community. The community organizers finally won in these efforts and the square was de-mapped in 2012. While this was happening, the Queens Museum was also partnering with a Cuban artist to set up a residency in a nearby house on Roosevelt Avenue. The house was known as the "Immigrant Movement International" (IMI) and it would be responsible for connecting

artists with programming in the Plaza and for other community events, activities, and organizing efforts. The Museum and IMI were not able to control the site, however, and the City's Economic Development Corporation (EDC) as well as other local government entities retained controlling interests in the Plaza. This local government control led to a purposeful "beautification" of the Plaza, and the loss of the relatively fluid, unstructured, and "un-beautified" plaza that the community had created.

The location of Corona Plaza is not incidental to its story. Corona's history is one that includes a sizeable and thriving black community (Gregory, 1998), which co-existed for a long time with a "white," and often 2nd and 3rd generation, immigrant community of Italians and Germans. That began to change in the latter part of the 20th century as the neighborhood became a destination for a growing number of immigrants from different countries in Latin America (Sanjek, 1998). This working class immigrant community has extremely high rates of housing overcrowding (DeFilippis, 2018), as well as a very limited number of public spaces. The neighborhood also sits along the Roosevelt Avenue/7-train (subway line), which has seen very substantial real estate development along its eastern edge in downtown Flushing and western edge in Long Island City and Sunnyside. The corridor, in short, is being squeezed from both directions, and control over public spaces along the corridor is inevitably inter-twined with the realities of these real estate pressures.

In this paper, we use the story of Corona Plaza to analyze the outcome of public private partnership models to design public space in New York City's neighborhoods and the model's impacts on the ability of immigrant communities to respond and organize given the real estate and political contexts. We look at how community consultation planning phases leverage communities' abilities to mobilize, organize and respond to pressures for government crafted participation; only to then position communities in the roles of users, consumers, and providers of entertainment for a public space that is managed, and ultimately controlled by others. By reflecting on the outcome of this planning model in Corona Plaza, we discuss the ways the it poses difficulties for communities to articulate oppositional politics to beautification; and how the model hinders non-market driven uses of spaces for cultural identity, expression, and other collective and public community practices. Finally we discuss lessons for and about communities that grapple with the struggle for community control of space in their neighborhoods. We do so by asking the basic questions of: who is the public, who is the private and how is the input of communities utilized in the processes of making public spaces?

UNDERSTANDING PERCEIVED AND IDEALIZED NEIGHBORHOOD LIVABILITY IN THE CONTEXT OF TRADE-OFFS BETWEEN HOUSING CHOICES AND TRANSPORTATION OPTIONS

Abstract ID: 571

Individual Paper Submission

YANG, Yizhao [University of Oregon] yizhao@uoregon.edu, presenting author

LEWIS, Rebecca [University of Oregon] rlewis9@uoregon.edu, co-author
PARKER, Robert [University of Oregon] rgp@uoregon.edu, co-author

In recent years, livability, a concept encompassing many domains of living environments across multiple spatial scales, has emerged as a frequently pursued regional vision and community goal that underpins various planning strategies aimed at expanding transportation options, promoting affordable housing, encouraging active land uses, and revitalizing urban centers (Herrman and Lewis, 2017; Harrell et al., 2014). Many scholars, practitioners, and policy-makers believe a place of greater livability supports a more active life style, a greater use of environmentally sustainable travel, and more social interactions, and thus see the convergence between urban livability and sustainability (Gough, 2015). Indeed, an interagency partnership among three Federal Agencies, US Environment Protection Agency, US Department of Transportation, and US Housing and Urban Development, labeled as “Partnership for Sustainable Communities” (PSC), actively engages with local communities to coordinate investments in and policies for equitable/affordable housing development and transportation-efficiency maximization, two major aspects defining a place’s livability (PSC).

While the consensus among many planners and designers appears strong about what should be the attributes or conditions for an ideal livable community or neighborhood, the specific factors that affect a place’s livability are shaped by the values/preference of its inhabitants, their perception of environmental qualities, and their unique, lived experiences in local environments. A growing body of empirical research has revealed that many livability-affecting factors are context-dependent and some of the factors are very much subjectively determined and culturally embedded (Okulicz-Kozaryn, 2013). Nevertheless, housing, transportation, and land use are the factors receiving the most and immediate attention in the planning field when it comes to create livable communities (US DOT).

This paper examines opinions about and perceptions of neighborhood livability from residents living in three communities in Oregon. Specifically, this paper aims to address how residents’ perceived neighborhood livability is affected by availability of transportation options and housing choices. Data were collected via a targeted survey within three MPOs in 2017 - Albany, Eugene-Springfield, and Medford – in Oregon. These MPOs represent a small, medium and large MPO within the state, exhibiting varying political and economic conditions. Information collected from the survey helps reveal respondents’ assessment of various neighborhood conditions, their attention paid to livability factors during their residential location decision-making process, and their visions for ideal neighborhood environments. GIS data are used to measure the physical characteristics of a neighborhood (e.g., land use mix, housing densities, transportation services, etc). Using logistic regression analysis, this paper reveals that limitation in housing choices due to the lack of housing-type diversity and unaffordability constrains residents’ neighborhood livability outcome and affects their visions of livable environments.

This paper makes contribution to the livability literature by understanding the perceived and envisioned neighborhood livability in the context of trade-offs between housing choices, transportation options, and service accessibility that housing consumers have to make during their location decision-making process. With the post-WWII (sub)urban environments in the US being the product of little coordination between housing and transportation planning, it is not unreasonable to speculate that residents, especially those residing in suburbs, have to face those trade-offs frequently. Such experiences could lead people to internalize certain residential environments, such as low-density, exclusive single-dwelling neighborhoods poorly connected with other land uses, as the only feasible livable options. Such internalization may have significant implications for implementing planning strategies aimed at retrofitting existing residential landscape via densification and public transportation investment.

DISCOURSE, POWER, UNEVEN ACCESS AND CONTROL: REPRODUCTION OF URBAN INJUSTICE IN BAYVIEW-HUNTERS POINT

Abstract ID: 572

Individual Paper Submission

SHIRAZI, M. Reza [UC Berkeley, Institute of Urban and Regional Development] shirazi@brookes.ac.uk, presenting author

In June 2018, San Francisco Board of Supervisors unanimously approved amendments to the Candlestick Point-Hunters Point Shipyard Development Plan, the 'biggest redevelopment project in San Francisco'. This project envisions a new, mixed-use community consisting of 12,000 new residential units and several thousand feet office, recreational, and commercial space. It is located at Bayview-Hunters Point, once a majority African-American neighborhood and one of the most disadvantaged areas in terms of economic and environmental injustice, unemployment, crime, and health disparity.

Hunters Point Shipyard was declared a 'Superfund Site' in 1989 due to high level of contamination resulted from toxic naval activities and radioactive experiments during the Second World War and afterwards. This site has been subject to massive remediation program supervised by the Navy and other regulatory agencies. Only seven months before approval of the revised plan, an EPA report revealed widespread deliberate data falsification and soil sampling manipulation conducted by Tetra Tech, the company in charge of decontamination. This turned the 'biggest redevelopment project in San Francisco' to the 'biggest case of eco-fraud in US history'.

In this paper I argue that the Shipyard project has been a site of 'discursive battle' between the Global (federal, state, and city regulatory agencies and authorities) and the Local (community members and activists). In order to exercise its 'persuasive power' (van Dijk, 1996) and speed-up the development project, the Global has operated a 'control apparatus' that advocates an uneven regime of 'access to discourse' to exclude community members from decision-making and clean-up procedure. The Local, in response, has used multiple methods of resistance and protest to dis-functionalize and distract the dominant control regime. Achievements have been promising: botched clean-up has gained national attention, remediation will be re-done and re-scheduled, and Tetra Tech faces federal and local legal challenges, to name but a few.

I utilize ‘critical discourse analysis’ method to study how social power, dominance, and inequality are enacted, resisted, and re-produced through argumentation and discourse (Fairclough et al., 2011). The paper concentrates on ‘control of, and access to, discourse’ as the main arena for the practice of power, domination, and injustice. Corpus of the analysis is multiple types of semiosis, including text, speech, reports, official documents, media coverage, and advertisements. I will examine a number of events in which the Global and the Local exercise and resist the ‘control apparatus’. This includes two ‘critical discursive moments’ in which the discursive battle intensified, namely the dismiss of community-based Restoration Advisory Board in 2009 and establishment of a closed ‘Tiger Team’ in 2017 to internally handle consequences of the botched clean-up. Then I will elaborate on two ‘critical discursive instruments’ by which the Local distracts the ‘control apparatus’ of the Global, including the role of ‘whistle-blowers’ in revealing the ‘culture of fraud’ exercised by Tetra Tech, and the utility of ‘Freedom of Information Act’ to access important unpublished documents and reports.

My research has following key findings. First, it empirically shows that power and dominance are essentially related to ‘control of discourse,’ and injustice is (re)produced by exercising an ‘uneven access to discourse’ (Reisigl and Wodak, 2016; van Dijk, 2008). Second, community members employ different instruments to distract the ‘control apparatus’ and get access to critical resources that challenges dominant regimes of truth. Third, the ‘control apparatus’ may be distracted, but quickly recovers itself to perpetuate delimiting decision-making circle in favour of the powerful and the capital.

This paper highlights significance of discourse and argumentation in planning (Marston, 2004) and their linkage to injustice, power, and truth, through providing first-hand evidence of an ongoing case of community resistance and the struggle for social justice.

PLANNING FOR DEMOLITION IN SHRINKING CITIES - EVALUATING NEIGHBORHOOD PLANNING IN YOUNGSTOWN, OHIO

Abstract ID: 612

Individual Paper Submission

GAO, Shuqi [Southeast University] shuqigao@mit.edu, presenting author
RYAN, Brent [Massachusetts Institute of Technology] bdr@mit.edu, co-author

In most cases, demolition is the widespread way to solve the problem of vacant, abandoned or foreclosed properties in shrinking cities. In the US, the public sector has two major ways it can conduct demolition: counties can use tax foreclosure to gain the title of a tax delinquent property and may subsequently execute demolition, while municipalities can use code enforcement to demolish properties with code violations without needing the title. However, either process of demolition lacks transparency and democracy. It begets local conflict in shrinking cities because the number of demolitions is limited due to the scarcity of public resources. Therefore, understanding the spatial distribution of demolition is crucial. It's necessary to have a demolition-oriented plans to serve as a guide for public action as well as to protect the process from for private interests. However, such plans didn't emerge until 2015 when Youngstown, Ohio, a small city but one widely known for its "smart-decline" comprehensive plan, released multiple Neighborhood Action Plans (NAPs), which gave specific suggestions for demolitions to be carried out by the city government and the county's land bank. But what were the outcomes of these plans' implementation? By adopting a parcel-based GIS method, this study examines seven NAP's suggested demolitions and compares them to the actual demolitions by employing two perspectives: conformance and performance. Additionally, semi-structured interviews were conducted to obtain the opinions of local informants on the implementation of the plans. Quantitative research findings reveal that the NAPs were much better implemented from a performance perspective than a conformance perspective, and that the land bank outperformed the local government from both perspectives, varying much less among neighborhoods when compared to the local government. Qualitative analysis uncovered four major potential explanations for the quantitative research findings: the fundamental difference between the local government's management of properties under code violation and the land bank only managing tax delinquent properties; the overlap between the local government and the land bank; political interference in plan implementation, especially by local government agents; and the changing targets of NAPs rooted in quarterly neighborhood meetings. Our findings indicate that the idea of planning for demolition is still viable and feasible to carry out; however, we offer several major suggestions for improving these plans in other shrinking cities in the future, including shortening the plan's effective duration or regularly updating plans, technically assisting civic engagement and randomizing representatives, guiding neighborhood-level plans with a city-wide plan, and establishing an independent entity to partially takeover code enforcement.

MAKING A PLEASANT STREET: THE EVALUATION ON THE OPEN STREETS EVENT OF PEACHTREE STREET, ATLANTA USING TWITTER DATA

Abstract ID: 632

Open Streets are programs that temporarily open city streets to people by closing them to automobiles, which is regarded as an important approach of Tactical Urbanism (Open Streets Project, 2019). ‘Atlanta Streets Alive’ is one of the influential Open Streets events in Atlanta, GA for years. Peachtree Street, a major street of the city, has been involved in the event many times. Using Peachtree Street as an example, we explore Open Streets programs through mass Twitter data to understand: (1) whether the Open Streets strategy has improved the quality of the streets; (2) what the determinants of the improvements are if any. Overall, we question what key factors are making the street a pleasant place for people.

This study is based on a theoretical framework of New Urbanism, which has discussed various factors of making a good street (Robert & Langdon, 2003). Although the characteristics and factors of a good street have been explored by previous research, little is done to link the planning efforts for city streets with the unstructured mass data of social media. Studies of detecting people’s emotion for project evaluation through qualitative research and crowdsourced data have offered an approach to address our research questions (Helen et al., 2018; Sagl et al., 2015). In this study, we take a closer look at a specific Open Streets program and examine the mechanism of its effect in the time and space dimension.

We define ‘pleasant’ through sentiment analysis of people’s tweets. We collected 98,843 pieces of twitter data about Peachtree Street over the past seven years, during which the Open Streets event has been held for many times. To evaluate the performance of Open Streets on Peachtree Street over time, we conduct a semantic analysis to examine the changing attitudes of people who tweeted about Peachtree Street; by extracting keywords in people’s tweets, we investigate what the key factors people care. Furthermore, we dive into the detailed history of the Open Streets event in Atlanta, especially on Peachtree Street, about both the event itself and the neighborhoods and streets involved and interacted with the event. Based on the analysis in time and space dimensions, we map diverse activities organized during the event over the years. We track the changes in the numbers, sizes, and locations of those activities, the funding sources of the events, and the planning of the activities (e.g., the length of streets, the duration, and the number of people involved). In addition, we track the transformation of neighborhood and streets including the greening area, public facility, number of commercials, crime rate, the density of buildings and population, and so forth. By combining the document analysis on the event history and the text analysis on the Twitter data, we illustrate the mechanism of people’s attitudes and identify the key factors of making a pleasant street.

The results of this study reveal a fluctuation and polarization of the attitudes towards the Open Streets event and Peachtree Street in the first three years. After a few years of excitement and criticism, people became indifferent and neutral towards the event, as the sentimental curve tended to be plain. Further, negative attitudes become stable in the following years. The attitudinal trend provides insights into how to organize good Open Streets events and how to benefit the local through the events. We also discuss the policy implications regarding the infrastructure, land use, walkability, and other factors interacted with the event, which may be of use to make a pleasant street in a city.

REMAKING INDUSTRIAL SPACE INTO FINANCIAL ASSETS AND ITS IMPLICATIONS FOR PLANNING AND URBAN FABRIC IN THE CITY OF CHICAGO IN THE POST-2008 PERIOD

Abstract ID: 664

Individual Paper Submission

KIM, Youngjun [University of Illinois at Chicago] youngjunkim84@gmail.com, presenting author

The recent global financial crisis (GFC) in 2007-08 has gained scholarly attention to the intensification of the entanglement between financial markets and the urban built environment. Despite the potential impacts on planning and urban fabric under the growing importance of the finance capital over property markets, less attention has been paid to how the logics of finance capital shape urban redevelopment projects through influencing planning practice and instruments as standardizing development projects and circulating the standards which conform to financial investor's expectation.

In this study, the role of financial investors and property developers are analyzed through a case study of redevelopment projects on the formerly industrial space in the city of Chicago (West Loop and Kinzie industrial corridor). The analysis of planning practices including negotiations over physical planning (including urban design, historic preservation and land use regulation), and economic development issues between planners and developers – throughout property development and spatial transformation of the industrial areas – identifies the titled power relations between investor's expectations and a government's ability to implement an agenda that potentially departs from the expectations of financial investors; and the implication as reshaping goals and strategies of planning practices over manufacturing economy and space towards creating new norms and standards that accommodate such development projects which met standards and expectations of financial investors. Thus, given the growing interests of institutional investors in the formerly industrial used property and space as a new asset class in the post-GFC era, the study reflects not only conventional downtown redevelopment but also industrial redevelopment as the outcome of power relations that initiate in the circulation of investors' standards and expectations.

In this paper, I provide a preliminary exploration and analysis of the recent industrial property redevelopment and the process of rescaling its template from property level to district level by employing (1) archives of local news letters, planning documents, and documents and marketing materials including project profiles produced by property capitalists (i.e., investor, developer, and asset manager) and (2) in-depth, semi-structured interviews with key actor groups (i.e., investor, developer, fund manager, loan officer, planner, architect) involved with negotiating and implementing both urban redevelopment projects and the planning instruments in the recent transformation of the West Loop area. The analysis will include identifying development templates for a formerly industrial-used property over time and how the templates are created and reshaped by the negotiations and interactions between planners and developers; and how these templates and standards affect not only planning practice but also development practice and industry itself.

MASUDA, Kanako [University of California, Los Angeles] k.u.masuda2011@gmail.com, co-author

Prior to the massive injection of Japanese capital into Los Angeles' real estate economy in the 1980s, early Japanese investors sought to involve themselves in comprehensive neighborhood redevelopment in Little Tokyo. A retrospective literature sought a deeper understanding of this pivotal moment in the planning history of Downtown Los Angeles (Soja, Morales, & Wolff, 1983; Davis, 1996; Kurashige, 2002; Suga, 2004; Davis, 2005). While this cogent body of work documents the contestation of Nikkei communities to early instances of outside investment in neighborhood redevelopment, few studies have examined the facilitative role that Japanese Americans also played.

In the present paper, we make three related arguments: (1) that Little Tokyo Nikkei and Japanese investors indeed 'called' to each other in various ways during the 1960s and 70s, leveraging shared interests in comprehensive community development, and thereby complicating commonplace narratives, which, as others have pointed out, tend to pit Japanese Americans against Japanese corporations (Suga, 2004); (2) that kinship and cultural ties were meaningful drivers of Kajima Corporation's early extraterritorial endeavours in Little Tokyo, specifically the Kajima Building in 1964 and the New Otani Hotel in 1977; and (3) that redevelopment policy facilitated the movement of transnational capital by 'scaling up' development.

We utilize Japanese and English primary sources from community and corporate organizations, in order to tell a fulsome story of global community development. In doing so, this research advances an understanding of community action and diasporic relations in state-led neighborhood planning, as well as the spatial consequences of these dynamics.

MEOWING AT A RINO? HOW SANTA FE’S SUBURBAN, IMMERSIVE ARTS ORGANIZATION -- MEOW WOLF -- IS EXPANDING INTO THE URBAN ARENA

Abstract ID: 704

Individual Paper Submission

KEMPER, Rebecca [Ohio State University] rebeccafkemperlarrimer@gmail.com, presenting author
MEYER, Justin [COSI] justinmeyer553@googlemail.com, co-author

Meow Wolf, an immersive arts start-up in Santa Fe’s suburban outskirts, represents a striking departure from the city’s established identity as a traditional, Southwestern arts and crafts hub (NPR, 2018; Owens, 2019). An innovative response to cultural preference changes of Millennial and Gen-Z cohorts, Meow Wolf has ostensibly built a successful arts business model with plans to expand into Denver’s RiNo arts district (Abraham & Harrington, 2015; Fenich et al, 2014; Nechvatal, 2009; Solomon, 2018).

Meow Wolf’s financial success has extended its marketplace reach into more competitive creative urban contexts. Meow Wolf has accepted Denver’s challenge to support the city’s local creatives within its development plans. In response, Meow Wolf produced the, “Denver Social Responsibility Visioning Plan” for its organizational expansion (Garcia, 2018). However, creative city planning requires a balanced integration between two conflicting scales, that of protecting an area’s authentic, local culture and promoting global standing (Scott, 2006). This research is interested in how an arts organization can expand into a different operational context while accurately aligning its development vision to the localized, planning needs of an established creative district. We conducted a document analysis of Meow Wolf’s Denver expansion plan to evaluate how its vision’s scale aligns with nine identified creative city policy rationales and their respective global/local implementation practices (Evans, 2009; Simatei, 2002). Plans were scored one point for having an identified policy rationale practice, and two points for having a policy rationale practice and an associated implementation strategy -- in keeping with established planning evaluative methods (Conroy & Jun, 2018). Here we compared the plan’s localized mission with its score along these policy rationale practices. While we found significant alignment between the vision’s stated mission and the plan itself, we also discovered many missed opportunities for a more holistic, locally-scaled creative development initiative. As privatization continues within urban creative city placemaking, understanding the alignment of for-profit development activities to a city’s localized, creative economic needs is critical to guiding future decision-making and managing sector growth.

NEIGHBORHOOD SATISFACTION AMONG MOBILE HOME DWELLERS: A COMPARISON WITH OTHER HOUSING AND COMMUNITY TYPES

Abstract ID: 743

Individual Paper Submission

LI, Yanmei [Florida Atlantic University] yli22@fau.edu, presenting author

As a viable option of affordable housing, mobile homes and mobile home parks play important roles in the U.S. housing markets and communities. Based on the U.S. Census Bureau, about 6.2% of the housing units were mobile homes, housing 5.6% of the population in 2016. However, studies on mobile homes, especially among planning scholars, are scanty. A few studies, notably led by Gregory Pierce, have explored water access deficiency of mobile home parks (Pierce & Jimenez, 2015) and how mobile homes in Los Angeles have been “improperly zoned, spatially-marginalized, and poorly-served” (Pierce, Gabbe, & Gonzales, 2018). Mobile home living in the U.S. is also associated with the stigma of “trailer” living (Kusenbach, 2009), even though mobile homes are viewed by some immigrants in Florida as a “symbolic marker of upward social mobility and personal success” (Kusenbach, 2017). All the negative images and realities associated with mobile homes and mobile home parks may affect the residents’ perception of and satisfaction with their housing and neighborhoods. An analysis of neighborhood satisfaction by housing types among 305 residents in North Carolina in the 1980s found that there are different factors, which were mostly not captured by the study, determining neighborhood satisfaction among mobile home owners, compared to conventional homeowners and apartment dwellers (Gruber & Shelton, 1987).

To further understand housing and neighborhood attributes and satisfaction of mobile home dwellers, this study uses the 2013 American Housing Survey (AHS) data to compare factors determining neighborhood satisfaction of residents by housing and neighborhood types. Standalone mobile home dwellers, residents in mobile home parks, single-family dwellers, and multi-family dwellers will be the primary types of residents and communities. Household characteristics, housing attributes, and neighborhood attributes will be the control variables when exploring the impact of housing and neighborhood types on residential satisfaction. Descriptive statistics and an Analysis of Variance (ANOVA) will be used to explore and compare satisfaction, household, housing, and neighborhood attributes among these housing and neighborhood types. Sets of Ordinal Logistic Regression models for all valid observations by housing and neighborhood types, and for observations within the income range of mobile home dwellers, will conclude the multivariate analysis of the study.

Preliminary results indicate that about 3.8% of the housing units in the AHS dataset were identified as mobile homes, and mobile home dwellers were statistically less satisfied with their neighborhoods, when compared with other types of housing and neighborhoods. The ANOVA analysis indicates significant between group differences in satisfaction. When exploring specific satisfaction items, they were less satisfied with police protection. When only looking at the mobile home dwellers using a stepwise Ordinal Logistic Regression model the study found that older residents, and/or rural residents tend to be more satisfied with their neighborhoods. Residents with a college degree and/or white residents tend to be less satisfied with their mobile home neighborhoods. For other types of housing and neighborhoods, positive neighborhood amenities, such as waterbodies, open space, etc., and income are also significantly related to neighborhood satisfaction. Among all housing and neighborhood types, when there are problems in the neighborhood, such as trash pileups, roads needing repairs, and/or abandoned housing nearby, residents tend to be less satisfied. When residents are more satisfied with police protection they tend to be more satisfied with their neighborhoods.

This research will help planners understand more about mobile homes and their occupants, and propose the best strategies to preserve these homes and to promote the quality of life of mobile home dwellers. Although planning strategies will not be able to directly intervene with cognitive perceptions, improving the physical environment of neighborhoods will likely benefit all residents in a neighborhood.

THE NEIGHBORHOOD DYNAMICS OF IMMIGRANT INTEGRATION

Abstract ID: 764

Individual Paper Submission

NEMETH, Jeremy [University of Colorado Denver] jeremy.nemeth@ucdenver.edu, presenting author
BURCIAGA, Edeline [University of Colorado Denver] edeline.burciaga@ucdenver.edu, co-author
RIGOLON, Alessandro [University of Illinois at Urbana-Champaign] alessandro.rigolon@gmail.com, co-author

In this study, we investigate the role urban planners can play in building pathways for immigrant integration. We define immigrant integration as the dynamic, two-way process in which immigrants and their receiving society work together to create secure, vibrant, and cohesive communities. Current research in this area suffers from two major gaps. First, integration in a receiving society is typically

measured using variables such as economic incorporation, language acquisition, or educational attainment (Portes and Rumbaut, 2014). Second, the field has not seriously considered the role of the built environment in creating a sense of belonging for immigrants. We address these gaps by asking if and how the spatial qualities of neighborhoods can contribute to a greater sense of inclusion for first-generation immigrants. We move beyond traditional measures of immigrant integration to specifically examine “sense of belonging,” or an immigrant’s perception of inclusion.

We conduct more than 300 surveys in neighborhoods around the Denver metro area, which we chose for three reasons. First, it includes a well-defined central city and suburban edges, both of which have attracted immigrants in recent years. Second, Denver is a re-emergent immigrant gateway that has experienced rapid immigrant growth in the last 30 years (Singer, 2015). Third, the Denver area is considered a moderately-supportive political climate for immigrants, one with a welcoming central city and more politically conservative suburbs (Burciaga & Martinez, 2017; Mollenkopf & Pastor, 2016). Within the Denver metro area, we selected neighborhoods purposively to allow for significant variations in built environments.

To examine associations between immigrants’ integration and the built environment, we analyze the physical qualities of the neighborhoods in which survey participants live, such as residential density, walkability, transit access, small businesses, and public spaces. We use spatially-adjusted multivariate regressions to assess associations between respondents’ experiences of belonging and integration (dependent variables) and the built environment qualities of their neighborhoods described above (independent variables). We are particularly interested in whether residential density and distance from downtown (e.g., urban core, urban edge, suburban) impact experiences of integration for immigrants. We control for potentially confounding variables such as education levels, duration of stay in the U.S., and legal citizenship status in order to focus specifically on the impact of the built environment on perceptions of belonging.

Our initial findings indicate that, for one, first-generation immigrants who live in low-density suburban neighborhoods with high property values and lower shares of co-ethnic residents in fact feel more welcome, integrated, and less-discriminated against than residents of high-density, immigrant-heavy neighborhoods in the urban core. Specifically, living in neighborhoods with high shares of single-family homes is strongly associated with sense of belonging in the U.S. ($B = 0.644$, $p < 0.01$). This might suggest that immigrants tend to feel more “at home” when they live in the suburban neighborhoods that represent a vision of the American Dream for so many, rather the traditional urban ethnic enclave.

This study contributes to an emerging body of literature and policy in a number of ways. First, it introduces a key spatial-analytical construct for immigration scholars that can help tease out the relationship between the built environment and immigrant integration (Németh, forthcoming). Second, it recognizes the important role that planners and designers can play in building more inclusive and integrative spaces for underserved populations. Third, it helps nonprofits, policymakers, and other state actors advocate for built environment improvements in existing and potential arrival neighborhoods. And finally, it can benefit the daily lives of immigrants in the Denver metro area and beyond by showing the powerful ways that “place matters” for immigrant integration.

COMPARING FORMAL AND INFORMAL APPROACHES TO COMMUNITY WEALTH BUILDING: A COMPARATIVE ANALYSIS OF RICHMOND, VA, AND NORRISTOWN, PA

Abstract ID: 825

Individual Paper Submission

SWEET, Elizabeth L. [Temple University] elsweet1@gmail.com, presenting author

HARPER-ANDERSON, Elsie [Virginia Commonwealth University] elharperande@vcu.edu, co-author

Community wealth building (CWB) has become a popular strategy to combat poverty and ever-widening wealth gaps, which have made poor communities vulnerable to violence, homelessness, joblessness, sickness, and generally diminished prospects for well-being. Increased engagement in CWB has resulted in tremendous variation in specific strategies and tools used to achieve its goals ranging from housing cooperatives and worker-owned businesses to land trusts, community gardens and many things in between. Some cities created formal CWB initiatives and institutions, others developed organic and grassroots approaches. For example, Richmond was the first city in the nation to create an Office of Community Wealth Building (OCWB), as an official part of city government. Other cities have since followed. Additionally, NGOs and grassroots groups have supported informal CWB projects including worker cooperatives, and strategies such as community gardens for food production, savings clubs, and healing programs. Formal and informal approaches each have advantages and disadvantages. In this paper, we explore two cases: one in Richmond, VA and one in Norristown PA where a group of mostly undocumented immigrants developed a multi-pronged CWB approach.

Four research questions drive this study: 1)What is the nature and structure of both formal and informal CWB initiatives? 2)What are the benefits and challenges of each? 3)What are the outcomes of each? 4) What are the ways planners can support and engage with both formal and informal CWB projects? Our mixed-methods used to address the research questions included stakeholder interviews, participant observations, and archival research. The 44 interviews (19 Norristown, 25 Richmond) conducted were transcribed and coded for key themes in each site and across cases. In each case, one of the authors was a participant observer in a key organization central to the CWB effort. In Richmond, one author serves on an advisory board for the OCWB. In Norristown, one author serves as a collaborator with the Coalición Fortaleza Latina. Each attended relevant meetings and events permitting them to observe the evolution of each project. In addition, archival research was used in each case to understand the CWB initiative in its unique local political and economic context. Both researchers reviewed codes for each case to identify similarities and differences allowing for both individual analysis and cross-case analysis.

Results suggest there are advantages and disadvantages to each approach. While the codification of CWB as part of local government provided funding stability, visibility and vast opportunities for collaboration

with both governmental agencies (such as workforce development and economic development) and non-governmental agencies, being situated in government mired the Richmond OCWB in politics and bound it to inflexible bureaucratic processes. In the case of Norristown, the organic nature of the initiative allowed for a wide variety of traditional and nontraditional activities including urban farming, alternative healthcare, a housing cooperative, skills development workshops, and political advocacy. At the same time, the patchwork of funding and volunteer supports produced uneven and unreliable results.

In their quest to create livable, sustainable places, planners are confronted daily with the poverty and uneven distribution of wealth which results in housing insecurity, food insecurity, joblessness, violence, and health crisis. The CWB approach aims to address these complex issues by weaving together strategies to build an economic and social foundation upon which individual and community wealth can grow. This work helps planners and policymakers evaluate various models of CWB so that they can help evaluate the best choice for communities.

CREATING ECONOMICALLY DIVERSE AND INCLUSIVE LIVABLE CITIES: A PRAGMATIST PLANNING PERSPECTIVE

Abstract ID: 867

Individual Paper Submission

WOODS, David [NYU] dwoods@stamfordct.gov, presenting author

Some key elements of livable cities that are closely related to their economic diverse citizens are: housing or shelter, transportation, a sustainable and aesthetically embracing urban environment, and adequate incomes to support stable, dignified, diverse, creative, and socially engaged lives. Creating such cities requires democratic citizen participation in visioning, comprehensive planning, development of regulations, planning processes of approving plans for housing and commercial development, and the design of economic plans for job creation, and small business development. However, these citizen participation processes must be guided by a widely shared value of democratic social equity, including some version of “a right to the city,” as well as a awareness of undressed inequities in the cities and its nations earlier history. Moreover, it must incorporate a realistic understanding of the laws and practical limits that must be reflected in any phase of a feasible and desirable planning process. In contemporary

American cities, this pragmatist model of planning faces two major kinds of challenges: both from neo-liberal models of planning that often lead to gentrification and exclusion of those who can not afford market rate housing, and from features of the current built environment, the transportation grid, and the livable income situation. Because of the convergance of these challenges, many American citizens and aspiring immigrants face a cascade of losses: first their housing, then their neighborhood network, then their jobs, and then their self esteem as people who have a rightful place in the city. This paper will show that these obstacles are real, why they must be overcome, and how planning strategies in some American cities are rising to these challenges.

USING RAPID ETHNOGRAPHY TO UNPACK PERFORMANCES OF AUTHENTIC COMMUNITY: AN ART FESTIVAL CASE FROM VICTORIA, BRITISH COLUMBIA

Abstract ID: 888

Individual Paper Submission

TATE, Laura [Eastern Washington University] laura@lauratate.ca, presenting author

This article builds on recent literature which asks our discipline to better discuss and share qualitative methodologies in a more consistent manner (Du Toit et al, 2017). It focuses on exploratory research to unpack the performance of authentic community as a construct, through a an arts event case study in Victoria, British Columbia, Canada. In particular, it makes use of techniques associated with rapid ethnography, as a means of circumventing obstacles which might otherwise preclude the research. Rapid ethnography is used in other disciplines, and may hold promise for planning research—particularly in those instances where resource and time constraints pose barriers. Given the event's institutional affiliation, and in order to ensure a non-hierarchical and collaborative approach, the research had to unfold over a relatively short window of time. It also required distinct strategies to respect the needs of different stakeholders.

Authenticity is a broad and often contested construct with a range of potential meanings and applications. It can be moral (Bendix, 1997:7), driving people forward to take appropriate action. It can be a means of conveying individual and cultural identity (Brown-Saracino, 2009; Zukin, 2010:3). It can most certainly be normative, or prescriptive, both individually and in the context of making choices that may reshape material places and communities. The quest for the authentic has, in part, been fuelled by people seeking something other than uniformity of products, buildings, and spaces which can result when elite groups with global lifestyles use technology to quickly and easily replicate features associated with their own lifestyles (Augé, 1995; and Castells, 1996; see also Author.).

The arts event, known as the TD-Art Gallery Paint In, involves the display, creation, and sale of pieces made by local artists. It unfolds over roughly eight city blocks, all closed for the day. The 2018 version of this event involved 190 artists, and is roughly estimated to have accommodated somewhere between 30,000 and 35,000 members of the general public. The Paint In's locale, Victoria, is both a government town and a tourist town, benefitting from historic buildings, beautiful gardens, and its status as the capital city of British Columbia. Victoria is also a stop for Alaska-bound cruise ships, whose volume has been ever increasing (Duffy, 2018). It is a city that obtains a significant portion of its revenues from tourism. In this context, the Paint In is a locally exceptional summer event of its scale, due to its focus on residents of the city and broader region. Rather than being held in the city's downtown core, as with most other events that welcome a large proportion of tourists, the Paint In is held on Moss Street, in an inner suburban neighbourhood, and on a street which is predominantly residential.

The study's rapid ethnography surmounted some research obstacles, including the potential for qualitative research to be costly, labour- and time-intensive. The study illustrated three broad ways in which community authenticity was performed through this particular event, time and place. The event did so: by fostering inclusivity; by helping people build desired connections; and through boundary-blurring rituals (of the non-religious sort) which reduced the divide between artist and spectator. While study conclusions are not generalizable, by calling attention to certain practices, they can likely help to reinforce and adjust them in ways that could strengthen the event's ability to enhance perceptions and performances of authentic community. Through its focus on relationships between people, materials, and processes, the research also took an important step in helping to unpack the notion of authentic community.

GENTRIFICATION AND THE HOUSING STOCK CHANGE IN HARRIS COUNTY, TEXAS

Abstract ID: 892

Individual Paper Submission

PARK, Han John [Rice University] john.park@rice.edu, presenting author
SHELTON, Kyle [Rice University] kyle.k.shelton@rice.edu, co-author

The research explores how gentrification has affected residential housing stock in neighborhoods in Harris County, Texas. It shows how neighborhoods' residential stock has changed in response to

gentrification trends by exploring both new construction and demolition trends. The housing stock change is analyzed in several types of neighborhoods classified by both historic gentrification trends and the mix of new construction or demolition that occurred there. In addition to examining the housing stock, this research explores how gentrification has altered socio-demographic profiles of Harris County communities.

This research aims to connect an analysis of gentrification patterns with a change in the residential stock in the county. How has the status of the residential building stock changed in neighborhoods in high-turnover construction and demolition areas? What are the unique residential stock characteristics of the areas that have been experiencing or are vulnerable to gentrification? How are these changes associated with socio-demographic characteristics in such neighborhoods?

Gentrification is a signature issue in the county, and documenting residential changes in neighborhoods experiencing significant shifts can situate its impact. Within high-turnover neighborhoods, it analyzes specific housing structure changes (e.g., from a single family dominant residential area to a neighborhood with a number of multi-family complexes; from a regular multi-family residential area to an upscale multi-family neighborhood).

The work relies on Harris County Appraisal District annual public datasets from 2005 to 2017 and demographic, socioeconomic, and other information from the American Community Survey (ACS). This research aims to help city planners understand how neighborhood change is alerting the housing stock. The results provide profound insights regarding Houston's residential development patterns based on the finest parcel-level data over 13 years to comprehend how the gentrification has occurred in neighborhoods of the Houston area. The results also offer a detailed idea of what kinds of characteristics of neighborhoods are highly associated with active gentrification. As Houston has continuously gained population, this research will help city planners and residents have a better understanding of what demographic groups have been clustered and what types of residential units have been constructed and demolished in gentrified areas.

PIVOTAL MOMENTS IN COMMUNITY ENGAGEMENT STUDIOS: MÍSTICA, ENSEMBLE AWARENESS AND GROUP PROCESSES IN INFORMAL MONTERREY

Abstract ID: 895

Individual Paper Submission

WILSON, Patricia [The University of Texas at Austin] pwilson@mail.utexas.edu, presenting author

STAINES, Leon [The University of Texas at Austin] leon_staines@msn.com, co-author
STYCOS, Mary [The University of Texas at Austin] mary.stycos@gmail.com, co-author

In the informal community of La Campana in Monterrey, Mexico, a community's installation of a mere drainage pipe was a critical pivot. A pivot, commonly used in basketball, is a turn or rotation while maintaining one foot grounded. When applied to community engagement work, a pivot implies a key moment or turning point for students and/or community actors when there is remarkable movement towards a new path, perhaps generated by a surge in energy or revelatory experience. The drainage pipe installation, one of many other equally significant pivots from the Monterrey case, is an example of the type of productive processes emerging from a new wave of community-based participatory planning studios.

Planning studios have long provided opportunities for direct community engagement, presaging the current popularity of user-based design. Now planning studios are contributing to the next emerging frontier in community engagement: process design for awareness-based systems change (Scharmer, 2018). Awareness-based systems change is based on the premise that a system cannot change unless the awareness of the people in the system changes. In the case of the community-based planning studio, the participants in the system include not only the community actors and NGO but the students (and instructors) themselves.

Through a fine-grained analysis of a master's-level participatory planning studio in an informal settlement in Monterrey, Mexico, we aim to address the following issue: how to define and identify the subjective and experiential elements of process design for awareness-based systems change. Focusing directly on the relationship between the students, partner NGO, and the community actors, the systems change involves a shift in awareness of both the students, the NGO, and the community, and the overlapping relationships between all three. The implications for planning studios are paramount. No longer are we just the observers, researchers, trainers, service-providers, or even change agents: We are changed ourselves.

The paper identifies the key pivots or process inflections in each of the stages of the Monterrey studio: the pre-trip class preparations, the time working with the community and NGO on-site, and finally the self and group reflection and follow-up processes afterward. Special attention is given to the turning points or "pivots" throughout the process. Basing our in-depth case study in the new concepts of 'ensemble awareness' and 'mística' (Wilson 2019) our research will provide a framework that outlines the factors, patterns, and moments that, taken together, provide a productive and transformative process for awareness-based process design and enactment. This conceptual analysis based on self and group observation and reflection will illuminate what the system and individuals need in order to shift from being "service providers" to being catalysts and provokers of change. Participant interviews and written reflections illustrate the significance of the experience for the students' and community's own awareness of process, of self, and of the social field.

The findings are compared to the efforts of the World Health Organization (WHO) to provide awareness-based training in community engagement for health workers. The similarities and differences between the WHO framework (2018) and the Wilson framework (2019) are compared. The findings are related also to the emerging literature on generative social fields (Scharmer, Mette, et al, 2018). Additionally, of note is that our approaches and conclusions conflict with most mainstream literature regarding informality planning approaches in the Global South. Finally, the implications for planning practicum design and studio pedagogy are set forth, including but going well beyond relationship-building and group process skills.

CITIES, CHOICES, AND OUTCOMES: THE PROCESS AND RESULTS OF COMMUNITY DEVELOPMENT BLOCK GRANT PLANS AND INVESTMENTS

Abstract ID: 900

Individual Paper Submission

TONKOVICH, Marsha [Bloustein School, Rutgers University] marsha.tonkovich@comcast.net, presenting author

This paper will assess local community development planning and decision-making processes within the United States, including how community problems are determined and addressed under the Community Development Block Grant Program (CDBG). Each local CDBG grantee develops a three to five-year Consolidated Plan and an Annual Action Plan that describe how resources will be used. Within general program regulations, CDBG grantees have significant flexibility to select and fund activities that meet local needs and priorities. However, only a limited body of recent research has assessed local CDBG planning and investment decision-making processes and resulting outcomes across grantees nationwide. The research questions for this paper explore the connection between local governments, community needs, the CDBG investment planning process, and the results of this funding, and include:

- What types of processes are used to develop CDBG plans and investment approaches? What is the level of community and organizational engagement in defining needs and determining investments?
- What is the relationship of the planning and investment process to the reported level and type of CDBG outcomes?

For these research questions, the paper will assess cross-grantee planning and outcome differences/similarities based on: city population; geographic location/region; level of urbanization; CDBG funding level; sociodemographic characteristics; and economic status. This study will sample approximately 150 of the 1,200 CDBG city and county CDBG entitlement grantees, ensuring regional, grant size, population, and socioeconomic diversity within the sample. For the sampled grantees, the research will review the Consolidated and Annual Action Plans and develop a planning and decision-making typology based on the nature of local process tasks, actors/public engagement, and categories of planned CDBG activities. For each of these 150 jurisdictions, this planning information will be married with U.S. Census American Community Survey data on each city's economic and social demography. The research will then review the Consolidated Annual Performance and Evaluation Reports (CAPER) submitted by each grantee and accomplishment reports published by HUD. These outcome data will be compared to the planning information, assessing correlations and relationships between planning approaches, jurisdiction demographics, and reported program results. This analysis is intended to demonstrate whether and how the CDBG planning process and/or city socioeconomic

characteristics shape types and levels of reported program outcomes. The initial hypotheses include:

- The types of CDBG planning and investment processes are correlated to city socioeconomic characteristics, as well as region.
- Cities with more inclusive, thorough and transparent needs assessment and planning processes have relatively higher levels of CDBG outcomes.
- Cities with a clear connection between local needs, goals and investment decisions have relatively higher levels of CDBG outcomes.

Per the HUD National Accomplishment Reports, CDBG touches the lives of millions of Americans in cities nationwide every year, particularly including persons who are low to moderate income. Thus, it is vital to understand how grantees can make effective planning and investment decisions with this limited resource. This paper will expand our understanding of how cities approach CDBG decisions and the social and economic context of this planning. In addition, the paper makes the connection between these planning and investment choices and CDBG outcomes, a nexus that has rarely been studied to date. These results have relevance not only to community development scholars but also to federal, state and local practitioners.

GOING SLOW TO BUILD RESILIENCE: LEARNING FROM CHEONGSANDO AND OTHER CITTASLOW COMMUNITIES IN KOREA

Abstract ID: 910

Individual Paper Submission

KIM, Karl [University of Hawaii] karlk@hawaii.edu, presenting author
LEE, David [KAIST] david733@alum.mit.edu, co-author

CENTRAL THEME: Planning for Community Resilience. Much of Korea's rapid economic and social development has focused on urbanization, industrialization, and globalization. With growing prosperity and increased democratization, there have also been demands to better balance environmental quality, public health, cultural heritage, social welfare and development. These challenges are particularly apparent in rural areas where chronic stressors such as depopulation, lack of investment, and limited political capital have contributed to decline, exacerbating social inequities.

APPROACH: Using a combination of quantitative and qualitative data, interviews, and field investigations, we investigate a small, remote island community in South Jeolla province, part of Wando County, known as Cheongsando (Green Mountain Island). A focus on small islands provides unique opportunities to examine natural, physical, and social processes across time and space (Pelling and Uitto, J., 2011). Cheongsando was the first community in Asia in 2007 to be designated as a “slow city” by the international Cittaslow organization (<http://www.cittaslow.org/>). Initiated by mayors in Italy protesting globalization, with linkages to the slow food movement, Cittaslow emphasizes quality of life, heritage tourism, and healthy lifestyles (Pink and Lewis, 2014). There are now several hundred Cittaslow communities across the world. We study the Cittaslow designation process and trace its indicator-based implementation in Korea by first examining Cheongsando and then comparing it to other communities in Korea and elsewhere. We integrate analysis of quantitative and qualitative data from interviews and site visits.

FINDINGS: Of particular interest is the investment in planning, transportation infrastructure (Kim, Francis and Yamashita, 2018), sustainable economic activities, and the connections between food security, agriculture, and community resilience. This small community with a resident population has approximately 400,000 visitors annually, with many coming for special events such as the “Slow Walk Festival.”

RELEVANCE: Our analysis highlights the value of planning, the necessity of strategic investments, communications, and demonstrating the benefits and returns to the community. There are on-going challenges with managing growth (and success), sustaining progress and adapting to change. Our analysis centers on both the measurement and appropriate use of data and indicators of success and also the construction and meaning of resilience. Our research provides insights not just in terms of the Korean experience, but to other communities grappling with rapid change, economic development and going slow in the face of the “resilience imperative” (NRC, 2012).

REGENERATING AS A CREATIVE JUST CITY: JUST CITY AGENDAS AND ARTIST ENGAGEMENT IN SEOUL

CHOO, Soyoona [University of Southern California] soyoona@usc.edu, presenting author

Under a national government that emphasizes “ending deeply-rooted evils (chŏkp'ye ch'ŏngsan)” to become a “just country (chŏngŭiroun nara)”, and a city government that aims to shift from demolition-based, large-scaled urban redevelopment to a more humane, participatory, and incremental “urban regeneration (tosijaesaeng)”, how are socially engaged artists (Helguera 2011) in Seoul, South Korea self-reflecting and engaging themselves critically to imagine and actualize such change? Despite the visible role they play in calling out what values should lie behind urban development (Shin 2018), such artists are an under-recognized/researched group in the urban planning discipline. Seoul serves as intriguing case where what I call “just city agendas” for an equitable urban living are being actively sought at both grassroots and governmental levels, both with a significant artist presence. Hence, this research is guided by the overarching question on how Seoul could be an exemplar of a “creative just city” that combines ‘critically renewed’ creative city (Holub et al 2014) and just city values (Fainstein 2010), and in doing so, I seek why artists’ sensibilities, perspectives, and work matter for urban planning.

To conceptualize the cultural, social, and political production of urban Seoul’s just city agendas, I will be drawing from various disciplines to expand existing knowledge around ‘formalized’ participatory planning, cultural planning, etc. and thereby seek the social process of (re)constructing them. The study combines firsthand data (participant-observation and in-depth interviews), secondary data sources, and visual-spatial analysis of research sites in Seoul. The three categories of Seoul’s just city agenda will guide my research sites and interviewees. The sites will be selected from city urban regeneration projects with notable artist involvement, artist-led community organizations that engage or partner with city policies, and grassroots “solidarity activism” at neighborhoods with at-risk, non-artist evictees (in which I dub as “solidarity sites”). By delving into the artists’ individual experiences, socially engaged work, and interpretation of urban issues at these sites, I seek to answer the following research questions:

1. How do the artists define and view the role of justice and creativity in their work and in (equitable) urban development? How do they define and view themselves in their respective communities?
2. What drives an artist to be socially engaged in urban issues, and how do they develop their engagement methods?

I anticipate the research – considering both topic and site specificity – will contribute significantly to the discussion around the role of art and the artist in the city, especially how socially engaged artists can inform and enrich urban planning/community development practices. Furthermore, it will produce humanistic knowledge (Umemoto 2017) on the tensions and ‘growth pains’ behind the drive for a structural and culture change in a developed city.

MIGRATION AND MOBILITY IN THE NEIGHBORHOOD POVERTY TRAJECTORIES OF U.S. RESIDENTS

Abstract ID: 942

Individual Paper Submission

DAEPP, Madeleine [Massachusetts Institute of Technology] mdaepp@mit.edu, presenting author
GRAVES, Erin [Federal Reserve Bank of Boston] erin.m.graves@bos.frb.org, co-author
ARCAYA, Mariana [Massachusetts Institute of Technology] marcaya@mit.edu, co-author

Neighborhood poverty is associated with adverse health and socioeconomic outcomes (Chetty et al. 2016). Research from 1970-1990 suggests that residential moves are a key mechanism through which households reduce their neighborhood poverty exposures (Quillian 1999, 2003), but declining internal mobility rates (Molloy et al. 2011) and the increasing prevalence of concentrated poverty (Jargowsky 2013) may have impeded migration across neighborhoods of different poverty rates in the 2000s. The aim of this study is thus to characterize individuals’ trajectories across policy-relevant neighborhood poverty levels from 2003 to 2013 and to evaluate the durability of exits from high-poverty neighborhoods.

We link data from the decennial census and the American Community Survey with a novel, large-scale consumer credit database to estimate the neighborhood poverty rates experienced by U.S. residents. Our methodology is threefold. First, we apply sequence analysis to visualize individual neighborhood poverty trajectories annually from 2003 to 2013. Second, we construct transition probability matrices to calculate individuals’ probabilities of crossing policy-relevant poverty thresholds. We further disaggregate changes in poverty rates attributable to migration, moves across housing and labor market boundaries; mobility, moves within the same housing and labor market; and staying in place. Finally, we use survival analysis to estimate the probability that individuals who exit high-poverty neighborhoods will re-enter concentrated poverty within 5 years.

While the dominant experience for individuals in our data was one of gradual increases in neighborhood poverty rates, moving enabled individuals to reduce poverty exposures. People who left high-poverty neighborhoods through mobility were most likely (39.53%) to move to a mid-high poverty neighborhood (20-40% poverty rate); people who left through migration were most likely (39.51%) to move to a low-poverty neighborhood (<10% poverty rate). Moves out of concentrated poverty were long-lasting, with just an 18.9% probability that an individual who left concentrated poverty would return to another high-poverty neighborhood within five years. We conclude that moving may help individuals offset gradual contextual increases in neighborhood poverty.

Our use of a novel, large-scale administrative data set allows us unprecedented precision in our characterization of U.S. mobility, migration, and concentrated poverty over time. Our results contribute to growing evidence of a re-concentration of neighborhood poverty (Jargowsky 2013), while the continued importance of inter-regional moves for neighborhood attainment underscores a need to better understand the causes of declining internal migration in the U.S. (Molloy et al. 2011). Given the adverse effects of

exposures to concentrated neighborhood poverty, these trends may contribute to widening social and health inequalities.

BUILDING COMMUNITY KNOWLEDGE AND POWER IN GENTRIFYING NEIGHBORHOODS

Abstract ID: 959

Individual Paper Submission

MATSUOKA, Martha [Occidental College] matsuoka@oxy.edu, presenting author

Skyrocketing housing costs in the U.S. have fueled a new generation of research focused on gentrification, displacement, and neighborhood change, particularly how these urban processes impact low-income and working class individuals and households at the neighborhood level. While much of the literature focuses on use of secondary data, a growing body of community-engaged research on neighborhood change and displacement elevates the perspectives and strategies of impacted residents and community organizers (Themba-Nixon, Makani, Minkler, Meredith, and Freudenberg, Nicholas 2008; Slater 2006; McLean, Rankin, and Kamizaki 2015; Loukaitou-Sideris, Gonzalez, and Ong 2017; Annunziata and Rivas-Alonso 2018) .

This paper builds on this research and presents the method and findings of a community-based research project focused on neighborhood changes in northeast Los Angeles. The research involves a partnership between Occidental College and members of the Northeast LA Alliance, an organization committed to witnessing and documenting the changing socio-economic landscape of their community. Using a community-based research approach with mixed methods, the research examines parcel data from the Los Angeles County Assessor's office to analyze neighborhood level changes and identify parcels vulnerable to redevelopment. Driven by community-informed questions, methodology, and analysis, the research analyzed parcel level zoning, land use, ownership, and sales, and conducted visual analysis of building characteristics and use in order to assess current and potential changes at the neighborhood level. The research highlights the role of community knowledge and analysis in understanding changing neighborhood conditions and how such knowledge informs place-based community development and

leadership strategies that challenge traditional forms of knowledge production, influence local policies, and forge alternative planning and neighborhood development.

THE BROKEN LINK BETWEEN NEIGHBORHOOD AND LOCAL SCHOOL DIVERSITY: EVIDENCE FROM LOS ANGELES COUNTY

Abstract ID: 1032

Individual Paper Submission

COMANDON, Andre [UCLA Luskin School of Public Affairs] acomandon@ucla.edu, presenting author

Los Angeles schools are among the most segregated in the nation. Large parts of the region are socially and economically isolated. Inequality only seems to be going up. This is costing the region in economic terms and causing losses of opportunities for its inhabitants (Ong & González, 2019). To identify strategies to reverse these trends, I study neighborhoods and cities that are highly diverse.

This paper focuses on the neighborhood to school diversity link. The increasing number of ethno-racially diverse neighborhoods in regions like Los Angeles should translate to more diverse schools, which can have great dividends for the educational environment (Page, 2007). However, access to private, magnet, and charter schools undermine the link between home location and school. This has lessened the importance of the quality of local public schools as a factor in parents' choice about where to live and exacerbated the deteriorating quality of public schools in some districts (Bischoff & Tach, 2018).

Can policy and urban spatial structure mitigate this type of inequality? Los Angeles provides an ideal context in which to study this question. The region combines high levels of segregation, both residential and in schools (Orfield, Ee, Frankenberg, & Siegel-Hawley, 2016), and the largest number of highly diverse neighborhoods. It also makes large quantities of relevant data available to examine the influence of different types of neighborhood diversity on school diversity and performance.

The analysis uses elementary school attendance zones for Los Angeles County in 2002 and 2016. The countywide data-set includes both urban core and suburban cities and school districts (88 cities and 80 school districts). I use a panel-data statistical framework to relate changes in school composition and

performance against a set of diversity classifications. I conceptualize diversity to foreground racial inequality in access to the social and economic capital required to expand families' school choice. This means looking at the composition of the school-aged population, how neighborhoods are embedded within jurisdiction with wide resource disparities, and the socioeconomic trajectory of neighborhoods over time.

In Los Angeles, diverse school districts tend to reproduce inequalities through a process of residualization. High performing schools are more diverse in diverse districts, but because students with greater needs for institutional and classroom support outnumber those that can bolster educational quality, the number of diverse schools is automatically limited and only a small number of children have access. At the same time, the best performing school districts remain overwhelmingly segregated and exclusive thanks to the autonomy granted to school districts.

This study contributes to the study of segregation within a nested framework (i.e. neighborhoods within cities) that has become a key driver of spatial inequality (Trounstin, 2018). It also provides evidence for how different neighborhood trajectories, such as gentrification, affect local school. While diversification can lead to improvements, in financial resources for example, it is not enough to reverse the inequalities that persist in education. Supporting educational equity will require policies that can harness the benefits of residential diversity. The current trend seems to be doing the opposite, affording families choices that only deepen inequalities.

LOCAL ACTIVISM ONLINE AND IN THE BUILT ENVIRONMENT: ACTIVIST NETWORKS IN THE GENTRIFICATION DEBATE IN BOYLE HEIGHTS AND BEYOND

Abstract ID: 1054

Individual Paper Submission

HERNANDEZ, Ashley [University of California, Irvine] ashleych@uci.edu, presenting author

Boyle Heights is a historically working-class Latino neighborhood in Los Angeles where strong resistance to gentrification and a lack of affordable housing is present. The local landscape of social and political relationships continues to intensify due to growing housing insecurity and rising costs of living throughout the neighborhood. Long standing Boyle Heights residents and advocacy organizations fiercely engage in public debate with each other, local businesses, outsiders, and political elites. Collectively, residents and community-based organizations (CBOs) struggle to influence development plans in the

neighborhood, ensure an equitable distribution of resources, and expand affordable housing. One growing strategy involves insurgent planning (Miraftab 2009). This consists of a coalition of resource-poor activists and grassroots CBOs engaging the debate with direct, contentious tactics online and offline. They hold an anti-gentrification/anti-displacement perspective that directly targets gentrifiers and local capitalists, who are defined as local actors who are directly and indirectly implicated in processes of gentrification. Such local actors include certain businesses, political elites, professionalized non-profits, and local investors. Their underlying goals lie outside of traditional channels of local politics and the dominant frame of market driven urban development as they aggressively demand direct democracy in urban planning and community development. The political activities and networks of radical CBOs require a closer analysis to understand a growing perspective of this political landscape that challenges traditional channels of urban politics, notions of incorporation, conceptions of community, and visions of an urban future.

Resource-poor organizations are often interpreted as internally fragmented, unsustainable, and less influential compared to more professionalized organizations (Fitzgerald and Rodgers 2000). Yet, the anti-gentrification campaign created by grassroots activists and CBO networks in Boyle Heights has been successful in developing and sustaining a concrete understanding of who belongs to the community and whose rights to the city merit greater protection than others. Using a robust social media data set collected from Facebook and interviews from local activists from a coalition of organizations directly involved in the anti-gentrification and anti-displacement campaigns in Boyle Heights, this research will focus on the discursive processes involved in developing a collective identity (Wimmer 2013), sense of place (Martin 2003), and strategy to combat neighborhood change (Snow and Soule 2010). I hypothesize that such processes aid activists in interpreting the imminent threat of gentrification, constructing meaning around the threat through activist networks, and maintaining a sharply defined collective identity and sense of place in the city. My preliminary findings show that framing, narratives, and identity formation among groups in Boyle Heights and in other neighborhoods throughout the United States occur through activist interactions both online and through direct contact fostering inter-neighborhood activist networks. These networks appear to strengthen solidarities around structural conditions of gentrification while maintaining their unique place-based identities. Examining the tensions among CBOs and neighborhood institutions can provide important lessons on how urban phenomenon are interpreted, how political strategies are developed to combat neighborhood change, and how urban networks are fostered. These lessons have larger implications on the integration of marginalized voices in planning processes and civil society at large.

WEAVING IT TOGETHER: BRINGING COMMERCIAL AND RETAIL IN THE GENTRIFICATION AND DISPLACEMENT ANALYSIS FOR MARGINALIZED ASIAN IMMIGRANT COMMUNITIES

Abstract ID: 1056

Individual Paper Submission

SUNG, Seyoung [Toulon School of Urban Studies and Planning, Portland State University]
seyoung@pdx.edu, presenting author

Marginalized immigrant communities of color tend to become more perilous when their neighborhood gentrifies, because of their distinctive dynamics that are intertwined with economic, cultural, and social ties in the communities. Increased housing instability and job insecurity due to residential and commercial gentrification impose significant burdens on the very vulnerable in the communities. Often, “model minority” stereotyping for Asians in the United States leads the marginalized Asian immigrant communities to be less interested in the study of gentrification and displacement compared to other communities of color. The primary purpose of this study is to demonstrate disproportionate vulnerability to gentrification and displacement in marginalized Asian immigrant communities in transit-oriented neighborhoods in Los Angeles. Further, the research aims to suggest the new framework to examine gentrification and displacement risks comprehensively by incorporating commercial gentrification dimension into the existing indicators to capture neighborhood change.

The research questions are three-fold: how do the existing indicators of gentrification and displacement discern the risks and vulnerabilities in Asian immigrant communities in transit-oriented neighborhoods in Los Angeles? What particular vulnerability to residential and commercial gentrification exists in the communities? How does the new framework demonstrate gentrification and displacement risks in the communities?

First, the research examines whether the existing gentrification indicators by Urban Displacement Project (2015) work to capture the risks of gentrification and displacement in Asian immigrant communities in Los Angeles. Next, the research investigates the demographic, socio-economic, and housing changes in the communities for the last five years. Last, the research examines the trajectory of neighborhoods’ commercial activity in the communities with particular focuses on commercial rents, vacancies, and shifts in businesses from the last five years by utilizing CoStar, USPS Vacancy data, and NAICS code data. The data analysis will be represented as multiple sets of cross tabulations. In addition, the results will be mapped out in order to compare the results to the existing gentrification maps.

The findings of the research will enlighten a discussion of how to develop the existing gentrification indicators for a comprehensive understanding of neighborhood change dynamics by taking account commercial gentrification. Moreover, this study will contribute to better understand marginalized Asian immigrant communities and to bring more attention to those in the study of equity planning and gentrification study.

TRASH, TRASH, TRASH: COMMUNITY-DRIVEN SOLUTIONS TO A WEST BALTIMORE NEIGHBORHOOD'S TRASH ISSUE

Abstract ID: 1063

Individual Paper Submission

SANDERS, Tonya [Morgan State University] tonya.sanders@morgan.edu, presenting author
 GROVER, Raneitra [Morgan State University] ragro1@morgan.edu, co-author
 MISAGE, Kristen [Morgan State University] krmis2@morgan.edu, co-author
 LEVY, Theodore [Morgan State University] thlev1@morgan.edu, co-author

Franklin Square is a lower-income neighborhood in West Baltimore that is 94% African American. Take a walk through Franklin Square and one will find trash on the sidewalks, on the curbs, in the streets, in the alleyways, and on vacant lots. Franklin Square's trash problem is not from a singular source, which makes a solution to the problem and its ancillary affects more complicated. Trash in the alleyways may stem from evictions, illegal dumping, or debris from derelict buildings, but this is not the only source. Residents may improperly dispose of household trash, and passersby may litter food wrappers and remains. No matter how it arrives, the open-air trash in Franklin Square attracts rats and angers residents, creating negative health impacts.

This community-based participatory research (CBPR) project was an exploratory project based on community input that trash was a key priority for the neighborhood. The objectives were two-fold: (1) utilize the research process as a community engagement tool to bring awareness to the community about the impact of neighborhood trash on health, and (2) to develop with the community a tool that can be used to address the trash issue at the neighborhood level. It is believed that by motivating the community to address the issue, a corresponding improvement in health outcomes and general neighborhood aesthetics can be achieved.

The research utilized a mixed methodology. The first phase used local community members to recruit 3 focus groups (2 in-person and 1 telephone) to assess residents' perception of the trash problem and how it should be addressed. Utilizing Atlas Ti qualitative software, themes were extracted. The second phase made use of the responses from the focus groups to develop a survey questionnaire that was mailed to a stratified random sample of 500 homes in the neighborhood. The community tool was developed from the results of the questionnaire and further refined with the community through presentations and discussions.

The significance and implications of this research to the field are dynamic. The American Planning Association has joined forces with the American Public Health Association supported by the Centers for Disease Control and Prevention on a project called Plan4Health with the goal of increasing health equity. The CDC specifically has a goal of reducing health disparities in communities of color through Racial and Ethnic Approaches to Community Health (REACH). This CBPR project aligns with the movement of the fields (Planning and Public Health) to address health disparities in a more organic and racially and

ethnically sensitive manner. In addition, this project brings to light the visually dramatic differences between neighborhood experiences in Baltimore City, and explores the possibility of inequity in city services for sanitation. Experiences and results of this project are shared with the fields to better improve health equity and health outcomes for racial minorities.

DOES WALKABILITY COMPROMISE OR IMPROVE LIVABILITY? EVIDENCE FROM RELOCATION TO A WALKABLE COMMUNITY

Abstract ID: 1077

Individual Paper Submission

ZHU, Xuemei [Texas A&M University] xuemeizhu@tamu.edu, presenting author
XU, Minjie [Texas A&M University - College Station] mxu@tamu.edu, co-author
LEE, Chanam [Texas A&M University] chanam@tamu.edu, co-author
ORY, Marcia [Texas A&M University] mory@tamhsc.edu, co-author

Background and purpose: Walkable communities have been increasingly recognized for their potential in promoting physical activity and reducing environmental footprint.^{1,2} However, the availability of such communities seems to be lagging behind the demand.^{3,4} Meanwhile, important concerns still remain about the possible compromise of livability, such as increased traffic, worsened air quality, and social conflicts that may emerge from high-density and mixed-use features of walkable developments.⁵

Objectives: To better understand the nature of walkability-livability relationship, we studied residents relocated to an award-winning walkable community in Texas from diverse socio-demographic backgrounds. Research questions are: (1) whether the relocation to a more walkable community improved residents' physical activity, walking, and perceived livability; (2) how different domains of livability affect overall livability—the neighborhood being “a good place to live” and “a good place to raise children”; and (3) what environmental factors promote positive changes in perceived livability and whether socio-demographic factors play a role.

Methods: A retrospective survey (2016-2017) of residents (N=392) captured changes in physical activity, walking, perceived livability, and relevant personal, social, and physical environmental factors. SPSS was used for analysis. Descriptive statistics were reviewed and necessary transformations were made to some variables. Question 1 was assessed by paired t tests comparing pre- and post-move scenarios. For Question 2, factor analysis was used first to identify domains of livability, followed by binary logistic regressions predicting overall livability using socio-demographic and household characteristics and different domains of livability. For Question 3, multiple linear regressions were used to predict changes in perceived livability using socio-demographic and household variables and changes in neighborhood environments.

Results:

Question 1: T tests confirmed significant increases in weekly minutes of moderate physical activity by 81 minutes, walking for transportation by 39 minutes, and walking for recreation/exercise by 84 minutes ($P<0.01$). In addition, all items of perceived livability showed significant improvement, with an average increase of 0.75 on a 5-point scale ($P<0.01$). Overall perceptions of livability—"a good place to live" and "raise children"—increased by 0.99 and 0.82 on a 5-point scale ($P<0.001$), respectively. Standard deviations for 19 out of 23 livability items reduced after the relocation, implying reductions in related disparities.

Question 2: Four domains of livability were identified, including social cohesion, access to services, environmental quality, and convenient transportation. All domains have significant associations with overall livability—"a good place to live" and "raise children" ($P<0.01$). All socio-demographic variables (except age) are insignificant in predicting overall livability, implying the consistency across populations in how they assess livability. Number of children is associated with perceiving the neighborhood as "a good place to raise children."

Question 3: Increases in air quality ($\beta=0.20$), crime safety ($\beta=0.31$), street intersection density ($\beta=0.19$), attractive natural sights ($\beta=0.39$) and places to go within walking distance ($\beta=0.17$) are associated with increases in overall livability ($P<0.01$). Hispanic or Latino origin is a negative correlate for change in the neighborhood being "a good place to live" ($\beta=-0.60$, $P<0.01$) and "a good place to raise children" ($\beta=-1.01$, $P<0.01$). Number of children is a positive correlate for increase in perceiving the neighborhood as a good place to raise children.

Conclusions and Discussions: This study is limited to potential recall bias and one particular community. Findings from this study demonstrated the positive impacts of a walkable community on not only physical activity and walking, but also multiple domains of livability. It implies improved equities in livability after relocation to the walkable community. Both physical activity and livability benefits of walkable communities should be considered in future policies and practice. More studies in diverse settings using longitudinal design will help further advance this field of research.

ALTERNATE PERSPECTIVES ON PLACE-BASED POVERTY REDUCTION: RETHINKING IMPLEMENTATION AND EVALUATION FRAMEWORKS

Abstract ID: 1084

Individual Paper Submission

CONWAY, Megan [University of Waterloo] megan.conway@lycos.com, presenting author

The design and implementation of third-sector managed place-based poverty reduction programs has emerged in response to the state's absence in effectively mitigating the negative impacts of neighbourhood effects. This research examines the central research question of how to evaluate a place-based poverty reduction program across different geographic sites and scales through a case study of a specific third-sector designed and implemented place-based poverty reduction program in Canada. Specifically, this research explores this question through the lens(es) of urban youth participants in the poverty reduction program, Pathways to Education. Connected to this broad research question, I explore other inter-connected questions including:

-What are effective place-based poverty reduction implementation and evaluation frameworks, especially those that target youth?

-Do neighbourhoods matter to children and youth and if so, in what ways?

-How might ethical and methodological tensions be resolved to hear youth perspectives on neighbourhoods, youth, evaluation and poverty more clearly?

To answer this question, I craft a theoretical framework linking the concept of the right to the city as presented by Lefebvre (1996) to Uri Bronfenbrenner's (1977, 1979, 1995) understanding of the micro, macro, and meso systems in which children and youth operate. I then present a literature review that unpacks and analyzes the current dominant literature on neighbourhood effects, children and youth and evaluation. This research proposes alternate narratives on the themes of neighbourhood, evaluation, poverty and, ultimately, success, by challenging dominant urban planning constructs as to what it means to be both youth and poor. Utilizing a community-based participatory research approach, this research presents an evaluation framework that might be considered in examining place-based approaches to poverty reduction. It presents a counter-narrative to the dominant frame that all neighbourhoods that are poor require interventions and, ultimately, saving. It examines some of the associated ethical dilemmas of how best to mitigate neighbourhood effects, especially in some of Canada's poorest neighbourhoods where educational and health outcomes remain lower than middle-class or more affluent neighbourhoods. I present findings from data collected through interviews with national experts in the areas of evaluation, children and youth and neighbourhoods as well as data collected through focus

groups and surveys with program staff, and through traditional focus groups and arts-based methods with youth. This research presents a critical analysis to place-based poverty-reduction programs and proposes a framework to incorporate diverse stakeholder's perspectives, specifically marginalized youth voice(s), into place-based program planning and evaluation. It lastly provides concrete recommendations for planning, implementing and evaluating place-based policies and programs, especially those that target lower-income neighbourhoods.

ARTS, CULTURE AND THE ATLANTA BELTLINE: A STRATEGIC PLAN FOR INCLUSIVENESS AND SUSTAINABILITY

Abstract ID: 1097

Individual Paper Submission

RAO, Arthi [Georgia Institute of Technology] arthir@gatech.edu, presenting author

ROSS, Catherine [Georgia Institute of Technology] catherine.ross@design.gatech.edu, co-author

In urban planning research and practice, arts and culture planning and programming is seen as a broad strategy for economic and community development. While there are many strategies and methods for neighborhood revitalization there is a generally accepted idea that it is critical, “to recognize the role of those who ‘translate’ between community and external organizational spaces, and to integrate community knowledge and community institutions into participatory development processes” (Eversole, 2012). However, there is limited knowledge regarding specific place-based strategies to nurture arts and culture, particularly due to inadequate public participation (Markusen and Gadwa, 2010). The Atlanta BeltLine is a planned 22-mile loop of multi-use trails, modern streetcar, and park, situated along historic railroad corridors that encircle the city. It represents one of the most comprehensive transportation and economic development effort ever undertaken in the City of Atlanta and among the largest, most wide-ranging urban redevelopment programs currently underway in the United States. The Atlanta BeltLine is the ultimate urban connector and outdoor art gallery, linking 45 diverse neighborhoods via transit, trails, and additional infrastructure. Arts and culture play a critical role along the BeltLine in connecting neighborhoods to the BeltLine and connecting residents to cultural opportunities in their communities. The Art on the Atlanta BeltLine (AoAB) is now an eight-year-old program, run by Atlanta BeltLine Inc. (ABI), where artists are selected through a Request for Proposal (RFP) and jury process to showcase their work through a variety of mediums: sculpture, murals, dance, music, theater, photography, and more. Over time, AoAB has grown into the largest free, temporary outdoor art exhibition in the South with more than 1.87 million visitors to the Eastside Trail in 2017.

How can the AoAB be expanded to create a more inclusive and comprehensive arts and culture program along the Beltline? How can the plan help sustain local community traditions and cultural identity? The Arts & Culture Strategic Implementation Plan (ACSIP) was created in 2018 to provide a framework to expand ABI from a mostly-single program effort in arts and culture to a robust program that ranges from international works to everyday art in the communities that line the corridor, creating a unique place that celebrates the local and supports quality of life for all. The framework's purpose is to encourage arts and culture along the Beltline by synthesizing existing plans and programs and providing implementation guidelines and strategies towards expanding the current vision for arts and cultural initiatives along the corridor.

The presentation describes the planning process undertaken for the ACSIP, with a focus on the community engagement strategy that was used to develop the recommendations. Highlights of the strategy include the role and involvement of local artists as community organizers and expert stakeholders as well as the eliciting of local knowledge in developing the strategy. Outcomes of the planning process will also be discussed including the formulation of recommendations for programming, organizational capacity, spatial design and community collaboration to promote equitable access to arts and culture opportunities as well as sustainability of the artist community's continued presence around the Beltline.

WHO LEARNS WHERE: UNDERSTANDING THE CONNECTION BETWEEN CHARTER SCHOOLS AND NEIGHBORHOOD GENTRIFICATION IN THE DISTRICT OF COLUMBIA

Abstract ID: 1141

Individual Paper Submission

EISENLOHR, Andrew [University of Southern California] eisenloh@usc.edu, presenting author

For several decades, various academic fields have examined the connections between neighborhoods and their public schools. Often oriented around issues of equitable access, such research has typically identified significant relationships between neighborhoods' sociodemographic compositions (e.g., race), financial characteristics (e.g., home values), and measures of school quality (e.g., standardized assessment scores). Furthermore, due to the historical organization of schooling in residence-defined districts, these examinations have often drawn comparisons across districts or their attendance areas.

Charter school reform, however, has complicated and made more granular the potential relationship between neighborhoods and schools by allowing diverse public schooling options within districts, typically urban. And because urban charter schools have proliferated at the same time as substantial gentrification of cities, an emergent thread of literature now attempts to connect the two phenomena.

While this thread remains quite thin, it suggests charter schools may both result from and result in the gentrification of certain neighborhoods within a given city.

Nevertheless, more work is necessary to refine this potential connection. As a result, I seek to expand the field in several ways. First, I develop and utilize a 21-year longitudinal dataset that accounts for the location of each charter school campus in each school year within the District of Columbia, offering a more comprehensive and systemic view than many existing papers. Second, I consider multiple and multi-faceted definitions of gentrification that account for the different “life cycles” of the phenomenon. Third, I consider both overall charter school presence as well as presence of different “types” of charter schools. Fourth, I explicitly control for the presence of rail transit, which is known to influence neighborhood characteristics and may also influence where charter schools choose to operate, the latter for both neighborhood zoning and enrollment reasons. In accordance with the literature, I hypothesize that: (1) the presence of charter schools is significantly associated with neighborhood gentrification within the District; and (2) the charter school-gentrification relationship significantly varies by type of charter school(s) present.

Using these data, I develop a variety of descriptive analyses showing that: (1) the District has gentrified in a spatially uneven way, i.e., in certain neighborhoods; (2) the expansion of charter school campuses has occurred in a similar, spatially uneven way; (3) within the physical distribution of charter school campuses across the District, significant variation exists in spatial proliferation by type of school; and (4) sociodemographic enrollment within District charter schools has been uneven across multiple dimensions as well, including: the time at which a particular charter school organization began operating in the District, type of school, and neighborhood in which a school operates.

I then develop several regression analyses that empirically estimate the relationship between charter school presence and neighborhood gentrification within the District, again considering multiple measures of gentrification. In doing so, I identify a significant link between the overall presence of charter schools and neighborhood gentrification, as well as significant links between certain types of charter schools and neighborhood gentrification. Accordingly, I generate supporting evidence for each of my hypotheses.

These findings have important implications for both policymakers and scholars. First, they highlight charter school reform’s potential to accelerate urban gentrification at the neighborhood level. Second, they suggest an important variation in the charter school-neighborhood relationship that depends upon type of charter school – a complexity that only distinct threads of education literature have considered. Third, and more generally, they underscore a new way in which inequitable access to urban schools may occur: the gentrification of neighborhoods surrounding charter schools, and the subsequent “crowding out” of long-residing or displaced households from those charter schools due to limited enrollment space and/or physical inaccessibility.

REVITALIZATION OR ECONOCIDE? TWO TALES OF AN INNER-CITY NEIGHBORHOOD IN CINCINNATI

Abstract ID: 1176

Individual Paper Submission

LOOYE, Johanna [University of Cincinnati] johanna.looye@uc.edu, presenting author

Central Theme. On April 7, 2001, a 19-year-old Black man, Timothy Thomas, was pursued and shot by a Cincinnati police officer who claimed he did know that the multiple charges against Thomas were non-violent charges. Thomas soon died of his wounds and from April 9 to 13 unrest dominated in Over-the-Rhine and other poor neighborhoods in Cincinnati until a curfew and state of emergency were declared on April 13.

These events brought national attention to the city and to the neighborhood. Among these was the establishment of the Center City Development Corporation (3CDC) in July 2003, funded by large corporate sponsors, which were concerned with having “overall system to increase the effectiveness and efficiency of development activities in the City of Cincinnati” (3CDC.org, About).

Fast-forward to November 2012, when the annual ACSP conference was held in Cincinnati. Two events at that conference highlight the different ways in which scholars of urban areas examine the process of change taking place in the now-almost-20-years since Mr. Thomas died. One was a mobile workshop “Urban Renew [sic] on Vine Street,” led by the president and CEO of 3CDC, Stephen Leeper. The other was a pre-organized session entitled “Gentrification Policy in Over-the-Rhine,” which included papers on topics such as the public good, econocide, and colonialism.

Objectives. This paper will examine the two primary ways in which intervention and changes in Over-the-Rhine are portrayed. The 3CDC narrative follows a privatization and revitalization theme while the opposing viewpoint, espoused at the ACSP conference by three academic authors, takes a progressive stance.

Approach and Methodology. The paper will begin with a brief summary of key events that occurred in Over-the-Rhine, to provide context for the ensuing discussion. A brief discussion of analytical perspectives, namely conservative (neoliberal), liberal, and progressive, will ensue. It will be followed by an introduction of actors and their perspectives and interventions in the neighborhood. Key topics will include housing, including housing for homeless persons, the renovation of Washington Park, and business attraction and support. The discussion of these topics will focus not only on the “traceable” changes over time, but also on the political-economic dimensions of rationales, strategic choices, coalitions, and so forth. The purpose will be to provide a contrast in the often-implicit adoption of public interventions rather than to argue that, for example, gentrification is or is not occurring. This paper is seen as a “first cut” at exploring how rationales for intervention reveal or hide deeper intentions in the case of Over-the-Rhine.

Main results. The main result will be that Cincinnati's corporate leaders and 3CDC use a "free market" or neoliberal justification for their actions. In contrast, community organizations use a social justice narrative. While these two views dominate, in-depth research may reveal a liberal viewpoint, although I do not believe there is an organized coalition. As the two "sides" actually collaborate in some activities, e.g., housing, I do not expect to find sharp lines that divide them.

Relevance. Ultimately, this examination will contribute to our knowledge of a significant example of urban unrest in the U.S. and ensuing policy action to address it. For students, the explicit examination of the two narratives may enable them to more critically understand urban planning and policy "on the ground."

SCHOOL-CENTERED NEIGHBORHOOD REVITALIZATION IN BALTIMORE

Abstract ID: 1178

Individual Paper Submission

BIERBAUM, Ariel H. [University of Maryland, College Park] bierbaum@umd.edu, presenting author
BUTLER, Alisha [University of Maryland, College Park] abutler1@umd.edu, co-author
O'KEEFE, Erin [Loyola University Maryland] eokeefe1@loyola.edu, co-author

Schools are more than just spaces for learning; they are also social, political, and physical infrastructure in neighborhoods and cities. Despite the ways that schools are deeply tied to local conditions, we know less about how processes of school change interact with dynamics of neighborhood and urban change. School districts make facilities management decisions about closing, consolidating, rehabilitating, and building schools that shift the geography of educational resources and materially affect lived experiences in neighborhoods (Filardo, 2016).

We extend two main areas of research on impacts of neighborhood and school change. First, evaluation of comprehensive community development initiatives track progress toward economic development (e.g., the number of jobs, the number of firms, and the volume of annual sales), improved housing markets (e.g., home sale price, mortgage applications and originations), and changes in household well-being and stability (e.g., income and unemployment, demographics, and housing vacancy rates). Other efforts track program investments, organizational capacity, and mobilization of community members. (See e.g., (Baum, 2001)) Second, research and evaluation of school facilities programs examine the impacts of

physical improvements on student, staff, and teacher outcomes and on neighborhoods' home values and resident stability (see e.g., (Neilson & Zimmerman, 2014)).

Using a case study approach, this paper presents initial findings from a (currently in-process) study of the policy apparatuses and impacts of Baltimore's school closures, rehabilitation, and construction vis-à-vis patterns of uneven urban development and change in three Baltimore neighborhoods. Each neighborhood has seen new school construction as part of the 21st Century Schools Buildings Plan (21CSBP). 21CSBP is a cross-agency collaboration and investment of nearly \$1.1 billion to build or renovate 28 public schools in some of Baltimore's most neglected neighborhoods. State and city leaders have called for these schools to be high quality learning environments, community recreation spaces, and catalysts for neighborhood economic development. In each neighborhood, we have collected and analyzed data through archival research; Census and mapping; and interviews with 40 city and school district leaders, school site personnel, community-based organization staff, philanthropic partners, developers, neighborhood residents, and parents.

Our analytical framework draws on those from human and community development. An ecological theory of human development suggests that children learn and grow in the context of multiple, overlapping environments (Leonard, 2011). Community development practice and theory offers a place-based lens in which the neighborhood is the catchment area for intervention and where attention is distributed across a full breadth of residents' daily lives (i.e., issues of housing, transportation, health, education, etc.) (DeFilippis & Saegert, 2012). We argue for a community-based ecosystem framework that attends to relationships among individuals, collaborative organizational structures, and structuring policies – all of which may enable, constrain, or otherwise shape the dynamics and conditions of a particular school and neighborhood. It is attuned to micro-level issues at the neighborhood level (e.g., daily lives of children and families), meso-level issues at the neighborhood and city level (e.g., organizational collaboration, politics, and policies), and macro-level systems (higher level policies, politics, and/or economic structures) that influence and shape local level dynamics.

This research is the first to systematically collect data and analyze the extent to which the Baltimore 21CSBP is linked to and influences other neighborhood improvement efforts. It considers both physical and social conditions of schools and neighborhoods and operates across scales of intervention – from the individual student to neighborhood and school organizations to broader systems of housing markets and political processes. It builds on a growing body of multidisciplinary research on the relationship between neighborhoods and their schools, and explores the dynamics of neighborhood investment, racial inequality, and urban and educational change.

BUILDING YOUTH ADVOCACY THROUGH SUPPORTIVE LEADERSHIP

Abstract ID: 1190

Individual Paper Submission

OCONELL, Laura [Georgia Institute of Technology] l.katieoconnell@gatech.edu, presenting author
BOTCHWEY, Nisha [Georgia Institute of Technology] nisha.botchwey@design.gatech.edu, co-author

Community engagement is central to a democratic planning process as it creates dialogue between residents, government officials, local agencies, and developers. A well-designed engagement strategy generates a richer final product after putting effort towards a participatory process that includes a diverse coalition of constituents. By training youth to take an active role in their community, schools and youth-serving organizations (YSOs) can support youth advocacy as a vital component of the design process while building youth capacity and self-efficacy. One key to a successful program is supportive, multifaceted adult leaders that act as both guide and champion. The Youth Engagement and Action for Health (YEAH!) program is a 12-week curriculum that empowers youth to act as advocates for change in their community by completing neighborhood assessments, brainstorming solutions, and ultimately presenting their findings and suggestions to appropriate decision makers. Using surveys and interviews with adult leaders, community decision makers, and local champions, this paper assesses the YEAH! adult leaders' characteristics, group structure and dynamics, barriers to success, and technical assistance needs as well as assess decision maker's perceptions of interactions with youth advocates. The aim of this paper is to understand the role of adult leaders and decision-makers in supporting successful youth advocacy program.

ASSESSMENT OF AFFORDABILITY AND DESIRABILITY OF HOUSING OPTIONS IN THE CONTEXT OF THE CITIES WITHOUT SLUMS PROGRAM IN MOROCCO

Abstract ID: 1241

Individual Paper Submission

BELKADI, Meryem [University of Cincinnati] belkadmm@mail.uc.edu, presenting author

By 2030, the urban population in Morocco will reach approximately 38.4 million, thus increasing the housing market demand. As housing supply will likely fail to accommodate this demand, slums urban crisis can only be exacerbated in the future. Therefore, in its will to achieve the UN millennial goals, and improve the life of urban dwellers, the Moroccan government implemented the Cities without Slums Program (CWSP), that aligns with development goals established by UN habitat (i.e. Habitat III), and specifically Goal 11 to “make cities and human settlements inclusive, safe, resilient and sustainable” and “by 2030, ensure access for all to adequate, safe and affordable housing and basic services” (UN-Habitat, 2018).

Since 2004, the CWSP achieved a relocation rate of 66%, equivalent to 277,583 households. However, beyond the optimistic perspective offered by the statistical data in government reports regarding slum clearance operations in Morocco, the reality of it on the field is more complex. Indeed, the clearance of slums in the last few years was marked by forced mass evictions of slum dwellers, especially in the two biggest cities of the country – Casablanca and Rabat.

The forced evictions taking place in the country speak to the limitations of the CWSP and its inefficiency in presenting adapted solutions to slum dwellers. In this research, the focus is put on the financial tools in correlation with other constraints (i.e., increase in the number of slum dwellers, the low supply of housing units, as well as architectural and technical standards) to demonstrate to which extent these financial tools are adapted to the three first deciles of the population, and to assess the desirability of affordable housing supplied in the context of CWSP.

Therefore, how to define desirability, and specifically affordability of housing options destined to a household from the first three deciles of the urban population in the Moroccan context? Also, what are the financial tools currently available for households, and are these tools adapted to acquire a housing unit supplied in the context of CWSP?

- CWSP success is assessed on an incorrect basis, as the sole use of quantitative data to describe the achievements of the program does not speak to the situation of the relocated/evicted communities;
- Loan guarantees are unsuccessful in the context of CWSP, not only because of the low solvency of households, but because of the disinterest of households in the banking system. Hence, community-based solutions such as community funds are more likely to be successful;
- The government is subsidizing two types of capped-price apartment units, one category destined at middle-income groups, and another one destined at low-income groups including slum dwellers. The latter category, even if it is catered to slum dwellers, remains unaffordable and undesirable;
- The relocation projects initiated by the government contribute to the recreation of slums' social and spatial patterns by shifting urban poverty towards the city fringes and enhancing urban exclusion.

An analysis of the affordability of the housing supplied in the context of CWSP is completed. The calculations to examine the adaptability of the financial tools will be computed using the mortgage payment formula $P = M * \{ [((1+r)^n) - 1] / [(r * (1+r)^n)] \}$, and will concern the three first deciles of the urban population.

Ultimately, the research goal is a step-by-step investigation of aspects of the desirability of affordable housing, by implementing a desirability index (D) expressed as follows:

$$D = (\sum S*W)/5$$

Since the CWSP is still in progress, this research proposes a desirability index, to assess the adaptability of housing units already supplied in the context of CWSP in addition to future projects.

HISTORIC PRESERVATION AND PLANNING IN POST-INDUSTRIAL LANDSCAPES: GRASSROOTS ORGANIZING, CITIZENSHIP AND IDENTITY IN LOTA, CHILE.

Abstract ID: 1251

Individual Paper Submission

NOVOA, Magdalena [University Of Texas At Austin] mpnovoa@gmail.com, presenting author

Urban heritage in Chile is exclusionary. The spaces and places that are preserved and the histories that are validated through historic preservation and planning are largely decided by governmental institutions, policymakers, and heritage experts, while ignoring the social processes and the people related to historic sites if they are not associated with a positive version of colonial history or the capital, or if they represent dissonant cultural relations (Carrion 2013). This official mode of operation tends to privilege certain narratives about the past while obscuring the experiences of underrepresented communities. From the leading position of those in power- with the privilege right of urban heritage definition – that values are inscribed to the rest of society which in turn receives and accepts it. One example is the many mining cities around the world whose urban landscapes have been preserved and regulated as heritage sites after changes wrought by globalization and the neoliberalization of capitalist economies. These heritage representations are often controlled by company owners or government agencies reproducing historically inscribed relations of power or a sanitized corporate version of the past, rather than focusing on the social relations and labor struggles that shape the urban sphere.

However, while there are many examples of top-down processes in historic preservation and planning in Chile, there are also cases that challenge this dominant way of defining the urban landscape, evidencing it as a process related to social empowerment and an instrument of cultural control. The Chilean grassroots organization Mesa Ciudadana de Patrimonio, Cultura y Turismo de Lota from the ex-coal mining town of Lota is one such example. Since the closure of the coal mine in 1997 due to changes in the capitalist economy, Lota has faced increasing decay, abandonment and “ruination” (Stoler 2007) and today remain as one of the poorest municipalities in the country. This ruined landscape is more than aesthetics and the

celebration of the industrial capital. It is about job loss, health disparities, environmental changes and the contestation of gender roles, race and class inequalities. This paper offers an examination of the ways in which people living there are actively and critically engaging with processes of memory-work and meaning-making in the urban space to challenge a history marked by structural inequalities that continue impacting the community in the present.

Building on radical and insurgent planning theories, that problematizes everyday practices of the marginalized groups outside the margins of formal planning (Sletto 2013), I argue that moving across 'invited' and 'invented' spaces of participation (Miraftab 2009), Lotinos/as are capable of disrupting established structures of exclusion and inequality by appropriating historic preservation as a political tool. Resistance, therefore, occurs through tactics both formal and informal, legal and extra-legal, political and performative, traditional and innovative. While neoliberal capitalism promotes collective social amnesia, these insurgent groups promote collective memories and historicize the problems arising from the actions and inactions of authorities. The memory of their historical social struggles is located at the center of their actions (Sandercock 1999). Drawing on interviews, participant observation, archival research, and analysis of the built environment conducted in Lota between 2016 and 2019, I illustrate how people use historic preservation and planning in conscious and critical ways for: (1) negotiating and defining social and political values that shape the cultural identity of this working-class community, (2) improving their living material conditions in the city, and (3) creating new spaces of participation and citizenship in urban decision-making process.

JUMPING OFF THE LADDER: PARTICIPATION AND INSURGENCY IN DETROIT'S URBAN PLANNING

Abstract ID: 1256

Individual Paper Submission

LASKEY, Allison [University of California Irvine] alaskey@uci.edu, presenting author

NICHOLLS, Walter [University of California Irvine] wnicholl@uci.edu, co-author

Participation has become a central norm of urban planning. In the 1950s and 60s, with politically radicalized mass movements demanding redress for inequality and racism, influential urbanists like Sherry Arnstein, Jane Jacobs, and Paul Davidoff argued that authentic participation would ensure more

equitable outcomes, empower have-nots, and produce better cities. These scholars aimed to help planners redistribute power to citizens, but a key institution to include residents in decision making, the Community Development Corporation (CDC) has proven limited, and more institutional participation has not resulted in a substantially greater voice for low-income, minority residents (Arena, 2012; McQuarrie and Krumholz, 2011; McQuarrie, 2013)..

Based on a case study of participation and insurgency in Detroit's urban planning, we argue that CDCs structurally align with the planning establishment, serving as relays for governments and developers and controlling information. In Detroit, as in other cities, CDCs have aligned with government and developers to facilitate the redevelopment and gentrification of targeted areas (McQuarrie, 2013; Arena, 2012; Heil, 2018; Silverman, 2005). CDCs become dependent, deriving their resources and legitimacy from the planning establishment, while planners view partnering with community development corporations (CDCs) as necessary for participation.

These limitations have inspired insurgents to arise from the resident association Charlevoix Village Association (CVA) and to intervene in the planning process. CVA's insurgent activities and knowledge production have galvanized residents to engage beyond the participatory planning paradigm, developing independent, insurgent methods to assert their voices in different areas of urban planning (Friedmann, 1987; Beard, 2003; Meth 2010). CVA has demonstrated that insurgency can enable engaged residents to build power in ways that the participatory planning paradigm failed to account for. Networks are crucial for allowing insurgents to overcome planning's institutional limitations. Information and knowledge permit insurgents to pursue action in the public domain (Forester 1982; Friedmann 1987; Beard 2003).

This paper makes two contributions to the planning literature: it shows how institutional participation constrains resident empowerment, and it maintains that marginalized residents elevate their voice by "jumping off the ladder" of institutional participation through insurgency.

We suggest that CDCs have not been an effective means for redistributing power to marginalized residents. The tendency of professional planners to uplift CDCs as legitimate community voices while repressing insurgent tendencies is a way to reify planning's status quo and quash the fledgling space wherein residents may pursue their own interests on their own terms. We argue that planners interested in redistributing power to have-nots would be more effective if they jumped off the ladder of participation by accepting the legitimacy of community power, built through insurgent planning.

SELF-ORGANISED INITIATIVES: A PLANNERS' SUBVERSIVE TOOL FOR FRAGMENTED URBAN SPACES

Abstract ID: 1270

Individual Paper Submission

PESSOA, Igor [TU Delft] i.pessoa@tudelft.nl, presenting author

Brazilian metropolises are highly fragmented. Opportunity-led development created a disconnected urban patchwork where walls and inequality reign. However, the barriers in fragmented cities go beyond the physical ones. Breaking down invisible walls and connecting spatially disconnected areas does not necessarily erode the social inequality behind them or promote social connection. The walls in Brazilian metropolises are also social (Cortes, 2008). In that sense, traditional urban policies often fail to confront the spatial fragmentation in Brazil. At the same time, it is also common to observe bottom-up, informal and self-organised initiatives in such fragmented contexts. From housing construction to upgrading public spaces, self-organised initiatives are abundant.

Self-organising initiatives are not only being often recognized as important actors shaping the city, but they are frequently being led or supported by planners. It is interesting to observe that planners are taking part on these movements and pushing forward their agendas. To understand the participation of planners in self-organised initiatives was not the initial aim of this research; however, it became clear during the fieldwork that planners were taking a significant role on these initiatives. Nevertheless, the article will not delve into the reasons why planners are joining these initiatives. There are already research pointing out why young planners are trying non-traditional practice paths. According to Tasan-kok and Oranje (2017), young planners have a necessity to fulfill their ideological position and go beyond a technocratic function. This happens mainly due to a mismatch between the expectation created during their education and their professional practice after graduation. Top-down planning seems to be failing to fulfill the aspirations of young planners in Brazil.

In this context, it is not clear how these informal, bottom-up and self-organised initiatives supported by urban planners are shaping the built environment. Aspects like spatial fragmentation are being affected by these initiatives in terms of building new social connections and increasing the level of integration. This investigates if these self-organised initiatives are able to undermine the underlying dynamics of spatial fragmentation in Brazilian metropolises by promoting social connection in extremely unequal groups. Since self-organised initiatives promote not only spatial connection but also social connection between different groups, the primary premise of this study is that they have a positive impact on reducing the spatial fragmentation present in Brazilian metropolises. In that regard, the central question here is: to what extent can self-organised initiatives promote social connection in public spaces of highly fragmented and unequal urban contexts?

To answer this question the research used qualitative methods to understand the social dynamics in these self-organised initiatives. The analysis was based on data collected from 12 in-depth interviews with members of self-organised initiatives and field observations during some actions of the initiatives. Additionally, 10 in-depth interviews with public servants and experts were conducted to give a complimentary perspective on these initiatives. The interviews were conducted in Brasília, Rio de Janeiro and São Paulo, during a two months fieldwork. The three cities were chosen because they are the three main metropolises from Brazil according to the Brazilian Institute of Geography and Statistics and have abundant self-organised initiatives. The results show that self-organised initiatives can create new social ties even on public spaces with patent social inequalities.

PRIVATE MONIES AND THE GOVERNANCE OF URBAN PARKS: NARRATIVES OF EQUITY AND “FAIRNESS”

Abstract ID: 1283

Individual Paper Submission

SCHALLER, Susanna [The City College of New York, CUNY] sschaller@ccny.cuny.edu, presenting author

NISBET, Elizabeth [John Jay College, CUNY] enisbet@jjay.cuny.edu, co-author

“Parks equity” is increasingly on the policy agenda in cities across the U.S. The way equity is conceptualized is often not clear as narratives of equity among policy makers and parks stakeholders diverge. In urban parks policy discussions, equity narratives might focus on metrics such as acreage per capita, distance and access to open spaces, and appropriate programming to accrue health and cognitive benefits and racial and environmental justice (Kibel 2010; Sister, Wolch & Wilson 2010, Levitz 2014). But not all equity narratives become solidified in policies.

We look at the infusion of private dollars as part of public-private, or in this case public philanthropic partnerships and highlight the intersection of equity narratives with PPP governance arrangements. Our analysis of equity frameworks looks at two cities, New York City and Seattle. New York represents the epicenter of public-private governance of parks and launched new initiatives for the improvement of parks in which equity is a theme and ever more entrepreneurial partners play significant roles. Seattle is a city where public-private partnerships in park governance has until recently taken a distinct approach, but new development indicates that Seattle is more fully embracing PPP park regimes, specifically in the form of business improvement districts. We the following questions to guide our narrative analysis:

1. What narratives emerge that point to perspectives different stakeholders, including public officials and private or nonprofit-sector actors, hold about equity as they talk about funding arrangements related to parks in their cities and about the role PPPs play in parks management?
2. How are policy actors pushing back against or questioning PPPs to seek to limit their role or alter the way private funds are used, and how do these efforts correspond to identifiable equity frames advanced in their narratives?

We have conducted 15 interviews talking with public sector stakeholders, representatives of private nonprofits that support and/or manage parks and parks advocates. In addition we examined news articles, public hearings, public policies, press releases and planning frameworks. We draw on Modan’s (2008)

discussion of discourse communities, which advance ideologies of placemaking and governance, looking at the big D- discourse (e.g. austerity) and the small d-discourse, namely the ways in which groups of people talk about specific issues (i.e. PPP parks regimes and equity). We compare narrative frameworks or discursive “justificatory regimes” (Lake 2016, 14; Roe 1994) across cities as they relate to public-private partnerships being fostered in these cities. This comparison allows us to assess how equity is mobilized and to discern equity criteria underlying policy approaches rooted also in certain PPP governance arrangements. To explore how different interests groups anchor their parks governance and equity discourse, we home in on four different constituent groups: including elected public officials, city agencies and powerful private leadership organizations as well as smaller non-profit or volunteer-based organizations.

A policy narrative analysis has to be cognizant of the dominant ideological context in which these narratives emerge and operate. Consequently, we focus on bringing to the surface the values different stakeholders embedded in their policy narratives to reveal their commensurability or incongruity with a neoliberal metanarrative that hails public-private partnerships as a tried and effective strategy not just to inject private resources but also to infuse public values into entrepreneurially focused urban improvement initiatives while simultaneously countering demands for redistribution. We identified three divergent narratives frames related to private monies and organizations in parks governance: PPPs as saviors, as capacity-builders across the system, and as eroding public support for a "unitary parks system."

THE GENERATIVE SPACE OF COMMUNITY-BASED THEATER IN THE MIDST OF COMPLEX APPALACHIAN POVERTY IN SOUTHEASTERN KENTUCKY

Abstract ID: 528

Poster

LANGE, Zechariah [Florida State University - DURP] zjl13@my.fsu.edu, presenting author

Appalachian poverty diverges from normative discussions and interpretations of poverty, which usually focus on inner city ghettos, segregated communities, and urban landscapes. Poverty in Appalachia is overwhelmingly white, and rural, and does not fall into the usual categorization of white privilege (though

there are noticeable racial disparities in the region). The “culture-of-poverty” explanation of Appalachian poverty was a depiction of the Appalachian peoples during the late 19th to early 20th centuries that has, to this day, had a persistent resilience to overshadow the diverse and complex reality of Appalachian poverty as well as the resilient and industrial character of its people. In its essence, the “culture-of-poverty” explanation is a distillation of a belief that Appalachians are barbarous, ignorant, lazy, incompetent and incapable of self-development and growth.

The critical pedagogical nature of the theater studied is enacted through an engaged socio-cultural space, whereby by a performance co-created with the community engages the actors (which are community members), the audience, and the wider community. The community-based theater investigated enacts many complex processes such as those of acknowledging identity, creating sites of resistance and struggle, providing places of meaning-making, mourning, or social learning, and the building of relationships that foster an engaged and active community. As a form of intervention and as a method for communal relations, the investigated community theater works to draw out stories from the “background,” as well as stories of people’s lives as they relate to systemic challenges and issues. Such stories tell of pain and adversity stemming from oppression, inequality, poverty, patriarchy, exclusion, and disenfranchisement. As an empowering act, storytelling and community-based theater can be a catalyst for social change.

Research Questions

1. How does community-based theater function as a method for asset-based community development in environments of constraint?
2. How, and to what extent, does community-based theater create a generative space for adaptive capacity?

Methods

A qualitative grounded theory case study was applied for a two-week participant observation period wherein close work was performed with a small Appalachian theater located in an impoverished county in Southeastern Kentucky. Further, 16 interviews averaging 35 minutes in duration were performed to examine individuals’ experiences and the meanings they derived from the theater, as well as to investigate the relationships that the theater has with other community organizations. Lastly, documents were collected that pertain to the theater’s operations and its communications with community members.

Findings

Community-based theater in Southeastern Kentucky is acting as a generative space for adaptive capacity in the face of complex poverty. Community-based theater, which is the result of informal socio-cultural relationships, is further acting as a space of recognition for cultural identity to provide positive social experiences capable of alleviating the vicious effects of poverty through acknowledgment and the creation of positive intergenerational community development.

Relevance

The theater being studied works in a non-formal but public setting that is capable of flexible adaptation through loosely defined relationships outside of a bureaucratic environment. Further, the theater works to engage community members in participatory socio-cultural environments to help generate community relationships that can produce action for further community development efforts. The shared

responsibility of community development between the theater and the public is an expression of trust that was created through the co-creation of community performances.

A COMPARISON OF NEIGHBORHOOD SATISFACTION AND HOUSING VALUES IN GROWING AND SHRINKING CITIES

Abstract ID: 762

Poster

LEE, Ryun Jung [Texas A&M University] ryunjunglee@gmail.com, primary author
NEWMAN, Galen [Texas A&M University] gnewman@arch.tamu.edu, co-author
DAY, Wayne [Texas A&M University] waynecday@tamu.edu, presenting author

The neighborhood-scaled environment has a significant impact on both neighborhood satisfaction and housing values. Many studies have identified that the socioeconomic environment (which can promote safety) and the physical environment's appearance are key elements enhancing quality of life. Housing abandonment, which has been a chronic issue for most U.S. shrinking cities, has been shown to be a causal factor in decreasing housing values, sense of safety, and can eventually bring a threat of neighborhood decline (for instance, Han 2013)). However, people living in severely depopulating cities are not necessarily less happy than those living in growing cities (Hollander 2010); even the most rapidly depopulating areas still have persistent residents for which planning must still occur (Ryan 2012). Still, there is currently a limited understanding of how neighborhood abandonment influences residential perception and how it differs by city context. This research seeks to determine if the residents in shrinking cities are more tolerant or sensitive to observable abandonment in their neighborhood due to chronic depopulation. To answer this, we examine if the impact of abandonment on residential perception and housing value varies by city context, especially in shrinking cities. We first identify shrinking and growing cities for the 20 largest U.S. Metropolitan areas based on city size and population change in the past 10 years. We then analyze the different trends of abandonment, residential perception, and housing values in each shrinking and growing city at the neighborhood scale using American Housing Survey (AHS) data. Finally, we examine the effect of observable abandonment using environmental factors associated with residential perception and housing values through regression modeling. The results indicate that the satisfaction scores and housing values drop more in shrinking cities when multiple

abandoned structures are observed than in growing cities. However, when a single abandoned structure is observed, the rate of change is not significantly different. This study supports that planners and policymakers need different approaches to abandonment depending on city context. Results imply that demolishing abandoned structures -- a typical approach for efficient citywide management -- might be more effective when multiple abandoned structures are observed in shrinking cities.

This project employed Participatory GIS (PGIS) to engage stakeholders in mapping local assets and values, facilitating the integration of local values and knowledge into a long-term planning project. PGIS allows for a more inclusive, transparent process in which citizen stakeholders can share in the creation of project materials and outcomes.

Background and context

The City of Westport, a relatively isolated coastal community of 2,000 year-round residents located in Grays Harbor County, WA, has an economy that is supported largely by local natural resources and tourism. Westport's marina is home to the largest commercial fishing fleet and seafood processing plant on the outer coast of the Pacific Northwest, a collection of recreational charter boats and a U.S. Coast Guard station. Located on a low-lying peninsula along the Pacific coast, Westport is among the areas most susceptible to the impacts of a Cascadia Subduction Zone magnitude 9.0 earthquake and resultant tsunami. To help mitigate against this potential hazard, the Ocosta School District, which serves Westport and several small communities nearby, built the first tsunami vertical evacuation shelter in North America.

Using weTable in a PGIS stakeholder workshop

A key component of a broader public engagement protocol focused on coastal resilience was the development of a workshop activity to involve government and community partners in the mapping of community values and assets. The workshop format was based on principles of appreciative inquiry, which provides a means of engaging stakeholders in conversations about hazards while focusing first on local strengths and assets rather than on vulnerability and weaknesses.

By sharing the creation and mapping of vulnerabilities and capacities, communities can communicate local priorities for disaster risk reduction to policymakers (Krishnamurthy et al. 2011). Using PGIS enabled us to gather place-based knowledge from community stakeholders while drawing upon technical data from tsunami and sea level rise hazard models developed by the research team.

The project team gathered input from workshop participants using the weTable, an interactive public participation tool that combines Wii technology with other common devices to create an interactive computer interface on a tabletop surface (Mikulencak & Jacob 2011). It can be challenging to engage communities using PGIS due to the investments of time and money that are often needed to use PGIS systems (Elwood 2010). However, weTable's affordability, interactivity and relative ease of use makes it suited for a variety of purposes, including direct involvement of the public in planning projects.

PGIS as a tool for community empowerment

Participatory Geographic Information Systems (PGIS) techniques like the weTable can be powerful tools for planning. They allow communities to use the language and tools of their decision-makers and to be directly involved in the planning process. PGIS can empower communities by providing individuals with an opportunity to think more spatially about the places with which they interact, enabling them to “literally put their community on the map” (Pánek 2015). PGIS combines scientific GIS data with local knowledge from communities that would otherwise not be integrated into GIS analysis (Singh 2014). Additionally, unlike more traditional paper mapping methods, PGIS applications allow data to be created directly in GIS for later use and analysis.

Workshop participant survey results

As a follow-up to the workshop, our team sent a brief survey to all participants asking them questions about their experience with weTable. The participants found the weTable easy to use, and they appreciated the efficiency of being able to call up multiple layers of data as needed. Most participants felt the weTable workshop format provided equal opportunity for all group members to participate in the discussion.

FRAMEWORKS OF RECOVERY: EXPLORING THE INTERSECTION OF PLANNING, POLICY, & DECISION-MAKING AFTER HURRICANE KATRINA

Abstract ID: 1023

Poster

MOSBY, Kim [Louisiana State University] kmosby1@my.lsu.edu, presenting author

The 2005 hurricane season showed the world the danger racial inequality coupled with failing infrastructure and climate change poses for coastal African American communities, especially for those citizens that are poor, elderly, and/or female. Nearly fourteen years later, New Orleans recovery exemplifies the persistence of racial inequality within American society as many displaced and returned African American residents continue to struggle as a direct result of the federal levee failure that flooded 80% of the city. As floodwaters and federal disaster assistance dispersed New Orleans residents across the country, Houston, Texas, received the largest concentration of displaced African Americans (Weber & Peek, 2012).

Following the levee failure, the city of New Orleans embarked on multiple planning processes to guide long-term recovery and future development. The multitude of plans that emerged from the various recovery planning processes incorporated different degrees of citizen participation (Nelson, Ehrenfeucht, & Laska, 2007). The adopted plans employed neoliberal urban revitalization and poverty removal strategies adapted to disaster recovery that changed housing, employment, education, and healthcare opportunities in the city (Gotham, 2014). Prior research found disparities in recovery among different neighborhoods (Bullard & Wright, 2012; Gotham, 2014) but failed to examine the role of planning processes in shaping how displaced residents perceived the potential to return. Furthermore, researchers often study changes in housing, employment, education, and healthcare opportunities individually rather than exploring how these policy changes intersect in residents' experiences of return (Cho, Crenshaw, & McCall, 2013).

Utilizing a critical race and intersectionality theoretical approach, this study seeks to understand how local and national newspaper articles and African American residents frame obstacles to returning to post-Katrina New Orleans. Through a content analysis of news articles and qualitative interviews with displaced and returned residents, the project explores how recovery planning processes and policy changes influenced the decision-making processes of African Americans displaced to Houston. The study relies on a conceptual content analysis of Times-Picayune and New York Times news articles and two rounds of open-ended, qualitative interviews with seventeen participants representing three different cases: 1) those that returned to New Orleans, 2) those still displaced in Houston, and 3) those that relocated to Houston after returning to New Orleans for over a year. The researcher conducted initial interviews in 2011 and fourteen follow-up interviews in 2016 to identify how obstacles changed over time. Initiated after the 2011 interviews indicated the importance of the media in participant decision-making processes, the content analysis examines how local and national media sources portrayed policy changes and recovery efforts in Orleans Parish.

The findings show participants and the media framed disaster recovery policies as creating opportunities and gaps in assistance that varied by location. This created a push-pull dynamic between New Orleans

and Houston. Participants described how policy decisions that created gaps in assistance compounded the difficulty of returning for working- and middle-class African Americans. Overall, the study shows how disaster recovery planning and policies can operate as barriers and negatively affect the ability of low to moderate income African Americans to return from long-term displacement. In an era of where climate change is increasing storm intensity and frequency, the findings suggest planners and policy makers need to consider how post-disaster policy changes may intersect to create compounding difficulties that impede the ability of residents to return and rebuild their communities following catastrophic disasters.

SAILING THE TIDE: UNEVEN FOOTFALL IN COLLEGE TOWN COMMUNITIES

Abstract ID: 1136

Poster

HIWARE, Sagar [University of Massachusetts Amherst] shiware@umass.edu, presenting author

Local businesses have been considered propellers of small-town economic engines for decades. They play a vital role as basic economic building blocks by helping build a sense of community in such towns (Robertson, K.A., 1999). The economic resiliency of local businesses in the face of changing economic patterns (largely due to online shopping) is a testament to the operational hardship faced by business owners and stakeholders. However, in the context of ‘college towns’, another layer adds to those hurdles –the uneven footfall of the customer base. As most universities and colleges operate on semester patterns there is a constant shift in population for such towns which is described as ‘floating population’. This floating population results into uneven footfall of customers that jeopardizes the sustainability of locally owned business entities in college towns due to the constant influx and outflux of the student population throughout the year (RKG Associates Inc., 2015). Therefore, it is important to understand the niche under which such local businesses can function successfully to help strategize and strengthen the local economic model of small towns. (Lessem, R. et al, 1978) (Isserman, A. M., et al, 2009) This pilot study presents how local businesses adapt to the varying customer base (seasonal footfall) in college towns. It concludes with ways in which local business districts can incorporate policies that support more vibrant and resilient college-towns year-round.

The study looks at the business model of downtown Amherst, a city in Massachusetts that hosts both the University of Massachusetts and Amherst College. The methodology combines ethnographic and phenomenological qualitative research inquiry. As a researcher in order to gain an insider's perspective, I worked part-time for a year at a business entity in downtown Amherst. The gaps between policies and practicality were identified by comparing the needs and demands of successful functioning of a business in downtown. The research goal is achieved with a series of in-depth one-on-one interviews with local business owners and stakeholders from Business Improvement District (BID) of downtown Amherst collected over three months. Business owners shared how over the years academic institutions have encroached into various industry sectors in a quest to create an all-inclusive micro community for their patrons which in turn has treaded into a loss of customer base for these downtown businesses. The result is a furious competition, lack of harmony between academic institutions and local businesses that are forced to depend upon the loyalty of community members. The statements point to the need for policies that support different business models aimed at both students and the local community. Findings of the analysis include restructuring BID's scope as a liaison between institutions, local government and business entities to stimulate an economically resilient environment focused on partnership. Inferences delineate strategies that BID and business entities could benefit from, which includes: use of locational occupancy constraints, an adaptive coping mechanism with uneven liabilities in a business model and encouraging economic diversification within downtown Amherst.

Since the concept of sustainability emerged in the 1960s in response to concerns about environmental protection and economic development, sustainability has become an important term for evaluating the built environment development. There has been a conscious effort by urban planners, designers, and

researchers to understand the urban sustainability indicators that help evaluate environmental, economic, and social aspects of sustainability. The main challenge is to identify appropriate indicators of urban sustainability that determine the success and the failure of policies and strategies enforced to achieve sustainable urbanization.

This research addresses two major objectives. First, we examined multiple dimensions and contributory indicators of environmental, economic, and social sustainability. Second, appropriate assessment criteria were developed for evaluating the various aspects of three pillars of sustainability in planning practice. This research analyzed a case study of 38 neighborhood centers in Kansas City. Kansas City has pursued sustainable community redevelopment through various planning strategies.

This study employs a descriptive analysis to understand the relationship between spatial configuration and urban planning strategies in sustainable developments. This study illustrates challenges and opportunities of current sustainable development policies and strategies. Based on the findings, urban design guidelines and physical planning strategies for sustainable development are discussed.

TRACK 3 – ECONOMIC DEVELOPMENT

TRACK 3 - PRE-ORGANIZED SESSION SUMMARY & ABSTRACTS FOR THE SESSION

PRE-ORGANIZED SESSION - EMPLOYING THE CONCEPT OF PUBLIC VALUE CAPTURE FOR PLANNING AND ECONOMIC DEVELOPMENT: AN EXPLORATION OF THE VARIEGATED FORMS, CONTEXTS, AND BENEFICIARIES OF PVC TOOLS

ID: 5

Pre-Organized Session Summary

Includes abstracts: 90, 91, 92, 93, 94

Public Value Capture (PVC), the idea that local governments can recoup increases in property values resulting from public investments and zoning changes, has long been an important planning and economic development tool (Hagman and Misczynski, 1978). PVC can take on many forms. Special taxation for infrastructure, for instance, is one of the oldest public financing tools embodying the concept. Tax increment-backed debt financing, TIF, is also underpinned by the PVC concept. Similarly, upzoning in exchange for public benefits is another variant of a PVC tool. Despite its widespread application, nevertheless, empirical studies on PVC have reported mixed results at best. This session grapples with the concept of PVC, its applications, and impacts. We will critically examine the places that have been transformed by PVC tools, discuss the types and magnitudes of public benefits that had been recaptured, who benefited from the recaptured values, and how existing communities have been impacted. We examine the successes and shortcomings of PVC-backed economic development experiences to tease out the conditions under which PVC can become an equity tool.

Objectives:

- understand how PVC tools impact local communities
- understand the causes of the successes and failures of PVC-backed economic development
- identify the conditions under which PVC can be used to further social equity

VALUE CAPTURE BY ZONING: HOW U.S. LOCAL GOVERNMENTS ARE USING LAND USE REGULATIONS TO GENERATE PUBLIC BENEFIT FROM REAL ESTATE DEVELOPMENT PROJECTS

Abstract ID: 90

Group Submission: Employing the Concept of Public Value Capture for Planning and Economic Development: An exploration of the variegated forms, contexts, and beneficiaries of PVC tools

KIM, Minjee [Florida State University] minjeek@mit.edu, presenting author

Local governments can utilize their power to zone to increase the value of real estate development opportunities and capture some of the value increment for public purposes. I investigate the entitlement processes of large-scale developments in five major U.S. cities to explore their varied attitudes towards value-capture-by-zoning and initiate a systematic status report of the practice. I find that 90 out of 100

developments studied secured substantial density and/or height increases by taking advantage of existing incentive zoning programs and/or by amending the zoning code. Over half of these projects, in fact, entailed project specific negotiations to determine the optimal intensity of the development and the accompanying public benefit packages. While all five cities used zoning as a value capture measure, some leaned more towards the negotiated approach than others. I further find that the negotiation practice varied greatly by city and sometimes even within cities. The appointed officials of some cities were more hands-on, directly overseeing the negotiations, whereas others stayed at arms length, allowing developers to directly negotiate with other elected officials and citizens. I conclude by offering suggestive remarks on how the differing negotiation styles affect the scope, breadth, magnitude, and beneficiaries of developer concessions.

PUBLIC PRIVATE PARTNERSHIPS AS A LAND VALUE CAPTURE TOOL TO FUND SOCIAL HOUSING

Abstract ID: 91

Group Submission: Employing the Concept of Public Value Capture for Planning and Economic Development: An exploration of the variegated forms, contexts, and beneficiaries of PVC tools

AMBORSKI, David [Ryerson University] amborski@ryerson.ca, presenting author

The objective of this paper is to analyze the policy tool of using Public Private Partnerships as an approach for land value capture. This is a somewhat forgotten and underutilized tool when it comes to applying land value capture policy. Like all land value capture tools there are certain conditions that must exist in the land market and policy landscape for the tool to be applied effectively. Typically, this includes a land market that has experienced significant increases in land values, as well as a desire and capacity of the government agency to utilize public private partnerships.

This paper will analyze how public private partnerships have been applied in several jurisdictions to lever, the capture of land value to rebuild or provide affordable or social housing. There are three jurisdictions that will be included in the analysis: Toronto, Boston and Cape Town. In Toronto where the application is most advanced, this approach is being used by the Toronto Community Housing Corporation (TCHC). TCHC has recently applied this application. Its best-known case is Regent Park, an urban renewal public housing project built in the 1950's. As property values have increased significantly in Toronto, this provided the opportunity to capture the increased value to rebuild the old obsolete social housing. TCHC entered into an agreement with a private developer whereby the developer obtained several sites to build private sector condo's in exchange for rebuilding all of the social housing units and some public realm amenities. It has also extended the application to a number of other sites/projects that are under its control.

In addition to the TCHC example in Toronto, similar approaches are being used in Boston and Cape Town, South Africa. In Boston, the Boston Housing Authority is undertaking projects in Charlestown and South Boston, the McCormack project, The Cape Town attempt to apply this approach to using and value capture to build affordable housing is in the Woodstock and Salt River precinct. The specific applications and approaches of land value capture used in these jurisdictions and the potential outcomes will be compared and analyzed. Based on the analysis, recommendations will be made on how the use of this land value capture tool can be used most effectively to assist in the redevelopment/provision of affordable housing.

WHAT VALUE IS CAPTURED? PUBLIC-PRIVATE DYNAMICS IN LAND READJUSTMENT

Abstract ID: 92

Group Submission: Employing the Concept of Public Value Capture for Planning and Economic Development: An exploration of the variegated forms, contexts, and beneficiaries of PVC tools

SHIH, Mi [Rutgers University] mi.shih@ejb.rutgers.edu, presenting author

CHIANG, Ying-hui [National Chengchi University] yinghui@nccu.edu.tw, co-author

DING, Hsiu-yin [National Chengchi University] yin@mail2.nccu.tw, co-author

This article aims to examine the complex public-private dynamics in the process of value production and value capture in land readjustment in Taiwan. Particularly, the paper pays close analytical attention to the question of what value is captured in the planning process. Land adjustment is a government-led practice and process. It refers to the government's use of planning as a police power to consolidate small and irregular private land plots into urban development zones. At the end of readjustment, private landowners receive a portion (about 40%) of their previous land holdings while the government uses some of the remaining land area to build public infrastructure and sells the rest to raise funds to cover costs and to jump-start new readjustment projects in the city. The existing literature has discussed the important role that land readjustment plays in urban development, especially in Asia (Sorensen, 2000). In the USA, land readjustment has also been touted as a potential instrument of public-private partnership that helps reduce

private landowners' opposition to urban redevelopment (Sagalyn, 2007). What has not been sufficiently examined, however, is what kinds of value are captured and for whom (see Wolf-Powers, 2010).

In this article, we examine eleven land readjustment projects between 1980 and 2015 in New Taipei City, the most populous city in Taiwan. Our analysis focuses on three areas: changes in private vs. public landownership, the creation of a class of private homeowners, and land finance mechanisms. The eleven projects involved 523 hectares of land, most of which was farmland and 95% of which was privately owned. After readjustment, 73% of the land (383 hectares) was zoned for urban development and the remaining 27% (140 hectares) was used for public facilities and infrastructure, such as roads, parks, and public schools. Among the 383 hectares of developable land, 54% was returned to original private landowners and the remaining 46% was obtained by the municipal government under public ownership. The municipal government, however, mostly auctioned this newly acquired public land to real estate developers, who, in turn, built high-rise, high-priced residential apartment buildings. Our analysis also shows that land readjustment has been an important provider of serviced land for the real estate sector, and that the profit generated by land sale has been an important source of finance for the municipal government's urban development projects. We argue that the value capture mechanism of land readjustment is predicated on the real estate market. To ensure that the value-capture mechanism in land adjustment works, the municipal government needs to employ public policies to make sure land and housing prices continue to rise (Hua, 2000). Our analysis shows a much more complex picture of the public-private relationship in land value capture. Our study also aims to fill the gap in the literature on the developmental state in East Asia that has largely missed the role of land and real estate markets (see Smart and Lee, 2003).

MAKING VALUES CALCULABLE AND CAPTURABLE: THE POLITICS OF APPRAISING PROPERTY FOR LAND VALUE CAPTURE

Abstract ID: 93

Group Submission: Employing the Concept of Public Value Capture for Planning and Economic Development: An exploration of the variegated forms, contexts, and beneficiaries of PVC tools

WEBER, Rachel [University of Illinois at Chicago] rachelw@uic.edu, presenting author

In order for value to be captured, it must first exist. In other words, value is not something intrinsic to property that exists a priori to the calculations and transactions that define, extract, and exchange it. Values depend on “how valuation is done, when, by whom, and for what purpose... The value of an asset is, so to say, entirely in [the practitioner’s] hands” (Muniesa 2011, 28). In other words, values are defined by the methods used to estimate them.

This paper examines the ontological status of value through an examination of the tools and techniques that render value capturable. It draws from an ethnography of Tax Increment Financing (TIF) use in Chicago to analyze the appraisal and assessment methods that underpin value capture tools more generally.

Municipalities and developers have an interest in property values increasing within areas designated for land value capture because taxes on the incremental change in values are the repayment source for debt floated to fund infrastructure and developer subsidies. In the case of TIF, developers use TIF proceeds from the expected increase in property taxes to acquire, construct, or improve property, and the city uses the actual collected increase in property taxes to service the debt on the subsidies. Both public and private interests use models to show how the property values of the proposed project will be greater than whatever is there now, how the project will appreciate rapidly over the future, and how the project will pull up the values of neighboring parcels (McAllister 2017). They use different assumptions, data, and appraisal methods to make these claims on the future.

How does this abiding interest in appreciation influence the valuation methods used to estimate property values? I found that government agencies and property owners exploit the malleability of value to estimate them upwards when determining collateral and payback schemes for publicly funded projects. They do so by selecting methods -- such as those that use capitalization rates -- that incorporate the inflationary affect that the availability of cheap credit (from quantitative easing) has on sales prices. In other words, the calculative techniques adopted in these cases reflect the speculative nature of property markets in an era of financialization (Weber 2010).

The transaction that transfers the estimated increment to the developer does not signal the resolution of the problem of valuation. The private recipient of the state’s largesse – in some cases the original developer, in others the purchaser of the project -- often takes advantage of the flexibility of valuation to subsequently appeal their property values downward. Owners systematically devalue their holdings in to obtain appeals, and the value estimates they use in such cases bear no resemblance to the ones they have shown the city to obtain TIF subsidies. Property owners within areas designated for value capture can also apply for property tax abatements. Appealing and abating property taxes downwards can undermine the municipality’s ability to pay for its expenditures and repay debt.

Planners need to anticipate the fact that the multiplicity of potentially contradictory values may undermine well-intentioned value capture schemes. While they need to take measures that can protect future values, they should do so without compromising other public goals.

THE COST OF NEW YORK CITY'S HUDSON YARDS REDEVELOPMENT PROJECT

Abstract ID: 94

Group Submission: Employing the Concept of Public Value Capture for Planning and Economic Development: An exploration of the variegated forms, contexts, and beneficiaries of PVC tools

FISHER, Bridget [The New School] fisherb@newschool.edu, presenting author
LEITE, Flávia [The New School] fla.mfrl@gmail.com, co-author

Tax increment financing (TIF) has exploded in popularity on the municipal finance landscape as cities compete for scarce public resources to fund economic development. Previous studies evaluate TIF's efficacy and ability to spark economic growth. This research expands the evaluation of TIF by questioning the widespread understanding of TIF as a "self-financing" tool through an analysis of its risks and costs to taxpayers. We present a case study of the Hudson Yards redevelopment project in New York City, the country's largest TIF-type project. Our analysis reveals a project that, rather than being "self-financing," cost the city \$2.2 billion, largely due to tax breaks to incentivize development and standard development risks and costs. We conclude that positioning TIF and its variants as "self-financing" is incomplete and that analyzing costs and risks associated with TIF and TIF-variant projects is necessary to provide a robust cost-benefit analysis to those municipalities considering its implementation.

THE APPLICATION OF DATA SCIENCE IN ECONOMIC DEVELOPMENT

ID: 7

Pre-Organized Session Summary

Includes abstracts: 144, 145, 146, 148

Urban data science in recent years has attracted much interest in the field of urban planning, due to its wide applicability to solve urban issues with large-scale data in a timely fashion. Economic development scholars cannot shy away from this general trend, but instead need to start thinking about integrating these emerging methods into their research. In this session, we are interested in learning how economic development scholars can effectively apply a variety of data science methods, such as natural language processing, image recognition and other machine learning techniques, to address a wide range of

economic development issues. What novel findings can be revealed with these new methods? And how can economic development researchers communicate these complicated methods and findings in an easily-digestible and policy-oriented manner? We see the marriage between data science and economic development as a promising front for making new discoveries through data-intensive, computational-efficient, and real-time-responsive methods. We are excited to get together with colleagues to share experiences, address challenges, and identify a way forward.

Objectives:

- Effectively apply data science methods to analyze economic development issues
- Contrast findings of traditional versus data science methods
- Communicate complicated methods and findings in an easily-digestible and policy/practical-oriented manner

BREWING INNOVATION: ARE COFFEE HOUSES BREWING NOT ONLY YOUR MORNING LATTE, BUT ALSO NEW IDEAS?

Abstract ID: 144

Group Submission: The Application of Data Science in Economic Development

ADELAKUN, Femi [City78] fadelakun@city78.org, presenting author

FANG, Kerry [Florida State University] Ifang3@fsu.edu, co-author

GOETEMANN, Theo [City78] tgoetemann@city78.org, co-author

Research Question: Do coffee houses encourage social interactions? If yes, will these interactions subsequently encourage innovation?

Background: Inspiring smart people to mingle and collaborate is found critical for encouraging innovation (Jacob, 1961; Storper & Venables, 2004). Researchers have long discovered that urban agglomerations, i.e., concentrations of firms and workers, boost innovation and startups, simply because cities have a large volume and a variety of people interacting with each other (Acs & Varga, 2005). Researchers such as Jaffe, Trajtenberg, & Henderson (1993) directly quantified the magnitude of knowledge spillover across space with the trails of patent citations. Similarly, Glaeser & Resseger (2010) found evidence that human capital accumulates more quickly in urban areas because proximity spreads knowledge. But few studies have examined ongoing social interactions at the street level, and practical efforts to bring people together and create mingling spaces have been limited. One barrier for practitioners is the lack of knowledge of how much social mingling at the street level encourages innovation and how to create interactive social spaces to accommodate such interactions.

Methodology: This paper uses all the coffee houses in the state of Maryland that have Google Review entries from 2004 to 2017 to study the economic benefits of social interactions. We collected and matched three datasets: establishment data from the restricted version of Quarterly Census of Employment and Wages, patent application data from the United States Patent and Trademark Office, and the location and Google Reviews of coffee houses from Google. We adopted data crawling, text-mining and spatial cross-correlation analysis to identify the co-location of patent filing and coffee houses, and linked the number of patent filings to the appearance of “conversation”- and “network”-related words and phrases in Google Reviews of nearby coffee houses.

Findings: While the data analysis is still ongoing, a pilot study on the city of Rockville shows the spatial proximity between coffee houses and patent applications. 64% of patent locations are within five-minute

walking distance (500 meters) of coffee houses, and 100% are within ten-minute walking distance (1000 meters). In comparison, a random spatial distribution of coffee houses would have only covered 30% and 60% of patent locations within a range of 500 and 1000 meters, respectively. Our mining of Google reviews also identified customer comments related to social interaction and productive conversation.

Relevance: This paper is both academically and practically relevant. Academically, it is among the first to quantify the economic benefits of social interactions at the micro level; it explores one underlying mechanism that makes cities hotbeds for fresh ideas. Practically, it informs city managers, planners and designers the importance of cultivating better built environment and improving service quality, which can help with the establishment of local meetup locations, ignite social interactions, and subsequently boost innovation.

SQUARING THE CIRCLE (LINE): ASSESSING THE USE OF MACHINE-LEARNING TO PREDICT NEW BUSINESS CREATION AROUND TRANSIT LINE EXTENSIONS IN CHICAGO

Abstract ID: 145

Group Submission: The Application of Data Science in Economic Development

CREDIT, Kevin [University of Chicago] creditke@msu.edu, presenting author

LEHNERT, Matthew [University of Toledo] matthew.lehnert@rockets.utoledo.edu, co-author

ANSELIN, Luc [University of Chicago] lanselin@uchicago.edu, co-author

As North American cities have engaged in a rail transit construction “boom” over the past 25 years, assessing the economic development impact of these systems has become an important research topic in regional science and urban planning. While this literature has grown substantially in recent years, and generally finds that rail transit systems foster adjacent increases in property values and new business creation (Mohammed et al., 2013; Chatman et al., 2016), the advent of new, large datasets – such as the National Establishment Time Series (NETS) – and new methodologies – including machine-learning techniques that employ random forest and other algorithms – provide an important opportunity to improve the predictive capabilities of existing models. Indeed, a recent analysis (Credit, 2018) of new business creation around transit found that traditional non-spatial modeling techniques (of the type commonly used in the literature) produce as many as 52% Type I errors when compared with more advanced spatial econometric methods.

Given both 1) the scientific need to improve the methodological rigor of these analyses, as well as 2) the applied need for city planners and local government stakeholders to obtain realistic predictions of new economic activity around planned transit line expansions, the goal of this paper is to test the comparative performance of traditional non-spatial models, spatial econometric techniques, and a variety of machine-learning algorithms in predicting new business creation around transit stations. The paper will then apply the best-performing technique to predict new business creation around stations for several planned extensions of the Chicago Transit Authority's (CTA) rail network, including the Circle Line. Given existing disparities in neighborhood economic outcomes and transit service, Chicago provides an ideal case in which to analyze the predictive capabilities of these various methodologies. The results of this analysis can then be used to inform policy decision-making around transit line extensions in the city.

CREAMING OPPORTUNITY: WHAT ATTRIBUTES GO INTO OPPORTUNITY ZONE SELECTION?

Abstract ID: 146

Group Submission: The Application of Data Science in Economic Development

GREEN, Jamaal [Portland State University] Jamgreen@pdx.edu, presenting author

This paper seeks to identify what factors have gone into Opportunity Zone selections across the country. Opportunity Zones are a new economic development policy tool, managed by the Treasury Department, designed to steer capital gains benefits into disadvantaged census tracts in order to spur redevelopment. But recent articles highlight that many opportunity zone tracts are not actually suffering from true disinvestment, calling into question the features that dictated zone selection by the states. This paper will answer whether the selected tracts are, in fact, those most in need of investment or simply those are most attractive to investment. Using opportunity zone data from the US Treasury and varied Census datasets this paper will use both logistic regression and hierarchical clustering, this paper will identify the attributes that predict for opportunity zone tract designation. This study hopes to highlight the strategies of state and local governments as they seek to take advantage of novel tax and development instrument in the service of community redevelopment.

SHRINKING CITIES IN URBANIZED CHINA: DYNAMIC TIME-SERIES CLUSTERING

Abstract ID: 148

Group Submission: The Application of Data Science in Economic Development

XU, Yuanshuo [Cornell University] yx246@cornell.edu, presenting author

Shrinking cities are considered as one of the most critical challenges in urban planning. However, the issue of urban shrinkage has not been explored much in the developing world, especially in rapidly urbanizing China. The “developing” character tends to divert the research focus to the growing and megacities, masking the paralleled uneven development and the problem of shrinkage in other cities. In fact, the massive state-led urbanization in China has created different development trajectories for cities.

To fill the gap of shrinking cities in developing contexts, this paper contributes to the study of urban shrinkage in China both methodologically and theoretically. Instead of choosing two time points and calculate urban changes, this paper utilizes an innovative technique, Dynamic Time Warping (DTW) algorithms from data science, to conduct time-series clustering analysis on urban growth and shrinkage. It groups all 290 prefecture cities in China into different urban trajectories from 2006 to 2015, such as continuous growth, recent growth, stabilized shrinking, recent decline etc. The typologies are further created based on the trend of time-series clustering results of the urban population and economy dimensions.

Then, the paper further explores the factors that may affect urban shrinkage in China using a multinomial logistic regression. The impacts of state spatial selectivity, local responses to state rescaling, core-periphery neighboring effects and economic restructuring are examined across different urban trajectory typologies. In general, cities in northern China, especially in the Middle Yellow River region and the Northeast suffer from population loss and economic decline due to not being privileged by the state for development, higher local economic share in resource-based sectors, lower natural growth rate, less competitiveness and attractiveness to the market and developers. In contrast, shrinking cities in south-central China, especially in the southeastern coast and Middle Yangtze River, can be attributed to their proximity to state-selected high-level large cities that have a gravitational pull of people and economic activities. Since these middle and smaller cities are not favored by the state policies, they are likely to rely on debts to sustain local economic growth.

STREETLIFE - THE PAST, PRESENT AND FUTURE OF NEIGHBORHOOD-SERVING URBAN RETAIL

ID: 8

Pre-Organized Session Summary

Includes abstracts: 296, 297, 298

This session focuses on the current status and future prospects of small-scaled, walkable, and neighborhood-serving urban retail, a cornerstone of urban life and the urban experience. While walkable neighborhood-serving retail has demonstrated social, economic and other benefits, it has become increasingly difficult to maintain in times of ongoing retail consolidation and virtualization. From a range of methodological and disciplinary perspectives, the session papers assess the history and current status of walkable neighborhood-serving retail, definitions of urban retail districts, and spatial and organizational influences on retail viability.

Objectives:

- Visitors will learn about the historical patterns and current status of neighborhood-serving retail
- Visitors will learn about definitions of urban retail and urban retail districts
- Visitors will learn about trends that influence the viability of neighborhood-serving retail

HISTORY REPEATS? LONG-TERM TRENDS IN AMERICAN URBAN RETAIL

Abstract ID: 296

Group Submission: Streetlife - the past, present and future of neighborhood-serving urban retail

KICKERT, Conrad [University of Cincinnati] conrad.kickert@uc.edu, presenting author

Walkable ground floor retailers are the cornerstone of the American urban experience and its notion of urban vibrancy. The proximity of shops, coffee houses, bars and restaurants make for healthy, resilient and sociable urban environments, as they provide cities with destinations to walk to, places to socialize, and a heightened sense of community (Forsyth, 2015; Mehta & Bosson, 2010; Oldenburg, 1999; Stroope, Franzen, Tolbert, & Mencken, 2014). As a result, urban plans and designs frequently call for fine-grained retail, but often fall short on their promises. The mismatch between the desire for the corner store or tavern of yesteryear and the reality of ever-consolidating and virtualizing retail is often fueled by a lack of knowledge on retail dynamics and trends. Firstly, this paper surveys patterns of American urban retail transformation since 1929, comparing standardized economic census records of a selected group of large, medium-sized and smaller cities with national retail trends. It finds that even in relatively stable urban environments, the number of retail establishments has decreased by over 75%, with food stores dwindling even further, but bars and restaurants often demonstrating more stability. Secondly, the paper surveys contemporary trends in retail, dissecting how e-commerce growth and retail consolidation not only posits threats for urban retail districts, but also opportunities, depending on merchandise categories,

demographics and the experiential quality of urban settings. Also, it finds remarkable similarities and continuities between current and historical trends. Finally, the paper discusses which types of further research are needed to substantiate successful urban retail revitalization, especially focusing on spatial dynamics and social benefits.

Given the changing landscape of physical retailing over the past 30 years and the decline of small, local, independent retailers that imposes negative effects on neighborhood stability and active street life. Urban planners are increasingly interested in better understanding the characteristics of urban form and the built environment that foster resilience for small, local, independent retailers. This has become particularly important recently as researchers seek to better understand the influence of e-commerce shopping behavior on physical retail.

However, in order to analyze the relationship between urban form and independent retail resilience, we first need to obtain spatially-defined boundaries for concentrations of independent retail neighborhoods (or “Main Streets”). While a variety of theoretical characteristics have been proposed for defining Main Streets, such as density, mixed-use, fine grain design and permeability, it remains to be seen whether these characteristics can be generalized and readily used to define Main Street boundaries across a variety of urban contexts. In addition, new large business establishment datasets (such as the National Establishment Time Series in the US) provide the potential for creating entirely data-driven definitions of Main Streets, but it is unknown how these approaches would compare to the theoretically-driven Main Street boundaries.

Thus, in order to obtain readily-operationalizable Main Street boundaries, this paper compares definitions driven by the theoretical literature to definitions created using entirely data-driven approaches. Each of these approaches will be tested by comparing the results to “known” Main Street locations in Stockholm and Chicago. The results of this analysis can then be used in a variety of future research contexts, from analyzing the relationship between urban form and retail closures and openings (failures and opportunities) to comparing the online shopping behavior of “Main Street” and chain retail customers, and others.

FIRM DEMOGRAPHICS OF THE RETAIL SECTOR, A SPATIAL PERSPECTIVE

Abstract ID: 298

Group Submission: Streetlife - the past, present and future of neighborhood-serving urban retail

FARAH, Irene [University of Chicago] irene@uchicago.edu, presenting author

ANSELIN, Luc [University of Chicago] lanselin@uchicago.edu, co-author

Firm demographics study the life and death of corporations and industries using the formal methods of mathematical demography. While this approach has seen application in regional science and planning, e.g., in studies of the dynamics of manufacturing, high technology startups and the like, very little is known about the demographic characteristics of the retail sector.

In this paper we study the pattern of births and deaths in the retail sector, using detailed business establishment information on their location obtained from the National Establishment Time Series (NETS) data base. This allows us to track the locations over time and across space of new establishments (births), the disappearance of establishments (deaths) and their progression throughout the life cycle. It also allows us to compute a life table for retail establishments, culled from the transition between age groups from year to year. This gives information about several types of duration effects, such as the expected life span at birth.

We consider the differences and similarities of patterns between several U.S. metropolitan areas in terms of birth and death rates and life expectancies and relate those to characteristics of the metro areas. We also carry out a within-metro spatial analysis, focused on Chicago, by treating the birth and death locations as point patterns, and analyze them by means of a range of spatial statistical measures. Finally, we turn to a within-metro areal analysis at the neighborhood level (zip-code zones) and consider the spatial distribution of births and deaths relative to the overall spatial pattern of retail. We relate the characteristics of this spatial distribution to variables that capture the socio-economic profile urban morphological properties of the neighborhoods.

GENESIS AT WORK: ADVANCING INCLUSIVE INNOVATION THROUGH MANUFACTURING EXTENSION

Abstract ID: 333

Group Submission: Inclusive Innovation through Policy and Practice

LOWE, Nichola [University of North Carolina at Chapel Hill] nlowe@unc.edu, presenting author

SCHROCK, Greg [Portland State University] gschrock@pdx.edu, co-author

RANITA, Jain [Aspen Institute] Ranita.Jain@aspeninstitute.org, co-author

CONWAY, Maureen [Aspen Institute] maureen.conway@aspeninstitute.org, co-author

Inclusive innovation is a generative concept that offers a hopeful portrait of our economic future—not one in which technological advances displace up to half the current workforce, with little mercy for those already struggling to make ends meet—but one that instead repositions potentially vulnerable segments of the working population as critical actors in an on-going drive to support new product development and process improvements. This concept of inclusive innovation is particularly inspiring for U.S. manufacturing, helping challenge a dystopian narrative in which frontline production workers will be displaced by advances in automation and robotics and thus at risk of further economic marginalization.

But this inclusive turn within innovation studies also has its limits, most notably the tendency to narrowly focus at the individual worker level, pushing investments in higher education as a panacea for extending economic opportunity. What this educational-fix obscures are a deeper set of organizational challenges that keep many businesses from fully engaging their frontline workforce and with it, tapping their

creativity and ingenuity, regardless of formal educational attainment. While workforce training can play a critical role in that effort, such investments—in isolation—do little to transform established business practice in order to ensure there is organizational capacity and wherewithal to “pull in” and inspire a skilled workforce.

This paper draws on a three-year, mixed-method evaluation of a novel business-facing initiative called the Genesis Movement, to understand its role in reshaping the workforce experience within SME manufacturing businesses in Chicago, Illinois. Genesis was launched in 2014 by the Illinois Manufacturing Excellence Center (IMEC), with seed funding from local and national foundations. Housed at Bradley University in northern Illinois, IMEC is part of the Manufacturing Extension Partnership—a nation-wide network that was established by the U.S. Department of Commerce in the early 1990s to improve the competitiveness of small- and medium-sized manufacturing enterprises.

Genesis represents a major departure to more conventional approaches to manufacturing extension, which often focus on short-term projects to promote efficiency and productivity improvement through “lean” manufacturing principles. By contrast, Genesis-enrolled firms commit to a 24 month strategic planning process with the ultimate goal of integrating concurrent improvements to job quality with advances in business performance. While non-profit workforce service providers have long attempted to secure a similar job quality commitment from smaller firms, the Genesis experiment is the first to involve a federally-funded manufacturing extension program—one with a successful history of promoting innovative business strategies and technological modernization.

To study Genesis, we conducted a series of interviews with a range of stakeholders, including frontline workers, over the course of multiple site visits from 2014-2018. In addition we analyzed survey data and individual wage records collected from all participating firms. To contextualize firm level impacts, we also interviewed IMEC staff at yearly intervals. We find that Genesis firms adopt an inclusive organizational culture, using frontline worker engagement, skills training and job quality improvements to drive firm performance. As such, Genesis offers a scalable model with the potential to expand across a national MEP network already serving thousands of manufacturing businesses that collectively employ hundreds of thousands of workers.

This paper supports Genesis diffusion by offering insights for how other North American regions can leverage government and university commitments to manufacturing extension to inform technological progress and in ways that are inclusive of the frontline workforce. It also suggests opportunities for manufacturing extension providers to partner with workforce-service and advocacy organizations in order to magnify their combined impact on inclusion and innovation.

IDENTIFYING AND ADDRESSING DISPARITIES IN ROBOT ADOPTION AMONG US MANUFACTURERS

Abstract ID: 334

Group Submission: Inclusive Innovation through Policy and Practice

LEIGH, Nancey Green [Georgia Institute of Technology] nleigh@design.gatech.edu, presenting author
KRAFT, Benjamin [Georgia Institute of Technology] bkraft70@gmail.com, co-author
LEE, Heon Yeong [Georgia Institute of Technology] hlee706@gatech.edu, co-author

This presentation/paper draws on insights gained during multiple years of research on industrial robotics adoption in US manufacturing, with an emphasis on results from the Georgia Tech Survey of Advanced Technology and Robotics in US Manufacturing.

While robotics and other advanced manufacturing technologies are often seen as job displacers—a characterization that may be true in specific times, places, and industries—our research suggests that since the Great Recession, industrial robotics adoption in the US has broadly been associated with increases in manufacturing employment and wages at national and regional levels. However, only a small percentage of manufacturers has actually adopted robots in the first place, and these adopters are disproportionately large establishments in the automotive industry.

We discuss how long-running barriers to technology adoption exacerbate competitiveness problems for small and medium-sized manufacturers, especially in times of labor scarcity, and propose inclusive policies that may both reduce the technology divide between large and small firms and provide safer and more highly compensated jobs for workers.

EXPANDING DIGITAL OPPORTUNITY? INCLUSIVE INNOVATION AND THE 'ORDINARY' CITY

Abstract ID: 713

Group Submission: Inclusive Innovation through Policy and Practice

BRAMWELL, Allison [University of North Carolina at Greensboro] afbramwe@uncg.edu, presenting author

Post-industrial economic advantage depends on the capacity to develop and apply digital technologies. Digital platforms, robotics and artificial intelligence, additive manufacturing, and the Internet of Things, along with big data, new algorithms, and cloud computing are altering the very nature of employment and the entire structure of the economy (Kenney & Zysman, 2016). The implications are profoundly socio-spatial and socio-technical, begging important questions about where and for whom digital opportunity is created. Privileging ‘technology hotspots’ with the ‘right mix’ of skills, knowledge, and technology, we know much less about the prospects for smaller and mid-sized cities where most people actually live. We also know much about the secure employment prospects for workers and entrepreneurs educated to develop digital applications and content, but much less about the increasingly ambiguous future for those less well-positioned to benefit from rapid technological change.

As digital innovation accelerates it represents one of the fault lines that threaten most to exacerbate growing inequality - with important political consequences (Rodriguez-Pose, 2017). Simply creating digital opportunity is insufficient. Rather, it requires meaningful expansion to more people and places on the ‘wrong side of the digital divide’. As Kenney and Zysman (2016, 61) remind us, the broader impact of digital technologies “will be determined by the social, political, and business choices that we make”. The need for more intentional and inclusive forms of intervention implies essential strategic roles for both public policies and local institutions. Experimentation is increasingly evident with digital inclusion practices such as sector-based workforce development systems and career pathways into digital and digitally-supported industries and occupations (Lowe & Wolfe-Powers, 2016), supports for women and minority technology-based entrepreneurs (ICIC, 2015), and open access makerspaces. However, we as yet know little about how these programs are developed and implemented, or their actual impact.

This project compares ‘digital inclusion’ efforts in Saint Etienne, France, London, Ontario, Canada, and Greensboro, North Carolina, in the United States, three mid-sized cities in the midst of restructuring. Asking urban policymakers whether and how they seek to expand opportunity to groups typically under-represented in digital economy activities, we compare the multilevel interplay of public policies and local institutions in the three program areas identified. The results are decidedly mixed and these are ‘not success stories’. Digital inclusion is evident in two of the three cases. These include a career pathways program into software engineering for low income immigrant youth and a program to expand business supports to women and minority entrepreneurs in Saint Etienne and Greensboro respectively.[1] However, it is one thing for local programs to form and entirely another for them to perform; even with supportive public policies, durable cross-sector coalitions to support high impact programs are difficult to sustain (Bramwell, 2012). Jurisdictional ambiguity, weak local government or private sector participation, and inter-agency conflict underscore the political fragmentation that compromises local institutional capacity. Due partly to structural forces beyond their control and partly to local actor configurations and the policy choices that ensue, the implications of these sobering insights for planning scholarship and practice suggest that strategic efforts to support inclusive innovation in less advantaged regions will fail without attention to the political dimension of local institutional capacity.

[1] Inclusive innovation is least evident in the London case, which despite having the most robust local digital sector, demonstrates no digital inclusion efforts.

EXAMINING A DIVIDE WITHIN ENTREPRENEURIAL ECOSYSTEM

Abstract ID: 330

Group Submission: Inclusive Innovation through Business and Entrepreneurial Strategy

MOTOYAMA, Yasuyuki [Ohio State University] motoyama.1@osu.edu, presenting author

KNOWLTON, Karren [University of Pennsylvania] karren@wharton.upenn.edu, co-author

CLARK MUNTEAN, Susan [University of North Carolina, Asheville] smuntean@unca.edu, co-author

There has been an increasing number of scholars examining so-called 'entrepreneurship ecosystems' in the past decade, while much of the focus has been identifying elements of ecosystem, such as incubators, support services, venture capital, universities, and government (Breznita and Taylor 2014; Motoyama and Knowlton 2017). Some studies noted the importance of social capital in the ecosystem (Feldman 2001; Neck et al. 2004). However, they suffer from conceptual weakness because they do not differentiate elements and interaction between elements. A few studies have pointed out the importance of peer-based learning among entrepreneurs (Bahrami and Evans 1995; Feld 2012). However, virtually, almost no study has investigated the communal aspects of the system and assumed that every entrepreneur within a region has access to local resources.

In this study, we demonstrate that the ecosystem, its elements, or even connectivity does not reach to certain segments of entrepreneurs, most notably women entrepreneurs. We conducted 83 interviews of both male and female entrepreneurs, as well as leaders of support organizations in St. Louis.

We identified two structural reasons that women entrepreneurs did not get connected to the local entrepreneurship community. First, the networks of women entrepreneurs tend to be smaller than male

counterparts, and the network of female entrepreneurs had little interaction with those of male entrepreneurs. A further complicating factor here is that entrepreneurs often seek local resources and support groups based on word-of-mouth from other peer entrepreneurs. Thus, even when support organizations tried to recruit women entrepreneurs, spreading words through existing clientele, i.e. male entrepreneurs, had little effect to reach new and different segments of entrepreneurs.

Second and more importantly, even when female entrepreneurs were aware of such networks, they explicitly decided not to engage because the style of entrepreneurship was culturally different. We perceived this cultural dimension broadly and disaggregated at several levels: a) the use of vocabularies particularly related to startups and entrepreneurs vs. small businesses and owners, b) the types of business models, such as the growth patterns and exit settings, and the use of venture capitals, and c) a series of microaggressions that made women entrepreneurs felt uncomfortable to engage with the mainstream entrepreneurship stakeholders.

These two findings point out that an ecosystem is far from complete with the presence of elements, and much deeper analysis about connectivity and communal aspects between people is needed. We further provide a practical implication that open-door policy by support organizations is necessary, but far short of connecting non-mainstream entrepreneurs and achieving diversity within a local system.

LOCATING “LOW-TECH” INNOVATION IN INSTITUTIONAL AND GEOGRAPHICAL SPACE: THE CASE OF ROBOTICS SYSTEMS INTEGRATORS

Abstract ID: 331

Group Submission: Inclusive Innovation through Business and Entrepreneurial Strategy

KRAFT, Benjamin [Georgia Tech] Ben.Kraft@gatech.edu, presenting author

Robotics systems integrators are knowledge-intensive business service firms that design and implement industrial robotic automation systems. They work at the boundary of high-tech artificial intelligence technology applications—such as machine vision—and low-tech manufacturing applications—such as welding and painting. Industrial systems integration is a growing field that has thrived in a knowledge-based economy while carrying with it embedded legacies and practices of “low-tech” industrial cultures and approaches to innovation. These practices include emphasizing user-producer interactions, learning-by-doing, and incremental innovation. This presentation proposes that although these industrial

inheritances are often assumed to be at odds with contemporary innovation systems theory and practice, acknowledging and incorporating them can promote more inclusive innovation, especially in deindustrializing regions. It uses data from surveys of and interviews with robotics systems integrators to explore how they incorporate these industrial legacies into their innovation practices, and further discuss how these low-tech practices can more broadly be acknowledged in inclusive innovation strategies.

MAKING SPACES? PLANNING FOR NEW FORMS OF URBAN PRODUCTION

Abstract ID: 332

Group Submission: Inclusive Innovation through Business and Entrepreneurial Strategy

VINODRAI, Tara [University of Waterloo] tara.vinodrai@uwaterloo.ca, presenting author
NADER, Brenton [University of Waterloo] bnader@uwaterloo.ca, co-author

Are we in the midst of an urban manufacturing renaissance? New, more accessible and more affordable technologies, like 3D printers, laser cutters, and hobbyist CNC machines, coupled with social innovations, like the Internet, open source licencing, and social networking, are transforming high-tech and high-value urban manufacturing. Taken together, these innovations offer a counter narrative to the proclamations of the death of North American urban manufacturing. Buoyed by growing public interest in do-it-yourself culture, localism, and sustainability, these technological and social innovations collide in emerging maker culture and makerspaces. Akin to technology-centric manufacturing cooperatives, makerspaces are an understudied urban phenomenon. Optimistic accounts suggest that makerspaces provide foundational ideation and prototyping infrastructure for artisanal manufacturers, micro-manufacturers, and entrepreneurs (Anderson, 2012). Others suggest that urban makers, like their creative and knowledge industry counterparts, benefit greatly from the ecology of dense urban communities and proximity to customers, labour pools, and other manufacturers (Wolf-Powers et al., 2017). As such, makerspaces may be a primary mechanism for creating design-intensive, high-tech and high value production, representing a potent means of promoting high quality job growth and inclusive urban economic development.

There are two competing hypotheses related to the emerging geography of maker culture and makerspaces. On the one hand, technological and social innovations may encourage the further decentralization of urban manufacturing (Anderson, 2012). On the other hand, the networks and technologies necessary for successful makerspaces may be embedded in older industrial regions and urban neighbourhoods where there have been strong traditions of manufacturing (Clarke, 2013). To date,

there have been few systematic attempts to examine the underlying local geography of maker spaces. In an effort to address this gap, this paper asks the following questions: 1) what models, policies, and institutions exist that support, or hinder, these emerging forms of manufacturing in urban and regional economies?; 2) what are the neighbourhood characteristics associated with makerspaces; and 3) to what extent do these reflect more equitable forms of local economic and urban development.

To answer these questions, this paper uses census data to analyze the socio-economic neighbourhood characteristics of the locations of makerspaces located in twenty-one cities in the Canadian province of Ontario, as well as their associated urban planning and economic development strategies. These twenty-one cities are mandated to pursue population and employment densification, governed by the Province of Ontario's Places to Grow Act and the Growth Plan for the Greater Golden Horseshoe. The paper reveals how policymakers conceptualize artisanal manufacturing and making, and the extent to which equity and inclusion goals are considered. The paper goes further to analyze the neighbourhood characteristics associated with local makerspaces to understand the extent to which these spaces are embedded within neighbourhoods reflective of broader equity and inclusion goals. While this research is still exploratory, it represents an area of growing interest to local governments and professional planners wishing to support (or revive) new forms of innovative manufacturing in cities. However, the paper also raises questions about the potential of micro-manufacturing and maker spaces for creating higher quality jobs and inclusive development in North American cities.

TRACK 3 - ROUNDTABLES

ROUNDTABLE - REAL ESTATE DEVELOPMENT AND ECONOMIC DEVELOPMENT PLANNING EDUCATION: PRAGMATIC TURN OR TROJAN HORSE?

Abstract ID: 266

Roundtable

SCHROCK, Greg [Portland State University] gschrock@pdx.edu

GANNING, Joanna [Cleveland State University] j.ganning@csuohio.edu (moderator)

MALIZIA, Emil [University of North Carolina at Chapel Hill] malizia@email.unc.edu

WOLF-POWERS, Laura [Hunter College, City University of New York] aw2416@hunter.cuny.edu

KIM, Minjee [Florida State University] m.kim@fsu.edu
NELSON, Marla [University of New Orleans] mnelson@uno.edu
GEBHARDT, Matthew [Portland State University] mfg@pdx.edu

The economic development planning sub-field has long wrestled with competing emphases on industry, jobs and innovation on one hand, and land, real estate and finance on the other. Yet in practice, economic development planners routinely straddle these worlds, as efforts to spur new job creation or retain existing industries are deeply impacted by private-sector real estate developers seeking public approvals or funding support - or whose investment is said to be important for achieving local and regional economic development goals. On a pragmatic level, economic development planners need to understand how real estate development works; this is driving a growing student interest in courses related to real estate finance and development. At the same time, it is important to balance this pragmatism with a recognition that, if not taught effectively, real estate could become a “trojan horse” that weakens our orientation toward good jobs, addressing income and wealth disparities, and fostering community stability and well-being.

In this roundtable, faculty assess the unique challenges and opportunities inherent in teaching real estate to planners and think about how we use our time in the development finance classroom to shape students' understanding of the world they will face as professionals. Some questions we may explore are: How is economic development finance distinct from housing/real estate finance, practically and pedagogically? What is it important for students to know about the current status and political economy of development finance? What kinds of tools and curriculum content encourage students to think critically and integrate community-supporting values and conditions as they learn the basics of real estate financial analysis? And who should be teaching these courses - what are the appropriate roles of adjunct-practitioner and academic faculty?

More broadly for economic development planning educators, what does this “real estate turn” mean for how we frame the meaning and goals of the economic development sub-field to students, and to one another as scholars? What are the implications for the curriculum -- is the pro forma becoming more important than shift-share analysis? Ultimately, what role should real estate finance and development courses play in the training of economic development planners?

This roundtable will feature faculty who have been teaching at the intersection of real estate, planning and economic development - some as pioneers, others as relative newcomers. Setting the tone for the conversation will be Emil Malizia, Professor at UNC Chapel Hill, who was an early adopter of the idea that real estate finance should be integrated into the economic development curriculum. Designated by the Economic Development track chairs as the “chairs’ session,” this session is intended to spur dialogue about important issues facing the economic development sub-field. As a result, we encourage all economic development planning faculty to attend.

TRACK 3 INDIVIDUAL ABSTRACTS

REVITALIZING NEW YORK'S URBAN ALLURE THROUGH CREATIVE CITY STRATEGIES

Abstract ID: 26

Individual Paper Submission

GOLDBERG-MILLER, Shoshanah [The Ohio State University] goldberg-miller.1@osu.edu, presenting author

What are creative city strategies and how can they gain a place on a municipal agenda? Using the lens of Multiple Streams' agenda setting theory, I identify evidence of creative citybuilding and cultural policy on New York's municipal agenda in the decade following 9/11. New York underwent a creative resurgence, wherein the creative sector was a factor in a municipal strategy for revitalization after an exogenous shock. A policy opening revealed itself, and the challenge was finding ways to bring businesses and tourists back to New York City by providing a sense of safety and security.

I analyze data from 21 semi-structured interviews with policymakers, nonprofit leaders, developers, and philanthropists, together with archival and historical materials to uncover ways that creative city interventions were employed in New York. Anchoring the analysis are discussions of field building, agenda setting, the return to the city center, and facets of what I term, "urban allure." Urban allure consists of hard factors including the cultural built environment, arts and design amenities, live/work options and opportunities for the creative class to flourish as well as soft factors, such as the 'coolness' of a city, its attractiveness both as a tourist destination and a draw to residents, and the numerous cultural opportunities that make an urban center vital.

Findings include the recognition of the top-down and bottom up aspects of cultural policy and strategic planning for the creative city. Mayor Michael Bloomberg's agenda included keeping residents, business development, and tourism in the city. The vernacular creative sector played a less formal, but still important role in regenerating urban allure, often agglomerating in the boroughs outside of Manhattan. Arts and culture were on the economic development agenda for New York during the decade through the strategy of this dominant leader. Creative city tools leveraged include the use of city-owned land for cultural facilities, such as Whitney Museum's new home in Manhattan's Meatpacking district; branding research including a McKinsey study; and the enhancement of tourist and resident experiences, exemplified by two notable public art installations.

Creative city policy interventions such as cultural plans, widely used by Toronto, Vancouver, Chicago, and Austin were not a part of this strategy. The creation of a cultural plan, wherein a municipality convenes all three sectors to envision and strategize on the effective use of creative economy interventions, can be advantageous for cities facing exogenous or endogenous shocks and ensuing challenges. I offer ways to understand urban allure and discuss ways municipalities can leverage creative city tools. These findings are significant for academics and practitioners who wish to explore the use of arts and culture interventions in the fields of urban planning, cultural policy, and economic development.

LEVERAGING MAIN STREET AS A REAL ESTATE AMENITY: THE IMPACT OF RETAIL CORRIDOR REVITALIZATION ON RESIDENTIAL PROPERTY VALUES

Abstract ID: 71

Individual Paper Submission

VAN LEUVEN, Andrew [Ohio State University] vanleuven.3@osu.edu, presenting author

Downtown revitalization has become a necessary planning approach for communities attempting to reverse the pervasive momentum of suburban sprawl. One such endeavor, the Main Street Program, equips smaller towns and cities with the resources and know-how to leverage their dense, walkable retail corridor(s) as an economic development asset. This paper will assess the viability of the Main Street Program as a means of scalable, sustainable urban regeneration by empirically demonstrating the program's impact on local economic vitality, operationalized in terms of property value appreciation.

First, I estimate the causal link between a community's adoption of the Main Street Program and the health of its local housing market in the years that follow. I do this by implementing a difference-in-differences design which compares changes in residential property values between communities that implemented the Main Street Program and those that did not.

Second, I test the mechanism of this causal relationship. I hypothesize that improvements to (and revitalization of) the downtown retail corridor will increase the value of Main Street as a "walkable" retail amenity. Thus, the value of properties closer to downtown should reflect access to said amenity. To test this, I employ a hedonic price model which—aside from controlling for all the relevant property characteristics—will allow me to identify the association between a given house's distance from Main Street and its market price.

This study is motivated by the overall need to understand the viability and efficacy of smaller-scale urban regeneration efforts in non-metropolitan towns and cities. Walkable centers of smaller, older communities are one of few factors holding back an almost ubiquitous landscape of sprawl and a geography without identity. Main Streets serve as an anchor around which downtowns can be preserved as vibrant "third places." In order to preserve "Main Street" as the epicenter of an integrated civic and commercial fabric, communities need to identify programs and policies that work, and the Main Street Program shows promise as an economic development program that can help revitalize downtown. This paper starts the discussion toward determining just how well the MSP can deliver on that promise.

COMPARING ECONOMIC DEVELOPMENT AS A PRIVATE OR PUBLIC GOOD: THE EMPIRICAL EVIDENCE

Abstract ID: 76

Individual Paper Submission

FRANKEL, Bruce [Ball State University] bfrankel@bsu.edu, presenting author

The key theoretical choice in a local economic development strategy is whether the incentives for jobs and income derive from supply-side or demand-side economics. If supply-side, the overwhelming norm in such practices, then local and state governments subsidize the factors of production for the subject corporation as an inducement to relocate or expand. If the demand-side, then the attraction is to place creating a key set of public utilities of entrepreneurial opportunities, place-making amenities and quality of life, and affordability and niche markets to serve diversity and equity conditions.

We utilize six [6] national databases providing:

1. a comprehensive array of supply-side corporate incentives instated by all states and their minor civil divisions,
2. a 24-variable set of economic conditions by state,
3. two surveys of localities that promote demand-side economic development via place-making and public entrepreneurial opportunities,
4. surveys of affordability by place over the period 2000-2016, and
5. the economic performance of those localities over the same period

The statistical results, utilizing trend lines and regression analysis, demonstrates a slightly negative relationship between dollar volume per capita of supply-side incentives and economic condition. The results also demonstrates a 128% net job growth and 680% per capita GDP growth in identified demand-side places relative to all places in that state over the period 2010-2016.

We conclude that the worse the economy the more places spend on “corporate welfare” and that demand-side strategy affects local economic development meteorically. We examined the challenges of affordability, diversity and equity, but those findings are reserved for another manuscript, and due to the breadth of the empirical scope.

CHANGE VERSUS DECLINE: THE SUBURBANIZATION OF JOBS IN U.S. SHRINKING CITIES

Abstract ID: 77

Individual Paper Submission

GANNING, Joanna [Cleveland State University] j.ganning@csuohio.edu, presenting author

Spatial mismatch theory hypothesizes that as jobs suburbanize, minorities and low income households will disproportionately lose access to economic opportunity. This paper hypothesizes that the context of urban decline also challenges job accessibility. In shrinking cities, growth at the urban fringe not only expands the footprint of the region’s urbanized area, but unlike in most strong market settings, it simultaneously hollows out the core, challenging job accessibility for residents. This paper tests this hypothesis by presenting a block-group level model of job accessibility in the Principal Cities of 349 Metropolitan Statistical Areas (MSAs). The model finds that the context of urban decline reduces job accessibility for residents by 6.9%, other things equal. Descriptive statistics are then employed to analyze spatial changes in job location over time. The results suggest that as development pushes outward in strong market settings, the core shares in the growth, while in shrinking cities, spatial deconcentration disproportionately weakens the core. This process is hypothesized to lead to the decreased job accessibility found in shrinking cities.

Testing the hypothesis that urban decline exacerbates job accessibility through deconcentration bears important implications. First, metropolitan regions situated around shrinking central cities are aware of the threat of deconcentration on regional economic health. Regional planning organizations in such settings may benefit from knowledge that can assist in establishing effective incentives for core-based and node-based urban development. Second, and relatedly, companies considering moving to suburban locations may be influenced by information campaigns regarding the social costs of such decisions (although economics texts emphasize that information campaigns tend to be less effective than prescriptive or market-based interventions). Third, improved knowledge regarding the effects of deconcentration on job accessibility for shrinking city residents may guide strategic planning efforts around land use, zoning, and transportation, or provide support for transit riders’ unions to lobby for additional funding. Finally, the results of this research will apply to a not insignificant group of cities. Research on what constitutes a shrinking city is nascent, but one recent effort to reach a consensus (Ganning and Tighe, 2018) identifies 80 such cities in the United States alone; the phenomenon of urban decline is well-documented in Europe and elsewhere as well.

OPPORTUNITIES AND RISKS OF LOCALIZED INDUSTRIAL POLICY: THE CASE OF “MAKER-ENTREPRENEURIAL ECOSYSTEMS” IN THE UNITED STATES

Abstract ID: 83

Individual Paper Submission

WOLF-POWERS, Anna Laura [Hunter College, City University of New York]

aw2416@hunter.cuny.edu, presenting author

SCHROCK, Greg [Portland State University] gschrock@pdx.edu, co-author

In the past decade, the emergence of a “maker economy” in the United States has opened opportunities for small-scale, design-linked production enterprises. Tapping the availability of low-cost technology like 3-D printing and personal CNC machine tools, the proliferation of digital marketing platforms, and a growing supply of workers and consumers eager to associate themselves with materiality and craft, small-batch manufacturers have regained viability in industries like food and beverage, apparel, furniture, and even electronics. Concomitantly, “making” has become the object of place-based industrial policies, pursued predominantly at the local/urban scale. Makerspaces, incubators, meet-ups, and manufacturing skills training programs, if not initiated by the public sector, routinely receive government and philanthropic funding. Resources dedicated to making are urged in the name of reinvigorating moribund urban industrial economies through a “manufacturing renaissance” (Muro and Hirschberg, 2017).

The growth of the maker movement has the potential to take urban-level industrial policy in a new direction. Although local economic development policy in the U.S. has frequently revolved around beggar-thy-neighbour business recruitment efforts, there have also been progressive efforts to promote innovation, entrepreneurship, manufacturing retention, and job creation (Fitzgerald and Leigh 2002; Lowe and Feldman 2018). In this context, policymakers’ embrace of “maker”-specific industrial policies – both gestures of support extended to existing small-scale producers and efforts to incubate new such producers – are continuous with efforts to preserve industrial land, promote local and regional industry clusters, and build the capacity of small and medium-sized enterprises (SMEs). Maker-oriented industrial policies focus on the potential of local entrepreneurs to incubate and grow businesses rooted in place, generating jobs in core urban regions, both directly and through multiplier effects (Wolf-Powers et al., 2017). Local government has significant advantages as an industrial policy actor in this area, due to its potential to bridge diverse actors and institutions in a localized context.

But another defining feature of local economic development practice in the United States is the primacy of real estate interests. Under a “property-led” model, policy-makers favour opportunistic deal-making that privilege short-term increases in land value over longer-term economic development goals (Wolf-Powers, 2005). In this article, we use the case of “maker industrial policy” to examine the tension between efforts to build local-scale institutions to achieve industrial policy goals on the one hand, and ongoing pressures to facilitate the extraction of real estate profit on the other. Drawing on a study of maker enterprises and established manufacturers in six U.S. cities (Urban Manufacturing Alliance, no

date) and on case data from New York City and Portland, Oregon, the paper assesses the governance of maker-oriented industrial policy at the urban scale. Our conclusions are twofold. First, despite a tacit transfer of knowledge, skills, and routines from incumbent manufacturing complexes to local maker ecosystems, the urban political and institutional worlds in which traditional manufacturers and maker firms circulate are quite distinct. This matters because institutional bifurcation limits the spillover of knowledge and material assets from established firms to newer adjacent sectors; it also leaves makers politically isolated from local industrial policy constituencies who advocate for policies that are critically important for makers' ability to grow and scale. Second, the dominance of real estate-led economic development practice at the local level in the U.S. threatens to place opportunistic actors' pursuit of returns ahead of employment creation and other economic development goals. This creates barriers for maker-entrepreneurs who might wish to grow their firms in place and leaves potentially productive connections among designers, fabricators, small-batch producers, and mature manufacturers unrealized.

IS LOCAL GOVERNMENT TAX COMPETITION STRATEGIC? THE SPATIAL DISTRIBUTION OF BUSINESS PROPERTY TAX ABATEMENTS IN CHICAGO'S SUBURBS.

Abstract ID: 132

Individual Paper Submission

FUNDERBURG, Richard [University of Illinois at Springfield] rfund2@uis.edu, primary author
DRUCKER, Joshua [University of Illinois at Chicago] jdruck@uic.edu, presenting author
MERRIMAN, David [University of Illinois at Chicago] dmerrim@uic.edu, co-author
WEBER, Rachel [University of Illinois at Chicago] rachelw@uic.edu, co-author

We analyze the locations of property tax abatements awarded to businesses in Cook County, Illinois, from 2012 to 2014, in order to explore their spatial distribution and to infer local government motivations in awarding these business incentives.

Classic interjurisdictional competition models of local government behavior imply that tax abatements are awarded in responsive fashion and will follow the general pattern of business location. This dominant perspective is exemplified by the "shoot anything that flies" characterization of local economic development (Rubin 1988). Leviathan models of public sector behavior contend that locational

heterogeneity enables local governments to award incentives selectively, to maximize revenue or reward political patronage (Brennan and Buchanan 1980). We hypothesize that municipalities instead may take a spatially strategic approach to property tax abatements, harnessing them as a means for accomplishing policy goals such as influencing business location choices, promoting particular land uses or industrial sectors, or achieving fiscal zoning objectives (Fischel 2015, Merriman et al. 2017). A spatial pattern of abatements that diverges from the overall configuration of business locations would be consistent with strategic local government behavior, as well as with varying economic development and fiscal policy “regimes” (Craft, Drucker, and Weber 2017).

Through comparing property tax abatements to the existing distribution of businesses, our analysis reveals clustering of abatements at intra-municipal geographic scales. We also uncover amplified probabilities that businesses receiving abatements are located near tax increment financing districts or enterprise zones. We characterize the degree to which different municipalities exhibit clustering of abatement awards. Overall, our findings are consistent with the notion of local governments awarding business property tax incentives strategically to advance policy goals.

DEVOLUTION, DISINVESTMENT AND UNEVEN DEVELOPMENT: US INDUSTRIAL POLICY AND EVOLUTION OF THE NATIONAL NETWORK FOR MANUFACTURING INNOVATION

Abstract ID: 194

Individual Paper Submission

CLARK, Jennifer [Georgia Institute of Technology] jennifer.clark@gatech.edu, presenting author
DOUSSARD, Marc [University of Illinois at Urbana-Champaign] mdouss1@illinois.edu, co-author

In the absence of a formal industrial policy, the US supports manufacturing industries indirectly, and with minimal coordination. The resulting system constitutes a de facto industrial policy, whose contours and mechanisms are infrequently scrutinized. In this paper we analyze a rare, recent federal effort to consciously design and implement the National Network for Manufacturing Innovation (NNMI). We analyze to what extent regional Manufacturing Innovation Institutes (MIIs), seeded through the NNMI program, build new industrial specializations in the communities where they operate, and, alternately, to

what extent MIIs enhance and extend existing specializations by providing access to emerging and enabling technologies.

We examine in detail seven regional manufacturing institutes developed under the National Network of Manufacturing Institutes, a federal program that (1) invests in basic technology, (2) sites those investments within newly formed regional technology institutes (MIIs), and (3) attempts to link technological development to industrial capacity and, ultimately, job growth. We ask to what extent the Manufacturing Innovation Institutes seed new industrial specializations, as opposed to supporting old ones. Focusing on seven technologies and institutes founded from 2012 to 2015, we find that this federal program in fact devolves power, funding and development strategies to the newly founded technology institutes. This results in three de facto relationships between Manufacturing Innovation Institutes and existing industrial capacity. Three technology-sustaining institutes (in Detroit, San Jose and Rochester) tie new technology investments to mature industries in which innovation effectively props up older industrial concentrations. By contrast, two technology-seeding institutes in the greenfield sites of Raleigh-Durham and Knoxville invest in technologies with little past or present production capacity in their regions. Finally, agglomeration-seeding institutes in Chicago and Akron fund product design activities in regions with related manufacturing agglomerations. Despite these differences each MII's membership consists principally of large, incumbent firms, at the expense of start-ups and small businesses.

This creates a national industrial policy that links technology to production unevenly. The individual autonomy granted to the regional manufacturing institutes allows for program flexibility that often leads innovation policy to adapt usefully to existing specializations. Yet individual manufacturing institutes do not engage the third-sector organizations (educational institutions, unions, labor market intermediaries) crucial to upgrading manufacturing sectors in the US (Clark, 2014). This results in a system that amplifies, rather than diminishes existing regional disparities. Thus, formal industrial policy in the US in fact resembles the nation's longstanding, covert system of unintentional industrial policy. These outcomes follow from the design mechanism of political Federalism, whose devolution of funding and programming authority to regional entities appears to shape policy content more than do the program's formal goals and cross-Atlantic policy antecedents.

ECONOMIC DEVELOPERS' RISK PERCEPTIONS AND PLANNING ACTIONS IN FREIGHT-RELATED DEVELOPMENT STRATEGIES

Abstract ID: 197

Individual Paper Submission

CAMPO, Matthew [Rutgers University] mcampo@ejb.rutgers.edu, presenting author

Warehouses, fulfillment centers, and other freight-related land uses are sprawling in urban areas to support new distribution patterns driven by e-commerce and global value chains (Kang, 2018). Freight-related land uses exhibit both the nuisance characteristics of locally unwanted land uses (LULUs) and the job gains sought after by economic development officials (Yuan, 2018). Planners and economic development officials use a variety of urban planning efforts to balance future employment gains with concerns about job quality, transportation emissions, and other risks unevenly distributed by growing logistics-related land uses. Campbell (2016) presents the relationships between social, environmental, and economic risks of development as a set of tensions for participants in the economic development strategy to manage. There is evidence that process design, power dynamics, and personal attributes influence officials' initial perception and subsequent management of the tensions between social, economic, and environmental outcomes (Feldmann, 2016).

In this study, I used semi-structured interviews to describe the influence institutional settings, and personal values have on economic development officials' perceptions of economic, social, and environmental risks related to freight-related land uses. I propose that the scope risks that an economic development official chooses to measure are a function of the individual official's ability to observe and act on their perception of a given risk. Renn and Rohrmann (2000), propose that individuals perceive risk based on individual heuristics, emotions and values, institutional membership, and the prevailing modern culture.

Through a study of 25 economic development officials, I use a grounded theory approach to describing the influence institutional membership and emotions and values have on economic development officials' perception of benefits and risks while pursuing logistics-related economic development strategies. Study participants included a sample of local and regional economic development officials in the United States whose jurisdictions vary from international port gateways to rural distribution hubs. Participants completed a brief questionnaire, followed by an hour-long semi-structured in-person or telephone-based interview. I conducted content analysis using existing risk management and sustainability theory to develop an initial coding scheme related to the management of tradeoffs in economic, social, and environmental risk. Additional coding elements reflected participants' thoughts on institutional arrangements, personal values, available reference knowledge, and other correlates of risk perception outcomes stated during interviews.

I find evidence that both institutional structures and personal values and experiences affect the scope and focus of economic development officials' risk assessments. In particular, participants frequently referenced institutional barriers and conflicting responsibilities as an impediment to a more holistic consideration of social and environmental impacts of proposed freight-related economic development strategies. The spatial concentration of industry and officials' prior reference knowledge of working with freight-related industries in their jurisdiction also influence how economic development officials receive, develop, and act on risk information when negotiating economic development strategies. For planners, these findings demonstrate the continued importance of understanding how the potential for an official's emotions, experiences, and organizational barriers limit perceive and take action on social, environmental, and economic risks during economic development planning. As planners, we need to partner with economic development officials to generate strategies, recognize the limitations of individual participants'

perceptions and capabilities to create a more robust accounting of potential social, economic, and environmental benefits by other actors in the development process.

ARE LOCAL RETAIL SERVICES AN AMENITY OR A NUISANCE?

Abstract ID: 258

Individual Paper Submission

MELTZER, Rachel [The New School] meltzerr@newschool.edu, presenting author

GHORBANI, Pooya [NYC Independent Budget Office] ghorp982@newschool.edu, co-author

Much of the public finance and planning literature on neighborhood disparities and service provision focuses on the availability and quality of public goods and amenities. However, there is little research on how private services affect the quality and desirability of particular neighborhoods. Are they considered a nuisance or an amenity, and is this value capitalized into residential property values? Using a rich, micro-dataset on property sales transactions and business activity in New York City, we estimate the impact of neighborhood retail services on property values. Preliminary results show that the significance and magnitude of price capitalization depends on the type of residential property and the distance to the retail activity. Buyers of one-to-four family homes will pay more for nearby restaurants, but not any other types of services. Buyers of condos and coop units will pay more for nearby restaurants and frequently consumed services more generally. Prices for large multi-family buildings, typically occupied by renters, are negatively associated with nearby services that are more frequently consumed and classified as food and beverage. Overall, the magnitude of effects is quite small (in either direction). First attempts at instrumenting for retail activity show positive price capitalization from nearby retail establishments that is strongest at very close proximity and declines with distance from the property.

INCLUSIVE CLUSTER-BASED DEVELOPMENT STRATEGIES: CASE STUDIES OF THREE DISTRICTS IN NEW YORK AND MICHIGAN

Abstract ID: 260

Individual Paper Submission

VOLTOLINI, Patricia [LISC] PVoltolini@lisc.org, presenting author

GREENBERG, David [LISC] dgreenberg@lisc.org, co-author

Industrial cluster-based economic development strategies have gained popularity in the past couple of decades and investment in cluster-based economic districts has helped revitalize many urban neighborhoods throughout the country. Benefits of investing in place-based strategies focusing on particular industry sectors and their supporting infrastructure (job growth, attracting further investment) have been documented (Delgado-Garcia & Zeuli 2016; Hartley et al. 2016). What remains less clear is the direct benefits of the cluster-based approach to inner-city residents, often communities of color and without the skills and networks to access newly generated jobs (Bates 2006).

Investments in industrial districts in particular have been increasingly touted as a solution to inner city poverty, as manufacturing is still a vital component of the American economy and an industry of opportunity providing decent jobs with lower barriers of entry to less skilled workers. Despite increasing efforts to promote manufacturing and industrial districts, economic initiatives designed to attract and support businesses in industrial districts remain largely disconnected from workforce development programs. How can investments in industrial districts be linked to programs designed to train low-income residents of surrounding communities, so as to ensure they have access to local jobs?

Greater calls for integrating cluster-based economic development with workforce development have been made among scholars and practitioners but few studies have examined how effective linkages between the two are established and maintained (Harper-Anderson 2008, Wolf-Powers 2006). Through a series of interviews with industrial district and economic development practitioners as well as workforce development practitioners and advocacy organizations throughout the country, this paper seeks to fill that gap by conducting an in-depth qualitative examination of linkage strategies implemented in three districts in New York and Michigan.

Research findings suggest that effective linkages to connect inner-city residents to newly generated jobs in cluster-based industrial districts share a few similarities. Effective linkages capitalize on relationships developed around economic development to benefit workforce development and placement. Workforce placement is relationship driven and requires a high degree of trust that can originate with other services such as help finding loans, or dealing with parking problems and ticketing. For planners working to establish those connections, this highlights the importance of sequencing business support services before or in parallel to workforce efforts in order to build trust and use those relationships to advocate for job quality and worker advancement.

Furthermore, to benefit inner-city residents, effective linkages also require identifying structural and institutional, or historical obstacles that affect inner-city residents and devising mechanisms to address that. Thus, in addition to skills training and employment and career services, which are typical of workforce development programs, inner-city residents have the best outcomes when those services are bundled with a range of support services meant to help address these obstacles. These include providing income supports, financial coaching and education and low-cost financial products that build credit, savings and assets. Funding for workforce and economic development should reflect the full range of work needed to engage employers and connect low-skill residents to manufacturing jobs, an intensiveness of services that is not always met by funding limited to job-placement numbers.

Finally, effective linkages require real estate property stability. Industrial space needs to be affordable and stable with long term leases so manufacturers feel secure they can invest in their facilities, production, and workers, and so that they build relationships with local organizations and become vested in the community. This indicates the need for planners to adopt a targeted approach to zoning to help to protect industrial land-uses in hot property markets and allow its integration in a wider variety of neighborhoods in cities with further growth potential.

TARGETED HIRE POLICIES IN US CITIES: WHO IS ADOPTING THEM, HOW AND WHY?

Abstract ID: 264

Individual Paper Submission

SCHROCK, Greg [Portland State University] gschrock@pdx.edu, presenting author

In recent years there has been a re-engagement of local governments in the United States with policies designed to promote equitable and inclusive development. One of these areas is "Targeted Hire" policies, which obligate private-sector employers receiving public contracts or development incentives to take affirmative steps intended to increase employment opportunities for disadvantaged populations, particularly workers of color. These take a variety of forms, including "first source" or "local hire" requirements, and apply across a range of job-creating activities from construction to retail. These progressive policies have waxed and waned over the years (Schrock 2015) as elected officials have

negotiated political and legal opposition from business and suburban interests on one side, and pressure from activists and community organizations on the other.

Although there is a small but growing literature documenting this latest wave of policies (Douthat and Leigh 2017), there is no comprehensive inventory of which U.S. cities are adopting Targeted Hire policies, and how and why they are doing so. This paper presents results from a scan of the central cities of the 100 largest U.S. metropolitan areas, which shows a patchwork of different policy approaches. A small but increasing number of cities have TH policies relating to publicly-supported construction projects, while comparatively fewer cities have policies that cover non-construction public contractors, and other economic development incentive recipients. In general, cities with TH policies tend to be larger, face more local income disparities, but also experience more reinvestment activities, which creates opportunities for advocates and officials to attach hiring goals.

But why have construction-focused TH policies waxed while other areas have waned? I use the examples of San Francisco, Denver and Portland to illustrate the differential organizing and implementation dynamics underlying TH policies. Efforts in many cities to deepen community-labor partnerships have bridged historical divides between construction trade unions and communities of color, resulting in advocacy partnerships that effectively link construction-driven growth with robust, outcomes-oriented mechanisms for achieving distributional equity. By contrast, TH policies outside of construction have been hampered by their process orientation, which make them difficult and resource-intensive for public agencies and advocacy coalitions to enforce. But more vexing is the changing occupational character of urban economic development projects. TH policies have historically focused on “entry level” jobs requiring less than a college degree, and have mostly avoided asking employers for credible targeted hiring commitments around jobs requiring higher levels of education, despite persistent disparities in access and representation in those jobs, and evidence of the downstream impact of new in-migrants on local housing market outcomes. While this reflects a failure of planners and public institutions, I argue that it also reflects an inattention on the part of community-based actors to their potential leverage in extracting hiring commitments from businesses seeking urban locations.

These findings reinforce the idea that credible commitments to more just and equitable planning and development are unlikely to occur without a push from outside actors (Clavel 2010; Schrock, Bassett, and Green 2015; Doussard 2015). But especially with programs like Targeted Hire that require robust implementation in order to succeed, supportive planners and agency officials are necessary to the process as well.

TO PLAN OR NOT TO PLAN? CULTURAL AND CREATIVE CLUSTERS IN GUANGZHOU

Abstract ID: 376

Individual Paper Submission

LI, Xin [City University of Hong Kong] xinli87@cityu.edu.hk, presenting author

LIU, Ruoran [Cleveland State University] rrlu3-c@my.cityu.edu.hk, primary author

The notion of cultural and creative clusters, in particular artist clusters, has triggered discussions about the role of cultural and creative industries for urban regeneration. Since many cities entered the knowledge-based stage in the 1990s, policymakers and urban planners have promoted the idea of integrating Porter's industrial cluster and Florida's creative class theories by relying on cultural and creative industries for revitalizing deteriorating industrial spaces or old neighborhoods. Empirical evidence has demonstrated a relationship between a concentration of artists and economic growth (Zukin, 1982; Lloyd, 2002; Mould and Comunian, 2015).

Similarly, across cities in China, cultural and creative clusters have emerged in the policy rhetoric of the last decade as tools for neighborhood revitalization. Especially since 2005, we have noticed a rising number of artist clusters frequently touted in local news and government publications as promoting tourism, improving cities' images, and enriching urban lives. However, current realities present a more complicated scenario. These clusters initially have emerged organically from obsolete industrial areas, old downtown neighborhoods, or urban village settlements with low rent and loose controls, with some listed as the officially-recognized cultural and creative clusters whose development is to be integrated into the city's strategic plans. Yet the impact of this development is double-edged. On the positive side, the local government is likely to allocate public resources for brick-and-mortar investment and industrial preferential policies to attract creative people and businesses. However, as original artist settlers are gradually driven out due to rising rents and living cost or rigid entry control, such formal interventions may simply lead to the demise of a genuine creative cluster.

Academic discussions over the past decade in China have mainly focused on the formation and evolution of arts districts. What is clearly missing from the literature is a discussion of how formal planning and land policies inter-play with informal urban settlement development against the backdrop of arts districts. Additionally, throughout the development of arts clusters, the needs of ordinary artists, especially emerging and early-career individuals, and the neighborhoods they inhabit have been forgotten. To fill this gap, we position China's cultural and creative policy in the context of creative placemaking, a process emphasizing "arts-centered initiatives with place-based physical, economic, and social outcomes" (Gadwa Nicodemus, 2013: 213). As Markusen and Schrock (2006: 1661) point out, artists choose a locale in which to work and live "in response to a nurturing artistic and patron community, amenities and affordable cost of living." A question worth exploring in the Chinese context is, to what degree can artist clusters remain appealing to grassroots artists and still sustain their intrinsic creative nature?

Based on a field study of two cases in Guangzhou, we argue that one pitfall of the application and operationalization of cultural and creative cluster is that policymakers often prioritize capitalizing the economic value of cultural industry – but are frequently unable to provide a nurturing living and working environment that are essential for young artists to thrive. We maintain that village-based arts clusters are more successful in retaining their creative nature than top-down, arts-led neighborhood revitalization because they offer an environment characterized by its openness, inclusiveness, flexibility, diversity, and tolerance, all essential for creative people. Therefore, given these village-based arts clusters' capacity to

create an affordable, tolerant, and diverse socioeconomic environment, we suggest that urban villages function as an incubator for creative people and cultural-product industries. We find that organically grown, village-based artist clusters can better nurture creative people than planned arts districts, for the former cluster features a flexible and autonomous land development arrangement, frequent interactions between artists and village residents, and a broad spectrum of entrepreneurial opportunities.

SPATIAL AGGLOMERATION OF MANUFACTURING ACTIVITY IN URBAN VERTICAL FACTORY AND ITS IMPACT ON EMPLOYMENT

Abstract ID: 396

Individual Paper Submission

PARK, Jeong-Il [Keimyung University] sunpower217@gmail.com, presenting author

Most researches on agglomeration of industrial activity measured it at the regional level, without paying much attention to buildings because there are only one or several firms are usually located in a single traditional factory building. However, the emergence of so-called "vertical factory" has been receiving attention as new industrial spaces. The vertical factory is a three-dimensional, multi-story building located in high-density urban areas (Rappaport, 2016, 2017). Some buildings only have one establishment each, but in most cases many small establishments are located in the same building. Thus, a vertical factory can provide space for the agglomeration of small establishments especially in high-tech industries (Bae, 2015; Park, 2019).

This study aims to empirically examine how manufacturing activities are spatially clustered in urban buildings and how this spatial agglomeration influences employment, with a focus on vertical factories in the Seoul Metropolitan Area, South Korea. Using the Factory Establishment and Management Information System (FEMIS) database, an establishment-level database of manufacturing industries, it measures two different forms of agglomeration: specialization and diversity (or variety). This study uses the multi-level model approach to analyze how these two forms of agglomeration have impacts on employment levels in manufacturing sector. Based on the key findings, this study addresses an importance role of vertical factories in creation of urban manufacturing jobs and discusses some policy implications for urban industrial spaces.

RECENT INTRA-METROPOLITAN PATTERNS OF JOBS AND WORKERS: IMPLICATIONS FOR THE SPATIAL MISMATCH HYPOTHESIS

Abstract ID: 406

Individual Paper Submission

EOM, Hyunjoo [University of Maryland, College Park] hjeom15@gmail.com, presenting author
DAWKINS, Casey [University of Maryland, College Park] dawkins1@umd.edu, co-author

Since the seminal work of John Kain in the 1960s, scholars have explored the impacts of the spatial mismatch between suburban job opportunities and the residential locations of low-income African American workers on racial disparities in employment outcomes (Holzer, 1991; Ihlanfeldt & Sjoquist, 1998). Empirical studies point to housing discrimination, exclusionary suburban zoning, employer discrimination, social networks, and the difficulty of reverse commuting as important factors shaping the spatial mismatch between jobs and workers (Raphael & Stoll, 2002; Brueckner and Zenou, 2003; Martin, 2004; Stoll & Covington, 2012). Much of this literature takes as given a particular spatial pattern of jobs and housing that has dramatically changed since the early 2000s. The suburbanization of poverty, gentrification of urban neighborhoods, and proliferation of policies designed to promote transit-oriented development and integration of jobs and housing has reshaped U.S. metropolitan areas in ways that may have important implications for the spatial mismatch hypothesis. This study reexamines recent patterns of jobs and workers to determine whether the traditional spatial pattern assumed by the spatial mismatch hypothesis – centralized low-income African American workers and suburban job opportunities – still holds true in major U.S. metropolitan areas. In particular, we examine indices of job – worker imbalances to determine which metropolitan areas still exhibit patterns consistent with the predictions of the spatial mismatch hypothesis and which have been shaped by the relocation of jobs and housing. The findings of this study suggest that for African American workers, jobs-housing imbalance continued to persist in major metropolitan areas despite spatial changes in the location of jobs and housing since the early 2000s. This research provides useful information to planners seeking to promote spatial and racial equality in American cities.

EXPLORING THE GEOGRAPHY AND THE TYPOLOGY OF CREATIVE CLUSTERS IN THE UNITED STATES

Abstract ID: 502

Individual Paper Submission

GRANPAYEHVAGHEI, Tahereh [the University of Texas at Arlington]

tahereh.granpayehvaghei@mavs.uta.edu, presenting author

HAMIDI, Shima [the University of Texas at Arlington] shima.hamidi@uta.edu, co-author

Creative industries are finding their positions as strong catalysts for economic development, and neighborhood revitalization in communities, even though our knowledge of the location preference of the creative clusters needs further expansion. To demonstrate the formidable presence of arts and culture in the country, suffice it to say that nationally, 673,656 businesses with 3.48 million employees are involved in the creation or distribution of the arts, representing %4.01 %2.04 of all U.S. businesses and employees, respectively (Americans for the Arts 2017).

Existing literature demonstrates that creative industries tend to cluster. However, the contributors to the geography of these clusters are still in question. There are very few studies within the United States that try to identify the location patterns of creative clusters. Moreover, the extant empirical research mostly focuses on case studies and specific industries, such as fashion, cinema, or music (Scott 2002). This emanates, for the most part, from the fact that creative and cultural industries include an eclectic range of industries with diverse characteristics, and therefore, require specific attention.

This study seeks to address these gaps by investigating the geography of creative clusters of different specializations as well as the relationship between them, drawing upon hotspot analysis and a typology of creative clusters based on a comprehensive list of the North American Industry Classification System codes (Markusen et al. 2008). This is one of the first national studies that uses disaggregated address-level employment size and sales volume for all firms within the United States to quantify the geography of creative clusters. The authors categorize the creative industries into seven groups of 1) performing arts, 2) visual arts and photography, 3) film, radio, and television, 4) design and publishing, 5) educational services, 6) software publishing and gaming, and 7) museums and collections. Derived from 2016 ESRI Business Data Source, advanced statistical methods were utilized to create a mesh of identical hexagons created by ArcGIS, which helps ensure that all regions within the country are represented by the sampling results within similar geographies. In addition, this study uses cluster analysis to find specialization among creative clusters, demonstrating where in different cities and regions the different creative clusters locate.

The findings show that creative clusters tend to locate at the inner cities of large- and medium-size metropolitan areas. The hotspot analysis also demonstrates that some parts of the cities are more likely to embrace creative clusters of more than one category. For example, clusters of film, television and cinema tend to locate close to clusters of performing arts, while gaming and software programming clusters have a slightly different patterns. Our approach creates a systematic methodology that enables a comparative analysis across the country, by ranking the creative clusters in terms of size and the number of creative clusters. We also offer some more in-depth analysis to these clusters by investigating some of the largest and most diverse creative clusters in the Los Angeles and New York metropolitan areas.

Several policy implications for local communities are derived from this study. Planners and policy makers can benefit from the findings of this study as it offers a quantified measurement of where exactly the creative clusters locate in the country. Instead of anticatalysts epitomizing inequality and gentrification, a thorough understanding of where creative clusters locate and how they interact with other clusters and the built environment enables policymakers to utilize the benefits of these clusters as effective catalysts for urban and rural revitalization.

PLACE BRANDING, CITY PLANNING, AND THE URBAN IMAGINARY: UNTANGLING THE STIGMA OF THE PAST AND UNCOVERING DALLAS EMERGING NEW URBAN IMAGINARY

Abstract ID: 517

Individual Paper Submission

BONAKDAR, Ahmad [University of Texas, Arlington] ahmad.bonakdar@mavs.uta.edu, presenting author

AUDIRAC, Ivonne [University of Texas, Arlington] audirac@uta.edu, co-author

Place marketing and place branding have been the hallmark of the entrepreneurial turn to urban governance, with a growing emphasis on proactive, project-driven planning over traditional planning approaches that were deemed passive and reactive by new municipal administrations (OECD 2007). Instead, "measures called "imagineering" and "re-branding" [are being] extensively employed to redefine and re-image cities endowed with negative images inherited from the industrial era. Flagship developments have been employed as "hard-branding" to produce a significant impact on city image with their large scale, high profile, and innovative design by internationally-famed architects" (OECD, 2007, p. 2).

City planning processes have become central to these place branding approaches as both the material, hard-branding and symbolic soft-branding aspects of signature placemaking projects invariably involve the construction of new "urban imaginaries"(Greenberg, 2000; Zukin et al., 1998). Although place branding through placemaking has been the essence of physical planning since the 19th century's world

expositions that gave birth to the City Beautiful movement, not until the end of the 20th century, did place branding ideas begin to coalesce with city planning processes through participatory approaches and visioning exercises often led by planning consultants and municipal planners.

This research examines place branding strategies adopted by the City of Dallas over a century-long tradition of place promotion. It develops the notion of “urban imaginary” as an analytical framework drawing on Charles Taylor's concept of the “social imaginary.” Taylor (2004) suggests that the socially constructed imaginary constitutes the ways people imagine their social environment, through symbols, ideas, and stories. Changing Dallas' “urban imaginary” bedeviled with the stigma of its past (such as the “city of hate” after the JFK tragedy), has become a major endeavor of Dallas city leaders. Focusing on key moments of the city's history, this research looks at Dallas' urban imaginaries manifested in the redevelopment and planning approaches that aimed to forge a united identity for the city and to bridge its critical North-South social and economic divides.

Internet data, including social media, are the primary source of observations associated with Dallas. These include image and text related to promotional material by marketers, and redevelopment and master plans by architects, urban designers, and planners. The secondary data includes historical documents as well as 32 urban development plans prepared for Dallas since 1900. Based on relevance, scope, scale, and significance, 14 documents have been selected for analysis. These documents exemplify non-academic, concerted efforts led by the city leaders to change the urban imaginary, illustrating a progressive trajectory of development for the city.

Drawing on the content analysis and triangulation of the primary and secondary data, the authors' preliminary findings suggest that place branding and city planning processes in Dallas have gained a critical role. Being instrumental in visioning and redevelopment planning, these activities find expression most recently in the Trinity River Corridor Project. This placemaking project aims to craft a new identity and image for the city through striking river bridges designed by the famed architect, Santiago Calatrava, and to redress the multiyear legacy of social and economic divide between South and North Dallas through the material and symbolic construction of a “public space” uniting the two sides. The implications being that, in the current turn to urban entrepreneurialism, what urban planners communicate as goals and objectives in participatory plan-making is increasingly being appropriated and linked to the city's brand. And that, inadvertently or not, city planners are progressively playing a larger role in the place promotion, place marketing and place branding processes reshaping a new urban imaginary of the city.

LABOR VS. LABOR: WORKING CLASS INSTITUTIONAL POLITICS IN RESPONSE TO AMAZON AND GENTRIFICATION IN WESTERN QUEENS

Abstract ID: 617

Individual Paper Submission

STEIN, Samuel [CUNY Graduate Center] sstein@gradcenter.cuny.edu, presenting author
DEFILIPPIS, James [Rutgers, The State University of New Jersey] jdefilip@rutgers.edu, co-author

In November 2018, after a very public process that witnessed cities showering them with offers of various forms of subsidies, Amazon announced that they had selected Long Island City, Queens (LIC) as one of two locations for their second headquarters. The deal would be for a large complex/campus along the East River in one of the few remaining sections of LIC that had not already been redeveloped in the last ten years — years that had seen an astonishing amount of construction in the area. And while there had certainly been criticism and community organizing against the proposed deal, given that it had the vocal support of both Mayor de Blasio and Governor Cuomo, most New Yorkers had assumed that the deal would be implemented. Then, rather surprisingly, on February 14th, 2019, Amazon announced its withdrawal from the deal and its decision not to build the planned campus in LIC.

In the wake of this historic and quite-uncommon outcome in urban development politics, this paper asks two related but very different questions. The first question is: why were working class institutions so split over this issue? What were the fault lines that caused some unions — including the Teamsters and the Retail, Wholesale and Department Store Union — to vociferously oppose the Amazon deal, while others — including at first the Service Employees International Union's property service division and the Building Trades Council, but later also the Hotel Trades Council, United Federation of Teachers, and the Service Employees International Union's healthcare workers division — to vociferously support it? If all of these groups represented large numbers of people who are Queens-based workers, tenants and immigrants, what drove some of them to understand their class position as reason to side with the corporation and its political supporters, and others to understand their class position as reason to oppose them? Most importantly, what does this fragmenting of working class institutions tell us about the nature of labor in contemporary urban development politics, particularly in real estate-driven localities like New York City?

This leads us directly to the second question we are asking in this paper:

What does the future look for Western Queens? This section of Queens has long been a destination for new immigrants and has provided both housing and working class employment opportunities for them. That future is very much in doubt. LIC, as we have already indicated, has already experienced what can only be described as hyper-development in this decade, and the retreat of Amazon does not look likely to change that trajectory. Immediately north of LIC, the neighborhood of Astoria has undergone significant gentrification and its long history as a neighborhood of settlement for immigrants looks increasingly unlikely to be its future. Finally, immediately east of LIC, the Sunnyside neighborhood faces the prospects of a mega-development all its own, as planning is well underway for the covering of the Sunnyside railyards and the building of an enormous new complex. Regardless of the retreat of Amazon, the future of Western Queens is being shaped by the real estate industry and its supporters/enablers within the local state. How might the landscape of labor and working class politics play out in future conflicts over development and demographics?

Based on our political engagement in these areas and with these groups, as well as interviews with others involved in the Amazon and other land use fights in Queens, we will answer both of these questions and do so with our eyes on the much larger questions of: who is the city for and what kind of city will it be?

TECHTALK AND STARTUP STORIES: ASSESSING ENTREPRENEURIAL ECOSYSTEMS THROUGH TECH-PODCASTS

Abstract ID: 640

Individual Paper Submission

KAYANAN, Carla Maria [University of Michigan] kayanan@umich.edu, presenting author
RENSKI, Henry [University of Massachusetts Amherst] hrenski@umass.edu, co-author
SMIALEK, Alexandra Ola [University of Massachusetts Amherst] asmialek@umass.edu, co-author

A major challenge in developing local initiatives to support entrepreneurs is the confusion over understanding their explicit needs. Consider the entrepreneurial ecosystems approach, which has gained considerable attention in recent years as a viable framework for guiding policy investments that are broadly supportive of small and new innovation-based businesses. It emphasizes the various networks of associations that exist among entrepreneurs and the institutions that aim to support them. It also emphasizes attributes of place that are most valued by entrepreneurs, including aspects of the built environment such as livability and accessibility, as well as cultural aspects such as a shared entrepreneurial identity, willingness to support other local entrepreneurs, and prevailing attitudes toward risk and tolerance of failure. The various elements make prioritizing needs confusing for practitioners interested in supporting entrepreneurs.

One viable way to understand what makes for a successful regional entrepreneurial ecosystem is to speak to entrepreneurs themselves and ask them about which institutions and place-based factors matter most to their success. Yet, entrepreneurs are notoriously difficult to interview, making practical barriers such as non-response and selection a widespread source of inferential bias. As such, much of what we do understand about entrepreneurial ecosystems comes largely from institutional actors and public officials, who may have a more self-serving perspective on the relative importance of the institutions they represent. This is further complicated by the speed at which mobile technologies, forms of production, flexible boundaries of the firm, the rise of a contractual workforce, and apps that unlock potentials for managing strategies that allow people to work remotely and check-in from afar have altered our understanding of place.

Considering these changes and challenges, this research seeks to better understand the needs of today's innovative entrepreneur: How are they dependent on the region in which they are located, the stage of the ecosystem they exist in, or more nuanced factors like community culture and perceived resource needs? To circumvent the practical barriers of primary data collection, we use a previously un-tapped data source -- the tech podcast. Tech podcasts offer a rich and detailed source of information that provide tremendous insight into the many layers, subtleties, and perspectives of complicated and holistic innovation ecosystems. Although reluctant to make time for researchers, entrepreneurs are willing to share their stories and insights to an audience of peers. Though cognizant that the researcher has no control over the content of the interview apart from that afforded by selection of sources, podcasts offer high-level shop talk difficult to obtain from an interview with an academic.

We dig into the inner workings of entrepreneurial ecosystems through a content analysis 80 tech-industry podcasts transcribed from eight U.S. cities. Cities were selected to represent various stages along an “entrepreneurial ecosystem life-cycle” ranging from small and emerging ecosystems such as Des Moines, IA, to large and well-established ones like Boston, MA. Given the novelty of the data source and the lack of strong theory from which to derive hypotheses, our methods are largely exploratory and inductive. These podcasts point to the variations between how previous studies perceived the needs of entrepreneurs versus the actual needs of contemporary entrepreneurs. Assessed from the direct perspective of on-the-ground entrepreneurs, this paper provides further insights on the interchangeability of cities, regional advantage in relation to competition and access to resources, and the specific infrastructural needs necessary for tech-entrepreneurs to scale their ventures.

RETAIL AND WALKABILITY: THE ROLE OF URBAN DESIGN FEATURES ON RETAIL PRODUCTIVITY IN NEW YORK STREETS

Abstract ID: 649

Individual Paper Submission

SAKALKER, Amruta [University of Texas at Arlington] amruta.saki@gmail.com, presenting author
HAMIDI, Shima [University of Texas, Arlington] shima.hamidi@uta.edu, co-author

Since the past decade, there has been a major shift towards online shopping making many physical retail shops obsolete. At the same time, retail theory literature shows that consumers tradeoff for places that

provide a unique shopping experience against time and distance (Brown, 1993). Existing literature shows that clustering of competing and complementary commodities (Teller, Alexander, & Floh, 2016), improving experiential facilities for pedestrians (Leinberger & Alfonzo, 2012), improving accessibility and drawing from the character of the surrounding, makes retail destinations more attractive to customers (Sutton, 2014). Retail clusters which are able to provide such environments can possibly thrive and survive even while online shopping is gaining popularity. This indicates that street level urban design features that support walkability and create a memorable image and are key to improve retail productivity. While the literature has theoretically emphasized on the role of street level urban design features (Jacobs, 1993), there are very few attempts that have empirically examined their impact on retail productivity.

Drawing on structural equation modeling (SEM), this article uses an empirical lens to ask two questions: Is there a direct relationship between urban design qualities that improve walkability with retail productivity and agglomeration? Secondly, does some types of retail establishment more likely to locate in walkable streets than others? To study livability and walkability, we use Ewing and colleagues' method to operationalize urban design qualities into five categories of imagability, enclosure, human scale, transparency and complexity, to then measure against retail performance at street level (Clemente, Ewing, Handy, & Brownson, 2005). We use SEM to control for both direct and indirect associations between retail productivity and its key determinants including retail agglomeration, crime, urban design features, accessibility and neighborhood characteristics. Our measure of retail productivity is retail sales volume per employment obtained from ESRI Business Analyst 2015. Our study covers urban design qualities data for 588 streets randomly distributed across five New York City boroughs and we extract corresponding crime and other civic characteristics data from the city website.

We find that street level urban design attributes that improve livability and walkability also influence retail performance and clustering in that street. Also, retail category types that promote clustering and competition are more likely to locate in walkable areas.

While retail stores are concerned with surviving against the online shopping trends, retail agglomerations have been seen as important contributors to economic growth of cities and empowering businesses to improve their retail performance. Also, there is a large amount of literature demonstrating the role of walkability in creating a sense of community at micro level. As major retail discussion so far focuses on the role of planning in economic development at the macro level, this study represents a step towards focusing on street level qualitative attributes as important micro-level contributors to this larger discussion.

THE HIDDEN ECONOMIC DEVELOPMENT RATIONALE OF HOUSING POLICY, FROM LEVITTOWN TO HOUSING FIRST

Abstract ID: 666

Individual Paper Submission

DOUSSARD, Marc [University of Illinois at Urbana-Champaign] mdouss1@illinois.edu, presenting author

GREENLEE, Andrew [University of Illinois at Urbana-Champaign] agreen4@illinois.edu, co-author

Housing costs, quality and stability play important roles in developing and supporting the human skills and capabilities vital to contemporary economic development. Yet the practice and theory of economic development typically separate the core concerns of work and diversification from housing and household development. This de facto separation of work and housing continues despite the fact that housing policy itself has always contained explicit economic development criteria. Our paper reviews the history and evolution of housing policy's economic development rationales as a first step toward integrated housing and the sphere of social reproduction into economic development.

Drawing on policy documents and secondary research, we chart the economic development rationale for four key periods of federal housing policy intervention. First, we identify the economic stimulus concerns and arguments central to New Deal-era housing interventions. Second, we chart the competing rationales of post-war housing programs, which sought to quell the anxieties of downtown business interests facing central city decline via urban renewal while also fostering the distinctive consumption patterns of suburbanization. Third, we trace the nascent human development rationale embedded within support for housing vouchers and housing mobility programs in the 1970s, 1980s, and 1990s. We follow these analyses of key Federal housing interventions with the more recent emergence of Housing First strategies, which fund direct housing provision on the explicit grounds that housing promotes the development of household skills and capabilities (Sen, 1999).

The explicit and implicit economic development rationales of each of these housing policies closely maps onto concurrent "waves" of economic development theory and practice (Glasmeier, 2000; Leigh and Blakely, 2017). Furthermore, the institutional organization of each period of housing policy (beginning with the federal government and ending with a mix of public sector and not-for-profit organizations) matches the evolving institutional organization of economic development activities (Bauer, 1951). We show that the principal rationales from each period of housing policy continue to provide tangible pathways for integrated housing into economic development practice and research. More important, the current housing focus on human development provides a clear point of engagement for economic development practice that continues to focus on narrow issues related to the creation and maintenance of highly skilled workforces.

DEMAND-DRIVEN WORKFORCE DEVELOPMENT IN THE AGE OF NONPROFIT MARKETIZATION: THE CASE OF LOS ANGELES

Abstract ID: 679

Individual Paper Submission

LEE, Kevin [Massachusetts Institute of Technology] kevinjl@mit.edu, presenting author

The practice of creaming—or, the purposive selection of desirable clients to artificially meet organizational performance standards—is well-documented, especially among federally-funded workforce development nonprofits (WDNPs). Creaming is disappointing news, of course. But it is particularly devastating, given how WDNPs often receive Title I of the Workforce Innovation and Opportunity Act (WIOA), and are central actors in a “residual” system designed precisely to serve low-income populations facing barriers to employment. Here, the old story is this: federal performance metrics incentivize organization-level practices of creaming; organizations select and serve desirable clients, producing inequities in terms of who has access to workforce development. To address these inequities, LA has launched efforts to address systemic inequities through the establishment of local programs and performance metrics to serve and track “special populations” (including homeless populations, formerly incarcerated populations, transgender populations and veterans).

However, this old story of creaming fails to contend with the growing emphasis on labor market coordination within the workforce development system. Drawing on inspiration from the “dual customer” approach of organizations like the Center for Employment Training in San Jose—which envisions its central function as connecting and serving both program participants and employers—both scholars and practitioners increasingly see workforce development as workforce intermediaries offering a range of services to connect the right clients with the right jobs. Through mandating labor market analyses to understand employer needs as part of workforce development planning, and mandating heightened coordination between WDNPs within local service delivery areas, WIOA has further cemented the central role of labor market coordination within local workforce development systems. In the face of these changes, our understanding of creaming seems outmoded, in its rigid emphasis on organization-level practices.

Drawing upon qualitative interviews with executive directors, managers and street-level staff from both federally-funded and non-federally-funded WDNPs in the City of Los Angeles, this article takes on the old question of “Who is creamed from the workforce development system?” However, it aligns itself with the growing emphasis on labor market coordination and inter-organizational relationships in workforce development scholarship and practice. In this paper, I argue that the structural features and institutional arrangements of the federally-funded workforce development system causes local labor market coordination failures, resulting in the systematic exclusion of the “unemployable” from both federally-

funded and non-federally-funded WDNPs. Here, the “unemployable” refers to populations who face multiple, compounded barriers to employment, including: (1) authorized immigrants with limited English proficiency; (2) undocumented immigrants without work authorization and ineligible for Title I services; (3) special populations struggling with multiple welfare needs—such as formerly incarcerated individuals struggling with homelessness, or homeless transwomen struggling with substance abuse; and (4) unrecognized special populations who lack both robust supportive services and pipelines to employment.

To ensure that the most unemployable populations are not left behind, workforce development planners must be attentive to the structural and institutional dimensions of their local workforce development systems. In the case of LA, this much is clear: without prior structural and institutional reform, additional investments in federally-funded WDNPs will not address challenges of the unemployable, at the very bottom of the workforce development services hierarchy. Instead, urban workforce development planners could benefit from leveraging and investing in non-federally-funded WDNPs with limited workforce development services infrastructure—especially worker centers and small human service nonprofits with robust peer support and self-empowerment programs, and larger nonprofits with robust supportive services infrastructure—who may be more structurally equipped and amenable to serving the unemployable.

POLITICS AT ARM’S LENGTH: HOW PUBLIC AUTHORITIES’ RELATIONSHIPS IMPACT ECONOMIC DEVELOPMENT PLANNING

Abstract ID: 742

Individual Paper Submission

MARCELLO, Elizabeth [Columbia University] elizabeth.marcello@columbia.edu, presenting author

The Empire State Development Corporation (ESDC), New York State’s chief economic development agency, is a powerful public authority that can condemn property, issue tax-exempt bonds, and override local zoning ordinances. The ESDC plays a critical role in shaping local planning outcomes through its use of loans, grants, tax credits, marketing, and other forms of assistance primarily brokered “behind the scenes” and sometimes at the expense of local public planning. Despite its contemporary role facilitating private commercial and industrial development, the authority was initially created to develop housing for people with low and moderate incomes and eliminate urban blight. In the late 1970s, declining tax revenues and other financial challenges throughout the state shifted the authority’s focus to job creation

and retention and business development. For fiscal year 2018-2019 the authority boasted a budget of over \$70 million, and as of 2017 it controlled over 200 subsidiary corporations and other entities. The ESDC's new, broader scope and vast legal powers means that it has more opportunities to overlap—or interfere—with local planning efforts.

This paper provides a descriptive analysis of the ESDC's origin story to better understand the authority's contemporary policy behavior. I use qualitative data gathered from surveying historical documents including legislation, bill jackets, and executive memos at the New York State Archives; evaluating media reports; and interviewing retired and current staff members of the agency as well as former elected officials. The collected data yields a descriptive analysis of the political and economic factors driving the creation of the ESDC, as well as a relationship map that explains how the authority's political arrangements impact planning outcomes. Toward this end, this paper pays particular attention to the ESDC's engagements with other economic development planning efforts and local governments to highlight its intergovernmental politics and internal operation.

Using existing literature on the politics of planning (Forester 1989) and the role of public authorities (Doig 1983, Radford 2013), the paper then contextualizes the ESDC experience nationally and underscores the role of public authorities in the economic development planning process. Existing case-based research empirically documents the inherently political nature of planning (Altshuler 1965, Flyvbjerg 1998). But, fewer cases focus on the specific institutions like public authorities that are involved in planning, their intergovernmental politics, and their internal operation. The case of the Empire State Development Corporation in New York State is a first step toward filling this gap in the literature. This case further highlights the role of public authorities in economic development planning while adding a more nuanced view of the political relationships and negotiations that are endemic to the planning process.

THE INFLUENCE OF DISASTER LOANS ON LONG-TERM BUSINESS SURVIVAL IN GALVESTON, TX AFTER HURRICANE IKE

Abstract ID: 752

Individual Paper Submission

WATSON, Maria [Texas A&M University] mw574@tamu.edu, presenting author

XIAO, Yu [Portland State University] yxiao@pdx.edu, co-author

The U.S. Federal Government has taken an increasingly active role in disaster relief efforts, yet program analyses of the efficacy of Federal recovery programs—particularly for businesses—is limited. This dissertation fills the gap by exploring the effects of Federal disaster loans on long-term business post-disaster recovery outcomes. Using the case of the U.S. Small Business Administration (SBA) Disaster Loan Program in Galveston County Texas after 2008 Hurricane Ike, this research examines which businesses benefit from Federal assistance and whether loans improved odds of survival for businesses nine years after Hurricane Ike.

This dissertation contributes to the body of work on disaster assistance programs and business recovery through new methodological and theoretical approaches to these questions. This research is grounded in institutional theory, namely institutional logics and resource dependence, and uses quasi-experimental design to tease out the effect of the loan program from potential confounding factors that affect business survival. This research uses a combination of primary data collected directly from the field and secondary data, such as business information reported by ReferenceUSA, sales tax and franchise tax permit information from the Texas State Comptroller, and data provided by the SBA through Freedom of Information Act requests. Coarsened Exact Matching is used to match businesses that received a loan (treatment sample) to businesses without a loan but otherwise similar in damage and firm characteristics (matched sample). For the matched sample, conditional logistic regression is used to analyze the effect of disaster loans on survival. For the treatment-only sample, linear regression and logistic regression are used to examine determinants of loan amount and which businesses are more likely to utilize the loans.

This research found that businesses that received a loan had higher odds of survival compared to their control, however businesses differed in the amount of money they received and likelihood of accepting the loan based on their damage, their characteristics, and the characteristics of the loan, itself. This research concludes with suggestions of how disaster policy aimed at businesses might be improved, as well as how planners might fill potential gaps in recovery left by the SBA loan program.

SOLAR FIRMS IN FLUX: EVOLVING SOLAR ENERGY BUSINESS MODELS AND LOCAL SUSTAINABLE ECONOMIC DEVELOPMENT

Abstract ID: 757

Individual Paper Submission

EISENBURGER, Max [University of Illinois at Urbana-Champaign] meisen4@illinois.edu, presenting author

Responding to the threat of climate change and the long-articulated promise of “green jobs,” municipal and state governments in the U.S. are making increasingly ambitious renewable energy commitments. Yet in the U.S. and elsewhere, renewable energy systems are primarily built, operated and maintained by private firms. Cities’ ability to achieve both decarbonization and economic development goals accordingly depends upon questions of market structure and business strategies that are the regular object of economic development studies. Through a comparative study of lead residential solar energy firms and solar installation subcontractors in metropolitan San Francisco and Denver, this paper demonstrates how lead firms have adapted to technological, policy and market disruptions in distinctive ways that follow directly from their organizational capabilities and the constraints imposed by the end markets in which they operate. While one firm’s repositioning as an end-to-end, vertically integrated energy firm allows it to pool revenues, costs and customers across several product lines, another set of firms are specializing as matchmakers between smaller installers and residential customers. The emergence of these “closed competitor” vs “open collaborator” models results in distinct consequences for local workforce needs, entrepreneurial ecosystems, and the shape of future renewable energy grids. In addition to informing municipal renewable energy policies, this paper also makes a significant contribution to theories of economic development by demonstrating the effect of heterogeneous organizational capabilities on industry outcomes.

NEIGHBORHOOD ECONOMIC CHANGE IN AN ERA OF METROPOLITAN DIVERGENCE

Abstract ID: 760

Individual Paper Submission

SCHACHNER, Jared [Harvard University] jschachner@fas.harvard.edu, presenting author

Patterns of, and explanations for, neighborhood socio-demographic change have dominated urban research since the Chicago school. In recent years, growing academic consensus on the existence of neighborhood effects and amplified public scrutiny of one particularly visible form of neighborhood change – gentrification – have revived this line of inquiry. Despite widespread perceptions of fluidity, most analyses suggest change is the exception, not the rule; American neighborhoods’ economic positions are remarkably persistent when evaluated within particular metropolitan areas and on a national scale. Several scholars have inferred that even macro-level shifts – including social change, demographic transitions, economic transformations, and federal policy reforms – are insufficient to disrupt the reproduction of neighborhood inequality (Sampson 2012; Sharkey 2013).

However, urban scholars’ dominant focus on neighborhood- and macro-level patterns and predictors of change obscures metropolitan-level processes’ role. While a growing body of work has applied a metro-

level lens to communities' race-ethnic transitions (Crowder, Pais, and South 2012; Lichter, Parisi, and Taquino 2015), few studies have rigorously applied it to neighborhood economic stratification and change. As a result, clarity on whether neighborhoods remain “stuck in place” (Sharkey 2013) at similar rates across local contexts and on what metro-level processes shape neighborhood income inequality remains elusive. These concerns are particularly salient today, given the “Great Divergence” in U.S. metros' economic and social conditions (Moretti 2012).

Applying a metro-level lens not only clarifies the patterns of and multilevel processes driving neighborhood-level economic conditions; it sharpens our conceptualization of neighborhood inequality and change by highlighting a distinction central to income mobility research but peripheral to spatial inequality literature: relative versus absolute change. In the neighborhood context, local fluidity refers to change in a community's relative income position within an ecological unit such as a metropolitan area, whereas national mobility refers to absolute shifts relative to the entire distribution of U.S. neighborhoods.

In this paper, I articulate the theoretical differences between the two phenomena and empirically demonstrate that unlike their income mobility analogues, metro-level estimates of neighborhood local fluidity and national mobility are weakly correlated, suggesting the causes and consequences of each variant of change are distinct. I then construct multilevel models that estimate the variation in each outcome between (versus within) metros and that decompose each axis of variation based on distinct, theoretically salient neighborhood- and metro-level factors. Once I establish the distinctive theoretical features and empirical patterns of each type of neighborhood change, I use administrative data on all California neighborhoods' K-12 school quality, environmental toxicity, and crime rates to examine whether neighborhood local fluidity or national mobility is more closely associated with changes in neighborhood social conditions theorized to shape children's social mobility prospects.

Multilevel models employing Census 2000, American Community Survey (ACS) 2011 – 2015, and Equality of Opportunity Project data reveal that 7% of the variation in local fluidity and 14% of the variation in national mobility resides between, rather than within, metros. The place stratification and ecological context accounts of spatial inequality provide considerable leverage in accounting for each respective axis of variation. Specifically, metro-level income segregation is strongly and negatively associated with neighborhood local fluidity, while metro-level income growth predicts neighborhood national mobility.

From a theoretical perspective, these findings lay the groundwork for finer-grained, multilevel neighborhood change models that clarify the causes and consequences of various types of economic shifts. From a policy perspective, the paper reveals what place-based urban policies, operating at what spatial scale, might be most effective in disrupting the reproduction of neighborhood inequality, improving communities' lived conditions, and increasing the social mobility prospects of children who are raised within them.

UNDERSTANDING THE SPATIAL DISTRIBUTION OF NONSTANDARD WORKERS IN U.S. METROPOLITAN AREAS

Abstract ID: 813

Individual Paper Submission

NAZARENO, Luísa [Georgia State University] luisa.nazareno@gmail.com, presenting author
LIU, Cathy [Georgia State University] cyliu@gsu.edu, primary author

In the past twenty years, the share of workers in nonstandard work arrangements in the United States remained relatively stable at around 10 percent, according to the newly released Contingent Work Supplement Survey data (CWS). Such stability hides important variations at the subnational levels. In 2017, the share of alternative workers ranged from 3 to roughly 20 percent in large metropolitan areas. Nonstandard or alternative work arrangements comprise jobs arranged through intermediaries, such as temporary help agencies, or involving potentially unpredictable place, time and quantity of work (Polivka 1996). CWS definition of this group comprises four types: i) independent contractors, consultants, and freelancers; ii) on-call workers; iii) temporary help agency workers; and iv) contracted out. Despite considerable differences in terms of demographic composition, sectoral concentration, and job quality across these types, alternative arrangements have been empirically associated with higher insecurity and precarity (Kalleberg 2000). Consequently, understanding the spatial distribution of these workers across metropolitan areas and underlying mechanisms is important for economic development and workforce development policy and planning.

This paper addresses this question by examining what contextual factors help explain the level and growth of the share of alternative workers in total and by type in metropolitan areas in the United States between 2005 and 2017. We will mainly use CWS surveys from 2005 and 2017. We restrict our analysis to core-based statistical areas (CBSA) with population larger than 500k, leading to a sample size of about 100. Based on the literature, we hypothesize that three sets of MSA level variables would play a role in the concentration of nonstandard workers, namely urban economic structure, institutional/policy environments, and demographic composition. We will use descriptive statistics, spatial mapping, and statistical analyses to conduct our inquiry.

In terms of the urban economic structure, the literature suggests that the concentration of alternative workers varies across industries and occupations (Liu and Kolenda 2012). Unemployment has also been empirically associated with a higher incidence of alternative employment in subsequent periods (Katz and Krueger 2019). We also include average firm size (measured by employees), collected from the Businesses Employment Dynamics. Institutional environments with fewer protections to workers tend to have higher incidences of alternative employment (McLaughlin and Coleman-Jensen 2008; Katz and Krueger 2019). Likewise, some firms have been using alternative employment (and even misclassifying workers) to reduce labor costs. To account for these factors, we gather relevant state level policies from the National Conference of States Legislatures (NSCL) on right-to-work laws, and legislation to avoid misclassification of workers. Finally, we use CPS data to generate demographic characteristic variables

such as race/ethnicity, average age, immigrant share, gender, and educational attainment of the MSA population. Our results will indicate the relative weight of these explanations in understanding spatial distribution of nonstandard workers across MSAs and shed light on targeted planning efforts towards the rise of nonstandard workers at the local level.

PRAGMATIC MUNICIPALISM: US LOCAL GOVERNMENTS' RESPONSE TO FISCAL STRESS

Abstract ID: 848

Individual Paper Submission

ALDAG, Austin [Cornell University] ama296@cornell.edu, co-author

KIM, Yunji [University of Wisconsin-Madison] ykim535@wisc.edu, co-author

WARNER, Mildred [Cornell University] mew15@cornell.edu, presenting author

The 2007-08 Global Financial Crisis raised questions about the sustainability of government budgets. In a multi-level governance system, the impact of the financial crisis and responses to it can differ across the various levels of government. Scholars have warned that local governments are particularly vulnerable to fiscal stress given their position in the government hierarchy. Local governments must manage political pressures from higher-level state governments and citizens, while operating within several structural constraints, such as demography, economy, and state policy (on local taxation and labor union rules). In the highly decentralized US, some local governments responded with austerity reforms (e.g. cutting or privatizing services, shrinking employee benefits), but most local governments have explored alternative revenue sources and alternative service delivery.

Using local government finance and survey data nearly a decade after the financial crisis, we examine how political pressures (from state governments and citizens) and structural pressures drive local responses. Our 2017 survey includes over 2000 responding municipalities from across the United States. Regression models show how structural shifts in the economy, demography and state policy contribute to local government fiscal stress. These structural constraints shape local government responses. We measure shifts in form of service delivery (eg privatization) and search for new revenue sources (taxes, fees, etc). We find that city managers make pragmatic choices, balancing community need, with

pressures from economic restructuring in a rescaling state-local government system. Our results challenge the dire view presented by austerity urbanism scholars, and offer instead a more pragmatic municipalism response. This gives planners room to maneuver in an increasingly challenged local government sector.

THE IMPACT OF RAIL TRANSIT SYSTEM EXPANSION ON SPATIAL DISTRIBUTION OF LAND USE AND EMPLOYMENT: EVIDENCE FROM SHANGHAI, CHINA

Abstract ID: 852

Individual Paper Submission

ZHONG, Mengqi [Tongji University] 476333440@qq.com, presenting author

YU, Yifan [Tongji University] 45170753@qq.com, co-author

In the past few decades, Shanghai's rail transit has experienced tremendous development and brought great changes to the urban spatial structure. The objective of this paper is to examine the impact of rail transit system expansion on the urban spatial structure using land use and employment distribution as two indicators through a Shanghai case study. We focus on the expansion of rail transit system between 2008 and 2013, and try to figure out the changes of land use and employment distribution based on the data from the Economic Census Data. The spatial autocorrelation of events was investigated using the Moran's I to identify significant hot and cold spatial clusters. With a spatial regression model, it was also found the number of employments every 1 kilometer closer to a metro station is related to land diversity, which is defined by land use entropy, but not related to population density. The significance level was set at $P \leq 0.05$. The results identify the improvement of the rail transit system plays an important role in changes in urban spatial structure and promotes the mixed use of land along the rail transit. For example, higher development intensity of land and more diversity land uses occur in more accessible areas near the metro stations. Meanwhile, the improvement of rail transit system significantly promotes the development of Shanghai's centers as well as sub-centers and the accumulation of employment in this area. Additionally, the interrelationship between land use, employment and rail transit system generates redistributive effects

that are substantially associated with urban growth and reshape Shanghai spatial structure, which will lead to efficient use of the limited urban land resources.

UNDERSTANDING THE REVIVAL OF GREATER DOWNTOWN DETROIT: AN ASSESSMENT OF THE EFFECT OF REVITALIZATION INITIATIVES

Abstract ID: 879

Individual Paper Submission

VIDAL, Avis [Wayne State University] a.vidal@wayne.edu, presenting author

The near-collapse of Detroit in the wake of the financial crisis and the Great Recession led to widespread efforts to stave off the worst effects of the disaster and to foster renewal. Many neighborhoods will take decades to recover, but the housing market in Greater Downtown shows strong signs of revival, construction of new office space has begun, and selected other neighborhoods appear on the upswing.

Greater Downtown has been the target of numerous corporate, philanthropic, and public investments since 2010. These include financial incentives to stimulate housing demand there by employees of large firms and anchor institutions; an array of philanthropic and CDFI-type financing initiatives to stimulate housing development in a lending environment that continues to be risk-averse; and steady planning and investment efforts to improve quality of life, including safety. Housing and neighborhood conditions have clearly improved. Rental housing occupancy rates are now high, rents are sharply up, and the pipeline of new projects is vigorous.

This paper will report the final results of a multi-year analysis of the effects of demand and supply side initiatives intended to stimulate the housing market in Greater Downtown, placing them in the context of other factors affecting observed outcomes. Its goal is to inform the design and implementation of intervention strategies in other weak market cities, and to offer guidance on the conditions under which supply and demand stimuli are most likely to be effective. Findings to date suggest that (1) the demand-side stimulus served mainly as an initial stimulus and signaling device; (2) supply-side strategies are critical in very weak markets; (3) public sector incentives, while extremely important, need to be supplemented by other types of incentives in the weakest markets; and (4) these formal efforts are unlikely to yield sustained growth in the absence of employment expansion.

THE MATURING GEOGRAPHY OF BIOTECHNOLOGY: NETWORK FORMATION AND EVOLUTION IN LEADING AND LAGGING US REGIONS

Abstract ID: 881

Individual Paper Submission

SONMEZ, ZAFER [University of Illinois at Chicago] zsonme2@uic.edu, presenting author

Knowledge intensive industries such as biotechnology are characterized by spatial concentration and networks of organizations and inventors. Previous research generally acknowledges and has empirically shown that knowledge networks play a crucial role in sustaining the vibrancy of regional clusters and, by extension, the economic development of regions (Huggins and Prokop, 2016). However, we still have limited understanding of how networks emerge and evolve over time. Although there is a large body of research in regional studies, economic geography, and related fields that examines the association between regional/network-level factors and cluster outcomes, the research on factors that give rise to network structures is relatively scarce. Part of the problem in this area of research has been the paucity of methodological techniques that are capable of dealing with dependencies and simultaneity inherent in relational data (Glückler, 2007; Broekel et al, 2014). Additionally, this research rarely compares successful and less successful clusters in systematic ways and thus tends toward retrospective explanation, predetermining the importance of historical contingencies and geographical proximities in the emergence and transformation of regional networks (Powell, Packalen, and Whittington, 2012).

Our study takes a broader view by incorporating a broader range of regions and leveraging recent advances in the modeling of network data. Using patent statistics from 1976 to 2010, our analysis relies on a longitudinal co-invention data set with geographic and organizational indicators. First, we identify actor and dyadic-level factors in the formation of network ties using Multiple Regression Quadratic Assignment Procedure (MRQAP) to test whether the observed network relationship is extreme compared to what we would expect to find if assignment to network positions were random. The results from this procedure enable us to assess the relevance of factors such as institutional type, size, and geographical proximity in explaining properties of the knowledge network connecting biotechnology organizations.

Second, combining insights from organizational and economic sociology with the more spatial perspective of economic geography and regional studies, we examine the evolving regional geography of

the biotechnology industry in the US. For this purpose, we use conventional regression and dynamic social network modeling approaches to examine network evolution over time. This approach offers the opportunity to understand whether actors collocate because they already have knowledge ties or if they start to build relationships because they are already spatially close. The findings illustrate how organizational diversity within a regional network and a high share of intra-regional ties relative to extra-regional ties explain the diverging paths of leading and lagging clusters.

We envision this research as addressing sources of bias in attempts to extrapolate policy relevance from observational studies of the development of innovative clusters. Our findings differentiate the extent to which network properties, including the degree to which they are regionalized, are purely path-dependent or a product of regional and/or firm characteristics that might be manipulated through the levers of economic development policy. In addition, this framework could be extended to examine the link between network properties and a variety of outcomes of more general relevance to the region, such as functional specialization, tie-ins with anchor institutions, and employment outcomes.

GREEN, Richard [University of Southern California] richarkg@price.usc.edu, co-author
FLORIDA, Richard [University of Toronto] florida@rotman.utoronto.ca, co-author

This paper develops a theory of large corporate headquarters location in the modern age. We posit that human capital has become the primary factor in explaining where large firms are headquartered. We argue that such operations will locate in skilled cities that are also larger and globally connected. We test these hypotheses using data from the Fortune 500 from between 1955 and 2017. We estimate count models to test the relative importance of human capital, population size, and airport connectivity, alongside taxation and other measures that are said to be important. Our findings are consistent with our hypotheses. We also consider the local impacts of Fortune 500 and Fortune 1000 firms, net of local changes in labor demand and tax rates. There, we find evidence that large firms are public goods.

CODING BIDS FOR AMAZON'S HEADQUARTERS TO UNDERSTAND LOCAL ECONOMIC DEVELOPMENT "POLICY MIXES"

Abstract ID: 958

Individual Paper Submission

PIPKIN, Seth [University of California Irvine] spipkin@uci.edu, presenting author

The recent spectacle of and continuing political fallout from Amazon.com Inc's headquarters bidding process have brought local economic development policies to the fore of public debate. Concurrently, scholars are more forcefully making the case that "place-based" economic development policies provide answers to widespread dissatisfaction with corporate welfare and increasing intra-regional inequality, which tend to be associated with older, business-focused policies (see e.g. Porter 1998). In terms of providing an alternative, place-based policies involve a shift from aggregate regional economic catch-up to reducing intra-regional disparities through such efforts as support for locally-owned businesses, coordinated workforce development, and other strategies designed to maximize the positive externalities for local workers across a wide range of socio-economic backgrounds (Barca et al. 2012, Hendrickson et al. 2018, Miller-Adams et al. 2019).

This paper inquires into the extent to which cities and metropolitan areas that placed bids for Amazon's second headquarters already practice place-based economic development policies. It does so by developing a typology of "mixes" of economic development policies that local governments already employ. These local policy mixes are expected to include different components that may be place-based, along with other more traditional forms of business support and incentives. By cataloguing what forms of investment in economic development metro areas employ, as well as the resources and organizational actors involved, we aim to reach a better understanding of who implements place-based policies and how they implement them, as well as how these localities differ from those that employ such policies less or not at all.

We assess cities' and metro areas' mix of local economic development policies through textual analysis and coding of all publicly available bids for Amazon's "HQ2." These bids are detailed documents that respond to criteria stipulating the inclusion of information on public investments and inter-organizational collaborations related to infrastructure, workforce development, business development, and business incentives. The coding of these documents will allow for the detection of patterns in local "policy mixes," while also taking into account the organizational actors and resources involved.

Over 75 bids are analyzed, covering a wide range of metro area size, region, and median household income. The results will be of interest to scholars and practitioners interested in regional economic development policies, local governance, and intra-regional inequality. The typology of policy mixes will help us to better understand where policies diffuse as well as the organizational resources most commonly associated with a "place-based" approach. Moreover, this paper is intended to enable two further lines of

inquiry: first, cross-sectional quantitative analyses of the relationship between local demographic and structural features, type of economic development policy mix employed, and economic development results; and second, the processual analysis of how different policy mixes are designed and implemented over time.

GROWTH BEGETS GROWTH? THE DECENTRALIZATION OF THE BUSINESS PROCESS OUTSOURCING INDUSTRY IN THE PHILIPPINES

Abstract ID: 985

Individual Paper Submission

STERN, Justin [Harvard University] justindstern@gmail.com, presenting author

The Philippines is a major global hub for the business process outsourcing (BPO) industry, through which operations such as customer service work, back-office accounting, digital animation, and human resources management are subcontracted to third parties. As the country's second-largest source of dollar income, BPO directly employed about 1.3 million people across the Philippines in 2018. Scholarly questions are increasingly surfacing in an interdisciplinary context about the impact of the BPO sector, and "offshoring" more generally, on economic growth and urban development in metropolitan regions across the Global South.

This paper focuses on the decentralization of the BPO industry in the Philippines. In the Philippines, the vast majority of BPO offices are concentrated in Metro Manila. Over the previous decade, national and regional government agencies and private trade and industry associations alike have worked to propel the BPO industry into a handful of midsized cities. This paper documents these strategies and, in doing so, asks the following questions: What are the unique challenges faced by midsized cities in the Philippines as they attempt to capture inward investment from the BPO industry? How do midsized cities market themselves as BPO hubs? Is the expansion of the BPO industry in midsized cities, including the urban development projects it has triggered, distinct from those in Metro Manila? And, finally, what are the "urban futures" of the BPO industry in midsized cities, given rapid economic and technological change?

To answer these questions, the paper draws on three months of field research conducted in the Philippines. I focus in particular on the experience of two mid-sized cities, Bacolod and Iloilo, which are located in the Visayas region of the country. I adopt a mixed methods approach, which includes spatial

analysis, observational analysis, industry analysis and semi-structured interviews with business leaders, politicians, urban planners and BPO office workers.

Through this analysis, I draw attention to the different strategies that are being taken in the Philippines to decentralize what is currently the country's fastest-growing industry. I argue that the decentralization of the BPO industry is placing significant pressure on mid-sized cities to invest in electricity and telecommunications infrastructure, office space, technical training schools, and other initiatives so as to attract multinational corporations in the outsourcing sector. Such investments represent a significant reallocation of resources for metropolitan and provincial governments, and, in some cases, have resulted in the construction of excessive office space, unnecessary infrastructure, or a combination of the two. The paper concludes with a more generalizable discussion of how automation in the BPO sector undermines much of the economic development policy currently being implemented in the country.

CREATING TECHNOLOGY TOGETHER: THE IMPACT OF NORTH CAROLINA'S TRIANGLE UNIVERSITY LICENSING CONSORTIUM

Abstract ID: 1028

Individual Paper Submission

DONEGAN, Mary [University of Connecticut] mkdonegan@gmail.com, presenting author
FELDMAN, Maryann [University of North Carolina at Chapel Hill] maryann.feldman@unc.edu, co-author

The degree to which local institutions forge partnerships and work collaboratively on technology development contributes to regional vibrancy and long-term economic prospects. A region's research universities are key among these institutions, and together their diverse missions and capacities contribute to an informal regional system. Yet universities may also choose to pursue more formalized partnerships; inter-university collaborations such as science parks, innovation hubs, incubators, and joint campuses continue to increase (Addie 2018). In addition to reigniting debates about the role universities play in urban land development, these spaces—including Roosevelt Island's Cornell-Technion and London's Nanotechnology Centre—raise questions about how universities contribute to long-term regional innovation. That is: do collaborative efforts provide additive benefits to regional innovation? Or do they instead dilute university ecosystems, thus unintentionally dampening innovation?

In this paper we draw insights from an older university collaboration, North Carolina's Triangle University Licensing Consortium (TULCO), to deepen understanding of how institutional partnerships can best shape regional economic development and innovation (Goble 2013). In 1988, to help jumpstart lagging campus commercialization efforts, Duke University, North Carolina State University, and the University of North Carolina at Chapel Hill formed TULCO. The organization promised an efficient means for each university's commercialization efforts catch up to their research-intensive peers. Yet TULCO operated with full support for just five years (1988-1992) and dissolved in 1995, leading histories of the region's development to either overlook TULCO or frame it as a doomed experiment.

We demonstrate that TULCO was instrumental to the region's long-term development and can offer lessons for contemporary inter-university scientific collaborations. Our theoretical lens relies on institutional interpretation—or the process through which individual actors actively “interpret and reinterpret their institutional settings” to turn policy mandates and abstractions into institutional realities (Lowe and Feldman 2017, 3). Institutional interpretation is particularly useful for conceptualizing institutional change in periods of uncertainty, when actors within organizations face considerable gaps in understanding between formal and informal institutions. In this case, the Bayh-Dole Act of 1980 created the formal, legal institution of technology transfer (Eisenberg and Cook-Deegan 2018)—one quite apart from the disparate, often informal practices that existed on each campus (Donegan 2019). Despite the state-backed regional collaboration, officials from each of the three campuses separately and continually interpreted the collaborative's value against their own institution's long-standing missions and dissimilar attitudes towards industry engagement. Over time, each university came to embrace a different understanding of TULCO's usefulness—leading each to drift away from one another and, over a short period of time, leave TULCO.

Through semi-structured interviews with current and former staff at the three universities and a review of archival documents, we argue that in the rush to open TULCO officials overlooked the heterogeneous nature of the missions, motivations, resource needs, and deeply-ingrained cultures of the three participating universities. In doing so, the collaboration's architects missed a key window to shape officials' divergent institutional interpretations. Still, we argue that TULCO was critical for jumpstarting what would eventually become a recognized leader in university-led regional development. We draw four broad policy lessons. First, universities must go beyond recognizing shared goals to interrogate fundamental differences in motivations, power relationships and informal institutions. Second, collaborations must allocate access to distinct resource streams in mutually beneficial manner. Third, collaborations need established performance metrics, equitable and transparent procedures, and opportunities for functional exits for when universities need to withdraw and re-center around unique institutional needs. Fourth, even in failure, high-profile collaborations can play an instrumental role in scaling up campus support mechanisms and bringing universities into sync with supportive state economic development planning and policymaking efforts.

LOCATIONAL PATTERNS AND PRODUCTIVITY OF THE FASHION INDUSTRY IN THE U.S.

Abstract ID: 1033

Individual Paper Submission

CHO, Seongmoon [University of Southern California] seongmoc@usc.edu, presenting author

The fashion industry allows us to view the changes in the country's urban economic system. The fashion industry has evolved from a labor-intensive into a more design-oriented sector and a central part of the 'cognitive-cultural economy' (William & Currid-Halkett, 2011). The fashion industry cluster has brought the attention of researchers and policymakers, demonstrating the city's comparative advantage (Rantisi, N. M., 2002). Nevertheless, studies on differences in productivity among subsectors of fashion clusters have been limited. The fashion industry can be divided into subgroups, such as supply, manufacture, wholesale and design, according to production procedure. Although each group has different productivity, these subsectors have a close relationship in the production of clothing, so that they benefit from the proximity to the fashion cluster. Therefore, the study identifies how much fashion-related businesses with different productivity can have benefited from geographical proximity.

For this research, I define historical trends in the concentration of fashion industries for the United States from 1996 to 2016. Using ZIP Codes Business Patterns (ZBPs) from the U.S. Census Bureau, I study the spatial structure of the fashion industry by subsectors such as Supply, Manufacturing, Wholesale, and Design. Using Geographical Information Systems (GIS), I define and represent the spatial patterns of each subsector showing reconfiguration of its economic geography. The result shows that the fashion industry is inclined to produce regional network agglomerations. The results are consistent with the larger theoretical and empirical observations on the post-industrial landscape. After defining the spatial patterns of fashion clusters, this study confirms and quantifies productivity benefits from fashion clusters. Using panel data, I study the association between the agglomeration of the fashion industry and its productivity by subsectors. The econometric analysis provides empirical evidence of the economic benefits associated with the clusters. Also, the results explain the different productivity depending on the clusters such as the New York Garment district and the Los Angeles fashion district.

(RE)CREATING THE RURAL WEST: EFFECTS OF CREATIVE DISTRICT POLICY ON RURAL COLORADO PLACES

Abstract ID: 1035

Individual Paper Submission

SHELBY, Jennifer [Community Engagement Design and Research Center (CEDaR) at the University of Colorado, Boulder] jennifer.shelby@colorado.edu, presenting author

Creative districts have historically been used to spur revitalization, infuse character into a underutilized space, and stimulate economic development (Currid 2009; Ashley 2015). The implementation of a creative district appeals to local economic development entities as it requires low investment with the potential for high impact to the local economy. While it is assumed this is a purely urban phenomenon, evidence suggests rural places may also become creative centers, drawing creative producers with low cost of living and natural amenities (Markusen 2007; Polese 2011). Few scholars have acknowledged the existence of creative districts or similar interventions in rural places. This research aims to fill this gap by examining creative districts in rural Colorado to answer the question: does a creative district accomplish economic development and revitalization goals in rural towns as in urban areas?

To answer such question, this study examines the dynamic outcomes thought to be connected to creative district implementation such as changes in local place perception, physical spaces within the districts, and economic measures in rural places with attention to how these might differ from urban places. In Colorado, a unique state-led approach to creative district development aims to enhance and develop creative economies in individual places across rural and urban scales, promising enhancement of local identity, economic development, increased tourism, revitalization, and improved quality of life. Each place has a unique planning environment, varied amenities, a distinct arts ecosystem, and local governance practices. For this study, I focus on four rural creative districts across Colorado to highlight ways the creative district has or has not: 1) impacted local planning processes through the integration of arts and creative initiatives, 2) affected economic development in relation to creative industries, and 3) encouraged revitalization and placemaking in downtown spaces. Site visits to creative districts and interviews with stakeholders were conducted in 2017 and 2018 to the study communities in Colorado. In addition, assessment of economic data, planning documents, and local press have provided additional insights about the impacts of district implementation at the local level.

Findings indicate there may be certain attributes that support positive outcomes for rural places, such as a core of “supercreatives” (Goldberg-Miller, 2017), public-private partnerships, and specific kinds of local amenities. Creative districts supported by the local government, integrated into the local planning processes, and possessing strong social network ties seem to impact the community in the strongest and most positive ways. Districts lacking such connection to local institutions seem to struggle to achieve sustainable change in the local place and economy. While many of these findings resemble the attributes of successful urban districts, rural planning approaches require much more communication and collaboration with residents and local governments. This paper provides planners with insights about the nuanced approach of creative district development in rural places.

OPPORTUNITIES FOR WHOM? THE BENEFICIARIES OF OPPORTUNITY ZONES

Abstract ID: 1068

Individual Paper Submission

SNIDAL, Michael [Columbia University, GSAPP] msnidal@gmail.com, presenting author

Tucked into the 2017 Tax Cuts and Jobs Act was the largest Federal program for place-based investment in more than half a century. Opportunity Zones ("OZ") are expected to cost the US government over \$15 billion in forgone tax revenue through 2026. This means they "Trump" not only the Clinton Era Empowerment Zones but even the Great Society programs considered inconceivably vast.

The bi-partisan sales pitch for the passage of OZ legislation was that the primary beneficiaries would be existing residents in distressed communities – particularly those that have not rebounded from the recession. Yet 57 percent of all census tracts in America qualify for OZ designation based on their poverty and income demographics. The program guidelines also leave benefits to distressed communities far from guaranteed. There is no indication that regulations prevent individuals and corporations from receiving subsidy for investing in projects that would have gone forward without it. There is nothing in the legislation that guarantees clear benefits e.g. affordable housing, jobs or job training, public infrastructure development etc. for distressed communities and their residents.

This paper argues that 1) The OZ program was not designed to benefit distressed communities; and 2) failed program design is the result of a handful of private interests manipulating neoliberal ideas to co-opt public policy.

The analysis begins with a critical assessment of the OZ program design. This evaluation includes a statistical overview of the distress and gentrification levels of designated OZs; content analysis of the Joint Economic Committee congressional hearings and the final IRS rules and regulations governing the program; and semi structured interviews with the OZ program engineers and legislatures regarding the programs influences, and if and how the program was set up to ensure that benefits accrue to distressed community residents.

A historical and ideational account of the OZ Program follows. Using primary and secondary sources this paper explores how Peter Hall's original idea of "Freeports" was co-opted into a proposal by the Economic Innovation Group to offer capital gains tax incentives for wealthy investors. The paper concludes with a discussion of how the OZ program design can help diagnose federal economic development policy broadly. It also advances a proposal for an evaluation of the early outcomes of the OZ program.

MICRO-MANUFACTURERS: CAN THEY BE A SOURCE OF INCLUSIVE GROWTH?

Abstract ID: 1108

Individual Paper Submission

JUNG, Namji [Seoul National University] namji.jung@gmail.com, presenting author

Regarded as uncompetitive entities, incumbent micro-firms (older than 10 years with fewer than 10 employees) are frequently categorized as subjects of redistributive policies rather than important sources of innovation or job growth. However, this might be misleading stemming from a lack of quality data, which hampers a proper performance evaluation or a close investigation of economic contribution to local and regional economies—many studies on firm-level innovation and performance improvement are conducted at national or multi-national scales, and micro-firms are mostly excluded from analyses.

This paper, however, argues that this group of firms cannot be lightly neglected. Given the sheer number of incumbent micro-firms, they can be a significant source of innovation and job growth, particularly for local or regional economies that are largely comprised of constellations of small firms. Building on this recognition, this paper demonstrates the case of Incheon, where a group of micro-manufacturers are an important source of innovation and job growth. In Incheon micro-manufacturers comprise up 80% of the manufacturing sector. Combining a city-wide employer-employee matched panel data set and interview data with manufacturers, this paper reveals three important aspects: 1) micro-manufacturers account for 55% of employment in high growth firm (HGFs) in Incheon and are responsible for 25% of new net job creation, in average, from 2007 to 2016. More importantly, their job share has increased from 18.56% to 34.8%. Although each micro-manufacturer’s contribution is slim, as a group they appear to have sustained and consistent job creation effects; 2) the 50% of HGFs (innovative firms by definition) achieve their remarkable growth without actively investing in research and development (non-R&D). Interviews with manufacturers provide explanation: small firms hesitate to invest in R&D due to the high sunk cost and uncertainty associated with getting successful R&D outputs. 3) to understand important elements of high growth of non-R&D micro-manufacturers, this paper estimated the effects of firms internal activities from expenditure to human resource hiring practices by using logistic regressions. The results shows that these non-R&D micro-HGFs tend to forge their high growth by training their employees and adopting new technologies or equipment. They also tend to hire people who are in more vulnerable positions in the labor market and are, thus expected to be dedicated to the firm once they are hired, compared to then their non-high growth counterparts. However, a higher proportion of wages in total expenditures is negatively

correlated with high employment growth because the added cost weighs down the firm's growth potential.

All in all, non-R&D micro-HGFs' high reliance on local labor markets and day-to-day practice-based innovation rather than R&D together suggest that micro-manufacturers in Incheon are locally embedded. Thus their growth will carry direct and enduring local impacts. In conclusion, micro-firms as a group can be a potential source of inclusive local and regional growth. This, it is recommended that policy makers pay greater attention to this formerly untapped group of firms.

SEEKING FEMINIST ACCOUNTABILITY IN ECONOMIC DEVELOPMENT: THE CASE OF LINCOLN YARDS IN CHICAGO, IL

Abstract ID: 1122

Individual Paper Submission

CRAFT, Andrea [University of Illinois at Chicago] acraft2@uic.edu, presenting author

Transparency of public expenditures is the most fundamental reform needed for accountability - the responsibility for public officials to account for how they use tax revenues - in economic development (Mattera et al. 2010). Yet, effective transparency remains elusive due to technical and political challenges (Heald 2012), so research on governmental transparency tends to focus on improving methods of disclosure with the assumption that improving transparency will lead to greater accountability. We have little understanding, though, of whether transparency necessarily leads to accountability, which calls for an investigation of the presumed linkages between the two (Mabillard and Zumofen 2017). This research examines a case of contested economic development that has not led to perceptions of transparency and accountability, despite efforts to do so by elected officials and developers. I use qualitative methods to understand how transparency affects governing practices and why transparency mechanisms that meet formal requirements for such often do not lead to more public participation or better decision-making.

This research is a case study of the Lincoln Yards project in Chicago, a massive mixed-use redevelopment of a former industrial site in the Lakeview neighborhood, for which the city has committed nearly \$1 billion in tax increment financing (TIF). Local leaders held a succession of large community

meetings to vet the plan, all of which involved hours of public comment and heated debate over the validity and benefits of the project. Residents have expressed a range of concerns over the impact of the development on quality of life and equity, with opponents united in their claim that the planning process has lacked transparency and failed to build accountability, despite the long timeline of public engagement. In response, the plan has seen significant revisions, including cancelling plans for a stadium and large music venue, and breaking ties with its primary commercial sponsor. Despite the procedural transparency that took place, as well as Chicago's noted progress in TIF transparency via sunshine laws and open data, the project is still the subject of severe and widespread criticism that it lacks transparency, and the project's feasibility remains uncertain.

My research seeks to explain this discrepancy between transparency procedures and perceptions of transparency and accountability. Transparency's institutional complexity derives from interactions of multiple stakeholders, competing meanings, and diverging effects (Meijer 2013). Noting this, the literature has called for more in-depth qualitative studies of how transparency is constructed through these complex interactions.

I collected data through participant observation of over eight months of community meetings and public hearings related to the Lincoln Yards planning and approval process, as well as in-depth interviews with public officials and residents who participated in it. I analyze the impact of transparency on relations of accountability using Mabillard and Zumofen's framework of active enforcement versus discursive answerability, and I add to this framework Russo's concept of feminist accountability. Rooted in theories of transformative justice, feminist accountability is an ongoing practice of inclusion based on the willingness to understand others and to acknowledge that all are capable of harm (Russo 2018).

From this study, I conclude that transparency policies have not yet altered some historically problematic components of publicly-financed economic development, such as the privileges of non-disclosure afforded to private partners. Furthermore, existing frameworks do not reflect all aspects of accountability demanded by the public. A primary source of dissatisfaction with the outcomes of Lincoln Yards is the unwillingness for public institutions and private partners to acknowledge historical and potential harm resulting from economic development. Feminist accountability should be incorporated into planning models that aim for equitable development based on principles of transparency and accountability.

HOW TO RETAIN MANUFACTURING FIRMS IN A TRADITIONAL INDUSTRIAL CITY - A CASE STUDY OF CHANGWON IN KOREA -

Abstract ID: 1128

Individual Paper Submission

LEE, Woobae [Inje University] wblee@inje.ac.kr, presenting author

This research aims to find out determinant factors of firm relocation in manufacturing industry and suggest local government to prepare right strategies for retaining firms which are likely to be relocated. We surveyed 236 firms in Changwon national industrial complex in Korea and analyzed data using logistic regression model. A case study of Changwon, which is located in middle of the largest industrial belt in Korea, indicates that among twelve most important location variables in our study, accessibility to recreation and park services for laborers is the most influential and statistically significant factor for firm's decision of relocation. This result emphasizes growing significance of quality of life and cultural amenity of a community for retaining manufacturing firms. In addition, such factors as 'easy access to business information and services,' 'local residential environment,' 'logistics and delivery cost,' 'local labor costs' and 'feasibility of site expansion' are also found influential, but not significant in statistics. This research outcome suggests that traditional strategies, such as lowering land cost and providing tax subsidy for firms are not so much effective for retaining manufacturing firms as increasing amenity of cities and building business-friendly environment. This concludes that current debate of industrial location in knowledge economy can apply to cities in Northeast Asian countries as well as US and Europe.

FIRM INNOVATION AND JOB QUALITY IN SUSTAINABLE FOOD SYSTEMS

Abstract ID: 1153

Individual Paper Submission

KELMENSEN, Sophie [University of North Carolina at Chapel Hill] sophiekelmenson@gmail.com, presenting author

Natural resources provide the foundation of sustenance and economic activity in many communities. Economic development and sustainable natural resource management practices are traditionally positioned as being in tension with each other; however, increasing attention is being paid to sustainability, and the two have been positioned as generating innovation and evolution within both spheres. Much effort has been devoted to developing new technologies, information, and management practices in order to bring a "sustainable", in all senses of the word, environment and economy about.

How this change is brought about is unclear. Focusing on food systems – a sector that contributes massive amounts of greenhouse gasses -- this paper asks: how is the pressure to become more sustainable

influencing production in food systems? How are industries either innovating and/or upgrading, remaining unchanged, or going extinct in reaction to sustainability pressures? What will this impetus mean for the number and quality of jobs in those industries? Where are these shifts happening and is this shifting the geography of sustainable industries?

While some industries may not be able to evolve fast enough – for example many fisheries are disappearing due to over-fishing or because schools of fish are migrating to different habitats in response to ocean acidification or ocean warming – and new industries such as aquaculture may arise to take their place, other industries will be able to upgrade or develop new production methods to adapt. I hypothesize that in industries with significantly high enough demand for well-produced, sustainable goods, learning is more likely to be shared across the industry, hastening improvements.

To explore these questions, a novel dataset is compiled for local food systems jobs in the United States, and paired with case studies of sustainable food systems jobs and innovations across the country. The geography of jobs and job quality will be presented alongside case studies of innovation and upgrading success and failure.

RESILIENCY IN THE FACE OF RESTRUCTURING: A CASE FOR ECONOMIC REVIVAL IN ST LOUIS, MISSOURI

Abstract ID: 1168

Individual Paper Submission

LEWIS, Robert [Saint Louis University] bob.m.lewis@slu.edu, presenting author
COFFIN, Sarah [Saint Louis University] sarah.coffin@slu.edu, co-author

The global forces of industrial restructuring in the 1970s and 1980s led to massive deindustrialization in most of the significant manufacturing regions around the world. In countries like the United States, United Kingdom, France, and Germany, industrial cities faced dramatic disinvestment as manufacturing firms adjusted to technology innovations (though such adjustments weren't limited to manufacturing) that altered how manufacturing was done. In the US, these shifts also changed firm location criteria and decisions, upsetting over a century of locational traditions in core industrial sectors. In what became known as the 'rust belt' across the northern Midwest, metropolitan areas like Detroit, Pittsburgh, Cleveland, and St. Louis witnessed dramatic shifts in population and economic activity within urban core areas, losing over half their populations and jobs in a matter of decades.

The Brookings Institution characterized these as ‘weak market’ cities with stagnant economies where demographic and industry groups that drive strong economies were lacking (Vey 2007). Weak market cities did not substantially benefit from the 1990s’ robust global economic cycle. Instead, they faced vast and increasing levels of real estate vacancy (plants, homes, stores, offices, and land) driven by brownfield challenges and continued public sector disinvestment. Economic development responses in these post-industrial cities has been, until recently, criticized as weak and especially focused on refilling the economic and employment base with service sector, low-wage jobs. This paper also demonstrates that the same cities required above average periods of recovery following the Great Recession.

Using the city of St. Louis, Missouri as a case study, this paper examines the state of the urban economic development landscape of a mid-sized post-industrial city. Building on prevailing economic development trajectories, St. Louis has, since the early 1990s, engaged in a diversity of approaches that include leveraging brownfield and vacant land assets alongside a variety of innovation clusters (incubators, research centers, co-working facilities) which now extend to “maker spaces” that reuse older, vertical industrial buildings for manufacturing start-ups. These efforts have not only helped to measurably diversify the city’s economy but have also re-attracted a much-needed population of educated, skilled, and urban-savvy workers and their families. Moreover, St. Louis is, at long last, aggressively pursuing strategies to redevelop and reuse a wide range of vacant real estate—land and buildings—with emerging partnerships of non-profits, private business, and city agencies.

In this paper, we address two key questions: (1) To what extent will smart diversification strategies shape future prosperity in St Louis; and (2) Can St Louis become a model resilient city? Answers are based on a case study examining opportunities for re-engaging with the manufacturing sector in St. Louis. Components of the case study include an analysis of economic sector and occupational data showing crucial changes and improvements since 1990, and a multi-dimensional approach to reutilizing vacant industrial, commercial, and residential real estate now strongly underway. Ultimately, we intend to profile how postindustrial cities remain centers for innovation.

THE IMPORTANCE OF SUB-CENTERS TO U.S. CITIES.

Abstract ID: 1172

Individual Paper Submission

OSMAN, Taner [UCLA] tanerosman@ucla.edu, presenting author

While there have been signs of reversal in some cities, on the whole, the decentralization of jobs and people within US cities has been relatively constant since the Second World War. In relation to patterns of employment activity, decentralization is commonly measured in a binary way. Researchers often compare the share of employment in central business districts (CBD) to the share of employment in the rest of regional economies. Oftentimes these studies shed little light on the nature and form of employment decentralization, such as whether employment decentralization is diffuse and random in nature or concentrated into numerous centers of relatively dense activity. A notable exception in this regard is work on sub-centers, where a parametric approach is employed to identify multiple agglomerations of activity within cities. To this point, the presence of sub-centers has been measured in individual cities in a limited number of cases, but no study has attempted to measure the extent and importance of sub-centers across a large number of cities.

While, in U.S. cities, employment has decentralized from CBDs, limited evidence shows that a small number of sub-centers throughout a region can account for as much as 48% of metro region employment (Cervero and Wu 1997). This study seeks to measure the presence of sub-centers within the largest 100 metropolitan regions in the U.S. The research is motivated by three primary research questions. First, what percentage of employment is found within sub-centers across cities, and does this vary by city size and region? Second, what is the nature of employment activity within sub-centers, which industries tend to locate in sub-centers? Third, has employment within sub-centers become more or less pronounced over time?

The Census Bureau's Longitudinal Employer-Household Dynamic (LEHD) program will be the primary dataset employed in this analysis. LEHD provides employment counts by 2-digit NAICS category for census tracts over the period 2002-2015. For the largest 100 combined statistical areas (CSAs), sub-centers will be identified using the approach of Giuliano and Small (1991). Giuliano and Small define a sub-center as a cluster of contiguous census tracts, each having a minimum employment density of D , which together contain total employment of at least E . If the values of D and E are set too high, they will undercount sub-centers in small CSAs, and if the values are too low, they will inflate sub-sectors in larger cities. Therefore, the values of D and E will be adjusted for city size in an iterative process. GIS mapping software will be used to identify sub-centers of activity.

This research is guided by the idea that employment decentralization in U.S. cities is more nuanced than may be widely perceived. The primary hypothesis of this research is that significant economic activity, while not found in a single CBD, is found in multiple sub-centers of dense activity throughout cities, which approximate many of the benefits of central business districts.

THE RELATIONSHIP BETWEEN STARTUP BUSINESSES LOCATION & TRANSIT-ORIENTED DEVELOPMENT IN AUSTIN, TX

Abstract ID: 1220

Individual Paper Submission

HAFIZ, Mohammed [University of Texas at Arlington-College of Architecture Planning and Public Affairs (CAPPA)] mohammadf.hafez@yahoo.com, presenting author
ANJOMANI, Ardeshir [University of Texas, Arlington] anjomani@uta.edu, co-author

Cities are usually adopting development plans seeking to improve economic opportunities. Therefore, many cities have developed transit stations to Transit-Oriented Development stations (TOD's) to attract businesses to locate in these cities. Many industries have been relocating near these transit stations.

Transit stations especially TOD's embrace a higher population density, diverse income, and business clusters which are attractive for businesses to relocate in these areas creating an economic agglomeration. Moreover, TOD's are known as competitive areas for businesses. According to Nelson et al., (2015) TOD areas have shown an increase in office, education, healthcare, and entertainment jobs.

A research investigated the relationship between the birth of new firms and the proximity of the light rail of two metropolitan areas Dallas, TX and Portland, OR and found a positive statistically significant relationships in both metropolitan areas. Also, the research found the rail proximity increases firm birth in most industrial sectors. The research concluded that transit users increase firm birth near transit stations (Chatman et. al., 2016). Another study examines the impact of the light rail in Phoenix, AZ on new businesses in specific industries. The study found that new businesses in knowledge industry increased by 88%, the service sector increased by 40%, and retail increased by 28% (Credit, 2017).

In the past few years, Austin, TX was successfully attracting new businesses to relocate in the city. In 2016, Austin had \$626 million of venture capital investment (Florida, & Mellander, 2016). Also, Capital Metro in Austin has been developing their metro stations to TOD's in a different areas, seeking to improve more economic opportunities in the region, which seems to be successful.

However, most research focused on new businesses near transit stations, but there are few that investigate new businesses, or startups near TOD stations. Therefore, this research aims to investigate the relationship between TOD's and startup businesses in Austin, TX. It will compare startup businesses within a half-mile of TOD's to other new businesses that are not located near transit stations to find which are more successful in terms of location, and type of business or industry.

To investigate the relationship between TOD's and startup businesses a linear regression will be used as a method to fulfill the outcomes of this research. The selection of TOD stations will be based on the selection of Capital Metro stations as TOD's. Also, we will use a half-mile buffer of the transit stations based on the recommendation of previous research (Guerra, & Cervero, 2012). The research will use Geographic Information System (GIS) to locate new businesses based on the data. Our data is collected from different resources such as TOD database, Bureau of Economic Analysis County Business Patterns, U.S. patent and trademark office, Small Business Data Resources, AllTransit, and ReferenceUSA.

The result of this research is expected to find that startup businesses especially high-tech, healthcare, and entrainment are more likely to be located near TOD stations. The finding of this research will provide a better source of information for new business owners to choose the location of their business. Therefore, this research should help cities to know which industries are better to locate in their cities to boost their economic status.

Startup businesses is a path to increase economic opportunities in cities. TOD's have shown successful results in attracting businesses, population, and development in many cities in the past years. TOD's may be the reason for businesses to shift back to urban centers rather than locating in suburban areas.

THE ROLE OF AGGLOMERATION EXTERNALITIES ON THE SURVIVAL OF IOT STARTUPS: THE IMPLICATION OF THE SMART CITY POLICIES

Abstract ID: 1229

Individual Paper Submission

LEE, SUNGWON [Gangneung-Wonju National University] swl0906@gwnu.ac.kr, presenting author

Internet of Thing devices (IoTs) devices representing up-and-coming industries are growing rapidly in recent years. Every year the novel and relevant top IoT trends are reviewed and introduced, and market research institutes expect also the IoT market size and share to extend rapidly. According to Gartner, about 8.4 billion IoTs are applied as of 2017 and they will arrive about 20.4 billion until 2020, and Forbes predicts that the IoT market will double by 2021 reaching \$520B as well. The IoT platform market is an arena for competition among other major international companies, so they do not seriously depend on their locations. However, there are many innovative but vulnerable small-sized local startups developing IoT devices with applying general purpose technologies (GPTs). The local IoT device industries can be the driving force for regional growth, but they are quite fragile and flimsy with high failure rate despite the efforts of the local governments and other stakeholders to boost their performance.

The key aim of the study is to find the spatial determinants of the survival of the small-sized startups within the local IoT devices, empirically. This study focuses on comparing the effects of localized economics and urbanized economics in IoT device industry. Since Marshall (1890), Weber (1929), Arrow (1962), and Paul Romer (1986) introduce the benefits of co-location of economic activities enjoying positive knowledge spillovers among firms within the same industries. These key studies together are called as the Marshall-Arrow-Romer (MAR) or Marshallian externality. Substantial studies such as Lucas (1988), Krugman (1991), and Henderson, Kuncoro, and Turner (1995) support the localized positive cluster effects. Different from Marshallian externality, Jane Jacobs (1969) asserts that the local diversity leads to urban growth by allowing the cross-fertilization of ideas, and this idea is also supported by Glaeser et al. (1992), which is called by Jacobian externality. Current the concept of the 4th Industrial Revolution also support the positive Jacobian externality based on interdisciplinary project ideas.

Although many studies try to find the empirical evidences for both perspectives, still mixed findings are reported by different industries.

For an empirical analysis, this study applies time-varying survival analysis with 352,111 establishments of the new IoT device sector started in 2013 with a comprehensive firm level data (Korean Enterprise Data). Their performance is tracked for the subsequent five years within the context of hazard model in each month. To test the marginal effects of Marshallian and Jacobian externality, the risks of exist confronting each firms are controlled from the ownership and size, patents, neighborhood characteristics such as population density and employment density. To control the time-varying risk factors such as stock market fluctuation, and gross regional domestic product, advanced Cox model is used. The study shows that both Jacobian and Marshallian externalities significantly decreased the failure rate, but the influence of the Jacobian externalities is relatively smaller than Marshallian externalities under the standardized coefficient comparison.

REMOTE WORKER MIGRATION IN THE UNITED STATES: THE ROLE OF PLACE-BASED AND HOUSEHOLD CHARACTERISTICS

Abstract ID: 1247

Individual Paper Submission

WALLACE, Ryan [University of Southern Maine] ryan.d.wallace@maine.edu, presenting author

Rapidly evolving digital, mobile, and information and communication technologies have contributed to the decoupling of geography and labor and made it possible for many jobs to be completed from anywhere, particularly work that emphasizes the development and flow of information and knowledge (Carnoy, Castells, & Benner, 1997). One manifestation of this has been the emergence of the remote worker as someone untied to an employment location and may instead base location and migration decisions on other factors that accentuate access to amenities and other place based factors. There has been growing interest by researchers, policymakers, and economic development professionals on the implications of remote work, and the changing nature of the workplace more broadly, for local and regional economies, particularly in rural and small city regions (Gallardo & Whitacre, 2018). Remote work is viewed as a potential means to attract transient residents based on high quality of life factors, such as those recently implemented in the states of Vermont and Maine among other regions of the country (Gallardo, 2016; Vermont General Assembly, 2018).

This paper examines the distribution and differences of remote work migration in the United States. Building off of recent research on the geography of remote workers, I construct variables that measure the migratory flows of remote workers for two time periods drawing on individual and household level public use microdata from the IPUMS USA dataset. I construct several sets of variables that measure place-based factors (socio-economic, access to amenities, and infrastructure) and individual level characteristics (household composition, economic, wage differentials, and place attachment) to estimate regression models of remote worker migration in the US. I estimate negative binomial regression models to take advantage of an equivalence relation that exists with the conditional logit model (CLM) often employed for problems with large complex choice sets. The equivalent relation between the CLM and Poisson regression likelihood models were demonstrated by Guimaraes, et al. (2004) and used to model firm location decisions to overcome the several problems known to challenge estimation of CLM models.

The findings of this research shed light on spatial patterns associated with the latest industrial restructuring in the digital age and will help inform planners and policy makers on the strengths and weaknesses of respective policies designed to target such populations.

THE INDUSTRY SPACE: MODELLING STRUCTURAL CHANGE AND ECONOMIC GROWTH USING NETWORK ANALYSIS

Abstract ID: 1257

Individual Paper Submission

CHO, Jae Beum [Indiana University] jaebcho@iu.edu, presenting author

This paper focuses on a key characteristic of economic ecosystems, namely the interrelatedness of its different elements, where each component influences one another to bring about emergent outcomes. Concentrating on industrial structure as one aspect of the ecosystem of cities, I attempt to depict a picture of the “industry space” of cities where industries are connected to each other within a network of relatedness (Hidalgo et al. 2007). At the local level, cities diversify into and specialize in different industries as a result of regional competition and local comparative advantages. Accordingly, the evolution of a region’s industry space – and thus structural change – can be measured by analyzing shifts in the underlying industrial composition of the region.

A network by definition consists of two components; namely the 1) nodes, and 2) links. Utilizing data on new firm formation and industrial composition for MSAs taken from the Statistics of U.S. Businesses (SUSB) and unsuppressed County Business Patterns (CBP) data at the 4-digit level for the years 2005 to 2013, the underlying industry network is constructed such that the nodes are defined as individual NAICS 4-digit industries. The network links are defined using the Ellison-Glaeser index of coagglomeration (Ellison et al. 2010), to take into account the relatedness between any two industries. Then, any MSA's industrial structure is depicted within the network by assigning values corresponding to the location quotient for employment for each industry to the nodes.

The novel step is where I simulate shifts in any particular city's industrial structure over time by modeling industrial composition change as a shift in the location quotients for each industry node. I first utilize the Method of Reflections (Hidalgo and Hausmann 2009) to evaluate the economic capacities of a region based solely on location quotients. In essence, The Method of Reflections provides a synthetic way to measure regions' progress towards optimal economic development, defined as shifts in industry composition during different stages of development such that The Method of Reflections metric is maximized. By comparing the potential increases in economic capacity (i.e. The Method of Reflections metric) of a region brought about by potential shifts in location quotients across industries, it is straightforward to evaluate which industry composition brings about the largest increase in economic capacity. Multiple changes in industry composition can be represented by stepwise maximization of economic capacity, in which a region shifts its composition by a small increment in each step.

I restrict the industries that are able to experience change based on the "industry space" described above. Specifically, an industry is targeted for possible change only if it is highly coagglomerated with the current industry mix in a region. For example, a region focused on electronics manufacturing will have an easier time shifting to biomedical devices manufacturing, compared to for example, the arts industry. The underlying assumption of the simulation is that industry composition change is a gradual process that builds upon the economic foundations of the present.

Ultimately, this study attempts to answer two questions:

- 1) Do more successful regions show different patterns of structural change compared to those that are less successful?
- 2) How should regions faced with different circumstances promote structural change such that their economic development capacities are maximized?

Preliminary results suggest that the change in industrial structure over the years for which data is available are significantly correlated with the economic development outcomes of regions, and that in some cases these dynamics are more important than the actual industries in which these regions specialize in. In addition, more successful regions show distinct patterns of evolution that distinguish themselves with their less successful counterparts.

THE FUTURE OF THE SHOPPING MALL: AN INDEX FOR DETERMINING WHO LIVES, WHO DIES, AND WHY?

Abstract ID: 1273

Individual Paper Submission

BURAYIDI, Michael [Ball State University] maburayidi@bsu.edu, presenting author

In the twenty-first century, the shopping mall is doing to suburbs what it did to Main Street in the mid-twentieth century. As hundreds of malls close or are under-utilized, vacant buildings will proliferate the suburbs, large expanses of barren parking lots will litter the landscape, municipalities will lose tax revenues from lower assessed values of buildings in and near shopping malls, and the commercial nucleus of suburban neighborhoods will hollow out. This is becoming the reality of the suburban landscape as shopping malls are losing the appeal that they once did, toppled by reurbanization of the middle class, the change in shopping preferences of consumers towards experience rather than stuff acquisition, and by the convenience of online shopping. It is estimated that one in four of the remaining 1,100 malls in the U.S. will close between now and 2022 (Calfas 2017).

In 2017 there were nearly 7,000 retail closings, up more than 200 percent from 2016 (Thomas 2017). Most of them were the anchor department stores that provided the main draw for mall shoppers including Sears, Macy's, Kmart, JCPenney, and Target, to mention but a few. According to the Wall Street Journal vacancy rates at regional and super-regional malls hit 9% in the fourth quarter of 2018 and retail traffic declined by 7% from January 2017 through August 2018 (Fung 2018). In 2018, CoStar, a commercial real estate research firm noted that a record 145 million square feet of retail space was emptied from the closing of retail stores, the equivalent of shutting down the Pentagon 22 times over (Whiteman 2019).

This paper will present findings from research of shopping malls in the Midwest, a region that has seen significant disinvestment following the deindustrialization of the national economy and where cities have also been hardest hit by mall closings. The paper is based on research conducted through a survey of managers of shopping malls, an in-depth interview of managers of select malls, a survey of shoppers at malls, and a GIS analysis to determine the socio-economic factors characteristics of the market area of malls in the region. Data obtained from these studies is used to develop an "Index of Mall Health" which can be used to gauge the state of a shopping mall and to predict whether a mall will survive or die. The index is useful to developers and investors in helping them make decisions about investment priorities and the possible location of shopping malls.

THE ECONOMIC AND DEMOGRAPHIC IMPACTS OF WIND DEVELOPMENT ON RURAL COUNTIES IN THE UNITED STATES.

Abstract ID: 1286

Individual Paper Submission

SHOEIB, Eman [University of Massachusetts Amherst] eshoeib@umass.edu, presenting author

Wind power development has rapidly expanded in rural areas in the United States. Numerous studies addressed the impacts of wind development on rural communities focusing on economic, and environmental effects. This research uses two different secondary data analytical techniques to measure the net economic and demographic impacts of wind development on rural counties: Propensity score matching and longitudinal data analysis. The propensity score analysis is based on a quasi-experimental research design, where I match counties with wind development over 100 MW to similar counties lacking wind developments. I also use a longitudinal (mixed-effects) model to examine the impact of the accumulated wind power capacity in counties in the United States in the period of 1990 to 2015. I find a small, but significant, effect of wind development on rural economies. Increasing the accumulated wind power capacity leads to higher per capita and median household income. I likewise find that the introduction of large wind developments is associated with a slightly lower poverty rate.

A STUDY ON THE IMPACT OF AGGLOMERATION OF THE FOURTH INDUSTRIAL REVOLUTION-BASED INDUSTRIES ON URBAN GROWTH USING SPATIAL ECONOMETRICS MODEL

Abstract ID: 212

Poster

SIN, Hakcheol [University of Seoul] nextlord30@naver.com, presenting author
WOO, Myungje [University of Seoul] mwoo@uos.ac.kr, primary author

Cities have been transformed and developed with its industrial changes, which are the driving force for growth in terms of population and employment. Starting the first industrial revolution in the late 18th century, there have been four phases in industrial revolutions, and the fourth industrial revolution was first introduced at the World Economic Forum.

The fourth industrial revolution is a technological revolution characterized by a hyper connectivity in which all things are linked to existing industries, such as Internet, Artificial Intelligence, and Big Data. The World Economic Forum presented the 10 global risks and the Fourth Industrial Revolution was proposed as an alternative to overcome these risk factors. With the advent of the Fourth Industrial revolution, many countries and cities have started to respond to it.

An industry is a type of urban component which inevitably requires physical space and has served as a driving force for population and employment growth in urban areas. In particular, knowledge-based industries and manufacturing industries are thought to have a positive impact on cities through the concept of agglomeration economy.

However, little is known about the agglomeration effects of the fourth industry on urban growth. This is because the fourth industrial revolution is underway and there are limited ways to analyze its effects on cities. Nevertheless, efforts have been made in many countries to respond to the fourth industrial revolution, and research has been underway on the ICT and knowledge-based industries which are related to the characteristics of technologies for the fourth industrial revolution.

The purpose of this study is to analyze the spatial autocorrelation of the fourth industrial revolution-based industries in South Korea and to identify whether there is an impact of their agglomeration on urban space using the spatial econometrics model. First, this study classifies the fourth industrial revolution-based industries through the review of existing research. Second, the study analyzes the spatial autocorrelation of the fourth industrial revolution-based industries. Third, it compares the spatial agglomeration benefits of the industries through the spatial econometrics model.

The result indicates that the agglomeration of the fourth industrial revolution-based industries have lower spatial autocorrelation than those of the secondary and tertiary industries. However, the result of the spatial econometrics model shows that its impacts on urban population, employment, and income are higher than other industries. This result may provide policy implications for creating innovative clusters that are currently under the goal of balanced national development and self-sufficiency of local jurisdictions.

THE EFFECT OF ACTIVE TRANSPORTATION INFRASTRUCTURE PROJECT ON VULNERABILITY OF BUSINESSES: USING A SURVIVAL ANALYSIS APPROACH

Abstract ID: 313

Poster

CHO, Minji [Portland State University] minji2@pdx.edu, presenting author
 LIU, Jenny [Portland State University] jenny.liu@pdx.edu, primary author
 SHI, Wei [Portland State University] shiwei@pdx.edu, co-author

Many cities across the country have engaged in street improvement projects, characterized as introduction of active transportation infrastructure, sometime with a reduction of on-street parking or traffic lanes. Many scholars are built upon controversial debates about the effects of street improvements on economic health in the surrounding areas. Some researchers argued that street improvements could contribute to the economic vitality of neighborhoods and bring about positive impacts on locally-based retail business (Drennen, 2003; NYCDOT, 2013). However, studies asserted that economic benefits resulting from street improvements might vary depending on the type of businesses, and sometimes it can cause the displacement of establishments. Poirier (2018) found that the bike lane intervention did not increase the sales of all businesses, rather it made sales per local-serving establishment increase. In addition, Grube-Cavers and Patterson (2015) concluded that the proximity to transportation infrastructure, in their case is urban rapid transit stations, could result in an increase in probability of gentrification in most of cases they analyzed.

The purpose of this study is to investigate the impact of street improvement projects on businesses vitality and potential business displacement in surrounding areas. Despite the equivocal results of previous studies, there are few studies focusing on the difference in the impact of projects by type of industry, such as retail versus restaurant, etc. However, even if street improvements contribute to overall economic growth in surrounding areas, it is difficult to justify the project if it has a negative impact on a particular industry. In this regard, this paper tests the vulnerability of businesses to the street improvements by industry types. In particular, this study selects two bike lane upgrade projects in the city of Portland, Oregon, SW Stark & Oak Street (buffered bike lane) and SW Broadway (protected bike lane), as study case, which upgraded before 2010. In order to identify the effect of street improvements, this study analyzes the business opening duration time of the establishments along the two street improvement streets, comparing with other neighboring streets. We apply a survival analysis approach, which can analyze the expected duration of time a particular event occurs, in our analysis, the duration of establishment. This method is useful to find out the probability of survival depending on particular circumstances. The primary data source we used is National Establishment Time Series (NETS) database,

which includes annually business address, industry classification (NAICS code), employment and sales by establishment traced back to 1990.

The findings shed light on the impact of active transportation infrastructure on survival duration of different types of industry. It reflects the potential displacement effect on certain businesses differentiated before and after the street improvement. It can allow urban planners and policy makers to rethink about street improvement projects, especially the potential displacement/relocation effect for certain business types. This study emphasizes efforts to mitigate the displacement problem of business establishments are needed as well as to promote local economic growth through street improvements.

THE STORIES CITIES TELL: POLICIES AND STRATEGIES FOR POST-INDUSTRIAL CITY REGENERATION AND TRANSFORMATION

Abstract ID: 498

Poster

RIGOPOULOU-MELCHER, Aspasia [St. Cloud State University] arigopoulou@stcloudstate.edu, presenting author

Much of the efforts of the last four decades regarding local economic development in the context of post-industrial cities have focused on efforts to regenerate, diversify, and grow local and regional economies using single or multiple strategies together or separately or as part of the implementation of a variety of programs, policies, and processes. Some of the strategies have focuses on traditional models (industrial/smoke stuck chasing, attraction and retention efforts, endogenous business development incubation and development, emulation of success stories, etc.) while others have followed newer models (human development strategies, endogenous sectoral strategies, and/or the development of the consumer or bohemian city). However, the results of many of these efforts either as individual strategies, or as part of a multi prong policy(s) have in general produced only marginal results which though encouraging, have left many economic development practitioners, policy makers, and stakeholders wondering as to the reasons that their efforts have not been as successful, especially since much emphasis has been put in

supporting efforts, creating policies, and developing infrastructure appropriate to propel regeneration. In this context attention has been shifting to some recent efforts that indicate that regeneration and growth in the context of cities appear to focus on new multiprong models that suggest the importance and propulsive ability of new physical, economic, governance, and cooperation forms as the engines to bring cities out of depressive stages caused by structural economic problems and/or to move cities to areas of new opportunities.

This poster presentation will report on the results of secondary and survey research and data from personal interviews conducted between 2016-2018 that surveyed and asked about the challenges and the efforts for regeneration in the context of many post-industrial cities highlighting the road the city of Pittsburgh took towards its successful regeneration and newfound role in the new Economy. The data was empirically and via content analysis qualitatively analyzed. The results indicate the need for the application of new models of economic development that draw from within the local context and capacity and which involve and engage all local economic, civic, and political actors. So, in this context this presentation will address:

1. The trajectory, challenges, diverging paths and unique important assets and opportunities of post-industrial cities
2. The various strategies and approaches Pittsburgh took to overcome its economic downfall
3. Strategies and recommendations for change

Results of the analysis indicate the multiplicity of efforts and initiatives other focused on development, support of specific industries via an elaborate web of public, private, and non-for-profit partnerships, while others involve policies for a more focused or complete overhaul of the local environment to increase the marketability, attractiveness, and outside perceptions of the local environment. The characteristics of these efforts are instructive and speak to specific strategic initiatives prescribed in the context of post-industrial cities. Such an understanding can provide for more focused economic development planning, more effective administrative, organizational, and coordinating mechanisms, and wiser utilization of public resources and effort all of which can possibly guide a more successful, timely, and sustainable development.

Innovation district is a place-based development strategy aiming to attract and relocate the innovative institutions, resources, businesses and talented human capital in the targeted districts (Baily & Montalbano, 2018). This development model has been used in a number of places across the world such as 22@Barcelona Innovation District, Paris' Silicon Sentier in France, High Tech Campus Eindhoven in the Netherlands, Medellín Innovation District in Columbia, as well as the U.S. cases such as Boston's Innovation District.

Innovation districts typically emerge in proximity to educational and economic anchors, which could also shape the specialization of such districts. The anchor entities are most often specialized in high-tech industries such as information technology, life-science, bio-tech, etc. The majority of workforce and human capital of the districts are also highly specialized in such fields (Katz & Krueger, 2016). Therefore, these anchors might define the typology of innovation district; for instance, those specialized in life-science and biotech are called "Medical Innovation Districts".

While there is a consensus on the economic benefits of innovation districts, there exist different approaches towards the implementation. For instance, while Boston's Innovation District or San Francisco's Mission District target specific specializations (focus on medical, attracting the health and life science sectors), multiple cases such as San Diego I.D.E.A. welcome a variety of tech industries (Barnett, Benedetti, Fahey, Leza, & Linare, 2014). The existing literature on innovation districts is mostly theoretical or based on few observations.

This study offers a comprehensive framework for Innovation Districts based on reviewing the existing theoretical and empirical evidence and best practices using content analysis of the plans, websites, and published academic and professional articles, site visits of the districts, and interviews with the leaders, business owners and other contributive professionals. We present and analyze 15 medical, non-medical, and multi-purpose cases that are planned and/or implemented to be an innovation district. Our framework is inspired by the Brookings' innovation districts framework with the same three major assets including the economic assets, physical assets and networking assets, while our framework also accounts for the interactions among these assets as the foundation for an innovation ecosystem, the governing structures and the targeted industries (Katz & Wagner, 2014; Baily & Montalbano, 2018). Our analysis also offers a critical evaluation of challenges and lessons for the future attempts.

In most of the cases, universities play an important economic role, which can both thrive and cultivate innovation. Proximity to universities provides convenient access to both intellectual and physical properties for innovation, as well as the elements and amenities to attract both students and investors. Furthermore, some design strategies such as increased density, gathering open spaces, transparent facades and first level urban amenities increase both district's attractiveness and networking opportunities. On the other hand, one of the most challenging issues is to support existing businesses while attracting new ones. However, the way to achieve the optimum collaboration is physical proximity of different assets,

specially the economic assets; coping with providing buildings and places for co-working and communication for the newly added firms and startups. Finally, planning for innovation districts needs specific attention for the growth and continuing evolution at the planning stages and after implementation.

High tech industries have a growing share from national employment, Gross Domestic Product (GDP), and global economy, they are widely targeted by the policy makers and academics. Despite the key role that high-tech clusters play in forming the innovation systems, there is little quantitative evidence on where they locate and how they cluster in certain built environments. Furthermore, there has yet to be micro-scale quantitative research to identify the location of high-tech industry clusters or in the other words high-tech zones (Muro & Liu, 2017). Existing research mostly focuses on the neighboring counties or regions with the strong high tech economy using the measures of sectoral concentration (Feser, Sweeney, & Renski, 2005; Koo, 2005; M. Porter, 2004). Additionally, these studies have been inconsistent in their definition of high-tech industries and yet to control for the Research & Development (R&D) intensity of the output and input (Feser et al., 2005).

This study seeks to address these shortcomings by defining the geography of high-tech zones at the most disaggregated scale for 52 largest metropolitan areas in the U.S in two steps. First, we identify the U.S. geography of high tech zones as the local spatial peaks of high tech economic activity by employing tessellation grid, Principal Component Analysis (PCA), spatial statistics techniques, and the micro-level firm dataset from the ESRI Business Analyst Dataset (EBAD). Second, we develop a sectoral typology for these high tech zones using Herfindahl-Hirschman Index, Location Quotients and cluster analysis.

The findings from this study provides better understanding of the high-tech landscape of the U.S. large regions. Our findings show that these regions are widely diverse in terms of the number and the spatial distribution of their high tech zones. For instance, Los Angeles metro area, has the highest number of zones while in New York, San Francisco, and San Jose metro areas, the high tech economy is concentrated in fewer, but stronger, zones.

Furthermore, we found that the high tech economy in the U.S. highly depends on professional services (i.e. the firms primarily designed to support other businesses such as consulting, legal services, facilities support services, computer services, engineering and architectural services, and placement services) and most of the high-tech zones have diverse firms from multiple specializations. However, the large manufacturing high tech industries like aerospace have fewer zones mostly in the regions where the aerospace industry has had a strong presence such as Dallas-Fort Worth metro area in Texas. Lastly, our findings show that the major regional airports are anchoring the high-tech zones with diverse specializations. Such results call for more research on the role of major airports within large metropolitan areas in supporting multiple high tech employment hubs.

During the transforming period of economic growth mode, the Chinese government has placed particular emphasis on innovation and entrepreneurship. With the dual promotion of the government policy and market guidance, Maker Space, as an important part of the sharing economy has developed rapidly but disorderly. Maker Space is a new type of incubator to foster youth entrepreneurship. Different from the spontaneous Hackspace and TechShop in America and Europe, the developing Maker Spaces in China are dominated by government in location selection and operation pattern in many cases. In the context, it is worthwhile to figure out the spatial distribution law of these Maker Space and its relationship with their operating entities.

The research takes the 31 official Maker Spaces in Chengdu as the research objects. Through the literature analysis, interview survey and Analytic Hierarchy Process(AHP), Maker Spaces are sorted by the social performance. According to their leading industry, research objects are divided into four types: Art Creation, Software Development, E-commerce and High-tech Manufacturing. The top 4 Maker Spaces in each category (16 in total), operated by the government and private operator for half, are selected as samples for the following research. The research of spatial distribution law is conducted by figuring out whether the 16 samples are located within the service area of the five essential location impact factors: Historical Cultural Site (tourist attraction, cultural heritage), Elite Resource (university, scientific research institute), Infrastructure (business center, utility facility), Production Service (industry park, high-tech park) and Transportation (road and railway). The service radius is determined by the regional service level of each factor.

The spatial distribution law shows that:

(1) Software Development gives priority to Production Service and Rail Transportation conditions, followed by Infrastructure, Historical Cultural Site and Elite Resource; E-commerce gives priority to Infrastructure and Transportation conditions, followed by Production Service, Historical Cultural Site and Elite Resource; High-tech Manufacturing gives priority to Elite Resource and Road Transportation conditions, followed by Production Service and Infrastructure, then Historical Cultural Site; Art Creation gives priority to Historical Cultural Site and Transportation conditions, followed by Infrastructure and Elite Resource, regardless of Production Service.

(2) There are four special cases in Chengdu's 31 creative spaces that do not conform to the law. It could be explained from the perspectives of operating entities. On the one hand, the Maker Space operated by the government plays an important role in the promotion of regional development, sometimes ignoring its own necessary factors. On the other hand, some unwise private operators make location decision without considering its leading industry.

Based on the above law, the paper puts forward some location suggestions. For the government, it should operate Maker Space with more consideration of the position selection law, and also cautiously plan the special Maker Space for the long-term interests. Meanwhile, the government is responsible for the improvement of each factor in the city, thus creating a better innovative entrepreneurial environment. For private operators, it matters to combine their leading industry with location. Furthermore, these individual Maker Spaces can make new attempt on transforming their profit mode with multiple industries.

TRACK 4 – ENVIRONMENTAL PLANNING & RESOURCE MANAGEMENT

TRACK 4 - PRE-ORGANIZED SESSION SUMMARY & ABSTRACTS FOR THE SESSION

PRE-ORGANIZED SESSION - NEW STATE-SOCIETY PACTS FOR TRANSFORMATIVE URBAN CLIMATE FUTURES 1: WHAT ROLE FOR "COMMUNITY" IN URBAN CLIMATE ADAPTATION?

ID: 11

Pre-Organized Session Summary

Includes abstracts: 182, 184, 185

Organized movements and legislators are increasingly rallying around progressive social and environmental agendas, epitomized by the Green New Deal. This movement rejects two central tenets of urban planning theory and practice since the 1970s: acquiescence to neoliberal governance and adherence to communicative planning. More important than the GND itself is the fact that lawmakers and social movements are calling for national government action focused on environmental and social change. In renegotiating fundamental relationships between society and state under climate change, this emerging movement forces us to evaluate whether our known and accepted planning theories and methods are adequate for envisioning and moving towards possible and necessary urban futures. The panel's papers advocate for, interrogate, and challenge community planning processes in advancing transformative urban climate responses. Cases include local adaptation in Massachusetts, state-wide planning in Texas, fiscal stress from sea level rise, and a USDA forest stewardship program. A second panel in this sequence further probes emerging state-society relations.

Objectives:

- Identify examples of how community engagement can strengthen local adaptation to climate change
- Understanding the limits of community based adaptation given conflicting community, municipal, and state interests

RISING SEAS AND FISCAL DECLINE – THE ROLE OF STATE POLICIES IN SHAPING LOCAL VULNERABILITY AND ADAPTATION TO SEA LEVEL RISE

Abstract ID: 182

Group Submission: New State-Society Pacts for Transformative Urban Climate Futures 1: What Role for "Community" in Urban Climate Adaptation?

SHI, Linda [Cornell University] lindashi@cornell.edu, presenting author

ALDAG, Austin [Cornell University] ama296@cornell.edu, co-author

Coastal adaptation entails a paradox, well understood by electeds but less recognized by advocates of retreat or sensitive coastal development (Hino, Field, & Mach, 2017; Miao, Hou, & Abrigo, 2018). Common sense land use planning dictates municipalities avoid developing in low-lying areas or retreat out of harm's way (Burby, 1998). Yet, local reliance on property taxes precludes limiting development, particularly for small, built out, or otherwise geographically constrained coastal communities. Furthermore, financing adaptation through tax increment financing, resilience bonds and fees, and increasing property taxes require continued development in vulnerable places. Like a Ponzi scheme, the United States' land-based fiscal policy framework and fragmented local jurisdictional structure (as in many countries) dictate that cities need to sustain – even expand – coastal development to fund current needs and future adaptation. Operational in the short-run under low levels of sea level rise, this approach becomes increasingly fraught with long-term, accelerating rates of rise. Although this dynamic is clearest where climate change directly affects property values, the conflict between fiscal imperatives for development and need to move people from climate-exposed geographies is similarly relevant for hazards like wildfires, drought, and heat waves.

Few studies, however, have examined how climate change will affect fiscal health and local policy responses to climate-driven fiscal gaps (Shi & Varuzzo, under review). This paper presents research on the extent to which municipal property tax rolls are impacted by sea level rise, in 1- to 6-foot increments, for 14 East Coast U.S. states. Our analysis is based on a newly compiled database of property tax rolls, sea level rise, and 2012 census of government finance data. The data allow us to provide a first glimpse of fiscal vulnerability across states and over time, an assessment of the land use, built environment, and socio-economic conditions in the most fiscally impacted communities, and an exploration of the spatial distribution and disparities across state coastlines. For states with the most fiscally impacted municipalities, we examine how current state policies shape municipal capacity to respond to fiscal gaps brought on by climate change. We do so by first considering state restrictions on local government revenue generation and responsibilities for service provision, and then by qualitatively evaluating how municipalities in these states have responded to recent economic and fiscal stress.

With this analysis, we hope to open a dialogue on the interplay between fiscal policy, land use planning, and state-versus-local control over land use. While the paper could be presented in a land use planning session, its contribution to a panel on state-society relations and planning theory is to ask whether and how community-based engagement connects to their local governments' fiscal realities. Residents typically advocate for more resources from higher levels of government, reject significant tax increases, and object to major land use changes locally. While community-based adaptation can better tailor or more equitably distribute resources, community engagement does not necessarily change local fiscal envelopes or intervene in what will undoubtedly become stronger pressures from state governments to manage climate-driven fiscal stress. We ask how community engagement processes – and at what scale, with what coalitions – can enable the kinds of difficult conversations to address land use and fiscal policies. Attention towards fiscal policy, land use planning, and governance reforms with respect to climate adaptation has the potential to help cities make the “right” choices and redress long-standing drivers of vulnerability more broadly.

CLIMATE FUTURES AND PLANET TEXAS 2050: NEW KNOWLEDGE AND COMMUNITY-LED STRATEGIES FOR RESILIENCE IN TEXAS

Abstract ID: 183

Group Submission: New State-Society Pacts for Transformative Urban Climate Futures 1: What Role for "Community" in Urban Climate Adaptation?

LIEBERKNECHT, Katherine [University of Texas Austin] klieberknecht@utexas.edu, presenting author

Like many places around the world, Texas has entered uncharted territory as changes in climate, population, and urbanization unfold. New climate futures have already arrived, accompanied by increased wildfires, extreme heat events, floods, and hurricanes; examples range from Hurricane Harvey dumping up to 60 inches of rain, killing 103 people, and causing over \$125 billion in damages, to the City of Austin losing municipal water service for a week because of unprecedented flooding (Blake and Zelinsky, 2018; Lieberknecht, 2018a; Wuebbles et al. 2017). At the same time, over the next several decades, Texas's population could grow from 28 million to almost 50 million; 95 percent of the population growth is projected to occur in metropolitan areas (White et al. 2017).

Although some Texas municipalities have been proactive about climate planning, with representation in the Rockefeller Foundation 100 Resilient Cities (Dallas, Houston) and the Bloomberg American Cities Climate Challenge (Austin), the state remains vulnerable to climate change. In response, an interdisciplinary group of researchers at The University of Texas at Austin (UT Austin) has launched Planet Texas 2050 (PT2050), a decade-long grand challenge, or “moonshot,” research program focused on developing the knowledge and strategies needed to plan for resilience in the face of climate and population change (Lieberknecht, 2018b).

Planning theory and practice is embedded within the PT2050 initiative: planning scholars are members of their advisory council, a planner serves as chair of the faculty leadership team, a planning-focused research project is among the inaugural research projects, and planning theory informs their logic model and theory of change. Because of this planning lens, the program prioritized early integration of local knowledge, including surveying over 1,000 Texans to develop a baseline understanding of beliefs and knowledge about climate and community change, as well as preferences for desired futures. This article explores these survey findings to answer two interconnected research questions: what are Texans' views of resilience, and how can this local knowledge inform a long-term, statewide, big data driven research program focused on building knowledge about and developing strategies for resilience in the state?

In the fall of 2018, PT2050 undertook an online survey of 1,053 Texas residents representing each Metropolitan Statistical Area of the state as well as a grouping of rural areas. The survey asked respondents to report on beliefs about resilience and planning related issues, as well as potential behavior changes. Initial findings include strong support for water conservation policies, for policies to reduce air and water pollution, for policies to better prepare communities for extreme weather events, and for flood-resilient land use planning. In addition, respondents overwhelmingly agreed that the natural environment was important to them, that climate change will negatively impact their future interactions with the natural environment, that extreme weather events had become more frequent, and that climate change is due to human activity. However, despite these beliefs, direct climate change/extreme weather events did not make it into the top three greatest concerns respondents identified about the future (which were housing affordability, air pollution, and human health/healthcare). This article seeks to match these survey findings to PT2050's planning for the next five years of their "moonshot" research program, seeking to inform their approach to prioritizing new knowledge and designing a community-led approach to resilience strategy development.

Although focused on one state, findings will be relevant to planning practice in other areas experiencing an increase in extreme weather events, increasing urbanization, and rapid population growth; Texas's diversity, rate of population growth, and vulnerability to climate change make it a useful test case to examine approaches for planning new climate futures.

Cities face unique social and ecological challenges compounded by climate change, including recovery after extreme weather events, access to fresh food and clean water, and sustainable energy generation. Not unlike local governments, civic stewardship groups sustain and enhance socio-ecological systems. We define “stewards” as people who “conserve, manage, monitor, and advocate for the local environment” (Svendsen et al., 2016). Data from the USDA Forest Service’s 2017 Stewardship Mapping and Assessment Project (STEW-MAP) illustrates the role that community-based civic stewardship groups play in urban systems transformation, including advocating for and initiating responses to climate change. This paper will use planning theory, more than ten years of aggregated data from STEW-MAP New York City, and case studies to demonstrate the connections between grassroots stewardship and local planning and the potential for additional collaboration.

In the face of climate change, planners have taken new approaches to traditional practice by working collectively with diverse groups of civic actors (Rauws, 2016; Shandas & Messer, 2008; (Rauws, 2016; Shandas & Messer, 2008; Sirianni, 2007). The STEW-MAP project builds on this work by supporting civic engagement and coalition-building among these groups (Landau et al., 2019). Cloutier, Papin, & Bizier (2018) argue that “civil society stakeholders create a momentum that drives the city’s adaptation to climate change” (285). As local civic stewardship groups engage in acts of caretaking and claims-making on the environment (Andersson et al., 2014), planners have an opportunity to engage with these groups in collaborative processes. Cloutier et al. and other scholars support similar claims citing Lefebvre’s (1968) idea of “right to the city”, acknowledging that cities are created, improved, and transformed by their citizens.

The STEW-MAP project originated in 2007 to answer the question: Who takes care of New York City? The project has since been implemented in many other cities to understand and strengthen civic capacity (Svendsen et al., 2016). STEW-MAP 2017 survey data includes more than 800 stewardship groups that work throughout New York City and the surrounding region. Grassroots groups have collectively worked with hundreds of thousands of volunteers, and while tackling various challenges with a wide range of budgets and levels of professionalization “share the same belief that the environment can be a catalyst for social change” (Landau et al., 2019). The shared efforts of stewardship combat a broad scope of urban climate impacts, as responses show that groups tackle issues from ecosystem degradation to human health and social policy.

Relationships between planners and civic stewards should be empowering to both groups: as planners influence decision-making processes and control financial resources, they can provide support, funding, and expertise while enabling civic stewardship groups to take lead roles in community-level change. This requires acknowledging where power assembles in urban politics, just as Foglesong (1986) positions the planner between capitalism and democracy and Forester (1989) claims that planners can empower community action once they recognize this position of power.

STEW-MAP responses indicate that stewardship groups have an enormous capacity for knowledge production about the environments they work within. Their experiences can be a resource for planners with goals of transformative climate futures: they will be better equipped to pinpoint gaps and intersections in existing environmental management efforts. In turn, planners may better acknowledge the

power, agency, and claims of civic stewards. Information sharing should also benefit civic stewards in the spirit of “data democratization”, as Frantzeskaki & Kabisch (2015) argue that “professional planners and policy makers know how to turn data into information, information into knowledge, and knowledge into policy” (513). Planners and civic stewardship groups are well positioned to combat climate change together by identifying existing stewardship efforts, bolstering civic engagement, and sharing knowledge.

STRENGTHENING PLANNING FOR RESILIENCE IN BOSTON THROUGH LOCAL KNOWLEDGE

Abstract ID: 185

Group Submission: New State-Society Pacts for Transformative Urban Climate Futures 1: What Role for "Community" in Urban Climate Adaptation?

RACITI, Antonio [University of Massachusetts Boston] antonio.raciti@umb.edu, presenting author
REARDON, Kenneth [University of Massachusetts, Boston] kenneth.reardon@umb.edu, co-author

The City of Boston has received widespread praise for its efforts to analyze the risks residents, businesses, and institutions face related to climate change-related natural disasters. During the past decade, The City has mobilized a large network of university-based researchers and private consultants to evaluate the threats that climate-related natural events pose to local populations and organizations with funds provided by various philanthropic and public entities. These funds supported the production of the City’s Climate Ready Boston Report which is a comprehensive assessment of the natural disasters expected to impact Boston during the next thirty, fifty, and seventy years assuming the continuation of current economic, land use, and transportation patterns (Spector and Bamberger 2013). Using data from this report, the City engaged a cross-section of public officials, business leaders and civic leaders in a planning process designed to achieve a 20 percent reduction in greenhouse gases by 2020 and a 50 percent reduction in greenhouse gases by 2050. This process has been complemented by a more recent effort that extends beyond prediction of natural disasters by taking into account local communities’ capacity to cope with

climate change (Boston 2017). However, these documents did not fully address who is benefitting and who is paying the price of the City's current resiliency planning efforts (Vale 2014).

Based upon extensive archival research and interviews, the authors argue that, similarly to New Orleans before Hurricane Katrina, Boston has developed significant capacity to analyze future threats posed by climate change based upon sophisticated modeling of economic, population, land use and climatic change patterns by climate scientists, civic engineers, architects and urban planners. However, like New Orleans prior to Hurricane Katrina, it has developed limited capacity to mobilize its local residents and institutional leaders to undertake essential disaster preparedness, management, and recovery activities in the event the "unexpected" occurs. This lack of capacity is due, in large part, to the City's failure to involve residents and leaders from its many environmental justice communities who are most likely to experience the most serious negative impacts of climate change related disasters in their planning.

This paper argues for the creation of new forms of "third spaces" (Oldenburg 1989) – such as local associations, neighborhood organizations, and faith-based institutions – enabling future researchers to tap the "local knowledge" poor and working class residents and leaders possess of existing environmental conditions, likely climate change related threats, and taken for granted community resources, facilities, and competencies that can be activated to help residents respond to life threatening natural disasters. These places rather than local, state, and federal agencies and mega relief organizations are most frequently identified as the "first responders" (Olshansky 2006). From this perspective the paper suggests how academic research can support and expand the capacity of these spaces to cope with the "unexpected".

NEW STATE-SOCIETY PACTS FOR TRANSFORMATIVE URBAN CLIMATE FUTURES 2: BEYOND THE "LOCAL"

ID: 21

Pre-Organized Session Summary

Includes abstracts: 281, 282, 283, 388

Organized movements and legislators are increasingly rallying around progressive social and environmental agendas, epitomized by the proposal for a Green New Deal. This movement rejects two central tenets of urban planning theory and practice since the 1970s: acquiescence to neoliberal governance and adherence to communicative planning. More important than the GND itself is the fact that lawmakers and social movements are calling for national government action focused on

environmental and social change. In renegotiating fundamental relationships between society and state under climate change, this emerging movement forces us to evaluate whether our known and accepted planning theories and methods are adequate to the task of envisioning and moving towards possible and necessary urban futures. These papers call for new scales of engagement and conceptualize alternative publics towards transformative urban climate futures. They explore urban resilience and climate imaginaries in New York, London, and Los Angeles, and more concrete political interventions for planning. A second panel in this sequence further probes emerging state-society relations.

Objectives:

- The audience will learn about the challenges and opportunities for planning for climate change motivated by changing state-society relationships implied by a program like the Green New Deal.

THINKING THE UNTHINKABLE: A GREEN NEW DEAL AND JUST URBAN FUTURES

Abstract ID: 281

Group Submission: New State-Society Pacts for Transformative Urban Climate Futures 2: Beyond the “Local”

GOH, Kian [University of California Los Angeles] kiangoh@ucla.edu, presenting author

The urgency of climate change and the rise of a grassroots political-environmental movement in the US should change the way we think about and plan our cities. In 2019, Congress announced the Green New Deal (GND), a resolution to drive renewable energy investments and low-carbon economy job growth as well as protect against the impacts of climate change. The GND is distinctly political. Propelled by legislators such as Alexandria Ocasio-Cortez and progressive organizing groups such as the Sunrise Movement, it responds to climate threats and demands social change. The original FDR-era New Deal reorganized society and space in the US. It led to large-scale energy and water infrastructure, new typologies of public housing, and innovative public art. But it had uneven outcomes, its benefits eluding many communities, its impacts even harming them. The potential of a Green New Deal to remake cities in sustainable and equitable ways needs examination and specificity.

The urban implications of the GND include plans to reduce or eliminate GHG emissions in urban and infrastructural development, and to protect areas threatened by climate change impacts such as sea level rise, storms, heat, and wildfires – to make them resilient and adaptive. It would do this at the scope and scale necessary to help keep within 1.5°C of global warming and avoid catastrophic impacts (IPCC 2018), in ways that uplift and empower vulnerable communities. Urban planning research has not effectively addressed the intertwined considerations raised by this proposition: existential environmental crises, large-scale federal mobilization, and an explicitly progressive political imperative. How does a large-scale, government-led mobilization to address climate change, such as the Green New Deal, envision and implement transformative urban change while ensuring social and economic justice for marginalized urban residents?

This question challenges conventional research approaches because it spans modes of knowledge and worldviews. Climate change dissociates global scientific knowledge from local lived experience (Jasanoff 2010). It requires thinking the unthinkable, juxtaposing planning for yet imagined futures against empirical research of the past and present (cf. Quay 2010). Climate exigencies demand fast, large-scale action. But planning research attuned to the injustices borne by marginalized communities has supported participation in decision-making and smaller-scale, community-led, incremental change. These appear incompatible. I propose that just urban environmental futures can be envisioned through a coproductive analytical engagement between scientific knowledge and ideas about revolutionary social change. Here, I

delineate a theoretical and methodological approach to triangulate among: utopian urban visions, technocratic urban infrastructural and climate science, and grassroots movements for social justice.

This paper proceeds in two parts. The first is a theoretical synthesis of utopian urban plans. Speculative visions of the future are not often based on recognizable theoretical frameworks. I provide such a framework, analyzing utopian plans in relation to extant theories in urban planning, geography, and political ecology. The second is a methodological approach to problems of large-scale change and social justice. In a previous paper on the politics of flooding in Jakarta (Goh 2019), I used methods of mapping and observing places derived from landscape architecture and environmental ethnography to explain how different worldviews of urban ecologies define ways of thinking and acting on environmental problems in cities. For this paper, I elaborate on how such a reflexive, cross-knowledge-mode methodology is critical to understanding and expanding the bounds of possibilities of the GND and just urban futures, to situate positivist, often-quantitative urban climate resilience science in relation to theories of change in grassroots social movements. I illustrate how such a theory and method can reframe urban climate change research using case examples from my previous fieldwork in Northeast US, Southeast Asia, and Western Europe.

CONCEPTUALIZING EMERGING PLANNING PRACTICES AND THE CLIMATE IMAGINARIES OF CITIES: THE CASES OF NEW YORK CITY AND LONDON

Abstract ID: 282

Group Submission: New State-Society Pacts for Transformative Urban Climate Futures 2: Beyond the "Local"

JABAREEN, Yosef [Technion University] jabareen@technion.ac.il, presenting author

The rise of the mounting levels of evolving risk and vulnerability stemming from climate change is challenging the nexus between already existing planning theories and the new emerging countering climate change practices. Furthermore, the planning profession has been responding to climate change

issues through spatial practices and policies. However, planning theories have been failing to propose new planning theories, which address climate change, and which situated within the spatial context. This paper argues that the emerging risk stemming from climate change and its uncertainties present new challenges to the existing concepts, procedures, and approaches to the planning and design of cities. Strikingly, there is a lack of theorization in the planning field that helps characterize, and conceptualize the emerging risk-oriented practices, and which orchestrated the efforts of countering climate change through its spatial power as a discipline. What kind of future visions and imaginary these existing planning practices provide for our cities and societies, and what are the planning theories that existing climate-change practices apply in cities today?

Thus, this paper aims to build a conceptual framework for understanding the risk-oriented practices in the planning field. In other words, this paper seeks to produce a practice-induced theory. Empirically, this paper takes advantages of recent ambitious climate-change oriented planning efforts in two major cities, New York City and London. The empirical work analysis planning practices of major recent plans and policies in these cities.

Based on the empirical work, this paper proposes a new conceptual framework for comprehending climate-change-oriented planning practices, which is a construct of two interrelated logics: (1) The logic of risk, which directs and shapes public opinion regarding the principal risk(s) that a city faces. (2) The imaginary logic, which captures the motives behind the desire to change the current insecure conditions and having a better peaceful and resilient future for the city and its residents. These logics induce social and spatial practices aiming at coping with anticipated threats and risk. This paper concludes that planning practices are not mere objects, but responsive, logical, functional, and imaginary. The risk-oriented practices are responsive to the urban-targeted risk and have an imaginary function for reducing risk and filling security gaps aiming at achieving a more resilient and sustainable city.

MOVING FROM RANDOM ACTS OF GREENNESS TO A CLIMATE JUST CITIES AGENDA.

Abstract ID: 283

Group Submission: New State-Society Pacts for Transformative Urban Climate Futures 2: Beyond the "Local"

FITZGERALD, Joan [Northeastern University] jo.fitzgerald@neu.edu, presenting author

The recent IPCC report reveals that the planet is close to a point of no return. In view of this alarming mandate, we must support the most aggressive climate actions possible. Yet most cities pride themselves on simply plucking the low-hanging fruit—the easy, inexpensive fixes that require little systemic change.

The list is long: bike-rental systems, solar waste containers, weak green building requirements, and some recycling efforts. Going after the low-hanging fruit yields benefits, but unless such measures are part of a larger, coherent strategy for altering broad patterns of energy consumption and transportation emissions, these efforts are simply random acts of greenness.

But climate action cannot be undertaken in isolation from the interconnected issues of poverty, racial division, and gentrification ongoing in many cities. While many mayors say they are committed to reducing poverty and income inequality and to climate action, few city leaders are connecting the two issues (Demissie 2006, Saha and Paterson 2008, Fitzgerald, 2010; Bulkeley and Broto, 2013, Portney, 2013). An analysis of climate and sustainability plans of 28 U.S. cities found that equity was a relatively low priority (Schrock, Bassett and Green, 2015). An international survey of more than 100 cities implementing at least 600 climate change experiments found that only about one-fourth included environmental justice concerns (Broto and Bulkeley 2013). When social justice concerns are mentioned, they are more often isolated references rather than being integrated into climate action. (Waud, 2017).

The recent proposals for a “green new deal” could offer national support in four key areas in which climate action and social equity can be connected: building energy efficiency; transportation infrastructure; renewable energy adoption; and investment in resilient infrastructure to protect against sea-level rise and to better manage stormwater. Some cities are already implementing initiatives that link these climate actions to well-paying jobs and green revitalization of disinvested neighborhoods. Los Angeles has linked greening the port, which has improved pollution levels in surrounding neighborhoods, to investment in electric vehicles and linked purchasing of electric buses to well-paying union jobs in bus production Philadelphia has linked building energy efficiency to creating well-paying jobs for low-income residents (Fitzgerald, forthcoming). Boston has mapped where microgrids are needed to prevent grid outages during storms, emphasizing low-income neighborhoods.

The question is whether these will become a set of best practices academic planners write about over the next decade or whether the practitioner and academic planning community can unite around a Climate Just Cities Agenda. Several progressive mayors are already part of the conversation about what form a “green new deal” takes—a conversation that will be occurring during the presidential election cycle. It is ultimately a political agenda. This paper offers ideas for planners to step into the political fray and offer a concrete agenda for how a green new deal plays out in the nation’s cities.

SOWING ‘EMERGENT STRATEGY’ IN PLANNING EDUCATION: EXPERIMENTAL PEDAGOGIES FOR BEING DIFFERENTLY IN A CLIMATE-CHANGED WORLD

Abstract ID: 388

Group Submission: New State-Society Pacts for Transformative Urban Climate Futures 2: Beyond the “Local”

POLLANS, Lily [Hunter College, City University of New York] lily.pollans@hunter.cuny.edu, presenting author

Planning education trains students to “do” planning. Guidelines for program accreditation focus on practical knowledge in relevant subject areas like plan-making, research, and participation (PAB, 2017). To operationalize these learning outcomes, planning programs emphasize skill development through experiential learning and training in marketable hard skills.

This educational approach yields professionals able to execute key tasks in an admirable variety of settings. But it does not necessarily equip future planners to manage the urgent realities of climate change in a context of extreme inequality, depleted state capacities, and political division (Frick, 2018; Jabareen, 2015). If planners are committed to confronting our socio-ecological reality, we need to challenge the political and social institutions that have produced our current world; doing so may mean reaching beyond our standard tools.

Radical social movements offer some guidance. One particularly relevant concept is adrienne maree brown’s Emergent Strategy. Brown, a community organizer mentored by Grace Lee Boggs (among many others), argues that transformation at the smallest scales seeds radical change. This is not a recapitulation of “think global, act local.” Rather, drawing on a range of epistemological traditions from natural science, to civil rights, to religion, brown argues that being differently in our lives and work is the necessary first step to producing new systems.

Building on brown’s theory, I ask how planning education can propagate a shift from a task-oriented enterprise of doing to an embodied practice of being? One way to understand this shift is to recognize planners as people who act in the world in a variety of capacities, rather than one-dimensional professionals with interchangeable skill sets. To support this view, I developed two pedagogical experiments that ask planning students to actively and intentionally insert their value systems and everyday lives into their planning practice.

The first experiment, in a masters-level environmental justice class, targets how we ask questions, conduct research, and develop recommendations for action. Students were asked to articulate their personal political agenda for their research—what I called “the ‘project’ of the project.” This slight shift in methodological practice violates traditions of rationality and positivism in planning research. Because they have been trained towards “objectivity,” students were uncomfortable owning and articulating their points of view as part of a research project. But the process promises to yield a deep, rigorous, and radical set of research outcomes that challenge everything from bureaucratized decision-making within New York City public agencies to the practice of leasing public land in the American West.

The second experiment, still in the planning stages, pushes harder at the boundaries of planning. It will take place in a masters-level urban sustainability course, and puts the radical economic theories of plenitude (Schor, 2010) and degrowth (D’Alisa, Demaria, & Kallis, 2015)—which advocate for replacing some commodified productivity with more meaningful self-provisioning—in conversation with emergent strategy. Students will identify a good or service that they normally pay for, and to try to replace that good or service through other means. This might mean learning a new skill, bartering or trading, joining a

cooperative, or asking for a favor. The purpose of the project is to experience the impacts of radically shifting consumption practice. Building on this exercise, students will then be asked to examine, analyze, and reconstruct some more conventional approaches to urban resilience and sustainability planning.

This paper will describe the process and outcomes of the first experiment and present a detailed plan for the second. It will then offer reflections on the opportunities these experiments offer in terms of the practices of teaching and learning how to be a planner.

In the last decade, research universities have created interdisciplinary, institutionally-supported, and long-term research initiatives to address large, complex problems that remain unresolved through discipline-based research approaches. Several institutions are pursuing such research through Grand Challenges (GCs), projects bringing together researchers from across their respective university units and disciplines (Popowitz & Dorgelo 2018). Sustainability and resilience are a common theme among GCs. The University of Texas at Austin launched Planet Texas 2050, a GC focused on discovering the knowledge and developing the strategies needed to ensure a resilient Texas by 2050; The Sustainability Institute at Ohio State University integrates faculty across university departments to pursue a coordinate and inclusive approach to sustainability scholarship and teaching through interdisciplinary collaboration, campus stewardship and the development of applied solutions; McGill Sustainability Systems Initiative brings together experts from across McGill's faculties to build a robust and vibrant community of committed sustainability researchers. Given the broad skillset and collaborative nature of the field, few disciplines

are as well equipped to participate in such projects as are planners. Moreover, planners must, given the strategic opportunities to address environmental sustainability at the city-scale (Sassen 2010) and the acute need to make urban systems more resilient (Meerow et al 2016), be part of the solution. This panel brings together planning researchers from several sustainability or resilience focused GCs to answer the question, “What role has planning played in large, interdisciplinary projects and how can planners become leaders, not just participants?”. After brief introduction to each project, discussion will focus on the successes and obstacles faced by each group with an emphasis on the role planning has played in the GC.

TEWARI, Meenu [University of North Carolina at Chapel Hill] mtewari@email.unc.edu

Access to water supply and sanitation, recurring flood events, increasing water scarcity, and aging, absent, or inadequate water, sanitation, and wastewater infrastructure are just some of the water related challenges we are faced with today. Planning for water and wastewater systems are inherently interdisciplinary endeavors, ones in which planners have played a surprisingly peripheral role over the past two to three decades. Yet, planning for healthy, inclusive cities warrants a closer look at how planning intersects with water equity (broadly defined as ensuring universal access to adequate and safe water and sanitation services, and participation in its management). Planning has important contributions to make to global discourses on water and sanitation that both extend and enhance the engineering, public health, and economic perspectives that dominate the sector today. Participants will explore how planning research can contribute to a deeper understanding of the different dimensions of water and wastewater systems that foreground water equity. How does the concept of an integrated approach such as One Water shape our understanding of this resource and its distribution? How can such an approach promote water equity? How can a shared vocabulary between planners and water professionals be developed to facilitate collaboration that transcends sectors and scales? How can insights from planning advance local and global dialogue about informality and access to water and sanitation services? Are there alternative approaches to conventional water and wastewater systems that creatively integrate the natural and social dimensions for water equity?

WILLIAMS, Darien [MIT] darienaw@mit.edu

BUTLER, William [Florida State University] wbutler@fsu.edu

Hurricane Michael landed on the coast of Florida with winds of 155 mph and proceeded to rip through small coastal communities and a mostly rural area of Florida and southern Georgia. The Florida Department of Agriculture and Consumer Services estimates that agricultural crop damage alone accounted for \$1.5 Billion, most of this due to timber loss. In an industry that takes 20-25 years of investment to show a profit, this means that job loss and economic impact will continue for another 10-15 years. The economic impacts are huge, and yet, there are other impacts that will also be seen, as yet unaccounted for in the future. The timber loss has many considering alternative arrangements. Hemp and hop have been discussed in the media as resilient alternatives. The ecosystem effects of these decisions will be seen in the karst system hydrology, the endangered Apalachicola River, and in the biodiversity that exists within the timber forests, such as gopher tortoise habitats. The excess tree debris also increases wildfire risk and may clog or pollute the waterways, and on private lands, the farmers often do not have the resources to remove the debris.

Despite the extreme environmental risks, the highest concern for the area is economic. People without homes must make basic survival choices first. The financially constrained governments, whose meager

tax rolls will be further reduced by condemned properties, can do little to help on their own. Their hazard planning has been constrained by lack of funding and holds few mitigation projects ready to be implemented to deal with these hazards. The regional planning council has been hampered in recent years by lack of funding. In a rural area, likely to see a reduction of population following this disaster, the need for hazard and recovery planning is increasing.

Resilience is said to be a process, rather than a goal, but it is said to begin with the people of the community (Lerch, 2017). When that community is severely crippled, is the meaning of resilience to recover and maintain its identity the same (Appler & Rumbach, 2016; Holling & Gunderson, 2002)? Low density, low capacity of local government planning, and lack of economic resources will have immense repercussions for the capacities that help confer resilience: place attachment, leadership, community cohesion, community networks, and knowledge and learning (Faulkner, Brown, & Quinn, 2018).

This panel will explore the impacts from Hurricane Michael and recent extreme storms across the country to explore questions related to special considerations of disaster recovery planning in lower resource contexts in the US. How can planners shape recovery pathways that promote resilience and equity in the Panhandle? What are the cost implications of reconstruction for overburdened and impacted local governments? How are communities engaged to understand their risk?

TRACK 4 – INDIVIDUAL ABSTRACTS

STEERING URBAN WATER MANAGEMENT IN STRAINED ENVIRONMENTS CASE OF THE YAMUNA RIVER IN NEW DELHI, INDIA

Abstract ID: 7

Individual Paper Submission

VUPPULURI, Richa [University of Virginia] richa.vup@gmail.com, presenting author

Polluted urban rivers in rapidly growing cities of the developing regions are a barometer of the fundamental breakdown of prevailing urban and environmental planning systems. In India, the city of

New Delhi is the most significant polluter of the ailing Yamuna River – 2% of the river traverses through the city accruing 70% of the total pollution load through a network of 22 urban drains discharging into the Yamuna River. Over the past 26 years, multiple plans and investments to restore the river have consistently failed, revealing an evident implementation gap in the infrastructure vision and outcome. In the case of New Delhi, local governance systems are responsible for infrastructure delivery, yet the political processes for creating such infrastructure are often unidirectional. Decentralized efforts to mediate the urban-planning process and cultivate collective agency thus often fizzle. Informing the fundamental premise of this research that urban visions to revive the river consistently fail because there is a lack of integrated effort towards transforming socio-cultural and professional behaviors that strain the urban ecosystem. The study asks two, related questions: (1) can behavior shifts in decision-making processes at the local level bridge the implementation gap between visions and outcomes for urban infrastructures? (2) What interventions drive collective action at the individual, community, and stakeholder levels?

The study intends to integrate a socio-environmental approach with urban infrastructure planning, focusing on the issue of urban water management in rapidly developing cities. Situated within the framework of Pro-environmental Behavior (PEB) approach in the context of New Delhi and the Yamuna River pollution, this research is a scoping analysis of Behavior Change Techniques (BCTs) and interventions (Michie et al., 2011). Gifford and Nilsson (2014) outline eighteen personal and social factors that influence pro-environmental behavior or lack of concern, helping identify responsible factors in the study context. A scoping analysis outlines interventions and policies, at the level of individuals/household and groups/stakeholder level, recommending potential change agents like governance bodies, local institutions, NGOs and subsequently proposing an assessment of techniques deployed as well as overlooked. Data sources for this assessment is a preliminary field study (October 2018), and secondary sources like Yamuna Action Plans (YAP) launched in 1993 (currently in phase III), 2021 Master Plan of Delhi, Drainage and Sewerage Master Plans for Delhi 2031. Broad categories for BCTs are classified as restructuring the physical environment; regulation; service provision; disincentive; shaping knowledge & training; reward; social support/ relations; comparisons; identity & self-belief; goals, planning, and monitoring.

The scoping analysis demonstrates a lopsided emphasis on restructuring the physical environment through centralized capital engineered solutions. This analysis identifies the potential to integrate incremental and decentralized infrastructure solutions; also, there is a dearth of efforts to build social capital that create incentives, reward positive outcomes, nurtures social agency within communities and stakeholders. While changes in the physical environment are central to resolving this urgent environmental crisis, there is a significant opportunity in interventions that transform behavior through social support, rewarding incremental efforts, reinforcing identity and self-belief to drive collective responsible behavior. A strong implication of this study is on steering planning practice in complex urban environments by underscoring socio-cultural behavior and decision-making processes within local communities. The behavioral framework is a working model for further engaging local and expert stakeholders.

AFFORDABLE HOUSING AND VULNERABILITY TO EXTREME HEAT IN CALIFORNIA

Abstract ID: 41

Individual Paper Submission

GABBE, Charles [Santa Clara University] cgabbe@scu.edu, presenting author

PIERCE, Gregory [University of California, Los Angeles] gpierce@luskin.ucla.edu, co-author

About 600 people in the U.S. die annually from heat-related illness, and California experiences 10% of these deaths on average (CDC, 2017; CEHTP, 2016). These figures rise during extreme heat waves -- up to 655 California deaths were attributable to a 2006 heat wave -- and are expected to trend upward from climate change (Hoshiko et al., 2010; Wilson and Chakraborty, 2018). Indirect mortality, morbidity, and household welfare impacts are also caused by extreme heat events. Our research answers two planning-relevant questions. First, where are households most vulnerable to extreme heat in California? Second, are residents of certain subsidized housing types more vulnerable to extreme heat than residents of unsubsidized housing?

Vulnerability to extreme heat is not experienced equally. Children, the elderly, and those with pre-existing health conditions are particularly sensitive. Reduced adaptive capacity has been associated with low incomes; living alone; lack of a car; living in a mobile home; and lack of air conditioning and/or difficulty affording utility bills. Neighborhoods with little tree canopy and large areas of pavement are hotter from the urban heat island effect.

Residents of subsidized housing may embody several of these factors, yet there has been little research on how subsidized households are affected by climate change, including extreme heat. Additionally, since we are incorporating extreme heat projections (exposure), affordable housing may serve as a durable indicator of where vulnerable populations will be located in the future. Sensitive populations may move or shift geographies, but given the dearth of affordable housing stock in California, existing stock is likely to persist spatially.

Our analysis has three components: (1) tract level analysis of affordable housing, extreme heat projections, and sensitivity and adaptive capacity; (2) statewide analysis of affordable housing in terms of air conditioning prevalence, housing quality, and energy costs; and (3) tract level analysis of affordable housing, energy utilities, and water utilities.

With the first component we connect affordable housing data with downscaled climate data from 4 climate models and for 2 climate scenarios between 2005 and 2040. We also calculate a tract-level sensitive and adaptive capacity index based on Reid et al. (2009) and Wilson & Chakraborty (2018). Our spatial analysis identifies individual tracts and clusters of tracts with vulnerable housing and projected increases in extreme heat.

The second component entails a statewide comparison of subsidized and unsubsidized units in terms of air conditioning prevalence, insulation, and energy costs, using a combination of American Housing Survey (AHS), the California Residential Appliance Saturation Study (RASS), and the national Residential Energy Consumption Survey (RECS) data.

The third component overlays utility service data on affordable housing to identify disparities in terms of publicly-regulated energy utility and water utility service reliability, failures in which can exacerbate exposure to heat. We pay particular attention to service reliability in disadvantaged unincorporated communities and mobile home parks, for which counties in California are obligated to perform special service planning.

Preliminary results suggest that some types of affordable housing are disproportionately located in tracts with the largest projected increase in 90+ degree days (2005-2040, RCP 8.5 scenario). The top quartile of these tracts includes 31.8% of LIHTC units, 24.9% of public housing units, 23.9% of housing choice voucher units, and 20.7% of other HUD-subsidized units. These tracts include 31.3% of manufactured housing units, the most affordable type of unsubsidized housing. By comparison, these tracts include 22.7% of rental units in California. Additional results are forthcoming.

MEETING WATERSHED-LEVEL STORMWATER MANAGEMENT GOALS WITH A STORMWATER TRADING SYSTEM OF PARCEL-LEVEL GREEN INFRASTRUCTURE INSTALLATION

Abstract ID: 66

Individual Paper Submission

FU, Xin [University of Cincinnati] fuxinuc@outlook.com, presenting author
WANG, Xinhao [University of Cincinnati] xinhao.wang@uc.edu, co-author

Urban development and sprawl often lead to loss of natural habitat (e.g., vegetation and soil) and replace it with impervious surfaces that disrupt the hydrologic cycle of a watershed (e.g., stormwater interception, filtration, evapotranspiration, and retention) (Dhakal and Chevalier, 2016; Dolowitz, 2015). The result is increased runoff volume and flooding risk, and decreased stormwater infiltration and stream base flow (Roy et al., 2014). Green infrastructure (GI) has been recommended and adopted widely to reduce runoff from the built environment. Reliance on public land for GI implementation causes a heavy financial burden on local government. Economic incentives and market-based mechanisms may encourage public participation in a decentralized approach to managing stormwater by installing GI on private parcels. Cap and trade markets have been gaining acceptance in a wide variety of applications, such as the market of carbon and sulfur dioxide emissions in U.S. (Tietenberg, 2006). However, stormwater trading market has not fully developed in practice. To establish a market requires, in part, an authority to plan, organize, and manage the watershed-based stormwater trading market, the linkage of trading to the goal of the watershed management, and fully informed parcel owners for tradable allowances, costs, and benefits.

To address the aforementioned elements in stormwater trading, we propose a scenario-based Stormwater Management Planning Support System for Trading Runoff Abatement Credits (SMPSS-TRAC) to facilitate the calculation and allocation of runoff abatement credits, to assist the decision-making of investment in GI, to manage and update the credit pool, and to test alternative scenarios. We apply the SMPSS-TRAC to a sub-watershed, located in Hamilton County, Ohio, USA and develop five scenarios representing increased use of GI (rain barrels, rain gardens, shared detention basin, and porous pavements). We test the scenarios under a 5-year rainfall intensity and set the cap at non-development level (e.g., all grass land). Runoff is simulated using USDA TR55---Urban Hydrology for Small Watersheds (NRCS, 1986). Tradable credits calculator is designed for runoff abatement credits calculation and allocation. Using the tradable credits calculator, users can set different cap for the watershed, including actual runoff abatement, annual cost of GI, runoff allowance balance, and trading status.

SMPSS-TRAC indicates that a watershed authority must be established to guide all parcel owners either to install suitable GI, or to purchase allowances. In addition, the watershed authority would need to build detention basins on vacant lots and share costs and detention capacity with all parcels within the same sub-catchment to meet stated goals. All four types of GI on private properties and detention basins are needed to reach the market equilibrium and achieve the watershed level runoff reduction goal.

The SWPSS-TRAC can further be applied to test more scenarios for other watershed, such as scenarios for extreme rainfall event related with climate change, future land cover change, and new types of GI. In addition, the SWPSS-TRAC is an open system that allows users to customize objectives, models, indicators, and parameters for stormwater trading decision-making needs.

The increasing occurrence of extreme weather and climate events raised concerns in regards to hazard mitigation and climate adaptation. Local municipal planning mechanisms play a fundamental role in increasing a community's capacity towards long-term resiliency. This study employs the content analysis method to evaluate the 95 selected cities located in the U.S. Federal Emergency Management Agency (FEMA) region VII and examine how these local plans, including local comprehensive plans, hazard mitigation plans, and local emergency operations plans, prepare communities for climate change and possible extreme events. Results indicate that local plans delineated multiple resources and diverse strategies to reduce community climatic risks, where hazard mitigation plans have medium level preparation, and comprehensive plans and emergency operations plans have limited level preparation. Local hazard mitigation plans lead in mitigating for impacts from potential extreme events, but both local comprehensive plans and emergency plans are proactively adapted for climatic risks. Common strengths and weaknesses exist between different planning mechanisms. Large variations exist among plans due to varying jurisdictions among cities. However, the plans score similarly overall – higher on strategies and factual base but are short of clear and detailed goals, objectives, and agendas. Finally, despite the diverse vertical and horizontal outreach, there is inadequate integration among local planning mechanisms to share climate-hazard information. These findings can serve as a valuable reference for emergency managers, planners, and policy-makers to direct or conduct research and actions in coping with extreme hazardous events. This research can improve our understanding about local planning systems from the inland states in the United States.

LOCAL LAND USE POLICIES FOR ENVIRONMENTAL JUSTICE

Abstract ID: 87

Individual Paper Submission

BAPTISTA, Ana Isabel [The New School] baptista@newschool.edu, presenting author

Historically, zoning codes and land use practices have had the effect of hardening disparities and expressing forms of structural racism evident in the built environment. These processes continue to jeopardize the health and safety of communities of color and low-income communities throughout the country, also known as environmental justice communities. Zoning and land use policies can also be harnessed affirmatively to redress these impacts. Indeed, looking to zoning and land use policies to remedy local environmental injustices is critical, as state and federal environmental laws and regulations are limited in their ability to address the siting decisions that concentrate cumulative pollution burdens. Nor do these environmental laws directly speak to the socio-demographic characteristics of communities impacted by multiple pollution sources or the development process that can drive siting decisions locally.

A variety of planning and zoning tools are available to municipalities for the purpose of addressing environmental justice, including: comprehensive planning, eliminating nonconforming uses, using environmental reviews or impact analysis, and making change through local boards and commissions. Cities can also strengthen public health and building codes, augment public review and notification processes, impose development fees, implement overlay zones or special zone designations, or simply tighten existing zoning codes to make them more protective in communities of color and low-income communities. The right balance of approaches for any given place will depend on local conditions and priorities, along with state law regarding the powers of local governments vis-à-vis land use and environmental regulation.

This study explores how environmental justice advocates advanced policies that affirmatively use land use planning and zoning tools to address environmental injustices at the local scale.

A nationwide review of existing municipal, county and local government initiatives was conducted to identify policies that explicitly address environmental justice through local land use planning, zoning, or policy tools. It also includes an in depth analysis of the community led processes that resulted in the adoption of environmental justice legislation in the cities of Newark, New Jersey and Los Angeles, California. The methodology utilized for this study includes multiple case studies (Newark and Los Angeles) using semi-structured interviews, document analysis and a qualitative summary review of online sources employing key word searches.

The national review of policies identified 40 local policies focused on addressing environmental injustices across 23 cities, three counties and two public utilities. The policies were categorized according to six typologies: (1) Bans, (2) Broad EJ policies, (3) Environmental Reviews, (4) Proactive Planning, (5) Targeted Land Use Measures, and (6) Public Health Codes. The case studies of Newark, NJ and Los Angeles, CA further detail the community led processes by which the respective policies in each city were adopted. In both communities, a clear articulation and understanding of cumulative impacts,

leadership of community based environmental justice groups, strong local planning and zoning tools and a receptive political environment, led to the successful adoption of policies. The distinct approaches of each city, environmental review in Newark and proactive planning in LA, also reveal key catalysts for policy formulation and the challenges that can be anticipated in the development and implementation of these policies.

This study provides practical models for the many U.S. cities facing similar legacies of environmental injustice rooted in zoning and land use planning. It also sheds light on the diversity of approaches already in use in cities across the country and the potential for future affirmative local action led by impacted communities.

DEVELOPING NATURAL LANGUAGE PROCESSING (NLP) AND ARTIFICIAL INTELLIGENCE (AI) TOOLS ON OPEN DATA PLATFORMS TO TRACK ENVIRONMENTAL JUSTICE GOALS

Abstract ID: 89

Individual Paper Submission

LIM, Theodore [Virginia Tech] tclim@vt.edu, presenting author

Local governments are increasingly building Open Data Platforms (ODPs) to host local geospatial and administrative data. The goals of ODPs range from a desire to increase transparency to citizens and efficiency of government, to hopes of economic development opportunities that could make use of released data sets. Environmental justice (EJ)--the assurance of equitable access to environmental amenity and exposure to environmental hazard to all citizens--could benefit from the locally-relevant and potentially higher resolution geospatial data available in cities. However, there are challenges to assessing the extent to which local ODPs are currently hosting data sets useful to meeting EJ goals, including: locally specific goals for ODPs, different ODP catalog architectures, variation in data set organization and landing page navigability, and the diverse environmental and social conditions present in different cities. In this paper I present an open-source Python software package that I have developed to improve comparability between data sets hosted on ODPs in US cities. I demonstrate how the package improves data discoverability through the use of natural language processing (NLP) and artificial intelligence (AI) tools to identity EJ-relevant data sets, even given missing or erroneous categories and tags associated with

the data sets across local ODPs. The improvements in data discoverability and the construction of a common semantic network for EJ-relevant data allow for the creation of a web-based dashboard that can track the availability of environmental data available on OPDs and the improvement of data quality and resolution and variety over time. Lastly, I describe how the web-based dashboard could help both researchers and community activists identify locally unique environmental issues, community needs and goals, and inter-community collaboration toward reaching EJ goals.

SEEKING CLIMATE JUSTICE: INCORPORATING SOCIAL EQUITY INTO LOCAL CLIMATE CHANGE PLANNING

Abstract ID: 98

Individual Paper Submission

FRENCH, Emma [University of California Los Angeles] emma.mehlig.french@gmail.com, presenting author

Cities face unique environmental, social and economic challenges in the face of climate change. The impacts of climate change, such as the urban heat island effect and increased likelihood of extreme weather events, put additional stress on aging urban infrastructure systems. Racial, ethnic and gender disparities regarding vulnerability to climate change have been well documented and reveal the potential for climate change to act as a threat multiplier, reinforcing and exacerbating existing social and economic inequities within and across various geographic scales. In cities, and around the world, those who are most impacted by climate change are often the least responsible for causing climate change, generating debates about how to balance sustainable development with climate justice.

Due in part to their direct experience with climate change impacts, cities are increasingly seen as a promising space for taking meaningful action to both mitigate and adapt to climate change. Environmental planners are now frequently tasked with developing long-term sustainability plans that aim not only to improve local environmental conditions, but also to help mitigate global climate change. In the United States, hundreds of cities have committed to addressing climate change and many have developed Climate Action Plans (CAPs), which provide roadmaps for reducing emissions and preparing for and responding to the direct impacts of climate change that are already being felt by many. In practice, local climate change planning typically consists of some combination of mitigation strategies, which seek to reduce greenhouse gas emissions and prevent the worst case climate change scenarios, and adaptation tactics, which aim to minimize the negative impacts of climate change on communities. As CAPs are developed and implemented, concerns have been raised about the uneven impacts of these plans. Not only are the direct impacts of climate change unevenly felt, but efforts to address climate change, including

through planning, have had uneven, and sometimes negative impacts on certain individuals and communities, due in part to the plans' disregard for existing disparities. While ample research has documented the uneven impacts of climate change, less is known about the role of local climate change planning in challenging, maintaining or possibly exacerbating existing inequities.

This research explores the extent to which equity concerns are incorporated into local CAPs in California. In 2006, the State of California adopted AB32 the Global Warming Solutions Act, which created a comprehensive plan for reducing the State's greenhouse gas emissions. In the Scoping Plan for AB32, the State urged local governments to commit to reducing emissions by 15 percent (from 2008 levels) by 2020 to coincide with the State's goals. In response to this, dozens of cities around California have developed and begun to implement CAPs. The specific strategies and tactics proposed in these plans vary greatly based on the cities' size, location, vulnerability to climate hazards, political environment, and demographics. Similarly some plans explicitly seek to simultaneously address environmental and social equity concerns, while others focus more exclusively on the technical approaches to climate change mitigation and adaptation. Little research has been done to understand the various ways in which equity is included or left out of local climate action planning. This project seeks to expand our understanding of how equity shows up in climate change planning and offers insights into how planning can simultaneously address environmental challenges and underlying social injustices. Content and text analysis are used to evaluate direct and indirect references to equity in a subset of local CAPs adopted in California in the last 15 years. Broadly, this research contributes to a growing body of literature around balancing social equity and environmental needs in cities through thoughtful planning.

HOUSING PLAN AND LOCATIONAL OUTCOMES: THE RESILIENT APPROACH FOR COASTAL COMMUNITIES IN THE UNITED STATES.

Abstract ID: 102

Individual Paper Submission

TRAN, Tho [Texas A&M University] ductho2211@tamu.edu, presenting author

VAN ZANDT, Shannon [Texas A&M University] svanzandt@arch.tamu.edu, co-author

Housing plays a central role in connecting individual, family, and society in human life. Provide decent housing at an affordable price, in a suitable living environment is the ultimate goal of housing policy in the United States, as well as many other countries. The U.S. Department of Housing and Urban Development (HUD) creates a financial mechanism that requires the submission of a Consolidated Housing Plan to support affordable housing development and other housing-related activity in a city, as a condition of receiving funding through the formula block grants. These funds are used to support the proposed affordable housing development agenda of the local jurisdiction. The plan plays a crucial role in increasing affordable housing choice and providing quality community development activities for local people, especially for low-income households. Yet little research undertakes an evaluation of plan quality for Consolidated Housing Plans. Only two studies that tackled the housing issue in plan evaluation literature were found in a thorough literature search, and the most recent one was published a decade ago. More importantly, the quality of housing plan of coastal communities has never been addressed. This gap raises the concern toward how local government distributes federal resources in the areas that facing the increasing risk of natural disasters like a hurricane, flooding, and sea-level rise.

This research adopts the plan evaluation protocol in which the author developed in his previous research then apply to the coastal communities in the Gulf Coast and Florida. 60 coastal communities (30 cities and 30 counties) were chosen. Using four major criteria including Decent Housing, Suitable Living Environment, Economic Opportunity, and Fair Housing. The paper assesses the quality of the Consolidated Housing Plan by using the content analysis methodology. Each plan will be evaluated based on five components: Factual basis, Goals, Policies, Implementation, and Participation. The total score represents the overall quality of the plan.

The study compares the performance between coastal cities and coastal community in planning preparation to reveal the differences between two governmental levels. After that, two to four communities will be randomly chosen to reflect the outcomes of housing plan on coastal communities. By overlay the spatial distribution of housing and community development activities with the water-related risk map, the study indicates how the housing plan can impact local communities by the matching of geographic locations with vulnerable areas. Using Local Indicator of Spatial Association (LISA) and cluster analysis, this research will highlight the hot spot of low-income population and the concentration of public funded activities. More importantly, the geographic relation between these hot spots and the disaster risk will raise the concern toward how the public fund has been spent to address the resilient development of the needed population.

Finally, the findings are expected to create guidelines not only for policymakers but also for local authorities and researchers in supporting the affordable housing and community development nationwide.

A MODEL OF NETWORKED PLANNING? EVALUATING THE PLANS AND PEOPLE OF TULSA'S AWARD-WINNING RISK REDUCTION EFFORTS

Abstract ID: 110

Individual Paper Submission

LYLES, Ward [University of Kansas] wardlyles@ku.edu, presenting author

PENNEL, Penn [University of Kansas] penn@ku.edu, co-author

OVERSTREET, Kelly [University of Kansas] kelly.heiman@gmail.com, co-author

Planning scholars frequently use network approaches to understand numerous aspects of our field, from infrastructure planning to logistics planning to organizational management (Albrechts and Mandlebaum 2007, Innes and Booher 2010, Dempwolf and Lyles 2013). At a basic level, network approaches conceive of nodes (e.g. individual people) being connected through a relationship referred to as an edge or link (e.g. sharing information). Network approaches offer myriad analytical benefits, including understanding the agency of an individual node within a broader web of interconnected nodes that can enhance or constrain action. This paper draws on network concepts and network analytical techniques in two domains: networks of stakeholders involved in planning processes (Lyles 2015) and the network of plan documents generated by planning processes (Berke et al. 2015). To date, research linking networks of stakeholders in planning processes with networks of plans is quite limited.

To begin to fill this gap, we turn to the domain of long-term risk reduction planning, an area of planning frequently used for analysis of social science questions because of the ubiquity of natural hazard risks. This context of analysis allows us to draw on and contribute to an extensive body of knowledge about local long-term risk reduction planning, while also providing insights for planning more generally. More specifically, we pursue an in-depth case analysis of Tulsa (OK), a community recognized for 40-plus years as a national leader in long-term reduction planning and implementation, now often framed as planning for resilience. In this context we seek to answer three main questions: 1) What are the structures of the dynamic networks of stakeholders and plans in Tulsa, with particular focus on connections between planners and emergency managers? 2) How have the network structures fostered Tulsa's successes in long-term risk reduction? 3) What, if any, gaps or shortcomings in Tulsa's efforts are exposed by understanding the networks of stakeholders and plans?

To answer our questions, we draw on and extend well-developed research methods and analytical techniques including content analysis and network analysis. We collected and content analyzed a wide array of local plans related to risk reduction, including plans focused on hazard mitigation, comprehensive land use plan, sustainability, and resilience. We replicated and refined content analysis tools used to measure planning process characteristics, organizational involvement, plan integration, and policies and actions. We also conducted interviews and web-based surveys with key stakeholders, focusing specifically on the structure of the networks and the roles of emotional and social intelligence to weave and maintain the stakeholder network over time. We contextualized our findings from these primary data sets with insights from review of documents written about Tulsa's efforts over the last 40 years. Altogether, we apply network concepts and analytical techniques and triangulate within the case study to better understand how a community can develop a resilient network of plans and people to develop and implement those plans.

Our findings provide insights into the structure of networks of plans and networks of planning stakeholders engaged in planning processes. In particular, they shed light on variations in how traditional ‘silos’ of planning and implementation can be broken down (or not). The findings also provide insights into the interplay between individual-level characteristics of the ‘champions’ who have led risk-reduction efforts in Tulsa since the 1970s and the changing positions of those champions in a constantly evolving stakeholder network over time. We conclude by offering recommendations for a) planning practitioners interested in more effectively weaving networks of stakeholders and plans and b) researchers interested in applying network approaches to illuminate answers to key questions about planning processes and implementation.

WATERSHED PLANNING AS THE THIRD PILLAR IN MARKET-LIKE WATER QUALITY CONTROL

Abstract ID: 118

Individual Paper Submission

WU, Zhixuan [University of Wisconsin-Madison] zwu223@wisc.edu, presenting author

GENSKOW, Kenneth [University of Wisconsin-Madison] kgenskow@wisc.edu, primary author

Nutrients from regulated point sources (PSs) and unregulated nonpoint sources (NPSs) are among the most persistent contributors to poor water quality across much of the US, despite decades of efforts to reduce their contributions, especially from agricultural sources. In recent years, Wisconsin has established an innovative and promising approach for market-like transactions between farmers and regulated dischargers, focused on phosphorus. Enabled by statewide numeric phosphorus standards, this approach centers around compliance options to reduce nutrients entering water bodies without imposing heavy financial burdens on certain regulated dischargers such as wastewater treatment plants in small rural municipalities. The approach follows established trading principles that enable polluters with different phosphorus abatement costs to work together for watershed-level compliance, but also includes additional dimensions and flexibility. The trading option provides PS polluters the option of purchasing discharge permits from other PS and NPS polluters; a related adaptive management compliance option allows all the polluters in the same watershed to coordinate efforts to meet the ambient standard; and a third multi-discharger variance option allows qualifying dischargers (e.g., small rural municipalities) to pay a fixed price into a fund for agricultural NPS pollution control within the watershed. Compared to previous

efforts, Wisconsin's approach has catalyzed a relatively large volume of transactions between PS and NPS polluters.

The PS polluters' participation might be motivated by economic factors (e.g., cost saving), physical factors (e.g., co-existence of NPSs in the same watershed), institutional factors (e.g., flexible permitting system, brokerage service), craft factors (information made available by education and outreach activities), social factors (e.g., trust and long-term collaboration in the watershed), and cultural factors (e.g., the culture of civic engagement among dischargers). Similarly, other PSs who chose not to participate despite the high potential cost savings and social benefits may be hindered by lack of these key factors.

This research involves a series of case studies focusing on the trading projects, as well as matched PSs who chose facility upgrading over the market-like approaches. It looks at the precedent hypothesized factors and addresses questions of what factors can lead to successful implementations of market-like water quality control projects.

Findings are based upon a review of water quality permits and trading plans in Wisconsin since the trading policy began (2011). Case studies are drawn from a stratified random sample of projects using each of three trading options and matched with similar PSs in the same watersheds that are not using trading. Interviews with wastewater treatment facility managers, farmers, and permit writers in these cases provide insights on critical factors in participation and policy implementation decisions. A PS decision-making model further explains the behaviors of PSs by their three parallel roles: a rational firm in a competitive market, a node of the social network, and a group consisting of local community members. By examining the competition and combination of these three perspectives, the model identifies the key factors influencing PSs' compliance decisions and demonstrates the mechanism behind the decision-making.

This work's significance for watershed planning scholarship resides in its focus on an emerging phenomenon and its attention to non-economic factors' influence on environmental market outcomes. It also discusses the role of important planning elements, such as trust building, collaboration, and education and outreach activities, as the third pillar in market-like water quality control approach besides scientific modeling and market mechanism. It will also inform planning practice by recognizing the key factors for success. For regulators, local practitioners, and watershed groups in and out of Wisconsin, the lessons learned from this research will provide not only a roadmap for working with the PSs but also guidance on coordination of valuable resources.

Sea level rise is increasing flood risks in coastal communities, yet hazard mitigation planning often remains isolated from land use and other planning processes. This leads to inconsistent policies that put people and property in harm's way. Resilience planning has emerged as a new framework to coordinate flood mitigation and planning more generally, and is theorized to increase collaboration and avoid counterproductive outcomes that arise from treating interrelated problems in isolation. Many cities are now ostensibly engaged in resilience planning, however the extent to which resilience is actually transforming planning processes and long-term flood risks is unclear. We address this question by comparing the effects of 'networks of plans' on physical vulnerability to flooding in Boston, MA and Fort Lauderdale, FL before and after they engaged in resilience planning.

We apply the Plan Integration for Resilience Scorecard (PIRS) methodology to spatially evaluate the impact of city plans on physical vulnerability in Boston, MA and Fort Lauderdale, FL. We include all plans that were adopted by city agencies that contain policies intended to guide the use, location, density, and design of urban development in flood hazard zones. Our sample of plans includes comprehensive, resilience, climate adaptation, and hazard mitigation plans (among others). The PIRS analysis was conducted in 2015 and again in 2019. In these four years, both Boston and Fort Lauderdale have emerged as leaders in resilience planning. Boston joined the Rockefeller Foundation's 100 Resilient Cities program in 2014, and released its resilience strategy in 2017. Concurrent with the development of its resilience strategy, Boston prepared its first comprehensive plan in 50 years. Similarly, resilience is at the center of Fort Lauderdale's most recent long-term vision and 5-year strategic plan. Repeating the PIRS analysis as these cities pursue resilience planning allows us to examine whether resilience planning improves coordination across plans and reduces vulnerability in current and future flood hazard zones.

Preliminary results suggest that coordination across plans in both cities has increased and plans generally support a common policy framework on flooding. All the plans analyzed recognize flooding and sea level rise as critical issues, though some plan policies continue to guide additional development toward risky locations. While the plans in this study employ a wide variety of strategies to reduce vulnerability, both cities predominately rely on structural measures to protect existing and new development in areas at risk of flooding.

This is the first study to analyze how a city's network of plans impact on physical vulnerability evolves over time. As such, it has important implications for planning scholarship and practice. Our results demonstrate the potential for resilience planning to encourage coordination across a city, but it remains

unclear if greater integration leads to mitigating long-term flood risks. Though evidence was found showing increased awareness of flood risk, study cities are continuing to pursue development in risky locations, relying on structural protection measures.

RESILIENCE THROUGH REGENERATION: THE ECONOMICS OF RE-PURPOSING VACANT LAND WITH GREEN INFRASTRUCTURE

Abstract ID: 135

Individual Paper Submission

NEWMAN, Galen [Texas A&M University] gnewman@arch.tamu.edu, presenting author
LI, Dongying [Texas A&M University] dli@arch.tamu.edu, co-author
ZHU, Rui [Texas A&M University] zr1991@tamu.edu, co-author
REN, Dingding [Texas A&M University] dingding1987@tamu.edu, co-author

Nearly 17% of each large U.S. cities' land area is considered vacant, with an average of 4% of city structures unoccupied (Newman et al., 2016). The ratio of vacant land to city size has increased by 1.3% since 1998, indicating a growing problem. A small number of vacant parcels can be an indicator of economic growth (typically characteristic of populating cities), while larger proportions of vacant area typically can indicate symptoms of urban decline (typically characteristic of depopulating cities) (Hollander, 2010). Disaster events can exacerbate the vacancy condition, resulting in massive increases in vacant parcels and abandoned structures. When a disaster strikes, vacancies can catapult, forcing communities to rebuild in ways that improve their capacities for the next event. Further, the pace of recovery is not uniform; it varies both across and within communities (Quarantelli 1999).

Many urban areas affected by flood disasters are becoming increasingly ecologically and socially fragmented due to the accumulation of vacant properties. While redevelopment is often viewed as the primary objective in regenerating vacant properties, they can also potentially provide land for ecological and hydrological land uses. Populations in many coastal cities are increasing, despite the increased flood risk. However, despite overall population in-migrations in flood prone regions, some neighborhoods within these areas are still characterized by excessive amounts of vacancies. Rather than chasing development based incentives for regenerating vacant lots in high flood-risk communities, a balance should be sought between new developmental land uses and green infrastructure to help counteract stormwater runoff and flood effects.

This research examines the economic costs and benefits of retrofitting green infrastructure into community resilience plans as a strategy for vacant land regeneration. We seek to determine if the long term impacts of using green infrastructure to help mitigate flood issues outweigh their upfront costs. Using three flood-prone, underserved, and high vacancy-rate neighborhoods in Houston, TX (South Park, Manchester, and Sunnyside), we use performance models within the EPA's Green Vaues national Stormwater Calculator to evaluate the economic and hydrologic impacts of green infrastructure-based urban regeneration plans.

The Texas coast is one of the most frequently impacted areas by coastal storms globally. Houston, one of the fastest growing U.S. cities, has one of the highest numbers of flood-related fatalities in the past 50 years (Highfield et al., 2013) but reports nearly 11% of its land as vacant (Newman et al., 2017). Many vacant properties in Houston are peripheral greenfields which have been annexed for future development. Many of the non-greenfield vacant properties are, however, concentrated in marginalized communities, which are also typically characterized as highly vulnerable to flooding (Berke et al., 2015).

Results suggest that, when using green infrastructure to regenerate vacant properties, 1) flood risk continually decreases, 2) upfront economic costs increase in the short term (when compared to conventional development), and 3) the long-term economic return on investment is much higher. The analysis shows that the plans capture 7–40 million gallons of stormwater per year across the three communities, representing an increased capacity of 22.2 million gallons annually. Other benefits include more tree coverage, walkable space, and green space, including improvements to nearly all of the vacant lands. For the three sites, construction costs ranged from \$8 million to \$30 million. Sunnyside had the highest total annual green benefits of \$5 million, and the site would take 20 years to produce a return on investment. On average, the sites would about take 40 years to produce a return on investments.

UNDERSTANDING THE ROLE OF PLACE-BASED SOCIAL NETWORKS IN COMMUNITY ADAPTIVE CAPACITY

Abstract ID: 178

Individual Paper Submission

IDZIOREK, Katherine [University of Washington] kidzi@uw.edu, presenting author
ABRAMSON, Daniel B. [University of Washington] abramson@uw.edu, primary author
CHEN, Cynthia [University of Washington] qzchen@uw.edu, co-author

This paper reports an empirical pilot study of the role of social connections in disaster preparedness for place-based communities. Our community-engaged action research uses social network analysis to better understand how place-based relationships could be leveraged to enable community adaptive capacity (Folke et al. 2010) in the event of a disaster, operationalized here as access to critical skills and resources. The project takes place in the Pacific Northwest, where recent advances in seismic hazards science has heightened regional interest in disaster preparedness, especially for a potential magnitude 9.0 Cascadia Subduction Zone (CSZ) event. Were a CSZ event to occur, communities would likely need to be self-reliant for a number of weeks, highlighting the critical role that local resources and social infrastructure play in community resilience (Aldrich & Meyer 2015).

Working in this same broad context, Freitag et al. (2014) developed a stakeholder workshop protocol for pre-disaster community resilience planning that foregrounds place-based values and assets – built, natural and social capital – and leverages them to deal creatively with both everyday challenges and potential disasters. Adopting that approach, this project further focuses on characterizing the social capital that community stakeholders identify. The community setting for this pilot project is Laurelhurst, a Seattle neighborhood of approximately 4,000 residents.

Together with Laurelhurst Earthquake Action Preparedness (LEAP), a neighborhood-based earthquake preparedness group, we co-organized a values- and asset-mapping workshop to better understand local priorities and resources. The information gathered in the workshop helped to inform the development of a survey instrument for learning about place-based social networks and disaster preparedness within the community. Our agency and health care partners also reviewed and contributed to the content of the survey, which included modules on community access to health care, disaster preparedness and social connectivity. The survey also addresses the role of place attachment and social trust in disaster preparedness (Bonaiuto et al. 2016), as well as community members' willingness to share different kinds of preparedness resources as contingent on the strength of social ties. Further analysis evaluates the implications of the community's social network structure for horizontal and vertical integration as relevant to adaptive capacity (Berke, Kartez and Wenger 1993).

The data gathered through the workshops and survey was integrated to determine whether resources available through local social networks could potentially fill gaps that might arise in the event of a major seismic event. Although this particular neighborhood is rich in resources, findings from the survey reveal variation in willingness to share certain preparedness items depending on the strength of social ties. While Laurelhurst experiences few if any barriers to obtaining access to health care and wellness resources on an everyday basis, results indicate it will face unique context-specific challenges in the event of a disaster, including the delivery of emergency health care to an aging population and dealing with an urban form that presents a likely impediment to emergency access. The findings from this pilot project, while not broadly generalizable due to our focus on a specific community, will help to inform a subsequent stage of inquiry engaging additional communities along spectra of urban-ness and socioeconomic status to better capture regional variation in adaptive capacity.

A NOVEL APPROACH TO THE MEASUREMENT OF SUSTAINABILITY THROUGH SUSTAINABILITY INDICATORS: A CASE STUDY OF COLUMBUS, OH

Abstract ID: 211

Individual Paper Submission

OZBILEN, Basar [The Ohio State University] ozbilen.1@osu.edu, presenting author
AKAR, Gulsah [The Ohio State University] akar.3@osu.edu, co-author

Measurement of sustainability through a set of indicators is discussed for the very first time at the United Nations Conference on Environment and Development (United Nations, 1992). Although there is a significant body of research on sustainability indicators, there is a lack of consensus on which indicators would be the best to measure the three pillars of sustainability, namely economic, environmental, and social sustainability (e.g., Wilson et al., 2007). This is not surprising as the literature on sustainability underlines the variety of urban amenities (such as transportation, housing, and infrastructure), and how their impacts on sustainability require the consideration of geographic context (e.g., Miller et al., 2013). Consequently, it is important to develop a novel approach that is valid globally and acknowledges contextuality.

This study develops a sustainability indicator framework that assesses the commonalities and differences among different indices across the world. For that purpose, through a systematic review of the grey and academic literature on sustainability indicators/indices, we identified 20 national and international sustainability indices, including the UN-Habitat Agenda Indicators, Austin Area Sustainability Indicators, and Reference Framework for European Sustainable Cities. These 20 indices were selected using three main criteria: 1) the index addresses all three pillars of sustainability; 2) the index provides information on specific indicators; 3) the index provides a comprehensive indicator list that addresses a variety of urban amenities (natural environment, economy, social equity etc.) Overall, we looked at 430 different indicators. As expected while some of these indicators existed in multiple indices, some were only included in a few. We grouped the indicators under 12 different categories, such as energy related, water-waste management, transport and infrastructure, etc. Then we identified the common indicators among all indices, and within each category. Our analysis provides a set of widely used indicators that enable the comparison of different cities with a consistent indicator set. The results of the analysis show that when it comes to environmental sustainability the indicators are quite consistent across indices, but it is not the case in social and economic sustainability.

In the second phase, we introduce Columbus, OH as an excellent case study area for innovative research on sustainability indicators. Columbus is the winner of the U.S. Department of Transportation's Smart City Challenge in 2017 and the 8th fastest growing large city in the U.S. (among cities with populations of 50,000 or more in 2016) (U.S. Census Bureau, 2018). It is expected that the projects implemented as part of the Smart City Challenge coupled with the projected population increase will result in significant

changes in the city. This will require continuous assessment of sustainability outcomes. This assessment can be done with a comprehensive set of indicators that consider the local needs and allow a comparison with similar-sized cities. For that purpose, we examine the sustainability indicators introduced in Mid-Ohio Regional Planning Commission's (MORPC) Regional Sustainability Agenda 2017-2020 (MORPC, 2017). We find that although most of the indicators put forward by MORPC are consistent with our set of indicators, there are some differences. We discuss these differences and possible context-specific measurements that can grasp the local perspective for sustainable development.

This research presents a set of widely used indicators through detailed assessment of 20 national and international sustainability indices, and provides a final set of indicators for Columbus, OH that addresses local needs and has global validity. There is no one-size-fits-all approach for sustainability indicators; however, findings suggest an accurate methodology for the construction of indicator sets for specific localities. The contribution of this research to the literature is the development of an approach, which is possible to calibrate to other contexts.

UNEVEN WATERS: UTILITY, CHINESE CONTRACTORS AND MIDDLE CLASS HOUSEHOLDS IN THE CITY OF KHULNA

Abstract ID: 247

Individual Paper Submission

AHMAD, Farhana [Cornell University] fta8@cornell.edu, presenting author

As many cities appear to be endorsing universal piped infrastructure and in some cases shifting into distinctive 'post-neoliberal projects', diverse configurations of public, private and community providers are fast developing to meet the water and sanitation needs of these places. These new configurations have become increasingly complex and interconnected with respect to the level (between local and global) at which they take place and the range of actors engaged in them. Yet we know little about the effects of these governance configurations in practice.

Through my ethnographic research with a water utility that is using a Chinese contractor to provide “free” and “formal” networked water services within the city of Khulna, Bangladesh, I argue that how and in what scale these actors are used can further exacerbate socio-spatial water inequalities within a city. My main finding was that the Utility use the Chinese contractor to differentiate between households as they connect, allowing for the elite and middle class to expand further their claims on the city, while the poor are further disenfranchised from the formal water. This article is based on my dissertation field research conducted in Khulna, Bangladesh from January through December 2018. The research consisted of participant observation and action-research. Additionally, extensive and recurrent semi-structured interviews were held with utility staff, state officials, policy makers and contractor staff who were involved in providing piped water connection in Khulna. The field data collected were triangulated to obtain consistency and representation.

FROM FORESTRY MANAGEMENT ACTIONS TO A PLANNING FRAMEWORK TO MITIGATE EMERALD ASH BORER: A CASE STUDY OF BOULDER, COLORADO

Abstract ID: 263

Individual Paper Submission

TABATABAIE, Sara [University of Colorado Boulder] sara.tabatabaie@colorado.edu, presenting author
MULLER, Brian [University of Colorado Boulder] brian.h.muller@colorado.edu, co-author
SZUBERLA, Michael [University of Colorado at Boulder] misz9545@colorado.edu, co-author

Emerald Ash Borer (EAB) infestation has become a prominent urban forestry and planning issue, killing hundreds of millions of ash trees in the US and threatening an estimated 7.5 billion ash trees across the country (Gulick, 2014). Boulder, Colorado is now struggling with this issue and will lose 25% of its tree canopy to EAB in the next five years (City of Boulder, 2018). Literature on urban resilience has mainly focused on devastating natural hazards and terrorist events. Very little of the literature addresses the unique needs and characteristics of cities under stresses like tree diseases and insect infestation (Godschalk, 2003). Municipalities have different approaches to responding to tree infestation and its consequences. Some cities solely take responsibility for trees on public lands (Sadof, Hughes, Witte, Peterson, & Ginzler, 2017). Other cities use forestry management techniques, such as diversifying planted species (Carrus et al., 2015). Mitigation efforts, however, necessitates a more holistic approach to the issue that garners support from all public, and private stakeholders (Tidball & Krasny, 2007). This study investigated how a population’s baseline knowledge about trees, their home ownership status, as well as their level of civic engagement affected EAB mitigation efforts across neighborhoods in Boulder. Accordingly, we developed a planning framework that links education and collaborative efforts to

effective management of threats to the urban tree canopy. The results of this research can inform the City of Boulder and other municipalities about factors that influence the effectiveness of urban forestry practices.

This project was conducted in partnership with the City of Boulder. We applied a mixed methods approach. First, we conducted a population-based survey to gauge Boulder residents' baseline knowledge about urban trees, and their awareness of the EAB. The survey included sections on home-ownership and tree management efforts. Next, we interviewed 15 homeowners and key-informants to obtain in-depth knowledge about public-private partnership and planning efforts to address tree threats in Boulder. We also utilized GIS data about the spread of EAB, impervious areas, and socio-economic status across Boulder. We applied both quantitative and qualitative methods to interpret these data and make conclusions about adaptive capacities and responses post-disturbance.

Preliminary results suggest that income at the neighborhood level and people's knowledge about trees are positively associated with EAB mitigation practices across Boulder. We did not find a significant association between homeownership and awareness of the EAB. Our model suggests that a successful campaign engages citizens, homeowner associations, educational institutions, and other non-governmental organizations. In order to optimize urban forestry practices, cities should integrate social marketing and environmental education efforts to motivate private actors to maintain and restore the urban tree canopy.

URBAN RESILIENCE GOVERNANCE: FROM THEORY TO PRACTICE

Abstract ID: 315

Individual Paper Submission

MEEROW, Sara [Arizona State University] sara.meerow@asu.edu, presenting author
MILLER, Thaddeus [Arizona State University] thad.miller@asu.edu, co-author
FASTIGGI, Mary [Arizona State University] Mary.Fastiggi@asu.edu, co-author

Urban scholars have been debating the concept of resilience for some time, but it is only in the last few years that resilience has become a major focus for city governments. Whether driven by international funding opportunities like the Rockefeller Foundation's 100 Resilient Cities program, the federal

government's National Disaster Resilience Competition, or concerns about climate change impacts, many cities are now attempting to integrate the fuzzy notion of resilience into their organizational structures, plans, and policies (Davoudi et al., 2012). Theoretical literature on resilience is extensive and growing, but few empirical studies to date compare emerging urban resilience practice across different cities (Keenan, 2018; Woodruff, Meerow, Stults, & Wilkins, 2018). This paper helps to address that gap, providing more generalizable insights on how North American cities are operationalizing and planning for resilience.

This study is based on interviews with high-level officials (e.g. Chief Resilience Officers, Sustainability Directors) from twenty North American cities actively engaged in resilience work, who were asked a set of questions related to their definitions of resilience, the organizational structure of their resilience efforts, coordination and communication around resilience, and lessons learned. The study has both practical and theoretical motivations and applications. The research design— including the cities interviewed and the interview questions – was co-produced with the City of Portland's Bureau of Planning and Sustainability. Portland was grappling with how to structure their own nascent resilience efforts and eager to learn what research and other cities recommended. We initially developed a report for Portland city staff summarizing the practical insights from the interviews, which was also shared online and with the other city officials we interviewed. For this academic paper, we add a systematic review of the literature on urban resilience definitions and governance to identify common theoretical principles (e.g. Beilin & Wilkinson, 2015; Meerow, Newell, & Stults, 2016), which we then use to code the interview transcripts. This allows us to assess the extent to which resilience practice matches with theory.

Consistent with the academic literature, we find that cities' definitions of resilience vary, but are generally evolving to incorporate a broader array of shocks and stresses, to focus more on equity, and to be more transformational. We also find that cities are organizing their resilience efforts in many different ways. Not all of the cities have a Chief Resilience Officer position, and even those that do house them in different departments. Most cities centralize resilience work in a single department, although a few classified their efforts as more dispersed. Cities reported collaborating most frequently with planning, public works, sewage and water, emergency management, parks and recreation, and public health departments. Offices that multiple cities mentioned wanting to engage more included community development, education, engineering, equity, police, public works, and transportation. The resilience governance literature stresses the importance of involving diverse stakeholders and inter-departmental collaboration, which was also identified by the city officials as a critical factor for success. Tradeoffs between more centralized and distributed organizational structures, and housing resilience efforts within specific departments, such as sustainability or emergency management, also emerged as key themes from the interviews. As more cities start to integrate resilience into their organizational structures, plans, and policies, this information about how other cities are operationalizing resilience and their lessons learned could be useful. This empirical data can also help us to refine theoretical frameworks for urban resilience.

ASSESSING MUNICIPAL PLANNING FOR GREEN INFRASTRUCTURE TO MANAGE STORMWATER

Abstract ID: 326

Individual Paper Submission

KIM, Chaeri [University of Pennsylvania] chaeri@upenn.edu, presenting author

Each year municipal wastewater treatment facilities with combined sewer systems (CSSs) discharge nearly 850 billion gallons of combined sewer overflows (CSOs) into U.S. water ways (EPA 2015). Municipalities with CSSs have attempted to alleviate this problem through installing and incentivizing green infrastructure to reduce, capture, and infiltrate urban stormwater runoff. As of 2018, more than 40 municipalities were under CSO consent decrees with the Environmental Protection Agency (EPA), and total compliance with Clean Water Act (CWA) requirements is estimated at over \$32 billion. Of these municipalities, 18 included green infrastructure provisions in their CSO consent decrees and committed to significant spending and investment in green infrastructure projects.

Unlike traditional stormwater management measures (e.g., a treatment plant at a designated location) which may stem from a top-down and centralized approach, green infrastructure (e.g., green roofs on individual properties) requires a cooperative and decentralized approach involving the environmental, economic or social interests of various public and private actors (Heckert and Rosan 2015). While the primary goal of such environmental initiatives is to satisfy legal requirements (i.e., reducing volume and/or frequency of CSO events within agreed time), such projects also have other potential environmental outcomes (e.g., improving air quality), economic benefits (e.g., increasing property values), and social impacts (promoting community cohesion). The literature suggests these benefits are unevenly distributed across a city's population based on racial and socioeconomic status (e.g., Wolch et al. 2014; Schwarz et al. 2015). Some studies argue for developing environmental justice indices to provide a better understanding of the status quo and to facilitate the action of green infrastructure projects (e.g., Harner et al. 2002; Heckert and Rosan 2016). However, the application of these indices has received less attention.

To understand how municipalities make green infrastructure planning decisions to manage CSOs and comply with the CWA requirements, this study asks two questions: 1) What environmental, economic and equity considerations do municipalities make when deciding to fund public and private green infrastructure projects? 2) When there are competing values, such as economic or social benefits, how do municipalities prioritize them?

The results of this study are based on a qualitative approach with structured interviews to analyze the decision-making processes of 18 municipalities currently under CSO consent decrees with green infrastructure provisions. By exploring how municipalities select locations and types of green infrastructure projects to manage CSOs, this study holds significant implications for how to facilitate desired outcomes in environmental planning.

EARTHQUAKE READINESS IN VOLATILE REGIONS: THE CASE OF ISRAEL

Abstract ID: 327

Individual Paper Submission

SHMUELI, Deborah [University of Haifa] deborah@geo.haifa.ac.il, presenting author
SEGAL, Ehud [Hebrew University] ehud.segal@gmail.com, co-author
BEN GAL, Michal [University of Haifa] bmichal@geo.haifa.ac.il, co-author

REICHMAN, Amnon [University of Haifa] reichman@law.haifa.ac.il, co-author

The Middle East is highly volatile, with war and terrorism seen as the major threats. A less salient threat, though of no lesser magnitude, is a destructive earthquake in the eastern Mediterranean, particularly along the Jordan Rift Valley. Due to the low frequency of earthquakes in the region, with the last major earthquake occurring in 1927, the issue has low salience on the public, political, and planning agendas. However, their low frequency probably makes earthquakes in the region deadlier due to poor readiness at all governance levels.

This research examines the implications of the immediate risks for earthquake readiness. Due to data availability we focus on Israel's readiness for earthquakes and compare our findings with a cursory review of readiness in the proximate countries. Readiness refers to planning for three timeframes: Before - mitigation (actions to reduce long-term risk to person and property from a disaster incident) and preparedness (programs and preparations to save lives and property during the response stage); During - response (actions during and immediately after the occurrence of a disaster to provide assistance in an emergency); and After - recovery (actions promoting a return to normal or enhanced functioning post-disaster).

Regulatory Impact Assessments were not applicable to a regulatory system evaluation (Weiner, 2007). To examine earthquake readiness, we developed a regulatory system scan and assessment (RSSA)

methodology and applied it to the Israeli case. The methodology includes structured mapping and evaluation of the relevant regulatory system as well as actual policy outputs. The process includes inputs from policy makers, planners, experts and stakeholders. Findings show that the country's earthquake readiness regime is heavily biased towards immediate response which is continually advancing and improving, managed by security-related bodies. In contrast, mitigation efforts such as retrofitting of buildings and infrastructure, are deficient and little is being done to improve the situation. A survey of readiness efforts of other countries along the Jordan rift points to a similar situation.

To date, strategies developed for disaster risk reduction have largely overlooked the interplay between security conflicts and natural disasters. Yet, multiple examples have shown higher devastation in areas where conflict and natural disasters intersect (IBRD 2014, 19). One substantial aspect of this interplay is that in geopolitically unstable regions, such as the Middle East, governmental capacities develop to a great extent in response to security threats. Within this context we explore the implications of geopolitical instability for earthquake readiness efforts – that is, does the emphasis on national security affect the pattern of readiness?

This study suggests that in volatile areas, security concerns lead to the prioritization of response and preparedness as there is an institutional affinity between the bodies involved in these facets of earthquake readiness (mainly the military and other security agencies) and national security concerns. Mitigation is a key factor for saving lives and for effectively preparing for earthquakes. Retrofitting residential apartments, schools, hospitals other public buildings and seismic upgrading of infrastructure is what enables well prepared states and countries such as California, Chile, New Zealand and Japan to experience powerful earthquakes with limited casualties. But, in volatile regions where national security concerns are imminent while earthquakes are infrequent, mitigation efforts do not receive adequate attention. This leads to ineffective earthquake readiness, whereby resources are directed to the elements whose marginal contribution to the protection of lives and property is low, while the actions that are most effective are overlooked.

The research results point to specific readiness gaps and the methodology and results contribute to the fields of disaster planning and regulatory system assessment.

UNDERSTANDING THE RELATIONSHIP BETWEEN URBAN FORM AND ENERGY CONSUMPTION PATTERNS

ROZHKOV, Anton [University of Illinois at Chicago] arozhk2@uic.edu, presenting author

Energy is a significant element in many visions of future urban development, including carbon-neutral cities, self-sufficiency, and resilience. It is also true in more wide-ranging emerging concepts such as a smart city, which requires continuous and uninterrupted power supply. In these cases, the benefits proposed by technologies can potentially be weakened by the inefficiency of aging energy infrastructure.

Fossil-fuel energy sources are depletable and limited at the global level (Meadows, 2009). Also, the dependence of cities on fossil-fuel consumption is now tremendously high, due to the high-energy-consuming processes in everyday life and in the urban development of science, discovery, communications, and health, among others. Therefore, cities will have a substantial advantage if they start adapting to and preparing for more efficient energy demand and supply.

In this paper, we analyze the impact of the urban form on building energy consumption profiles for a number of neighborhoods with different predominant urban form within the City of Chicago. Like many large cities, Chicago relies on an aging infrastructure for many of its critical services (City of Chicago, 2019, p. 74). By exploring the Chicago Energy Benchmarking data and applying the geospatial analysis with geographical information system as a main tool to measure the effect of the urban form on energy use intensity (EUI), we project different scenarios about future energy use patterns.

One of the main notions studied in this research is the causality of the different components of the supply-demand profile. Understanding this complex relationship and interdependence between design variables, components, and systems is one of the major challenges and essential part of this study (Yang et al., 2018). A number of factors affect energy consumption patterns, such as urban context, building design, efficiency of building systems and occupant behavior (Ratti et al., 2005; Amaral et al., 2018). We propose spatial arrangements based on the analysis of the relations between these components and energy flows. Investigating the energy consumption of buildings, this research is focusing on two groups of building components: passive design strategies that could help buildings to reduce its EUI, and active technologies that could help to save or even produce energy.

Further work is aimed at exploring what urban forms may be more energy efficient than others, taking into account the given need for the new critical infrastructure in Chicago. The study also contributes to identifying the regulatory and planning approach in the urban development and energy consumption decision-making processes that might make urban areas more resilient.

TVA'S VISION 2020 IN RETROSPECT

Abstract ID: 341

Individual Paper Submission

ANDREWS, Clinton [Rutgers, The State University of New Jersey] cja1@rutgers.edu, presenting author

Twenty-five years ago, the Tennessee Valley Authority (TVA) prepared a long-term plan, the TVA Vision 2020, that looked forward to today and considered what its electric power infrastructure investment portfolio should include. It is timely to revisit this plan in order to accomplish three things. First, and most fundamentally, this paper re-asks for the current era the question posed in Selznick's (1949) classic organizational study of TVA: What is the fate of ideals in the course of social practice? Second, and more instrumentally, it characterizes how the world of energy planning has evolved over the quarter century since publication of the 2020 Vision, due to market-oriented structural reforms, cheaper natural gas and renewable energy sources, and transformed environmental concerns. Third, and tying back to the first question, it investigates how TVA has responded to these external changes and the ongoing pendulum swings in national politics that have echoes in TVA's politically-appointed senior leadership. The approach this paper takes to address these questions includes reviewing the 1995 TVA Vision 2020 plan (to which the author contributed) and subsequent plans published in 2011, 2015, and 2019; examining the extensive records of public comments associated with each (they doubled as environmental impact statements and hence collected voluminous public input); interviews with key agency personnel and stakeholders; and analysis of production, technological, and financial data from the U.S. Energy Information Administration and TVA. The key finding is that changing external conditions have forced the agency to adapt in significant ways that do not align with concurrent political forces. Actual peak electricity demand (30,000 MW in 2018) is much less than the 41,000 MW that had been predicted in 1995. The agency spent much of the Obama era trying to finish the last new nuclear power plant in the nation, even as the rest of the federal government was jump-starting renewables. During the first two years of the Trump administration it closed two coal-fired power plants because they were no longer needed given slumping power demand, even as Appalachian politicians derided climate change worries. Planning for flexibility is the theme of the agency's newest plan, although, ironically, its planning methods haven't changed much (or needed to change) since 1995. Throughout, the agency has held true to very instrumental ideals: provide low-cost electricity, encourage regional economic development, and provide reasonable levels of environmental protection. TVA's practices have never matched its founders' loftier New Deal aspirations and they still don't. Its objectives better reflect those of the power industry than those of federal policymakers. Implications for planning are to expect a disconnect between organizational ideals and actual practices, acknowledge the power of changing circumstances to redirect organizational practices, and recognize that the forecast is always wrong, albeit for different reasons each time.

URBAN FORM AND TRANSPORTATION ENERGY CONSUMPTION

Abstract ID: 344

Individual Paper Submission

KAZA, Nikhil [University of North Carolina at Chapel Hill] kaza.nikhil@gmail.com, presenting author

Since the early work of Newman and Kenworthy (1989), we have posited the role for urban planning and physical design of the cities in promoting more efficient transportation energy use. While the link between transportation behavior and land use patterns is unassailable, the effectiveness of using urban form to promote sustainable transportation patterns and therefore energy consumption is subject to considerable debate (e.g. Boarnet and Crane 2001; Echenique et al. 2012; Handy 2005; Stevens 2017). Much of the above debate relies on the measurement of total distance travelled assuming a direct link between amount of travel and energy consumption (see e.g. Glaeser and Kahn 2010; Lee and Lee 2014). However, the consumption is also affected by other important factors such as, but not limited to, mode choice (e.g. Dieleman, Dijst, and Burghouwt 2002), elasticity of travel (e.g. Ding et al. 2017), fuel efficiency of the fleet (e.g. Lutsey and Sperling 2005) and alternative fuel availability (e.g. Qiu and Kaza 2017; Stephan and Sullivan 2008). Thus, relating transportation energy consumption to urban form directly, rather than through travel volume, is important. In particular, we want to explain if compact urban form has implications for total energy consumption independent of the size and distribution of the population. This study provides evidence that it does.

In many of the above instances urban form is coarsely measured through population density and other demographic variables (see also Bento et al. 2005; Lopez 2014). However, there is a substantial literature that relates different dimensions of urban form (such as density, diversity, design, destination accessibility) to travel patterns (Cervero and Kockelman 1997; Krizek 2003) and therefore should be properly accounted for. In studies that do account for these different dimensions, the geographic structure of the economy of the place is largely unaccounted for. While it is true that residential sprawl is a significant dimension of urban form in the US, job sprawl and polycentricity are becoming increasingly important (Glaeser, Kahn, and Chu 2001; Kneebone 2009). In this study, we account for these dimensions of urban form.

In addition to these measures of urban form relying on census and administrative data, previous research has shown that satellite based imagery provides a complementary picture of urban form (Bereitschaft and Debbage 2013; Herold, Scepan, and Clarke 2002; Burchfield et al. 2006). Because population and jobs are mobile, while urban development is durable and largely irreversible, changes to urban landscapes are largely orthogonal to changes in demographic and economic variables. Satellite based measurements can show that urban areas are fragmentary or contiguous irrespective of population density. These measurements have already shown to have correlations with air quality through non-point source pollution such as arising from transportation (Yuan et al. 2018).

In this paper, I use a rich dataset compiled from different sources to test the effectiveness of urban form on energy consumption in the transportation sector. I proxy the consumption with retail sales from gas

stations for most of the conterminous United States at a county level. In this paper, borrowing from the methodology developed by McCarty and Kaza (2015) we build urban form indices for many of the counties in the conterminous United States. Using both demographic, economic and landscape characteristics of urban form I tease out the effect of different dimensions on energy consumption. I find that compact and contiguous urban form is modestly associated with lower energy consumption and is more important than demographic concentration in explaining the variance.

RESEARCH ON COMPREHENSIVE EVALUATION OF LOW IMPACT DEVELOPMENT MEASURES BASED ON OLD RESIDENTIAL AREA RENEWAL

Abstract ID: 345

Individual Paper Submission

CHEN, Tian [Tianjin University] chentian5561@vip.sina.com, presenting author
ZHANG, Rui [Tianjin University] 383931517@qq.com, primary author
SHI, Chuanmiao [Tianjin University] 976604188@qq.com, co-author

At present, there are a large number of old settlements to be renewed in many Chinese cities. With the deterioration of the global climate and the rapid development of the city, urban water-logging in such settlements has become more and more serious in recent years. To solve the problem of urban rain water-logging, a number of low-impact development measures introduced in the "Sponge City Construction Technical Guide" proposed in 2014. Many cities have begun to explore and practice since then, however, they are mostly concentrated in new towns or park green spaces, and are less used in the renewal of old settlements. Low-impact development technologies have been developed in developed countries such as the United States for many years, and have formed perfect laws and technical systems. In China, various studies are still in their infancy. In the screening of low-impact development measures, some scholars (2014) have carried out research on the comparison and selection of low-impact development measures, but the research on old settlements needs further exploration.

Generally speaking, the current low-impact development measures can be divided into structural measures and non-structural measures. The research object of this paper is structural measures which refer to permeable ground, green roof, sunken green space, grass ditch, initial rainwater abandonment facility, water storage facility, constructed wetland, wet pond, infiltration pond, delay regulating ponds,

artificial soil percolation, infiltration trenches, etc. Based on the analysis of existing research and engineering experience at home and abroad as well as take the actual situation of old residential settlements in China into account, the study will use analytic hierarchy process to build a multi-objective comprehensive evaluation index system and determine the weight of impact factors. Through data review and experience summarization, taking into account the principles of science, comparability and operability, the evaluation index system is established in three levels. The target layer is multi-objective comprehensive evaluation of low-impact development measures, and the constraint layer is made up of rain control effect, comprehensive cost, environmental benefit and social benefit, and then select the impact factor of each influencing factor according to the characteristics of each factor. The rainwater control effect is caused by three factors: total runoff, flood peak reduction and flood peak delay time. The impact factors of comprehensive cost are construction cost, management cost, maintenance cost and operation cost. The environmental benefits include three factors: landscape benefit, heat island mitigation benefit and pollution mitigation benefit. The social benefit impact factor has construction interference degree, service period and public acceptance. This paper will provide a quantitative analysis approach for the selection of low-impact development measures in the process of updating old residential areas as well as improve the scientific nature.

Taking Chuanfu New Village, a typical old residential area in Tianjin, as an example, using the established evaluation system to screen the applicable measures, the SWMM software is used to simulate the drainage before and after the measures are taken, to verify the feasibility and implementation of selected low-impact development measures in old settlements. According to the simulation results, the selected low-impact development measures were used without changing the original municipal drainage facilities and residential layout . Under the condition of low cost and low interference, the comprehensive runoff coefficient, rainwater discharge and peak of rainwater in the settlement are effectively reduced, the water accumulation in the site under heavy rain conditions is alleviated, and the time of draining rainwater is shortened. Furthermore, it is able to collect excess rainwater for recycling, improve the management efficiency of rainwater, make up for the shortage of drainage facilities in residential areas, and verify the scientific nature of the evaluation system.

ASSESSING THE HEAT VULNERABILITY IN THE CITY OF AUSTIN: FOCUSED ON COMPARISON OF DIFFERENT PROXIES OF HEAT EXPOSURE

BAE, JINHYUN [Texas A&M University - College Station] jinhyun2009@tamu.edu, presenting author
KIM, YOUJOUNG [Texas A&M University - College Station] kyj0244k@tamu.edu, co-author

Heat waves are one of the most dangerous natural risks that global cities are facing. They increase the heat-related mortality rate with the damage to social life and the environment. To address this problem, heat vulnerability assessment becomes essential as a way to provide scientific evidence for urban strategies and policies related to heat hazard (Yin.C et al. 2018). However, there is a significant limitation in that Land Surface Temperature (LST) is widely selected as a key proxy for heat exposure, which is limited to represent heat stress on human beings. Thus, by using the thermal index considering the physiological thermal comfort of a person, we hypothesize that the assessment accuracy and validity of thermal index will be improved.

This study aims to evaluate heat vulnerability and to examine vulnerable areas in the city of Austin. Heat Vulnerability Index (HVI) was adopted for the assessment, which is composed of spatially explicit indexes of exposure, sensitivity, and adaptive capacity (Inostroza.L et al. 2016; Bao.J et al. 2015). Accordingly, natural, built and socioeconomic factors that determine the level of heat vulnerability were investigated (Buyantuyev.A et al. 2010). Moreover, the evaluation outcomes produced by different proxies of heat exposure - LST, Air temperature and Thermal stress - were compared to test the relative performance of heat-related factors. The unit of analysis was the census tract of 191 in the boundary of the Austin. This cross-sectional study used the datasets of satellite images collected from USGS (Landsat8, Resolution 30m, 2016), and 2016 socio-economic data from American Community Survey (ACS). The analytical tools used in this study were ENVI, ArcGIS, STATA, and COMFA model.

For the evaluation, this study follows four steps; 1) Processing & Modeling 2) PCA analysis, 3) Estimation of HVI and 4) Statistical Analysis with OLS regression model. Firstly, for the image processing and thermal stress modeling, ENVI, ArcGIS, and COMFA tools were used. ENVI and ArcGIS were adopted to estimate LST. And COMFA model, a physiological thermal index, was employed to estimate the level of outdoor thermal stress. The value of each variable, which were LST, Thermal stress and land cover, were averaged and mapped at the census tract level by ArcGIS. Secondly, PCA analysis with the SOVI algorithm (Schmidtlein MC et al., 2008) was performed for the variable selection and equal weighting. Thirdly, the selected variables were normalized and summed up to produce the final score of heat vulnerability by census tract. Lastly, the relationship between the heat vulnerability and variables were identified with the coefficients indicating the most influential ones that determine the vulnerability.

The outcome of study indicated that there is a considerable difference in the results of vulnerability assessment depending on what kinds of heat proxies adopted for exposure factor. While central and northern areas in Austin were identified as vulnerable spots using LST proxies, those vulnerable spots were clustered in the central and southern area using air temperature and thermal comfort proxies. Moreover, key influential variables that determine the level of vulnerability were identified as forest, urban and grassland cover in built and natural factors. However, socioeconomic variables were all significant but have minor impacts on heat vulnerability.

Improving urban air quality is an essential component of planning for healthy cities (Northridge et al., 2003). A widely used modeling approach – Land Use Regression (LUR) – has the capability to estimate pollution levels at the neighborhood level, but few studies have performed independent evaluation of LUR models at national scale (Johnson et al., 2010). Community-based low-cost sensor networks (e.g., PurpleAir) offer the opportunity to assess national LUR performance using data that is separate from the EPA’s regulatory monitor network typically used in model development (Kelly et al., 2017). Integrating these community led monitoring efforts into model building and validation has the potential to capture pollutant sources not well characterized by regulatory (e.g., EPA) monitoring alone.

The PurpleAir sensor network is a community led air quality monitoring initiative that offers publicly available real-time and historic air quality data (e.g., PM_{2.5}) worldwide. This network is maintained by individuals, researchers, non-governmental, and governmental organizations. A few studies have used independent validation data from multiple sources to supplement existing modeling effort (Knibbs et al., 2016), but no study has tested the use of the PurpleAir data. Previously, empirical national-scale LUR models for air pollution have been developed to provide publicly available model predictions at a high spatial resolution (Kim et al., in review). In this study, we use the PurpleAir sensor network to conduct external validation of LUR model predictions at census block level for PM_{2.5} in US with the goal of assessing how community-led monitoring efforts could improve model performance.

We first retrieved and assembled PM_{2.5} data by hour (2015 - 2018) from the PurpleAir website for 8 urban areas where there were at least 7 EPA regulatory monitors and PurpleAir sensors each. Then, we conducted quality assurance (e.g., measurement anomaly) and corrected the valid measurements using real-time temperature and relative humidity which are important when using low-cost sensors. Finally, we computed the PM_{2.5} annual average concentrations (at sites with measurements of at least 18 hours/day and 244 days/year) to validate the national LUR model predictions at the census block level. We evaluate the comparison between the model predictions and the sensor-derived measurements.

Our results showed that annual average PM_{2.5} concentrations (10.0 - 18.0 µg/m³) for the 8 urban areas (296 total PurpleAir sensors) were consistently higher than the nearest US Census block centroid LUR predictions. Generally, the national LUR models captured 20% of the spatial variability at all external validation sites (35% when excluding Riverside, CA). LUR performance for individual urban areas varied; for example, the external PurpleAir validation in Pittsburgh, PA performed better (R^2 : 0.56; Mean Absolute Error: 3.40 µg/m³) as compared to the random (0.08; 0.86) and spatially-clustered (0.10; 1.27) 10-fold internal validation. Conversely, in some urban areas (Los Angeles and Riverside, CA) where many PurpleAir sensors were available, the external validation (~0.23; 7.81) was worse than the internal validation (~0.80; 1.09).

We found varying levels of LUR performance by city and that low-cost sensors (e.g., PurpleAir) could potentially serve as useful external data for model validation and accurately characterize air quality in communities. Additional work is needed to assess how low-cost sensor siting using crowd-sourced data impacts validation results. For example, whether the external validation of LUR models differ by location type (e.g., near-traffic vs. urban background locations), user (e.g., individuals vs. governmental organizations) and proximity to the EPA regulatory monitors.

To our knowledge, our work is the first study using a community-based low-cost sensor network to validate air quality model performance at national scale. As such, our approach could be used to improve characterization of air quality in communities towards influencing policies and the planning of health-promoting communities.

MODELING STAKEHOLDER KNOWLEDGE INTEGRATION USING FUZZY COGNITIVE MAPPING: A COLLABORATIVE PLANNING APPROACH IN WATER QUALITY DECISION-MAKING FOR UTAH LAKE

Abstract ID: 409

Individual Paper Submission

BANERJEE, Debolina [University of Utah] banerjee15d@gmail.com, presenting author
HINNERS, Sarah [University of Utah] sarah.hinners@utah.edu, co-author
CLARK, Brett [University of Utah] brett.clark@soc.utah.edu, co-author

Collaborative planning involves integrating lay and scientific knowledge, to gain a richer understanding of relationships, conditions, information, and options. In part, this is necessary, given that knowledge is recognized as being diverse, with multiple claims and numerous ways of knowing present for any given situation (Sandercock, 1998). Agents interact dynamically exchanging local heuristics while creating a diverse knowledge pool that can be distributed throughout the entire social system (Innes and Booher, 2010).

To address adaptive management issues and effective, resilient outcomes of a complex social-ecological system, integration of diverse knowledge types is necessary to lead to a more adaptive and less rigid structure of knowledge. The specific research questions pertain to **firstly**, how stakeholders' knowledge about the system can be integrated with the help of fuzzy logic cognitive mapping and **secondly**, how do cognitive maps help to communicate stakeholders' views to decision-makers.

Our case study area is focused on Utah Lake, which is the largest freshwater lake in the Great Basin. It exemplifies a multi-stakeholder complex system that provides vital ecosystem services through fishery, micro-climate moderation, and waste assimilation. But with increased development and population pressure, this water body is facing a myriad of pollution issues. The Utah Division of Water Quality has initiated a diverse stakeholder-driven process to set nutrient standards for the lake that will guide future management and decision-making. But there is little consensus about fundamental issues like sources of lake pollution, utilization of the lake in future, policies that affect the lake, and current action levers to bring change.

Face-to-face interviews with 15 key stakeholders (from diverse groups associated with regulatory, fisheries, agriculture, recreation, stormwater, wastewater treatment, academia, etc.,) provided the data to construct fuzzy logic cognitive maps, with the help of a web-based open source software, 'mentalmodeler' (Gray, 2012). Fuzzy logic cognitive maps are simple mathematical models used to represent the structure and function of a knowledge system at both individual and stakeholder group levels (Axelrod, 1976; Ozesmi and Ozesmi, 2004). They are used to model systems comprised of components and causal links and are based on graph theory. Participants were shown a generic example of fuzzy logic cognitive maps and then asked to list major components and relations within the Utah Lake social-ecological system. They drew relational arrows among those components, such as drivers of environmental degradation, and provided values (-1 to +1) on causal links between components. While individual map helps to visualize stakeholders' mental understandings about the system components, an aggregate stakeholder map serves as the basis to construct knowledge integration.

In our findings, the individual cognitive maps highlight current knowledge regarding drivers of changes in the system and potential action levers for change. It notes overlapping, divergent, and erroneous knowledge regarding the existing system. While the maps indicate a consensus regarding pollution sources as non-point agricultural runoff, silviculture, urbanization, and industry, there was a distinct difference in the degree of influence assigned to each of these. Consequently, this shaped the community level maps and highlighted divergent paths of solution from direct scientific intervention to more data needs to policy level changes. Such information assists in establishing shared knowledge while identifying knowledge gaps, to create effective decision-making and stakeholder-driven process.

The primary significance of this study is demonstrating that diverse knowledge can be clearly mapped out in a way that enriches the collaborative planning, rather than serving as a barrier, so long as initial work is done to recognize, appreciate, and integrate this knowledge pool. The cognitive maps can easily be used for 'what-if' scenario analysis, modeling complex relations, and succinctly representing diverse interests while recognizing mutual interdependence.

THE ORIGINS OF COMMUNITY CHOICE AGGREGATION

Abstract ID: 416

Individual Paper Submission

HSU, David [Massachusetts Institute of Technology] ydh@mit.edu, presenting author

Aggregation — also known as community choice aggregation, community choice energy, or municipal or government aggregation — is a policy in which local governments can procure energy on behalf of their residents in restructured markets. Aggregation policies are designed to allow consumers to counteract the market power of groups of utilities, to enable local governance of energy systems, and to increase local energy expertise and decision-making.

This paper is motivated by the fact that after a slow period of initial implementation, aggregation has become a remarkably influential and fast-growing policy concept throughout the U.S. over the past few years. Policies allowing aggregation of residential energy demand were first implemented in Massachusetts in 1997 and have since been adopted in six U.S. states, with a rapidly growing share of California's population joining such efforts. Some analysts, regulators, and utility companies, however, are now concerned that aggregation efforts will disrupt existing utilities, markets, and efforts towards renewables.

This paper examines how aggregation was designed as a new way for local governments to act within the existing energy system. Like many new ideas, aggregation was designed in response to contemporaneous debates, but was often adopted during restructuring efforts as an afterthought. The history of the concept shows how relatively small groups used opportunities in direct democracy and social organizing techniques to influence much larger political debates and outcomes during restructuring efforts. Early challenges to implementing aggregation included unfamiliarity with the concept, bureaucratic

unwillingness to implement new legislation, and renewed price competition from private utilities. Aggregation therefore provides an excellent example of theories about direct democracy; policy networks, policy windows, and policy entrepreneurship; and implementation of legislation within bureaucracies.

This paper is chronologically structured, based on interviews with key figures and findings from archival materials and public regulatory proceedings. This paper largely focuses on four states that have been most active in aggregation activity in the past and present: Massachusetts, Ohio, Illinois, and California. A future paper will assess the prospects and challenges for aggregation going forward. largely focuses on four states that have been most active in aggregation activity in the past and present: Massachusetts, Ohio, Illinois, and California. A future paper will assess the prospects and challenges for aggregation going forward..

EXTENDING DISTRICT ENERGY SYSTEMS BEYOND CAMPUS TO REDUCE GHGS: NEW POTENTIALS FOR TOWN-GOWN RELATIONSHIPS OR ANOTHER PIE IN THE SKY?

Abstract ID: 435

Individual Paper Submission

HAN, Albert [University of Calgary] albert.han@ucalgary.ca, presenting author
LAURIAN, Lucie [University of Iowa] lucie-laurian@uiowa.edu, primary author
BRINKLEY, Catherine [University of California, Davis] ckbrinkley@ucdavis.edu, co-author

District Energy (DE) Systems are networks of hot water, chilled water or steam pipes that distribute energy for heating and/or cooling from a single plant to multiple buildings. They are common in Asia, Scandinavia, Western and Eastern Europe, and have a proven track record of operational cost reductions, energy efficiency and greenhouse gas (GHG) emissions reductions (Werner, 2017).

The International District Energy Association (IDEA), reports about 660 DE facilities in operation in the US. Most are on university campuses, (others include airports and hospital complexes). DE systems have reduced GHG emissions on many campuses. For instance, the University of Massachusetts Amherst

reduced campus GHG emission by nearly 27% in 2013, Iowa State University reduced GHG emissions by 25% since 2010 and Stanford University's new Central Energy Facility reduced campus greenhouse gas emissions by 68% (Stagner 2016). Despite these successes, DE systems are often under-represented as viable policy options in the U.S.

This paper evaluates the impact of DE systems on building energy consumption on US campuses, and assesses the potential for extending university district energy to local buildings located beyond campus boundaries. From a physical works perspective, extending campus DE systems requires some system excess capacity and the extension of pipes, ideally prior to building construction. However, there are many more barriers to such extensions, including energy sales agreements, statewide utilities regulations, university, municipal and private sector missions and motivations, as well as legal and insurance constraints. This paper seeks to identify whether and how some of these barriers may be addressed from both the town and gown perspectives.

The paper presents findings from a four-pronged study. First, we present findings from a survey of campus energy managers that identifies the motivations and barriers for extension from their perspectives, and to tease out system capabilities and campus leadership support for potential system extensions. Second, we present preliminary results from interviews with municipal energy and sustainability managers (as well as municipal utility managers where relevant) in the cities abutting the campuses in the survey sample. These interviews seek to assess whether or not municipalities see a potential for DE extension beyond campus boundaries, and the expected costs and benefits of extensions from a municipal standpoint. Combined, these survey and interviews shed light on barriers to DE extensions, on potential strategies to address these barriers, and on the motivations and concerns of campus and municipal energy managers.

The remainder of the study focuses on the locations where campus extensions seem feasible. We verify that DE systems actually reduced campus building energy consumption using the Environmental Protection Agency's Portfolio Manager dataset and campus-level energy consumption data. We also examine the potential for extending district energy to individual properties abutting campus boundaries (e.g., examining recent growth and further potential for large scale buildings, such as student apartments, hospitals or municipal buildings) using the CoStar private real estate dataset.

The paper concludes with a discussion of the local factors that support and/or hinder energy district extensions from the town and gown perspectives, and the specific areas in which more research is needed to identify and resolve the practical, regulatory and policy barriers to extending district energy use for local sustainable energy planning.

A STORY OF TWO LEVELS: HOW DO SUB-NATIONAL GOVERNMENTS INFLUENCE LOCAL CLIMATE CHANGE ACTIONS?

Abstract ID: 450

Individual Paper Submission

LIAO, Lu [Cornell University] ll743@cornell.edu, presenting author

In the U.S., in the absence of federal responsibility, states and local governments have stepped forward to take leadership in climate change. However, although scholars have called attention to the importance of multi-level governance in climate change, we knew little about the vertical interactions between the sub-national states and cities nested within the states. How do sub-national states influence local governments' climate change actions in the U.S.? To answer this question, I take four state governments' actions and characteristics - the adoption of a state-level climate action plan, the formation of a specific governmental agency targeting at climate change, goal setting on reducing greenhouse gas, and partisan control – as major independent variables. And empirically examine how these state level factors influence local governments' actions on climate change in three aspects, namely plan making, policy adoption, and regional collaboration on climate change.

The data of this research come from a national survey we conducted with the International City/County Management Association of 1,899 municipalities and counties in the United States in 2015. The survey measures local governments' climate mitigation plan-making, as well as the adoption of 29 climate mitigation policies in different fields such as energy conservation programs in transportation, exterior lighting, and buildings etc. I also compile my dataset by collecting data from exterior sources such as Center for Climate Change and Energy Solutions, Georgetown Climate Center and American Community Survey.

I run multilevel models to empirically test my assumptions. The preliminary results show that 1) The state-level climate action plan does not influence local governments' actions on climate change in any of the models. 2) The formation of a specific agency on climate change turns out to be more effective in enhancing local plan-making and policy adoption on climate change, but not on regional collaboration. 3) Setting a state-level targets on reducing greenhouse gas emission only influence local governments' policy adoption, but not on plan-making or regional collaboration. 4) Local governments' regional collaboration on climate mitigation is more of a political process influenced by state politics such as partisan control. Although state-level governments controlled by the Republicans are less likely to incentivize local actions on climate mitigation, but are more likely to enhance regional collaboration on climate mitigation. 5) The multi-level analysis at the local level further shows that dedicated sustainability staffing is the most important factor that leads to local climate mitigation plan-making. But local governments' policy adoption is a more complex process influenced by other local factors such as fiscal and civic capacity. Finally, local governments that have a major governing body of republican are more likely to form regional collaboration on climate mitigation.

The planning scholarship has acknowledged the important roles of cities in climate change. However, cities and communities cannot operate in isolation and usually work collaboratively under the legal and institutional frameworks of a higher level government. In this research, I develop a multilevel analysis and explore empirically how local governments respond to various types of state actions on climate change. My contribution to the literature lies in situating theoretically and empirically the role of sub-national states in the framework of multilevel governance in climate change.

CITY, ENERGY, AND SOCIETY NEXUS: A CANADIAN CASE STUDY

Abstract ID: 455

Individual Paper Submission

RAHAMAN, Khan [University of Alberta] krahaman@ualberta.ca, presenting author
AGRAWAL, Sandeep [University of Alberta] sagrawal@ualberta.ca, co-author

Cities and towns account for between 37 and 49 percent of global greenhouse gas (GHG) emissions. Much of this results from burning natural gas to heat residential and commercial buildings, burning gasoline and diesel fuel in the cars and trucks moving throughout the cities everyday, and, of course, consumption of electricity in case of Alberta that comes from coal-fired or natural gas power plants. As a result, how energy is generated, supplied, and distributed is becoming an increasing concern at the municipal level in Canada.

Community energy planning is defined as planning for the community energy systems, facility design and energy-related issues at a neighborhood level (i.e., community energy planning) such as: setting energy consumption targets, selecting energy resources, energy conversion technology evaluations (Huang, Yu, Peng, & Zhao, 2015), and setting a common vision around energy (Gilmour, Laszlo, Marchionda, Drapeau, & Lee, 2016). Urban Energy Planning (UEP), on the other hand includes the combined processes of resources extraction, refining, transportation, storage, conversion to the end services (Keirstead, Jennings, & Sivakumar, 2012). It also represents a balance between supply and demand and includes the socio-technical systems like markets, institutions, consumer behaviors and other factors affect the way technical infrastructures are constructed and operated (Keirstead et al., 2012). The ultimate goal in both cases are to engage stakeholders, create a vision, and establish targets as such, GHG emission reduction strategies; assess opportunities to create future energy scenarios based on the alternatives (Goodsite & Juhola, 2016); and determining the optimal mix of energy sources to satisfy a given energy demand (Maréchal et al., 2017). However, the question remains whether we can plan a city or neighborhood based on energy and emission production scenarios described in the Paris Accord.

In order to address this complex energy and GHG emission nexus at neighborhood and city scales, we have selected three neighborhoods in the city of Edmonton. They are: Oliver; Terwillegar Town, and

Summerside. These neighborhoods are chosen based on key assumptions such as; (i) population density, (ii) building types (e.g., old fashioned or newly built, residential or commercial, etc.), and (iii) trip distribution patterns (e.g., transit, personal vehicles, non-motorized transports). Based on collected information and analysis, we calculated the total GHG emission in three identified areas. The findings will help us understand why these selected neighborhoods may have differences in emitting GHG per capita and what lessons we can be derived in order to build new neighborhoods in the future. Our findings will also help cities to design new and retrofitting existing neighborhoods with appropriate proportion of built form, transportation systems, and population density to minimize GHG emission and thereby enhancing sustainability and quality of life at the neighborhood level.

THE EFFECT OF TRAVEL AND THE BUILT ENVIRONMENT ON THE URBAN HEAT ISLAND (UHI) USING GEOGRAPHICALLY WEIGHTED REGRESSION (GWR)

Abstract ID: 470

Individual Paper Submission

KIM, Junsik [University of Utah] profjunsik@gmail.com, presenting author
EWING, Reid [University of Utah] ewing@arch.utah.edu, co-author

The Urban Heat Island (UHI) is an important climate change issue for urban areas. In many previous studies, the correlation between land use and UHI has been studied. Many climate change scholars have studied the correlations among temperature, industrial area, residential area, commercial area, open space, green infrastructure, water, and building ratio. Generally, industrial land use and a higher building ratio are presumed to exacerbate the UHI effect, while the green area and water area decrease temperature. At night, thermal turbulence and surface heat flux increase, while the cooling effect decreases with a low Sky View Factor (SVF) value. For the building ratio, the density-built environment increases temperature due to a trap effect, especially at night. The outgoing longwave radiation is decreased by obstacles. This thermal pattern increases the net radiation and counter-radiation, which are absorbed by the ground surface or the surfaces of buildings, further increasing the UHI effect (He et al., 2015; Voogt, 2007; Yang X and Li Y, 2015).

However, in the urban development field, the smart growth movement has steadily progressed. This movement is a development approach aimed at transit-oriented, walkable, bicycle-friendly, and mixed-use development to prevent urban sprawl (Verma G et al., 2016). Also called “compact city” in the U.K., it is a way to promote mixed-use development through compact cities, reduction of car use, and promotion of public transportation (Stevenson, 2016). Smart growth is considered an effective urban planning method due to its advantage of reducing impervious surface areas, improving accessibility and transport diversity, reducing crash and transportation cost savings, creating a more walkable and livable community, conserving energy, reducing pollution emissions per capita, and preserving open space. Particularly by restraining sprawl, it maximizes the use of public transportation and reduces personal vehicle use, which can dramatically decrease CO2 emissions. Considering the entire city, it can reduce the UHI effect.

However, in previous papers, the smart growth effect on UHI was not sufficiently studied. Especially, transportation and the built environment were not fully considered. To account for this less researched area, this study not only implements traditional variables, including land use, green area, and building ratio, but also calculates 5D variables (Density (population density), Diversity (land use ratio), Design (four-way intersections ratio), Destination accessibility (job density), and Distance to transit (distance to nearest transit stop)). These are the representative variables in assessing smart growth, and they also illustrate travel and the built environment to calculate the quantitative effect on urban character UHI, which can lead to an understanding of planning strategies.

The study uses Landsat 8 satellite images analyzing Salt Lake County, selected by Neil Debbage and J. Marshall Shepherd (2015) as one of the most vulnerable areas, with the highest average annual UHI intensity. For a more precise analysis, the study analyzes block group units through Geographically Weighted Regression (GWR) analysis, looking at the neighborhood effect. The neighborhood effect should be considered as the size and distance of block groups greatly differs, and it also accounts for the characteristics that temperature effected by each other neighborhood unit directly.

The analysis results show that the industrial ratio and building ratio still have a large impact. Especially, job density and four-way intersections ratio had a bigger impact than population density and distance to transit, showing that the UHI effect was higher in areas with higher traffic volume and job concentration. This suggests that ensuring personal vehicles can have a more negative influence on UHI than public transportation. The study shows that ensuring public transportation may be preferred, which means it can play a role in decreasing the UHI effect.

MULTILEVEL GOVERNANCE OR STRATEGIC ALLIANCES? THE DRIVERS OF LOW-CARBON URBANISM IN CHINA

Abstract ID: 479

Individual Paper Submission

LI, Yunjing [Columbia University] yl2510@columbia.edu, presenting author

The mainstreaming of climate change issues in urban policymaking means a fundamental change not only for the objectives of planning but also its subjects. In particular, as the level of local carbon emissions becomes an important indicator of a city's overall sustainability, new actors speaking a 'carbon' language enter the landscape of urban governance as well as climate governance. This "low-carbon urbanism" composes an emerging dimension of the political and institutional environment where planning happens (Bulkeley, Broto, & Edwards, 2012).

Planners need a good knowledge about these actors and their language to understand with and for whom they are working under the new regime. In particular, this knowledge should include a global perspective considering the strategic role of international organizations and transnational municipal networks in local climate action. This is a challenging task in the face of longstanding north-south divide in the study of urban climate responses. Existing theoretical frameworks have been based on societies with advanced democracies and post-industrial economies. While the "endogenous factors" prove to be the primary driving forces of climate strategies in cities of the global south, they are neglected or approached only as contingent factors (Carmin, Anguelovski, & Roberts, 2012).

This paper highlights this theoretical insufficiency through the case of China. As a country where nearly half of its cities have set a goal to become a low-carbon city, China provides a prime opportunity to investigate low-carbon urbanism in developing countries. Focusing on the ongoing International Low-Carbon City (ILCC) Program in Shenzhen, this paper address the question of the agents driving/shaping the Program and how are they mobilized? The results come from three fieldtrips to the program site between 2015-2017, 39 key informant interviews, and review of related documents and records. I argue that the Program is organized around explicit hierarchies among and within state and non-state actors and an essential role of the national government in resource mobilizing.

The findings pose serious challenges to two popular theoretical frameworks in the study of Chinese low-carbon cities and other climate-oriented urban development. On one side, the global theory of multilevel governance, which highlights the "networked" form of urban climate governance, fails to appreciate the persistence and practical values of formal as well as informal hierarchies among different actors in China's urban landscape (Bulkeley & Betsill, 2005, 2013). On the other, the internally derived growth coalition theory for understanding developmental politics in urban China, accepts the status quo and understates the increasingly complex relationship between environmental and economic development in an era of climate change. Moreover, this type of theoretical fragmentation is not an exclusive problem to Chinese low-carbon urbanism, but is widely found in planning research in the global south.

With that in mind, this paper offers a conceptual lens of "strategic alliances" to capture the innovative and flexible cooperative relationships observed in urban climate action globally. The paper further suggests that these alliances are configured through the massive interpretive flexibility of the decarbonization discourse. In particular, ambiguities of indicators and measurement used in carbon governance contribute

to the mobilization of actors and resources from non-public sectors and, ironically, reinforce the government's role in predicting particular development genres.

The "strategic alliance" framework provides a basis for understanding the strategic and opportunistic activities under the decarbonization discourse which transcend the conventional political and economic calculations in urban development. In this respect, the framework may be useful for analyses of the interrelations between urban entrepreneurialism and the climate change agenda beyond China.

EXAMINING FACTORS INFLUENCING PLAN INTEGRATION FOR COMMUNITY RESILIENCE AT THE DISTRICT SCALE IN SIX US COASTAL CITIES USING HIERARCHICAL LINEAR MODELING

Abstract ID: 480

Individual Paper Submission

YU, Siyu [Texas A&M University] yusiyu_1989@tamu.edu, presenting author
MALECHA, Matthew [Texas A&M University] malecha915@tamu.edu, co-author
BERKE, Philip [Texas A&M University] pberke@arch.tamu.edu, co-author

Flooding remains the most dangerous natural hazard, and that which poses the greatest threat to property and the safety of human communities. Vulnerability is growing as a result of continued development in flood-prone areas and a lack of coordinated hazard mitigation planning. The resilience of the built and natural environments is strongly influenced by the development and growth management guidance provided by a community's 'network of plans', which often includes land use, hazard mitigation, and transportation plans, among others. These plans guide development, including in hazard areas. The ways these multiple and independent plans interact can significantly impact community vulnerability (Berke et al., 2015; Berke et al., 2018). A well-integrated network of plans can aid in building resilient communities and reducing losses from flood events. To date, little is known about the factors that influence coordination in a community's network of plans, though planning capacity and local community context have been identified as key factors that influence both plan quality and the intent to protect the natural environment.

This study investigates the influence of a series of factors on community plan integration for resilience at the district scale in six US coastal cities using Hierarchical Linear Modeling. We create and compare a set of hierarchical liner models – random intercept model, means-as-outcomes model, and random-coefficients regression model – to answer the following research questions:

- (1) What is the level of plan integration?

(2) What factors influence plan integration for resilience in six US coastal cities?

Findings show that communities with a larger “temporary” population and a lower socio-economic status are less likely to incorporate hazard mitigation in local plans, controlling for community planning capacity. The relationship between the planning capacity and plan integration performance is stronger in some cities (e.g. those with planning mandates, much hazard experience, or low physical vulnerability) than in others (e.g. those without planning mandates, little hazard experience, or high physical vulnerability).

This research explores theoretical and practical problems at the nexus of climate change and urbanization, and seeks to contribute to their resolution by testing and extending the scope of the novel Plan Integration for Resilience Scorecard method. Investigating the host of factors influencing plan integration may suggest a way forward, both for research and for communities struggling with issues of ‘siloeing’, conflicting plan guidance, and disaster preparedness. Deeper knowledge about the key drivers of plan integration for resilience can inform more effective approaches as practitioners reevaluate their plans and work to foster a more coordinated strategy.

A LEVEL PLAYING FIELD? MECHANISMS OF UPWARD GOVERNANCE CONFRONT ENTRENCHED WATER MANAGEMENT HIERARCHIES IN CALIFORNIA’S SAN JOAQUIN VALLEY

Abstract ID: 495

Individual Paper Submission

KRAMSKY, Yanin [UC Berkeley] yanin.kramsky@berkeley.edu, presenting author

California’s San Joaquin Valley is rife with water management practices that neglect the needs of primarily Latinx residents of Disadvantaged Unincorporated Communities (DUCs). Hundreds of DUCs are scattered across the Valley and confront disproportionate environmental burdens such as contaminated groundwater, dry wells, and insufficient water infrastructure. Municipal and state disinvestment, industrial agriculture, dairy farming, and geological circumstances lead to continuous water quality and quantity challenges for these communities. The Sustainable Groundwater Management Act of 2014 aims

to address the Valley's water vulnerabilities and requires proactive engagement with DUCs. Basin-wide Groundwater Sustainability Agencies (GSAs) are tasked with soliciting and incorporating community members' perspectives into a Sustainable Groundwater Management Plan (SGMP) by 2020. Through participant observation and semi-structured interviewing, this qualitative research analyzes the ways in which governmentalizing mechanisms and divergent forms of embodied and techno-scientific knowledge surrounding groundwater are framed, mobilized, and codified for the production of the SGMP, at public gatherings and behind the scenes. Due to the historical and material specificities of DUCs, residents are seldom able to break entrenched, systemic race and gender barriers that inhibit meaningful and ongoing participation in GSAs. The techno-scientific expertise, political savvy, time commitment, and documentation status required to effectively demonstrate embodied experiences of water vulnerability to GSA board members are unattainable for resource-strapped DUC residents. Consequently, marginalized residents risk falling through the cracks of one-size-fits all water management strategies that fail to capture diverse and nuanced experiences accompanying chronic water stress. That said, nonprofits that serve as intermediaries for these communities employ multipronged strategies to influence groundwater policy domains. Thus, this research provides an analytical framework of intra-institutional upward governance mechanisms through which water management and politics in the San Joaquin Valley can be understood.

RESILIENCE FOR WHOM? EXPLORING EQUITY CONTENT WITHIN 100 RESILIENT CITIES' LATIN AMERICAN RESILIENCE STRATEGIES

Abstract ID: 496

Individual Paper Submission

GIRALDO, Katelynn [University of Kansas] katelynn.giraldo@ku.edu, presenting author
 LYLES, Ward [University of Kansas] wardlyles@ku.edu, primary author

Since 2015, the Rockefeller Foundation's 100 Resilient Cities(100 RC) initiative has established partnerships with 100 global cities, to formulate urban resilience strategies addressing the impending impacts of climate change. Resilience typically refers to a system's ability to maintain key functions amidst a disruption and adapt to a new set of conditions thereafter. Resilience planning centers on the belief that interdependencies exist between chronic stressors and urban issues like poverty, aging, and climate change (Woodruff, Meerow, Stults, & Wilkins, 2018, p. 2). Aligning with environmental justice

literature, 100 RC's mission statement recognizes historically low-income and racial minority communities possess fewer economic resources to prepare for the effects of climate change. 100 RC advises cities to prioritize citizen involvement and reparation of institutional injustices in resilience strategy formulation (Schrock, Bassett, & Green, 2015, p. 284). In Latin America, 100 RC's mission presents a transformative opportunity to simultaneously tackle high levels of economic disparity and geographic vulnerabilities to climate change. However, research has yet to explore whether 100 RC's resilience strategies include significant equity content, matching the organization's equitable mission statement. The global sample of 100 RC strategy publications presents the opportunity to test whether the content of 100 RC's Latin American resilience strategies possess significant equity content and the likelihood of effective climate change mitigation for the region.

This study employed plan evaluation methods to compare inclusion and depth of equity content within the 100 RC resilience strategies of nine Latin American cities. Utilizing a framework of Environmental Justice Theory (EJT) we developed seven groups of equity vocabulary to determine the breadth and depth (frequency and significance) of equity content within each strategy from the sample. After separately identifying each occurrence of equity content and which passages exhibited significant equity examples, we reviewed our findings to agree on a total count of equity occurrences and significant passages to qualitatively analyze for each strategy. Next, using Bullard's three categories of environmental justice, we thematically coded each significant equity passage as representative of the pursuit of either procedural, geographical, or social equity (Bullard, 1994). This combination of quantitative and qualitative coding allowed for analysis of equity patterns across 100 RC's sample of Latin American strategies and verification of 100 RC's alignment on strategy content with the organization's mission statement.

This study adds to previous findings on the importance of centralizing equity concerns within major urban planning proposals (Allen, Johnson, Khalil, & Griffin, 2017; Caniglia, Vallée, & Frank, 2017). Previous studies explored the importance and inclusion of equity content within climate adaptation and hazard mitigation plans, but no studies have assessed resilience strategy samples from Latin America. By ensuring the inclusion of significant equity content across resilience strategies the study suggests the likelihood 100 RC strategies will improve climate change preparedness and environmental decision-making power for millions of urban citizens from the Global South. Our analysis reveals that while affiliation with 100 RC guarantees a city's resilience strategy will include equity content, overall the number of occurrences and focus of each city's equity content is highly varied across the sample. These findings highlight the unique equity priorities of 100 RC's partner cities alongside a common commitment to the resilience through equitable considerations.

URBAN HEAT ISLAND VARIATION AND MIGRATION IN THE CITIES: THE CASE OF SAN FRANCISCO AND TORONTO

Abstract ID: 520

Individual Paper Submission

KIM, Se Woong [Texas A&M University] sewoongkim@tamu.edu, presenting author

BROWN, Robert D. [Texas A&M University] rbrown@arch.tamu.edu, co-author

As cities develop, urbanization reduces trees and vegetated areas, paves over natural surfaces, and buildings are put in their places. Since the changes in the urban environments reduce the cooling effects provided by vegetation and moist soils, it is essential to better understand the complex processes found at the intersection of urbanization, climate, and human health. For the past few years, the level of urban heat island (UHI) in major cities has increased rapidly, leading to severe health problems for city dwellers, particularly children and senior citizens. Heat is primarily considered one of the big issues in cities where climate change causes extreme heat events aggravated by the UHI effect. Although a variety of scientific and technical solutions have been proposed to address the UHI problem, there is a lack of in-depth studies to explain how the urban fabric causes the UHI to vary and migrate through the day.

This research addresses the following primary research question: What is the relative contribution of urban geometries to hourly urban heat island migration and variation in a city? To answer the question, this study focused on how to analyze the temperature patterns while considering urban form elements in the cities of San Francisco and Toronto on an hourly basis during an extreme heat event. To this end, the primary data on the UHI problem in these two cities in which the UHI level is unusually high (e.g., urban geometry, land use plan, and detailed historical weather data) were collected and three-dimensional modeling was used to analyze existing urban form conditions. Secondly, it evaluates the physical conditions and heat capacity of existing urban forms of the cities and suggests a way to calculate three-dimensional UHI variation and migration trends during a day based on the primary data with fieldwork and data collection through the automatic weather station, as well as through spatial statistical analyses.

The results showed: (1) urban heat island volume in the central business districts of these two cities experienced greater temperature differences than that in residential areas, which was the main reason why the urban heat islands showed a remarked tendency to change in the city over time; and (2) the percentage of UHI volume showed differences based on land-use type and urban green canopy cover ratio. The results contribute to providing meaningful feedback to cities that have implemented planning codes on confronting extreme heat events and may encourage refinement of the codes and/or decisions to apply them to the city with the specific guidelines related to a useful measure to estimate urban heat island volume.

FROM GENERATION TO IMPLEMENTATION: HOW LARGE SCALE COLLABORATIVES USE KNOWLEDGE TO MANAGE NATURAL RESOURCE ISSUES ACROSS BOUNDARIES

Abstract ID: 527

Individual Paper Submission

JONES, Shanice [Florida State University] smj15e@my.fsu.edu, presenting author

Knowledge has the potential to reduce uncertainty and build capacity. Planning has used scientific knowledge to improve the plans and decisions not only surrounding economic and political issues, but also to manage natural resources (Freidman, 1987). While scientific knowledge has advanced significantly over time, a great deal of uncertainty remains. The increasing temporal and scalar dimensions of natural resource issues that cross multiple jurisdictions, like climate change and water quality, pose challenges for public managers. In response to these cross-boundary challenges, new arrangements using collaboration are emerging. While collaborative governance has been applied to natural resources management for several decades (Margerum, 2011; Innes & Booher, 2018), the scale of the problems has led to new larger-scale approaches to collaboration (Goldstein & Butler, 2009; Keen & Mahanty, 2006). Large scale-collaboratives are producing knowledge to address the ecological challenges that occur across multiple jurisdictional boundaries. These collaborative arrangements are attempting to connect resource managers with the applied science and tools for improved decision making and planning at regional scales. For management, the knowledge-based outputs developed these collaborative groups have to be generated, transmitted, and used through implementation (Koontz & Newig, 2014). Despite the substantial literature on the collaborative process, less is known about the influences on and mechanisms used to implement the outputs produced in collaborative arrangements, particularly those occurring at larger geographical scales. This study asks how knowledge-based outputs developed within large scale collaborative groups influences the implementation of natural resource management. To address the research question the study explores three collaborative cases involved in landscape conservation at regional scales. In depth semi structured interviews and archival data from the case studies are used to identify the similarities as well as the differences between the participating actors' perceptions and behaviors toward the process of using scientific projects and tools. This work increases our understanding of the extent to which and how large-scale collaborative arrangements navigate using scientific knowledge through implementation to manage natural resources.

IMPROVING COLLECTION AND TRANSPORTATION EFFICIENCY FOR SUSTAINABLE FOOD WASTE MANAGEMENT: A NEIGHBORHOOD-LEVEL CASE STUDY IN CHICAGO

Abstract ID: 551

Individual Paper Submission

AI, Ning [University of Illinois at Chicago] ain@uic.edu, presenting author

ZHENG, Junjun [University of Illinois at Chicago] j.j.zheng2012@gmail.com, co-author

Food waste management (FWM) is a growing challenge in urban regions. Currently, only 5% of discarded food is composted; 1% is reused for human consumption in the U.S. (EPA, 2016). Energy, nutrients, and water embedded in the food discards mostly end up in final disposal facilities (Pothukuchi, 2009). Although sustainable practices of FWM (e.g., food donation and community composting) prevent long-distance waste hauling, the high cost of separate collection and delivery presents one of the most significant challenges (ReFED, 2016). Notably, collection accounts for most waste management costs (Offenhuber et al., 2012; World Bank, 2018). Collection costs can be a particularly important barrier to food donation and recovery, given that small batches (and low market or residual values) are often scattered around a large number of locations. Improvements to efficiency of food discards/surplus pickups and deliveries to local food banks and composting sites could significantly address the inefficiencies of FWM through its value chain.

Emerging strategies and technologies can potentially help reduce food wastage and facilitate food waste logistics targeted at recovery and reuse. For example, alternative fuels, ubiquitous computing, sensing, crowd-sourcing, robotics, artificial intelligence, and social networking technology have all been promoting green logistics and transforming urban transportation systems recently (Ala-Harja & Helo, 2015; Rifkin, 2014). These technologies, however, have not been widely applied to waste management. Neither have the neighborhood-level transportation and environmental impacts been examined, were these emerging strategies and technologies to be adapted for urban FWM.

This study develops a generic model to quantify transportation impacts (e.g., travel distance) and greenhouse emissions that are associated with trips that (1) collect food donations and deliver them to local food banks; and (2) collect food discards and transport them to composting sites. Rather than modeling optimal routes, this research examines various logistics strategies that are potentially applicable for urban FWM, with a focus on these three: (1) crowdsourcing drivers; (2) chaining food discards/surplus pick-ups; and (3) designating food discards/surplus pickup locations (instead of door-to-door services). Then transportation and environmental impacts are assessed under various scenarios that involve one or more of these strategies. Under data constraints, this research employs the continuous approximation method. Heterogeneous neighborhood characteristics, such as food waste generation volume, land use pattern, and residential and building density, are categorized and integrated in model development and policy discussions.

Empirical analysis is implemented in the City of Chicago. While the scope of this study covers Chicago's 77 community areas, the focus is on the strategies and trips that potentially address the spatial mismatch of food surplus and shortage identified in a previous study (Ai & Zheng, 2019).

The findings suggest that local FWM can be more efficient and sustainable, compared to the current practice of long-hauling to remote landfill sites. Specifically, the preferable FWM solutions and logistics strategies are contingent upon the local characteristics. Strategic policy intervention may help promote efficient urban FWM for societal benefits.

DOES CARSHARING REDUCE GREENHOUSE GAS EMISSIONS? EVIDENCE OF EMPIRICAL STUDY IN INCHEON, KOREA

Abstract ID: 588

Individual Paper Submission

SEO, Jeemin [Hanyang University] jimni0508@naver.com, presenting author

LEE, Sugie [Hanyang University] sugielee@hanyang.ac.kr, primary author

This study examines the impacts of carsharing on the reduction of greenhouse gas emissions and discuss policy implications for environmental sustainability. In previous studies, it has been investigated that carsharing services reduce the number of vehicles on the road and exerts an environmentally positive influence. However, carsharing reduces the travel time for people who have not used the car at relatively low prices and increases the convenience of travel, which ultimately makes the car more attractive (Yin et al, 2018). Therefore, it is necessary to evaluate whether carsharing is an environmentally sustainable mode of transport, considering that mode switching occurs in public transportation, taxis, and private cars.

Using the unique questionnaire survey of 3,080 carsharing users in Incheon, South Korea, this study constructed a comprehensive model related to mode switching by carsharing and analyzed the impacts of carsharing on the greenhouse gas emissions. Modes considered in the model are private cars, taxis, public transportation, and bicycles. In addition, we calculated the amount of greenhouse gas emissions per person·km by dividing the number of passengers and the average distance traveled per person. Then, the calculation results are applied to the mode conversion model based on the carsharing, and the scenarios for changing the greenhouse gas emissions by using carsharing is suggested.

Finally, the analysis results reveal the current carsharing is less effective in terms of environmental sustainability. Increasing greenhouse gas emissions from public transport and bicycles to carsharing is

larger than the amount that can be reduced from private cars or taxis to carsharing. Therefore, we should consider planning and public policies to induce the mode conversion from private cars to carsharing by increasing the service for people who dispose of private cars. As an alternative, we should consider strategies to reduce greenhouse gas emissions by converting cars used for carsharing into hydrogen and electric cars.

It is meaningful that this study has examined the environmental sustainability of carsharing, a typical sharing economic model in the urban and transportation sectors. The results of the study show that the claim to advocate sharing economy does not necessarily lead to positive results. In order for catching to be a sharing economic model we expect, we will need to constantly analyze and feedback on usage patterns in terms of social, economic, and environmental sustainability.

URBAN RENEWAL STRATEGIES AND AIR QUALITY IMPROVEMENT—THE CASE OF HANZHENG DISTRICT IN WUHAN CITY

Abstract ID: 621

Individual Paper Submission

ZHANG, Chen [School of Architecture, Tianjin University] zhangchenplan@tju.edu.cn, presenting author

Frequent smog in Chinese cities has attracted worldwide attention since 2012. Today, air quality is a key issue affecting people health, social harmony and national image. Smog in the air directly affects and causes respiration discomfort of urban living. Smog's concentration and frequency are high in the Yangtze River valley where the winter is cold and the summer is hot. Smog in the valley's urbanized areas, particularly in denser urban cores, where there are many historic buildings with poor ventilation and narrow streets. Demolition and reconstruction of these historical buildings and streets are considered as urban renewal strategies to the improve the air quality.

For this purpose, the key parameters such as ambient crosswind and natural convection were incorporated into simulation models with the CDF (Computational Fluid Dynamics) software and user-defined-functions (UDF) to analyze the fluid flow and CO propagation characteristics of the study area -Hanzheng Neighborhood, Wuhan City. The simulation results are validated by data obtained from wind speed sensors and infrared CO analyzers to ensure the study's reliability.

Furthermore, two steps were taken to ensure air quality optimization. Step 1- some multi-story and high-rise buildings are hypothetically taken out for wind passages, then compare the simulation results with

that from the original urban layout. It is found that construction of air passages within the old city district can improve the local air quality; Step 2 – open spaces are set-up for villages inside the district according to four equal-area demolition schemes, namely, Corridor Shape Demolition (CSD) Plan, Wedge Shape Demolition (WSD) Plan, Central Demolition (CD) Plan, Scatter Point Demolition (SPD) Plan, which were designed to improve the ventilation of the polluted urban environment. the comparison shows that the four strategies all yielded better optimization results. We inferred that preserving some open spaces is conducive to the diffusion of pollutants and the improvement of air condition. Specifically, the results show that the optimization effects varies as follows: $CSD \approx WSD > CD > SPD$, which means more concentrated open spaces is more effective for improving the air quality. The air intake into the neighborhood also determines the concentration distribution level of pollutants to some levels.

Finally, based on the above simulation results, this research infers that neighborhood air quality improvement can be carried out through partial renovation in addition to large-scale reconstruction, and proposes four block-scale spatial renewal strategies, namely, reducing density, connecting passages, centralized advantages and reserved lines, in order to provide practical advices for the planning and design of old city renewal and create a healthier habitat.

CHANGES IN THE WATER: THE IMPACT OF NATURAL HAZARDS VULNERABILITY AND EXPOSURE ON POPULATION CHANGE

Abstract ID: 625

Individual Paper Submission

BRANHAM, Jordan [University of North Carolina at Chapel Hill] jordan.branham@gmail.com, presenting author

SCHWALLER, Nora [UNC Chapel Hill] nora.schwaller@gmail.com, co-author

The effects of sea level rise and an increased propensity for major precipitation events due to climate change are expected to drive a dramatic reduction in the availability of habitable coastal land and induce population migrations away from particularly vulnerable areas (Allen et al. 2018; McLeman 2011). However, there is little understanding of how changing risk vulnerability and hazard exposure influences individual decisions to relocate or the thresholds at which these decisions are made (Black, Adger, and Arnell 2013; Bardsley and Hugo 2010). In this paper, we seek to understand how different aspects of environmental risk impact relocation decisions. More specifically, we ask, how does physical vulnerability to flooding and exposure to major storm events interact to influence population change over time.

We address this question by examining physical vulnerability at the building-level and exposure to major storm events via federal disaster declarations. Our study area includes North Carolina and Florida over the period from 1990 to 2010. Using the Flood Risk Information System (FRIS) dataset, which identifies whether a building is located in a FEMA flood zone as well as its first-floor elevation, we are able to quantify the proportion of buildings within a census tract that are located in a floodplain. County-level disaster declarations due to hurricanes are used to quantify exposure to major storm events. We control for a number of mediating variables at the census-tract level, including demographics, economic indicators, geography, and population trajectories. Our analysis employs multilevel regression modelling, allowing us to assess the effect of our key explanatory variables at different geographic scales.

Our findings suggest that populations have differential responses to environmental risks based on geographic location, which are compounded when physical vulnerability is accompanied by hazard exposure. More specifically, while coastal communities have experienced significant population growth despite high levels of flood vulnerability, those subareas that are exposed to multiple disasters possess a negative relationship with population growth, suggesting that major disasters can act as focusing events that trigger population shifts. Comparatively, areas subjected to riverine-based flood vulnerability are inclined to population loss in reaction to moderate risk, but less reactive to major events.

Our initial analysis suggests that major storm events play a focusing role in raising awareness of geographic vulnerability and flood risk, which may induce out-migration from vulnerable areas following repeat storm events. We expect that these risk-responses will become more pronounced in an era of climate change as environmental risks increase and out-migration becomes self-supporting. Further, as population loss leads to reduced community resilience, the potential for the rise of nonlinear migration exoduses will increase (McLeman and Smit 2006). As a result, municipalities subjected to disaster-related impacts may also need to contend with a decreased ability to support its remaining residents' livelihoods. The policy-relevant findings from this study can be used to help identify areas at risk of nonlinear out-migration while also presenting a methodology that can continue to be used for similar analyses with future Census data.

BLACK OUT VULNERABILITY: INVESTIGATING THE SOCIAL AND PHYSICAL FACTORS THAT INFLUENCE RESTORATION TIME OF THE ELECTRICAL GRID IN ATLANTA, DETROIT, AND PHOENIX

Abstract ID: 635

Individual Paper Submission

LARSEN, Larissa [University of Michigan] larissal@umich.edu, presenting author

STONE, Brian [Georgia Institute of Technology] stone@gatech.edu, co-author

GRIJALVA, Santiago [Georgia Institute of Technology] sfrijalva@ece.gatech.edu, co-author

In developed countries, residents have come to expect uninterrupted electrical power supplies to support their daily activities and condition their interior environments. However, increasingly electrical power grids are failing in the United States. Blackouts in the electricity grid can be caused by factors such as unusually high demand, equipment malfunctioning, cyber-attack, or weather events. As climate change increases the frequency and intensity of extreme heat events in urban areas and thus the demand for electrical cooling, possible blackout conditions may have extensive life-threatening consequences. Anecdotal evidence raises concerns that lower income, minority neighborhoods may experience lengthier blackout periods. In this research, we investigate what social and physical factors explain the time to restoration for different neighborhoods in three U.S cities, Atlanta, Detroit, and Phoenix.

We developed a model that mimics the conditions of a significant weather event to investigate the spatial distribution of restoration times across the electrical grids of these three cities. The location of the customers with respect to available generation sources and the topology of the grid play key roles in determining the restoration requiring modeling both the transmission and distribution network. High voltage transmission lines convey electricity from the power source to substations where the power is stepped down through medium (23-7 kilovolts) and low voltage circuits (480, 220, 110 volts) substations before it arrives at the household. Due to the radial topology, restoration always takes place from the substation to the customer. Hence, customers that are located towards the end of the distribution circuit usually experience longer restoration times. The restoration of the grid after a blackout requires a combination of remote-control actions from a control center and crews working in the field. For the three study cities, our synthetic distribution circuit models assume only overhead lines. Our model tries to minimize restoration times by re-connecting as many customers as quickly as possible, while prioritizing the reconnection of critical loads such as hospitals.

This research examines what independent variables influence the restoration time after a power outage in three U.S. cities, Atlanta, Detroit, and Phoenix. Using multiple regression, we will determine the explanatory power of the independent variables on the time until restoration (minutes) by census tract. These independent variables can be divided into three categories; 1) characteristics of the grid system (age of grid, main transmission network (1 of 3), size of the distribution network), percentage of distributed renewable energy sources, 2) characteristics of the local environment (percentage of overhead versus underground transmission lines, distance from a sub-station, tree canopy, investment in new automated protection measures), and 3) characteristics of the local consumers (neighborhood age, average cost of housing unit, SES). This research is an effort to understand urban electrical vulnerability and investigate issues of energy justice.

SPONTANEOUS DISASTER RESPONDERS: UNPACKING THE CHOREOGRAPHIES OF ORGANIZATIONAL CHALLENGE

Abstract ID: 645

Individual Paper Submission

WILLIAMS, Darien [MIT] darien.a.williams@gmail.com, presenting author

The intentions of spontaneous, unaffiliated disaster volunteers are often seen at odds with those of large organized nonprofits and agents of government. This dynamic largely exists because of the wide-variety of goals, degrees of professional expertise, and organizational memory involving the challenges that arise following disaster events. In the US, newcomers, in the form of spontaneous volunteers, learn the choreography of organizational disaster recovery challenge very quickly when their efforts are not aligned with those of the state. The goal of this study is to understand to what extent do volunteers perceive they have formal institutional access in this state-managed disaster recovery process. Participant observation, semi-structured interview, and targeted written survey response across two sites in the Florida Panhandle immediately following Hurricane Michael generated useful perspectives for meaningful analysis of how different varieties of actors working in seemingly the same context perceive themselves, their local organizational ecosystem, and develop or perpetuate institutional incongruences and barriers to communication and coordination. Findings suggest a lack of cognizance of the full positive impacts of volunteer engagement on the part of spontaneously unaffiliated volunteers. This lack of cognizance is perpetuated by perceived burden associated with navigating and reporting to state agencies. State agents are also found to perpetuate this disconnect through their lack of inclusive, comprehensive communication strategy. Attempts at mediation and coordination have been made, though common uncoordinated points have been identified. These findings have practical implications for emergency managers, volunteer coordinators, and nonprofit organizations wishing to maximize the impact of their response and recovery efforts through identification of 'low hanging fruit,' or simple, inexpensive intervention. Scholarly contributions include one of the first instances of linking the goals and perceptions of individual actors with larger organizational dynamics, or neoinstitutionalism, in US disaster volunteer contexts.

ASSESSING CLIMATE-CHANGE-INDUCED SEA-LEVEL RISING AND WILDFIRE FOR THE NORTHERN CALIFORNIA NATURAL GAS SYSTEM

Abstract ID: 652

Individual Paper Submission

WANG, Chih-Hao [California State University, Fresno] cwang@csufresno.edu, presenting author

CHEN, Na [University of Cincinnati] chenna997@hotmail.com, co-author

CHEN, Yihsu [University of California, Santa Cruz] yihsuchen@ucsc.edu, co-author

Climate-change-induced hazards, such as sea-level rising and wildfire, are likely to increase the risk of functioning failure to the natural gas system in California. As a result, economic consequences could be significant as many industries rely on natural gas as their primary energy source. To help adapt to such climate-change impacts, various resilience options have been increasingly investigated in planning studies for mitigation. Without the information of risk assessments, neither the government nor the affected industries would be able to implement cost-effective resilience options to avoid potentially catastrophic events. Natural hazards and facility vulnerabilities are the two primary components in the risk assessment of the natural gas system under the threat of climate change. The objective of the study is to assess the potential risk of natural gas system failure resulted from climate-change-induced sea-level rising and wildfire with a focus on the northern California natural gas system during 2020 to 2100. The results will identify the locations of those natural gas facilities that are exposed to climate-change induced hazards and their risks in different time periods.

The concept of resilience has been used to cope with potential natural disasters resulting from climate change (Ainuddin and Routray 2012; Rose 2007). In this study, resilience is defined as the ability of a natural gas system to resist, absorb, accommodate, and recover from the impact of climate change in a timely manner, including mitigation of the impact and restoration of its essential functions (UNISDR 2009). A risk assessment typically aims at finding the 100-year events based on historical data of a certain type of natural disasters. Therefore, the existing infrastructure and facilities are mainly designed to sustain 100-year events, such as floods and earthquakes. For example, a recent study indicated that the Sacramento River Delta levees are sufficient to protect against overtopping during a 100-year storm (Radke et al, 2015). However, the effect of climate change might skew the underlying distributions, leading to a more frequent occurrence of those events in the near future. That is, the so-called 100-year events might occur more frequently than every 100 years when considering climate change. In addition, climate change might augment the magnitude of a 100-year event into a much intensive one that has never occurred in history. Therefore, it is extremely important to develop a new approach to assess risks that would better address the uncertainty in recurrence of and magnitude of catastrophic events resulting from climate change.

To fill this gap, this study assesses climate-induced risk by leveraging the California's fourth climate-change assessment's statistically downscaled climate change scenarios from the GCM (Global Circulation Model). Two climate-change-induced natural hazards are considered in the study: (1) sea-level rising and (2) wildfire. For the sea-level rising, its maximum value is extracted from the most severe climate change scenario RCP 8.5 (Representative Concentration Pathway) to identify those natural gas facilities (e.g., compressors, storages, and metering stations) that are subject to this extreme case. The probability is then computed for each facility in time periods of 2020-2040, 2040-2060, 2060-2080, and 2080-2100, indicating the percentage of time that the facility is inundated. Similarly, the simulated data of wildfire are used to compute the frequency by which a grid cell where a facility is located will be exposed to the wildfire risk, measured by the proportion of burnt area, i.e., 25%, 50%, 75%, and 100%, during four time periods, i.e., 2020-2040, 2040-2060, 2060-2080, and 2080-2100. The results would provide the energy sector valuable information concerning future climate-change-induced risk so that they can devise resilience options accordingly.

As elevated summer temperatures increase in frequency and duration, they pose threats to health and welfare of urban residents and increase the risk of morbidity and mortality among the most vulnerable population groups, such as the elderly (Bélangier et al., 2015; Kovats & Hajat, 2008). The percentage of the senior population living in cities is projected to increase in the US and a high proportion are likely to live in poor housing conditions (Arnberger et al., 2017; Harvard, 2016), which makes them more susceptible to environmental challenges. During Hurricane Irma, several heat-related deaths in Florida were attributed to power outages that exacerbated an existing medical condition by depriving residents of cooling (Issa, 2018). Such cases highlight the need to extend beyond indoor environments and provide

alternative spaces including adjacent outdoor amenities, which can have dual benefits for improved quality of life and long-term climate adaptation for the elderly.

Our work presents findings from a summer-long case study of seniors' outdoor activities and related behavioral patterns in three public housing sites, located in Elizabeth, NJ, USA. Each site belongs to a different neighborhood and can be separated from the rest in terms of outdoor amenities, building characteristics, and the residents' profiles. Our sample consists of 24 apartments and their senior residents, located within those sites. Our data come from interviews with the residents (demographics, health, household conditions, thermal comfort, heat-related behaviors) and from sensors installed in the seniors' apartments and outdoors (temperature, humidity, indoor occupancy). Additional information includes neighborhood maps and apartment, building and site plans (windows, floor, area, height, orientation, A/C, outdoor amenities). All data were gathered during summer 2017.

In this paper, we map the outdoor preferences and destinations of seniors within and outside the site boundaries, observe the temporal patterns of those activities, and document how and why residents interact with their immediate outdoor environments. Through Pearson correlations and a series of logistic regressions, we also illustrate the relative effect of indoor and outdoor heat indexes and the site where they reside on indoor occupancy, while accounting for a number of key personal variables.

The results of our analysis show that the most popular destinations among seniors are cooling centers, shaded yards, shopping stores and religious places, considering they are within walking distance, while having pets significantly increases outdoor activity. Therefore, variations are observed across participants located in different sites; residents in buildings with poor envelopes but rich outdoor amenities appear more active, and therefore more adaptive to heat, both in terms of time spent outside and in terms of the variety of outdoor destinations. Related to that is the effect of indoor heat index and overall thermal comfort, which strongly influences the decision to leave the apartment. On the other hand, the outdoor heat index, although a statistically significant explanatory variable, has only a small effect on indoor occupancy, which, as explained in the residents' stories, does not necessarily influence the seniors' outdoor routine. Lastly, the residents' recommendations for improving outdoor amenities highlight the need for safer, greener and more accessible destinations, with more sitting options.

The above findings confirm the value of providing alternative spaces and outdoor amenities, especially in sites where indoor environments are inadequate in providing shelter. They further indicate that there is a range of cost-effective and easily-implemented heat adaptation possibilities for the elderly and that sustainable design interventions can highly benefit from the users' perspectives.

CLIMATE JUSTICE AND ADAPTIVE MIGRATION PLANNING IN SOUTH LOUISIANA

Abstract ID: 685

Individual Paper Submission

BIRCH, Traci [Louisiana State University] tbirch@lsu.edu, presenting author

NELSON, Marla [University of New Orleans] , co-author

EHRENFEUCHT, Renia [University of New Mexico] rehrenfeucht@unm.edu, co-author

LAMBETH, Tara [University of New Orleans] tlambet1@uno.edu, co-author

WILLIAMS, Jessica [University of New Orleans] jwilli30@my.uno.edu, co-author

Increasingly, migration is recognized as a necessary adaption tool in response to long-term climate and landscape change. Since the 1980s, storms, droughts and floods have increased threefold, displacing unprecedented numbers of people (Laczko & Aghazarm, 2009). In 2008, 20 million between were forced to migrate or evacuate because of extreme weather, over four times the number dislocated by conflict and violence (ibid). In some cases, people are forced to evacuate after severe weather and depending upon damage and other factors, may not return, or settle elsewhere for years or decades.

In the U.S., the most common relocation strategy for increasing climate-related hazards is property acquisition targeted at individual households. Since the 1990s, FEMA has incorporated relocation into its national mitigation strategy through floodplain buyouts, home acquisition, and homeowner relocation programs (Fraser & Elmore, 2003; Schwab & Topping, 1998). Individual buyouts allow the household maximum flexibility in deciding where to relocate, and are the least complicated relocation schemes for government agencies to manage (Nelson and Ehrenfeucht, 2016). However, low- and moderate-income residents participating in buyouts, who have fewer resources and whose monetary compensation is often significantly less, are often priced-out of their communities (Fraser & Elmore, 2003). If buyouts are targeted at a particular community or neighborhood without providing designated relocation sites, residents may be dispersed to neighborhoods throughout and beyond the region, disrupting the social networks residents depend on and value (Nelson & Ehrenfeucht, 2016). This is of particular concern in Southeast Louisiana where attachment to place is strong and relocation can cause residents to feel alienated.

An additional challenge with buyout programs and, more broadly, of voluntary initiatives is that without full participation, some households remain in vulnerable situations and local governments must continue to provide services to those who remain (Fraser & Elmore, 2003). While the situation for residents who take buyouts and move outside of the area may improve, by leaving they can contribute to decline in their original communities, and those who decide to stay or rebuild in place may grow worse off over time. As a result, low- and moderate-income residents are dually vulnerable. They are more likely to stay put and are therefore increasingly vulnerable to the local impacts of climate shifts or, when they relocate, and are more vulnerable to negative economic implications and to the loss of community and cultural ties.

This paper draws from research funded by The Water Institute of the Gulf in support of the Louisiana's 2017 Comprehensive Master Plan for a Sustainable Coast. The plan lays out a 50-year strategy for reducing the state's climate-induced coastal flood risk through ecological restoration, structural protection, and hazard mitigation. In particular, this work investigates the state's plan for buyouts in at-

risk communities, and considers land use decision-making with regard to climate justice, equitable risk reduction and socio-cultural preservation. The researchers question how policy and planning initiatives can assist migration in ways that lead to better outcomes for both those who leave and who stay. Drawing on semi-structured interviews with 30 public officials, land managers, and planning and zoning staff from Louisiana, and a review of prior relocation and resettlement efforts across the U.S., this paper contributes to planning practice and scholarship by examining opportunities and challenges with designing effective and equitable relocation strategies that help retain traditional communities and place attachment while reducing risk.

MULTILEVEL CLIMATE GOVERNANCE IN THE UNITED STATES AND CHINA: A COMPARATIVE ANALYSIS OF LOCAL GOVERNMENTS' POWER AND PRIORITIES

Abstract ID: 708

Individual Paper Submission

WATSON, Siobhan [Columbia University, GSAPP] sw2850@columbia.edu, presenting author
LI, Yunjing [Columbia University] jennifer.yunjingli@gmail.com, co-author

China and the United States are often presented as opposites in the realm of climate policy. The simplified narrative of the difference between the two goes as follows: China, with its top-down system of government, can quickly implement climate-related policy if it chooses to do so at the central level, whereas the United States has been paralyzed at the federal level on the subject of climate policy, but has seen a great deal of bottom-up progress on climate initiatives from state-level and local governments. This paper asks how national and local climate and energy initiatives interact in the two countries in practice, and finds more similarities than might have initially been expected.

Drawing on the multilevel climate governance theory, we examined the dynamics between different levels of the government in delivering local climate initiatives. In China, case analysis of cities that were enlisted in a national low-carbon city pilot program demonstrates that local policy makers are often able to subvert national priorities in the local implementation of national climate policies, effectively substituting local priorities for national ones even when the freedom to do so is, in theory, highly constrained. In the United States, local experience with federal grants shows that the role of the federal government in shaping local priorities is essential, and that many municipalities relied on the federal government to justify and prove the need for local climate-related initiatives.

These findings indicate an urgency to rethink the meaning of “local climate action” and the context of planning toward such ends. Among different factors influencing effectiveness of multilevel climate governance, power relations between national and local governments is a decisive one but mostly overlooked by studies of subnational climate initiatives. The interdependency between these two levels, which is revealed by this paper, also questions the simplified dichotomy between “top-down” and “bottom-up” approaches to climate planning.

WATER AND SANITATION FOR ALL: THE ECONOMIC BENEFITS OF PROVIDING UNIVERSAL ACCESS TO WATER AND SANITATION SERVICES IN NATIVE ALASKAN COMMUNITIES.

Abstract ID: 710

Individual Paper Submission

FUENTE, David [University of South Carolina] fuente@seoe.sc.edu, presenting author

With adoption of the Sustainable Development Goals (SDGs) the international community has committed to the ambitious goal of achieving universal and equitable access to safe and affordable drinking water for all by 2030. Unlike previous global initiatives to improve human well-being, the SDGs’ focus on universal access brings the experience of marginalized populations in high-income countries into global focus. Though often not included in national or global discourse on water and sanitation, many Arctic and sub-Arctic indigenous communities lack access to in-home water and sanitation services. Recent research in Native Alaskan communities suggests that households with inadequate access to water and sanitation services face higher rates of diarrhea, pneumonia, RSV, MRSA, and infant hospitalization than households with in-home water and sanitation services (Hennessy et al. 2008). In addition to these health-related effects, households without in-home water and sanitation services also must invest time hauling water, disposing of their waste, and must also cope with the mental stress of persistent water insecurity (Eichelberger 2014; Eichelberger 2010).

Globally, it is often difficult to make a compelling economic case for providing rural, low-income communities access to high quality water and sanitation services. These communities are often dispersed, expensive to serve, and have limited financial resources to pay for water and sanitation services. These conditions are not dissimilar to the conditions in Native Alaskan communities. Indeed, Native Alaskan communities are particularly expensive to serve given their remote locations and extreme climate conditions. Given the unique nature of healthcare service delivery for Native Alaskans, however, there

may be an economic case for expanding access to in-home water and sanitation services in Alaska. Combining the most recent estimates of water, sanitation, and hygiene (WaSH)-related disease in Native Alaskan communities, the effectiveness of various WaSH interventions, and health billing records, this paper presents the first estimates of the potential economic benefits of providing universal access to Native Alaskan communities. Extending beyond the case of Alaska, this work has implications for how planners can more effectively advocate for providing high quality water and sanitation services to indigenous communities in high-income countries.

ENVIRONMENTAL INEQUALITY AND EXPOSURE TO HEAT IN U.S. CITIES: A COMPARATIVE ANALYSIS

Abstract ID: 712

Individual Paper Submission

WILSON, Bev [University of Illinois at Urbana-Champaign] bevwilso@illinois.edu, presenting author

Climate change and the urban heat island effect are contributing to rising temperatures in cities around the world. Exposure to extreme heat can lead to negative health outcomes or even death for members of vulnerable populations. This paper frames the threat posed by extreme heat in U.S. cities as an environmental justice issue and uses Pellow's environmental inequality formation (EIF) perspective to explore heat exposure in Baltimore, Dallas, Kansas City, and St Louis. Land surface temperature (LST) and the normalized difference vegetation index (NDVI) are derived from Landsat 8 imagery and mapped at the Census tract level and HOLC Residential Security Maps are used as proxies for historical disinvestment. The relationship between exposure to heat and measures from the environmental justice and public health literatures are explored with statistical tests and robust spatial regression. Consistent with prior research, this study finds that exposure to heat in U.S. cities is not uniformly distributed and that poor and minority populations are more likely to be negatively impacted. Mean LST is higher in areas that were rated as higher risk in HOLC Residential Security Maps, but that this relationship is mediated by other factors like the density, racial, and ethnic composition of the resident population. This implies that efforts to mitigate the negative impacts of rising temperatures in U.S. cities must be tailored to the local climate, built-environment, and socio-demographic history.

SCRUGGS, Caroline [University of New Mexico] cscruggs@unm.edu, presenting author

DISTLER, Lauren [UNM] distler@unm.edu, co-author

RUMSEY, Kellin [UNM] knrumsey@unm.edu, co-author

CRUZ, Maurice [UNM] mcruz03@unm.edu, co-author

Freshwater shortages are a concern around the globe, and experts believe that many communities will need to consider water from alternative sources to meet future potable water demands (Van Rensburg 2016). Planned potable water reuse, which involves augmentation of drinking water supplies with highly purified wastewater, may improve the sustainability and reliability of water supplies. The technologies exist to do potable reuse safely, with potable water reuse facilities around the world providing water to customers for decades with no known negative health consequences (Tchobanoglous et al. 2011). However, communities have rejected a number of reuse projects in recent years (Hurlimann and Dolnicar 2010; Po et al. 2003), leading numerous researchers to conduct surveys on public perceptions of potable reuse with the goal of aiding water planners in understanding the feasibility of potable reuse for their communities. Our own experiences with a large community survey suggest that surveys alone are not adequate to accomplish this goal. In this paper, we discuss the shortcomings of surveys and ask: what is the best way to understand public attitudes toward potable water reuse to make informed decisions about water resource and reuse options?

We surveyed 1,831 water utility customers in Albuquerque, New Mexico, on acceptance of potable reuse, trust in institutions, water scarcity-related topics, and demographic information. Using regression models, we demonstrated that demographic data can be used to predict with reasonable accuracy the probability of respondents' willingness to accept potable reuse. We then used chi-square tests of independence to further examine relationships between less-accepting demographic groups and their levels of trust in institutions, prior awareness of potable reuse, and knowledge of water scarcity in the region. However, the survey process contained many shortcomings that prevented a true understanding of public perceptions of and attitudes toward potable water reuse. For example, the survey format required us to ask people to form an opinion about a complicated topic with which they were not familiar, did not allow for adequate

education about the topics being asked about, and our population felt overwhelmed by inclusion of diagrams that attempted to simplify complex technical information.

We propose a broader, more holistic approach to understanding a community's knowledge and perceptions of local water resources and water reuse to engage in informed public dialog about options to improve the sustainability and reliability of the local water supply. We performed geospatial analysis of the water-related knowledge and opinion data collected through our survey, with Census tracts and the local Water Distribution Zones as the units of analysis. We identified "hotspots" of distrust in the local water utility, public willingness (or lack thereof) to accept potable water reuse, and lack of knowledge or misconceptions about water issues and climate change. Combining the public survey data, GIS software, and spatial statistics for hotspot analyses allows for a more tailored and effective approach to public education and outreach. Water planners can use this approach to determine which Census blocks or distribution zones should be targeted for distribution (e.g., through billing inserts) of educational information related to water resource misperceptions. It also provides an opportunity for the local water utility to build trust in pockets of the city where trust is low and begin collaborations with trusted community organizations to help with education and outreach. Finally, since an inclusive public dialog is needed to understand a community's values and enable discussion about future water resource options (Stenekes et al. 2006), we recommend that a Community Conversations format, which combines the best of focus groups and information sessions, can then be used across the city to provide needed education about specific water resource and reuse topics and collaboratively develop options.

PLANNING FOR DRINKING WATER PROTECTION: AN ANALYSIS OF GOVERNANCE AND MANAGEMENT IN OHIO

Abstract ID: 739

Individual Paper Submission

WILSON, Jessica [The Ohio State University] wilson.3499@osu.edu, presenting author

In the U.S., amendments to the Safe Drinking Water Act in 1996 established requirements for states to administer Source Water Protection (SWP) Programs. Under direction from state-level agencies and water industry organizations, public water systems create protection plans for groundwater and surface water drinking sources. Local protection and management efforts to reduce the risk of drinking water

contamination largely rely on land use-based interventions and policies (US EPA, 2002). Yet drinking water protection programs have received less attention in planning.

Previous SWP studies for systems in the U.S. detail procedural approaches to planning through guidance documents and water industry-specific standards, provide best practices for suppliers, and call for broad stakeholder participation (see among others: Sklenar et al., 2012). However, additional analyses are needed to examine the social dimensions related to planning for SWP in the U.S., including governance issues and collaborative efforts. As SWP programs approach the twenty-year mark, more research is needed to examine local and regional planning and implementation efforts to support drinking water quality.

Additionally, updates to the APA Policy Guide on Water call for an integrated approach to land use planning and water management, through “collaborative relationships that lead to holistic planning and integrated water resources management” (APA, 2016). This reframing to acknowledge a land-water nexus faces challenges in both research and practice. For example, barriers exist in collaboration and decision-making across jurisdictions for shared resources and in creating institutions that support the integration of historically separate planning and management institutions and activities (Mitchell, 2005). Literature suggests that “effective governance” is key to overcoming barriers to integrated management (Grigg, 2016). As such, I argue that established SWP programs present an opportunity to examine integration in practice, with a focus on governance and local and regional resource management. This paper uses a multiple-case study design to examine five SWP programs in Ohio that operate at different management scales – three groundwater and two surface water. The study asks two main questions:

1. How does the integration of land and water governance arrangements impact planning, decision-making, and management for the provision of safe and sustainable drinking water sources in Ohio?
2. From a governance perspective, how do practitioners measure SWP program success, and what are the barriers to successful SWP?

Drawing from the collaborative planning, governance, and adaptive management literature, as well as survey results from my larger study of SWP planning across the Midwest, I present a framework to assess the integration of land and water management through the lens of local and regional SWP programs in Ohio. First, I review the most recent SWP assessments and plans, comprehensive plans, land use ordinances, and related water management plans and policies associated with each case study. This content analysis informs question development for the interviews. Next, semi-structured interviews are conducted with public water supply managers, local and regional planners, state-level EPA representatives, and other relevant stakeholders involved in the SWP programs for the five cases, to address the second question. Through characterizing and evaluating the interactions between governance, planning process, and management, the results inform a land-water nexus approach to planning practice and water resources management.

DOES COASTAL REAL ESTATE MARKET PRICE THE RISK OF SEA-LEVEL RISE: EVIDENCE FROM PINELLAS AND MIAMI-DADE COUNTY, FL

Abstract ID: 741

Individual Paper Submission

FU, Xinyu [Georgia State University] xinyufu@ufl.edu, presenting author

Sea level rise (SLR) has increasingly become one of the greatest concerns facing low-lying coastal areas (Butler et al. 2016). Frequent tidal flooding and severe hurricane storm surges are all the reflections of the increasing risk posed by SLR to coastal communities and its economy. The coastal real estate market, a central component to coastal economy, has been booming because of the preferable amenities like being proximate to the coast, while it is simultaneously considered to be increasingly vulnerable in the face of SLR. This is a particular imminent concern to the coastal communities that rely heavily on their real estate economy, causing challenging policy and planning problems for coastal resilience and sustainability. Recently, a growing number of studies have investigated the potential impacts of SLR on the coastal real estate market (e.g. Bernstein et al. 2019 and Walsh et al. 2019). Notably, Keenan et al. (2018) have found that climate gentrification is already taking place in Miami, FL with properties in higher elevations appreciating at higher rates.

These recent studies all indicate that properties in the potential SLR zones would be sold at a discounted price because of their increased risk and vulnerability to potential coastal hazards. However, few explicitly study the levels of risk that the coastal real estate market has incorporated and its spatial heterogeneity. Thus, this research tests the price effects of different sea-level scenarios and investigates where these depreciated sales are taking place. Miami-Dade and Pinellas County, FL are chosen as two case study areas for their knowingly high exposure to SLR. Using the sales transactions of single-family properties for the period Jan 2004 – Feb 2019 from both counties (i.e. 201729 sales transactions for Miami-Dade, 156442 for Pinellas), a coupled hedonic and linear mixed effect model is applied to disentangle the potential price effects of future SLR scenarios (i.e., 1 to 6 feet). The results highlight that the real estate market in both counties are incorporating the threat of future SLR while the price effects vary between and within each county. For the whole Miami-Dade County, properties exclusively in the 3- and 4-foot SLR zones are appearing to be sold at discounted rates, whereas, surprisingly, the most vulnerable zones (1 to 2ft of SLR) appears to be not affected. For Pinellas County, property sales located exclusively in the 1, 2 and 4-foot SLR zones are at discounted rates. When investigating the price effects in individual cities or town in both counties, many barrier islands are where these discounted sales take place that can be explained by their high risk and vulnerability to future SLR. However, there exist many other highly vulnerable areas that are insensitive to the risk of future SLR, requiring further research.

Our findings highlight that purchasers in both counties have already priced future sea-level rise, yet at different levels. Such preferences are expected to be amplified as sea levels continue rising into the future, stressing the future challenges of finding resilient and sustainable planning pathways facing coastal

planners and decision-makers. Finally, this study concludes by offering perspectives on key issues related to the future public uptake, market responses, and the needed adaptive planning transformations.

Although gradually increasing, the scientific understanding and longitudinal knowledge about the social and physical impacts of a dominant land conservation method in the United States, the conservation easement (CE), is far surpassed by their ubiquity. In addition to a federal tax deduction that has been increased and extended over time, CEs are now supported through enabling acts in all 50 states (Levin, 2014). But there is little to no institutionalized coordination between these private, contractual but arguably perpetually permanent decisions and local comprehensive planning—except in limited circumstances such as conservation subdivisions (Reed et al., 2013; Gocmen, 2009; Arendt, 1996), local government ordinances requiring CE placement with open space set asides, or local government as a qualified CE holder under federal tax law. Local governments conduct land use planning through regulatory mechanisms such as comprehensive plans and zoning ordinances. Land trusts (LTs) are more regional in nature, and depending on their size, mission, resources, incorporation, and affiliation (with national umbrella land trust nonprofits such as the Trust for Public Lands, the Land Trust Alliance (LTA), etc.), the LTs will use different strategies—both opportunistic and sometimes systematic—when deciding to accept or to actively pursue a CE. Gerber (2012) and Gerber and Rissman (2012), using three total case study sites in two regions, found that there is sporadic and informal coordination between the governmental entities and smaller LTs, and that “an international land trust like The Nature Conservancy maintains an uneasy relationship with the tools of local land-use planning” (Gerber and Rissman 2012, 1852). CE acquisition may contrast with the local government's rational planning approach for land uses within its jurisdiction, but this area is rife for broader examination. In response to this need, we examine

the role and processes of LTs' systematic and coordinated conservation planning in ecoregionally-differentiated but rapidly growing exurban areas of the country.

To do so, we used a semi-structured interview method with the staff of the LTs that we identified through CE instrument coding for CEs placed between 1997 and 2008/2009, where possible, in twelve counties in six ecoregionally-representative states (CA, CO, MN, SC, PA, and VA). With the help of the LTA, we sought to interview the entire population of the LTs holding the CEs placed over this time period. The interviews focused on the LTs' criteria for prioritization (depending on land trust mission and size); whether there is a relationship between the conservation decisions and other conserved lands, and that effect on the other criteria; the role of climate change in their criteria and the relationship with other conserved lands (if at all); the formal and informal coordination mechanisms through which land trusts engage with governmental entities to leverage their conservation priorities and processes; and barriers to coordination with the same. Using two coders for intercoder-reliability, we coded these interviews with first and second cycle coding.

Our findings reveal considerable variation depending on the LT purpose, mission, and their sources of funding for CE acquisition. There is no consistent trend in relationship with the local and county governments, except that public oversight in the CE determination process corresponds to fiscal support. The amount of coordination with local governments or public oversight depends on the CE funding (state, federal, local), which also relates to the LT mission, and the CE holder type. A systematic conservation process is associated with LTA accreditation, and to the CE funding. Climate change considerations are beginning to be incorporated, particularly in areas with immediate physical impacts. The planning community could benefit from greater engagement—whether formal or informal—with their LT counterparts in these rapidly growing exurban areas.

MUNICIPAL TREE PLANTING: A STRATEGY FOR CARBON SEQUESTRATION AND FOR CREATING A RESILIENT REGION

Abstract ID: 754

Individual Paper Submission

WOODS, Tiffany [Utah State University] tiffany.woods@aggiemail.usu.edu, presenting author

BLIESNER, Aaron [Utah State University] abliesner@aggiemail.usu.edu, co-author
MANN, Erin [Utah State University] erinkelleymann@gmail.com, co-author

Climate change is the defining challenge of our time (UNDP 2010). While it has been a natural phenomenon throughout the history of our planet, anthropogenic factors have contributed to unstable and rapid changes in climatic conditions that no longer fall within the normal range of variability. Human related greenhouse emissions, specifically carbon dioxide (CO₂), have been identified as the primary driver of recent and projected climate change (Masson-Delmotte et al. 2018; EPA 2016). Recognition of the issue and driver allows individuals, communities and/or political units to identify potential solutions and integrate resiliency measures into future planning.

One example of a community committed to reduce its contributions to anthropogenic caused climate change is Park City, Utah. This mountain town plans to achieve carbon neutrality in most municipal operations by 2022, and city-wide by 2032 through their net-zero initiative. While considerable effort has been dedicated to transitioning municipal operations to renewable energy and implementing energy and water efficiency measures, attention has now shifted to improving or establishing carbon sinks. One of the more ambitious carbon sequestration projects includes the planting of 100,000 new trees on city-owned property and private land. This project was the basis of our research, which aimed to determine if the planting of 10,000 trees is a feasible option for reducing atmospheric carbon for a western mountain town.

Municipal tree planting initiatives are not novel strategies. They have been implemented in rural and urban (Pincetl, 2010) communities, with varying degrees of success. However, this project is unique because it is the first instance where planting is only one component of a municipality's strategy to become carbon neutral and because other carbon sequestration alternatives are analyzed in conjunction to select a scenario that establishes the greatest level of resiliency within the community and surrounding region. Our study is separated into three primary phases and is influenced by the Steinitz method (Steinitz, 1995). First, we completed a land suitability analysis that considered various native tree species, geomorphic features and resource requirements. Second, we identified potential limitations or risks associated with the project. Due to Park City's geographic location and projected population growth, water availability and quality as well as wildfires could limit the project or be adversely impacted by the influx of new vegetation. Finally, we considered other carbon sequestration alternatives, such as wetland restoration, to identify the best scenario that should be adopted for Park City's initiative. Geospatial analyses resulted in maps and visualizations that were uploaded into a web hosted storymap to ensure that the findings could be easily disseminated to all interested parties.

Our preliminary findings have ascertained that while the planting of 100,000 is physically possible, the constraints of space availability, irrigation, open public property, and risks make it inadvisable to pursue such an endeavor without reducing or substituting the number of trees planted with other sequestration alternatives. These key contextual, biophysical, social and economic considerations directly influence the feasibility of the initiative. While the findings of this study are specific to Park City, they could benefit similar municipalities or communities throughout the West that are implementing their own carbon neutral or reduction initiatives. If the recommended scenario is adopted by Park City, further research should be pursued on the project's implementation success as well as the long-term impacts the initiative will have on climate change mitigation and community resiliency.

IDZIOREK, Katherine [University of Washington, Seattle] katherineidziorek@gmail.com, co-author
ABRAMSON, Daniel [University of Washington, Seattle] abramson@uw.edu, co-author

Hazard mitigation planning generally takes place at the municipal or county level and is rarely incorporated into comprehensive planning (FEMA, 2013). This paper reports on the initial stages of a community workshop-based action research project to consider multi-hazard mitigation as a step in updating a local comprehensive plan, and in the process: (1) identify opportunities for more robust mitigation strategies than is typical in “worst-case” hazards planning processes -- i.e. strategies that are appropriate for more than one type and severity level of hazard, as well as for the achievement of on-going community development goals --, and to (2) articulate more clearly the nature of conflicts between mitigation and those goals. In order to capture a meaningful extreme of robustness in the strategies they generate, community stakeholders considered scenarios of both gradual change (sea level rise) and sudden, more existentially threatening change (near-source megaquake tsunamis). Moreover, both types of hazards were presented according to varying levels of likelihood.

The context for the project is the Washington coast, where there is a 10-15% chance of a magnitude 9 earthquake occurring along the Cascadia Subduction Zone (CSZ) within the next 50 years. Although rare -- with recurrence intervals of 250-500 years or approximately 2,500 years, depending on the magnitude -- coastal areas are preparing for shaking intensities, tsunamis, subsidence and other hazards resembling the 2011 east Japan event. A CSZ megaquake could kill more than 10,000 people and injure over 30,000; economic loss could exceed \$70 billion (CREW, 2013). Recognizing the serious natural hazard threats it faces, the Westport/South Beach community, located on a low-lying peninsula at the mouth of Grays Harbor, self-funded and constructed the first tsunami vertical evacuation site in North America. To build on this achievement, the City of Westport seeks to incorporate broader hazard mitigation into its Comprehensive Plan update, to apply for FEMA Tsunami Hazard Mitigation assistance for additional vertical evacuation structures, and to develop more comprehensive land use strategies and infrastructural investments for mitigation that are synergistic with long-term planning goals.

The University of Washington team and community partners began by reviewing the Grays Harbor County Multi-Jurisdictional Hazard Mitigation Plan and City of Westport Comprehensive Plan to identify opportunities and challenges for integration using FEMA’s Safe Growth Integration Tool (FEMA, 2013).

We then used probabilistic sea level rise projections, two tsunami inundation models and maps of post-coseismic-subsidence coastline change to inform a series of community workshop activities focused on the development of strategies for both immediate response (safety, in the case of tsunami inundation) and long-term adaptation. In the workshops, prior to working with the hazard information, participants first identified and mapped community values and assets they would like to preserve or enhance through hazard mitigation and comprehensive planning.

We found that a significant number of mitigation strategies developed in the workshops were focused on community survivability and transformation because the tsunami scenarios were existentially severe, while the sea level rise scenario left greater room for mitigating strategies that would preserve recognizable community identity. Given time, however, even strategies to mitigate a devastating tsunami (e.g. safe evacuation and resettlement on higher ground inland) could accommodate community identity if prepared for gradually and incrementally.

In this project, we found that values-driven, asset-based participatory community workshops in which stakeholders can consider both chronic/gradual and episodic/sudden hazards can aid in producing long-term, localized resiliency plans. Considering multiple, low-to high-severity hazard scenarios is helpful for developing robust land use strategies for inclusion in comprehensive plans, while focusing only on severe (but low-probability) existential threats produces a more limited set of strategies.

CLIMATE CHANGE AND URBAN PLANNING IN KOREA

Abstract ID: 772

Individual Paper Submission

BESHIR, Agraw Ali [University of Seoul] agrawbali@gmail.com, presenting author
SONG, Jaemin [University of Seoul] jmsong@uos.ac.kr, co-author

Climate change agenda has become a serious threat to the globe and Korea, in particular, has experienced a much higher temperature increase than the global average, 1.7 degree Celsius, over the last century. The country has introduced various measures to combat climate change, leading the green growth advocate on both global and domestic level, the concept of which emphasizes an opportunity of countries to achieve economic growth in a sustainable way. However, not much research has been conducted to assess whether the country has well addressed the climate agenda in its urban planning, which plays an important role in both climate change mitigation and adaptation. Against this backdrop, the study aims to first review ROK's policies for climate change and evaluate the magnitude of attention given for climate

change mitigation and adaptation in spatial plans prepared for major Korean cities by conducting a content analysis. The measuring criteria and framework for the content-wise evaluation of the spatial plans in response to climate change mitigation and adaptation were developed based on a thorough review of international and local researches. The general framework for the evaluation focuses on major components of spatial planning that are closely related to climate change agenda, including land use, transportation, energy, waste, construction, water, and biodiversity. Horizontal evaluation has been done on spatial plans prepared for six metropolitan cities in South Korea, namely; Seoul, Busan, Daegu, Daejeon, Incheon, and Ulsan for a selected spatial plan year, 2030. This revealed a strong and nationwide attention to climate change mitigation and adaptation agenda during the preparation of spatial plans as almost all of the important aspects have been well addressed. On the other hand, a vertical evaluation, which was conducted for the evaluation of spatial plans prepared for Seoul metropolitan area for planning years, 2011, 2020 and 2030, discloses the positive change in the integration of climate change mitigation and adaptation agenda in spatial planning through time. The results suggest that the efforts to incorporate climate change agenda in urban planning at the government level has played a major role towards achieving climate resilient cities in the country.

RECOVERY IN COASTAL NEW JERSEY AFTER SUPERSTORM SANDY: A LONGITUDINAL EVALUATION OF THE FEDERAL DISASTER RECOVERY PROGRAMS

Abstract ID: 776

Individual Paper Submission

ZHANG, Yang [Virginia Tech] yang08@vt.edu, presenting author

WANG, Qiong [Virginia Tech] wqiong7@vt.edu, co-author

Decisions to rebuild or relocate after disasters have the potential to cause dramatic changes in the composition of a community, either redressing or exacerbating pre-existing socio-economic conditions. The quality and speed of recovery after disasters is most clearly manifested through housing recovery within the impact area. The trajectories and distribution of housing recovery over time and space reflect both the speed and quality of disaster recovery and are therefore major indicators of the success or failure of the overall disaster recovery policies.

Superstorm Sandy, which caused extensive damage in New York and New Jersey coastal areas in 2012, was one of the most economically and physically damaging disasters. To assist disaster-impacted states' recovery efforts, the federal government enacted the Disaster Relief Appropriations Act of 2013, which

appropriated one of the biggest disaster relief and recovery assistance package in U.S. history. Among the monies appropriated, \$16,000,000,000 were allocated in HUD's Community Development Block Grant Disaster Recovery (CDBG-DR) Funds.

This paper presents a longitudinal evaluation of the CDBG-DR program. Our research questions are twofold. First, did the CDBG-DR program facilitate a speedy recovery after Superstorm Sandy? Second, did the CDBG-DR program take the opportunity of the disaster recovery to build back better (i.e. incorporating disaster mitigation strategies to reduce future risk)?.

Data on CDBG-DR recovery grant allocation was collected from the State of New Jersey Office of the State Comptroller. This office publishes quarterly reports on funds distribution within the State of New Jersey. Other data for this analysis came from three different sources. Pre-disaster socio-demographic information of the impact area was collected from the US Census Bureau American Community Survey 2011 5-year estimates. The damage variables were collected from the State of New Jersey Department of Community Affairs. Damage assessment was based on FEMA Individual Assistance Records.

Our analysis showed that disasters can magnify and accelerate housing processes already occurring in communities. During the recovery process, pre-existing housing inequities related to household characteristics and housing tenure are at risk of being exacerbated. Differences in hazards exposure, the structural quality of homes, financial capabilities, and uneven performance of federal housing recovery programs widen housing gaps between population groups during disaster recovery in the impact areas. Three approaches to overcome these problems in the United States are discussed.

A STUDY OF RISK PERCEPTION IN COMMUNITIES RESIDING NEAR NUCLEAR POWER PLANTS

Abstract ID: 781

Individual Paper Submission

CROWLEY, Julia [Western Carolina University] jccrowley@wcu.edu, presenting author

The nuclear power industry has experienced a considerable amount of controversy since its early development in the 1950s. The efficiency of nuclear energy is quite apparent, but concerns have remained throughout the industry's history regarding the potential consequences if a facility malfunctions. In spite of the incidents at Three Mile Island, Chernobyl, and Fukushima, growing concerns regarding greenhouse gas emissions and climate change along with an increased demand for energy have cast nuclear power in a positive light as nuclear power plants do not burn fuel (Duke Energy Progress, 2018). However, public

opposition has often hindered the growth of the nuclear power industry in the United States. Numerous studies have been conducted through the years to understand public perception of nuclear power plants, but the results of such studies tend to be heavily influenced by the events at the times they were conducted. A study published in 1983 found that the public perceived nuclear power plants as high-risk facilities while natural gas burning power plants, coal burning power plants, and oil burning power plants were perceived as low-risk facilities (Lindell and Earle, 1983). Bickerstaff et al. (2008) conducted a study on public perceptions of nuclear power in the United Kingdom with growing concerns regarding climate change. They found that only 2 of 32 individuals consistently viewed expansion in the nuclear power sector as an acceptable route to mitigating climate change (Bickerstaff et al., 2008). Influxes of studies regarding public perceptions of nuclear power risk were published following the Fukushima incident of 2011. Siegrist and Visschers (2012) conducted a longitudinal study on public perceptions of nuclear power before the incident at Fukushima, immediately after, and half a year later. They found that the incident at Fukushima had a negative impact on the acceptance of nuclear power (Siegrist and Visschers, 2012). Furthermore, Ramana (2011) found that public support for nuclear power has declined since the Fukushima incident in Japan as well as many other countries.

There appears to be a lack of recent literature on public perceptions of nuclear power. Such studies are extremely important, as the United States has attempted to expand its nuclear power industry with growing concerns over climate change and the demand for energy. However, the literature is also lacking studies that examine vulnerability in relation to residents residing near nuclear power plants. The purpose of this research project is therefore to observe risk perceptions of residents residing near nuclear power plants in order to examine if the expansion of the nuclear power industry in the United States is worth the risk. This question was addressed through door-to-door surveys of residents residing within 10 and 20-mile radii of two nuclear power plants in Illinois. Questions pertained to perceived benefits of the nuclear power plants, perceived levels of safety, resident awareness of preparedness strategies, and resident understanding of how nuclear energy works. Results were analyzed with a variety of statistical tests in SPSS. The overall findings suggest that most respondents found the nuclear power plant in their communities to be beneficial, and provided high overall levels of safety. Most of the respondents reported receiving preparedness strategy packets, but very few had Potassium Iodine pills at home. Finally, about half of the respondents were able to provide an accurate description of how nuclear energy works. This research poses important implications for the scholarship and practice of planning by giving a voice to the residents who face the highest risk in the event of an incident at a nuclear power plant, and addressing some of the strengths and shortcomings of the current preparedness procedures in the two case study communities.

REGIONALLY- AND GLOBALLY-MINDED CITIES FOR BIODIVERSITY

Abstract ID: 794

Individual Paper Submission

PIERCE, Jennifer [University of British Columbia] piercestudio@gmail.com, presenting author
MOORE, Jennie [BCIT] Jennie_Moore@bcit.ca, primary author

The concept that the environmental impact of a particular area may occur at a distance and even at a larger scale than is immediately apparent is called telecoupling (Liu et al. 2013). Folke et al. quantified the impact of cities to be 500-1000 times larger than their legal boundaries (1997). Global-level initiatives such as the Aichi Targets and measurement tools such as the ecological framework (Rees and Wackernagel, 1996; Rees, 2008) are intended to aid cities in making connections with larger scale impacts. But, are cities using them in their actual ecological planning?

This research project investigates how North American cities make the connection between local biodiversity plans and biodiversity outcomes beyond their borders. The primary research question is: How are cities considering the implications of their biodiversity planning at scales beyond their borders? Subquestions considered here include:

1. How do cities communicate global implications and connect them to local concerns and decisions?
2. What indicators do they use to track their impact on global biodiversity?
3. Which programs do they rely on to standardize their approach?

Cities and metro regions in Mexico (2 plans), Canada (20 plans) and the USA (18 plans) have produced plans that discuss biodiversity. These plan documents will be the primary data source for this research. Using lexical analysis software (NVivo), we have analyzed these plans for references to biodiversity impacts outside of their borders. We located references in the plans to global biodiversity measures (carrying capacity, planetary boundaries, ecological footprint, ecological integrity, Aichi Targets, and the sustainable development goals (SDGs)) and regional measures (watershed, rural, region). Occurrences of these terms were then manually reviewed and analyzed for their communications strategies and connections. We also conducted a corresponding analysis of urban biodiversity programs used by cities in the region, such as the ecological footprint, the Biophilic Cities Network and the BiodiverCities approach.

The outcomes of this research include an analysis of the scales that cities consider when it comes to biodiversity planning, a typology of approaches taken by cities and the identification of those approaches that have promise in terms of taking a more comprehensive approach to larger scale impacts and connecting to global indicators.

We found that while it was relatively common for cities to discuss regional-level concerns and connect their activities to concerns at the watershed (65%), rural (63%) or regional scale (80%), it was far less common to consider global concerns. Eight plans, all in Canada, discussed the concept of an ecological footprint. Only Saskatoon included the results of city-level ecological footprint calculations. None mentioned the BiodiverCities approach nor their membership in the Biophilic cities network. Only Rancho Palos Verdes references the SDG framework to guide its biodiversity planning. Only Mexico City discussed Aichi targets. Only Calgary referred to their National Biodiversity Strategy. Thus, programs for

biodiversity planning seem to have not yet had a standardizing impact on these cities. No cities stood out in particular as having comprehensively considered scales above the regional level.

These findings reinforce the theory of a gap between biodiversity actions at the local level and outcomes and actions at national and global scales. Based on these findings, we would encourage more cities to consider their impact on a global scale, and to link their activities to global targets and national strategies. In regards to urban biodiversity programs, our findings suggest an increased responsibility for these programs to link national and global scale initiatives to local planning. Our findings also suggest that global and national initiatives may not consider local concerns and context, and thus may be difficult for cities to integrate into local planning.

INFORMAL SETTLEMENTS AND LAND SURFACE TEMPERATURES IN MUMBAI, INDIA: A FRAMEWORK FOR ADDRESSING VULNERABILITY TO EXTREME HEAT

Abstract ID: 804

Individual Paper Submission

CHAKRABORTY, Arnab [University of Illinois at Urbana-Champaign] arnab@illinois.edu, presenting author

LI, Xijing [University of Illinois at Urbana Champaign] xijingl2@illinois.edu, co-author

Heat waves are getting longer and more intense. While responding to this growing threat is a priority in cities around the world, megacities in developing countries face a particularly difficult challenge. Many of these cities have a history of heavy casualties attributable to extreme heat, a large share of extremely vulnerable populations, and depleting natural resources.

Numerous frameworks have emerged to map and respond to these challenges, but their impact remains limited. Within the umbrella of climate planning, Heat Action Planning is the predominant approach to organizing and coordinating response activities (Stone 2012). In India, efforts such as the Ahmedabad Heat Action Plan (NRDC 2017) and Heat Action Plan for Odisha (OSDMA 2016) are the most visible municipal and state efforts, respectively. These efforts, however, are likely to have limited efficacy due to little attention such efforts pay to the environmental and social factors that create urban vulnerabilities.

In this paper, we attempt to address this gap using the case of Greater Mumbai region in India and by better understanding the relationship between informal settlements – areas with concentrated vulnerable populations – and land surface temperature, and by examining additional environmental and physical factors that mediate this relationship. First, we develop and apply a spatial data framework that captures key urban typologies such as informal settlements more appropriately. These datasets employ municipal data for 2015 (latest data available) along with Land Surface Temperature data from Landsat 8 for May 2015, the hottest time in Mumbai for which such data is available. On the selected day land surface temperature in Mumbai varied from 25 degree Celsius to 45 degree Celsius. The different data layers are initially consolidated into five – residential (formal), informal, forest, roads, and others). Notably, our analysis involves adding a dataset that captures degree of development intensity, separately from land use type. For this, we use Defense Meteorological Satellite Program's nightlight data.

Second, we use a novel statistical approach called geographically development weighted regression model that capture the relationships more appropriately and accurately than other approaches. To measure the localized land use's contribution to LST, the evaluated land surface temperature is chosen as dependent variable and the six classified land uses are chosen as independent variables. The research area is divided into 1922 cells whose size is 500m*500m which is commonly walking distance. The development level which is derived from nightlight data is assigned to each cell as the third dimension of the model. The model measures the different kinds of land uses' contribution to LST considering the spatial and development heterogeneity.

Comparing the results of our model shows that proportion of informal settlements are the strongest drivers of land surface temperature, and variables such as forest cover and tree canopy provide expected cooling effects. Formal settlements are also positively correlated with higher LST but much less so than informal settlements. Our ongoing work is exploring how the model results vary seasonally, for night time temperatures, and when additional factors such as air quality variations are taken into effect.

We hope to use the findings from the models in the future to explore implications of different land development scenarios, especially for the vulnerable populations in informal settlements, and the role of urban greening practices currently popular in Mumbai and around many Indian cities.

A THREE-DIMENSIONAL DIGITAL CITY APPROACH TO ASSESS THE ROLE OF URBAN SHADES IN MICROCLIMATIC MODERATION

Abstract ID: 828

Individual Paper Submission

PARK, Yujin [The Ohio State University] park.2329@osu.edu, presenting author
GULDMANN, Jean-Michel [The Ohio State University] Guldman.1@osu.edu, co-author

This study examines the role of urban trees in regulating the local microclimate, with special attention to the heat mitigation capacity of urban shades created by tree canopies and buildings. Devising a natural and design-based solution to combat local warming is a very important urban planning issue. Increasing temperatures are expected to strike urban communities more harshly due to the Urban Heat Island (UHI) effect, threatening public health and safety. Extreme heat waves are already responsible for more deaths in the U.S. than any other climate-related hazard such as hurricanes, tornadoes, and flooding, with more than 65,000 Americans suffering acute heat illness every year (USGCRP, 2016). To advance our understanding of a more climate-resilient urban structure and design, this study examines the feature of urban land-use structure that could better counteract rising temperatures, with a particular focus on the effective use of shades.

Recent advances in geospatial analytics and the proliferation of public geospatial big data have opened the door to a more sophisticated digital representation of complex urban geometry in three-dimensional (3D) space (Park & Guldman, 2019). Large-scale parameterization of 3D building structure and street viewshed have shown that building configuration affects localized temperatures by regulating solar irradiation absorption, air ventilation, and shadow area (Alavipanah et al., 2018). One underexamined but critical aspect, however, is the role of shades projected by trees. There is only limited research on tree shadow effects, mostly experimental and focusing on a few sites and individual trees (Zheng et al., 2018). Tree canopies are omnipresent, especially in residential settings, and particularly relevant for controlling summertime temperature, when trees reach their full potential in evapotranspiration and shading. Also widely missing in the literature is the joint consideration of the area and location of the produced shades and the type of ground covered by them. There is only limited research that interfaces a 3D vegetation model with surface temperature analysis at city-scale, and no study has analyzed the effects of shade amount and sub-shadow land-use heterogeneity.

The three major component of the research are: (a) developing a system of multiple map layers representing 2D/3D land uses, including shade layers geometrically derived from a 3D digital city model consisting of buildings and trees, as well as 2D land covers and features; (b) computing 2D and 3D land-use variables; and (c) estimating statistical and machine learning models that predict observed thermal variations. Urban thermal conditions are represented by land surface temperatures (LST) as derived from thermal infrared remote-sensing imagery. The summertime surface temperatures in 2015 are obtained from Landsat 8 Thermal Infrared Sensors (TIRS) Analysis Ready Data (ARD), with a thermal band of 100m resolution (USGS Earth Explorer platform). The City of Columbus, Ohio, is the study area, covering both urban and suburban areas. It is a particularly relevant case for urban heat risk studies, as Columbus is ranked as top 8th among sixty largest U.S. cities for UHI severity (Kenward et al., 2014).

The key aim of this research, the quantitative modeling of the relationship between land-use structure and local temperature, is critical for the development of metropolitan greening strategies and judicious decision-making on land development. The research outcomes could also be used to formulate detailed guidelines about community greening and tree planting efforts in terms of effective spatial configuration of local trees (tree crown size and location) by providing empirical evidence on local heat mitigation.

ADAPTING THE SOCIAL-ECOLOGICAL SYSTEMS FRAMEWORK (SESF) TO ENVIRONMENTAL PLANNING & INFRASTRUCTURE PROVISION IN SLUMS

Abstract ID: 862

Individual Paper Submission

SYAL, Shruti [University of Illinois at Urbana-Champaign] syal2@illinois.edu, presenting author

I adapt the Socio-Ecological Systems Framework, developed for natural resource management, into a new context: waste management infrastructure provision in urban ‘slums’ precariously located along stormwater drains flowing into one of the world’s most polluted rivers.

Drain-adjacent slums as Social-Ecological Systems (SES)

An SES perspective reveals that environmental planning for Delhi stretch of river Yamuna is interwoven with lack of sanitation and waste disposal infrastructure in drain-adjacent slums. Residential sewage contributes high organic load and fecal matter into open-access stormwater drains emptying into river Yamuna; within this subset, ~250 drain-adjacent slums appear as “blank spaces” in plans for river remediation and infrastructure (Syal 2019a). Continued lack of access to infrastructure means continued waste disposal into drains. As a drain flows along a slum, water quality worsens with respect to some parameters, but pollution predominantly occurs upstream of the settlements, likely from waste discharged by ‘formal’ facilities like dairies, industrial areas, residential areas (Syal 2019b). While per capita contributions are smaller, excluding ~1.54 million people in plans means that sewage treatment plants and drains are unprepared to deal with their fecal matter (ecological_{site-scale} ↔ ecological_{regional-scale}). Not only does waste disposal result from inadequate, inaccessible, infrequent and incomplete infrastructure and service provision, but the same waste cycles from one space to another within the SES due to regulatory overlap (ecological_{site-scale} ↔ social_{site-scale}) and becoming an excuse for unjustified evictions (Syal 2019c). An institutional analysis helped decipher that several formal and informal rules provided by State and National legislations incentivize different stakeholders to act in ways that result in problematic outcomes: deficient infrastructure/service provision, improper waste disposal, flooding (social_{site-scale} ↔ social_{institution-scale}) (Syal 2019d). These multi-scalar, nonlinear, reciprocal dynamics between drainage flow dynamics, waste-related infrastructure, land development, and the institutions managing them must be studied in an integrated way, using the SES Framework.

SESF analysis

In an SESF, first-tier variables (Resource System, Resource Units, Governance System, Actor Groups) interact to produce outcomes at the SES level, second-tier variables are characteristics that describe the first-tier variables, and third-tier variables are sub-categories of second-tier variables. For instance, rules are a second-tier variable describing one aspect of the governance system, a first-tier variable, and rules can be sub-categorized as constitutional, operational, or collective-choice, making those three third-tier variables. To describe the second and third-tier variables in my framework, I used data on drain water quality, land use, policy and legislation on infrastructure and service provision as well as regulations on environmental quality and 'slum development', and data from in-depth semi-structured interviews with settlement dwellers, regulatory agencies, and nongovernmental and community-based organizations involved in sanitation and/or environmental remediation in Delhi. I systematized interactions between Resource System (drain), Resource Units (clean drain water), Governance System for infrastructure/service provision, and Actors (residents, regulatory agencies, NGOs). Then, I analyzed how these interactions produce the outcome of improper waste disposal into drains. The goal of analysis is not (yet) to determine causality, but thoroughly document the variables describing the system (hence the term 'framework' not 'model'), and qualitatively assess the myriad interactions between social and ecological components.

Significance

Already engaged in developing the framework in case studies on different resources—irrigation, fisheries, forests, lakes—across the world—Nepal, India, US, Chile, Mexico (Hinkel et al 2015), SESF theorists have called to adapt the framework to contexts beyond resource management. SESF is a critical tool to study metropolises as socio-natural systems, not just socio-politico-economic entities adjacent to (or dependent on) natural systems.

SESF analysis involved using primary and secondary data on ecological impact, infrastructure access, stakeholder behavior, and wastewater governance, so it is a first step in demonstrating the use of a complex analysis framework in a notoriously data deficient context: urban informality.

ENVIRONMENTAL GENTRIFICATION OR ENVIRONMENTAL JUSTICE? THE FRAMING OF URBAN GREEN SPACE

LAUER, Caroline [University of North Carolina at Chapel Hill] clauer@live.unc.edu, presenting author

Public urban green space has been touted to provide a variety of social and environmental benefits, such as filtering air, attenuating noise, cooling temperatures, receiving stormwater, and replenishing groundwater.[1] Green space amenities, however, are not equitably distributed and are “highly stratified based on income, ethno-racial characteristics, age, gender, disability, and other axes of difference.”[2] The disparity in access to green space has been recognized as an environmental justice issue that advocacy organizations have dedicated themselves to addressing. As green space has expanded in traditionally underserved neighborhoods, however, those same organizations have begun to frame the arrival of green space as environmental gentrification.[3] While scholars have studied how organizations have engaged in environmental justice or environmental gentrification processes, tracking the evolution of an issue from “justice to gentrification” has not yet been addressed. How has the framing of publicly owned urban green space by community organizations changed over time, specifically in relationship to changes in demographics and property values?

This question is addressed in this paper through a comparative case study of two neighborhoods and organizations that have been at the center of environmental justice and environmental gentrification conversations: Alternatives for Community and Environment (ACE) in the Roxbury neighborhood of Boston, MA and WE ACT in the Harlem neighborhood of New York, NY. An “attention indicator” was created for each organization by coding their publications, social media presence, op-eds, as well as news coverage of the organizations from 2000 – 2019 to categorize their work on green space as either an environmental justice or environmental gentrification issue. This attention indicator was tracked alongside U.S. census data of demographic changes and changes in property values in the respective neighborhoods to understand the corresponding context of the change in framing of urban green space.

Preliminary findings suggest that the framing of urban green space by advocacy organizations as an environmental justice or environmental gentrification issue is correlated with a change in the demographic composition of a neighborhood but not a change in property values. An environmental justice framing is more common when a neighborhood is a majority-minority population and an environmental gentrification framing is more common as white residents begin to outnumber minority residents of a neighborhood. The change in framing is not correlated with a change in property values.

This research makes an important contribution to bridging the environmental justice and environmental gentrification literatures by studying how the same issue can be framed differently by the same organization over an extended period of time. This analysis of shifts in framing may also have important implications for our understanding of belongingness in a gentrifying neighborhood, a key research agenda for those studying neighborhood change.[4]

(UN)EQUAL TERRITORY OF ACCESSING URBAN GREEN SPACES: A COMPARATIVE STUDY OF 341 PREFECTURE-LEVEL CHINESE CITIES.

Abstract ID: 883

Individual Paper Submission

WU, Longfeng [Harvard University Graduate School of Design] lwu@gsd.harvard.edu, presenting author

Urban green spaces (UGS) provide multiple ecosystem services to residents, including recreation, air cooling and cleaning, storm runoff mitigation, soil preservation and carbon sequestration, and more. In Chinese cities, typically in dense urban built-up areas, green spaces are often limited due to ongoing processes of rapid urbanization which deprioritizes UGS development. This often leads to the unequal provision of UGS among a city’s residents, which results in a number of negative consequences for both social integrity and sustainable development at a boarder scale. Though a limited number of studies investigate spatial mismatches of UGS in individual cities, it is difficult to compare the results across many distinct cities due to the varying definitions, scales, and evaluation methods employed within each. Fueled by contemporary development of big-data, this study develops two useful urban green space equality indexes based on the Gini-coefficient to compare the green space-related inequality among multiple cities. One is an urban green space equality index (UGSE) measuring the equitable distribution of overall urban vegetation within a city; and the other is an urban public green space equality index (PGSE) focusing on public’s access to vegetated spaces.

The UGSE and PGSE at the national scale are 0.459 and 0.631, respectively (higher means more unequal). Strong disparities have been found in urban green space provision within the 341 case study cities. The UGSE ranges from 0.087 (Alashan) to 0.884 (Jiuquan), and the PGSE ranges from 0.059 (Naqu) to 0.884 (Lasa). Statistical analysis confirmed a significant association between urban green space equality and socio-economic statuses of a given city. Cities with a greater percentage of highly educated residents tend to have a higher level of inequality of accessibility to urban green spaces and parks. The

average housing area per capita of a city is negatively associated with urban green space inequality. A city with a higher share of urban hukou residents (often considered to be advantaged residents of a city) provides more equal distribution of both urban green spaces and public green spaces. These findings can help decision makers evaluate regional disparities in urban green space inequality thereby providing important information for urban green space provisioning, policy, and planning.

Understanding the spatial pattern of energy consumption within buildings is essential to urban energy planning and management. In this study, we explore the spatial complexity of residential energy usage intensity, with a focus on urban form and geomorphometry attributes of urban ventilation, solar insolation, and vegetation. We use building energy use data in Chicago at a Census tract level and merge information from various datasets including parcel attributes, three-dimensional geometry, aerial imagery, and Census. Using spatial regression models, we find that while vegetation and isolation have more local impact on energy intensity, urban porosity and roughness length have consistent spillover effects on building electricity usage intensity in Chicago. Additionally, these relationships are seasonally varied.

This study can aid planners to think critically about low-carbon urban form and formulate spatially explicit policies to improve residential energy efficiency through land use patterns. Our findings indicate that local planning efforts to mitigate climate change should include urban ventilation strategies. In

addition, the spatial spillover effects must be carefully considered when developing these strategies in summer to reduce building electricity EUI. For instance, the urban porosity level in adjacent neighborhoods must be kept high to promote the intrusion of the cool air, especially in summer. Meanwhile, the surface roughness must be kept low to potentially formulate the ventilation path in urban environments (Barlag and Kuttler, 1990; Gál and Unger, 2009). Finally, neighborhood-based urban form strategies should become part of the policy mix to control EUI, as well as to mitigate and adapt to climate change, regardless of the effectiveness of the current local planning efforts to increase building energy efficiency at the building or household levels.

INTEGRATED CLIMATE ACTION: HARMONIZING CLIMATE CHANGE MITIGATION AND ADAPTATION IN TRANSPORTATION AND LAND-USE PLANNING IN CALIFORNIA CITIES

Abstract ID: 902

Individual Paper Submission

ALEXANDER, Serena [San Jose State University] serena.alexander@sjsu.edu, presenting author
WEINSTEN AGRAWAL, Asha [San Jose State University] asha.weinstein.agrawal@sjsu.edu, co-author
BOSWELL, Michael [California Polytechnic State University, San Luis Obispo] mboswell@calpoly.edu, co-author

Recent extreme weather events in California—wildfires, drought, and flooding—make abundantly clear the need to plan effective responses to climate change. At the municipal level, comprehensive planning for climate change involves a two-pronged approach, identify and implement strategies to both reduce greenhouse gas emissions (“mitigation”) and adapt communities so that they will be less affected by the adverse impacts of climate change (“adaptation”). The goal of this paper is to identify municipal transportation and land-use (TLU) policies and programs that support both climate mitigation and climate adaptation goals—so called “integrated actions”—as well as to identify state actions that can support cities planning integrated actions to address climate change. The value of integrated actions has recently become widely acknowledged; current research emphasizes the importance of integrating mitigation and adaptation in order to develop cost-effective strategies to combat climate change and protect vulnerable communities. The overarching question that we aim at answering is: how can California maximize the opportunities for local governments to adopt TLU programs and policies that reduce transportation GHG emissions while simultaneously enhancing community resilience to climate change impacts? This research involves three major phases: a comprehensive review of the literature; a content analysis of 23

municipal climate action plans (CAPs) and their related documents, such as any progress monitoring documents, general plans and zoning codes; and interviews with municipal and state administrators involved in the CAP processes. We found a wide diversity of planning processes and documents to address climate change and a range of efforts to integrate mitigation and adaptation in TLU planning in California cities. Despite the theoretical benefits of integrated actions, planners might find them hard to develop in practice for a variety of reasons. One problem is that both local and state governments have often addressed mitigation and adaptation in separate plans, and also sometimes prioritized one over another. The result can be major conflicts between mitigation and adaptation strategies. For example, encouraging high densities in urban areas can reduce vehicle miles traveled, and thus mitigate transportation emissions. However, densely-built environments risk making communities less resilient: communities with less open space may face higher flooding risks and be more likely to suffer from an urban heat island effect. As a conclusion, without a clear, coordinated effort to combine adaptation and mitigation goals into a holistic vision, mitigation strategies can potentially undermine adaptation goals and vice versa. Findings of this research can help planners identify steps that local and state government can take to create positive interrelationships between mitigation and adaptation in the TLU sector through innovative planning, policymaking and implementation.

CARRERA, Lindsay [University of Minnesota] carre043@umn.edu, co-author

In 1969, Ian McHarg published his seminal book *Design with Nature*. In it, he articulated an ecologically informed theory and method for planning. In the same year, McHarg and his colleagues, Wallace, Roberts, & Todd, prepared a report on the ecological conditions of the Twin Cities for the Metropolitan Council of the Twin Cities, which applied McHarg's approach, at scale, for the first time (Wallace, et al. 1969). This paper uses WMRT's work in the Twin Cities to evaluate the practical impact of McHarg's

approach to designing with nature. Here, we report on a two-pronged, mixed-methods evaluation of “An Ecological Analysis of the Twin Cities Metropolitan Region” completed to commemorate the fiftieth anniversary of the publication of “Design with Nature.”

First, we conducted a qualitative analysis of policy changes made by the Twin Cities Metropolitan Council in reaction to the WMRT report. We analyzed historic documents and conducted key informant interviews to identify McHarg’s recommendations to the Metropolitan Council and assess how those recommendations influenced regional policy development. Findings from this analysis were inconclusive. On one hand, the documents we reviewed pointed to a connection between McHarg’s report and policies adopted by the Met Council. However, key informant interviews suggested that, behind-the-scenes, McHarg’s influence on regional policy was negligible.

Second, we conducted a quantitative spatial analysis of the product of McHarg’s method: the Intrinsic Suitability Map. The purpose of this analysis was to compare McHarg’s map to contemporary land cover in order to assess the predictive accuracy of McHarg’s method. McHarg’s original paper map, which was approximately 45,000 square centimeters and contained more than 13,000 unique, hand-painted spatial features, was scanned, geo-referenced, and digitized. ArcScan, an add-in to Esri ArcGIS Desktop 10.6.1, was used to convert the image to a line vector layer defining the ecological areas. While the scanning process identified the majority of the lines, about 130 hours of manual editing was required to close polygons and remove leftover artifacts. Finally, the lines were converted to polygons, allowing the ecological area attribute to be added. The resulting spatial dataset was then rasterized and compared to 2016 land cover using tabulate intersection, which creates a matrix of values comparing both input layers. Preliminary results show that McHarg’s vision for land use has consistently tracked land use change in the Twin Cities Metropolitan region over the last fifty years.

Taken together, results from this study provide an intimate portrait of regional planning in the United States. While McHarg’s method was billed as the rational integration of ecological science into environmental planning (McHarg 1981), like other rational planning models, it struggled to account for the political dynamics of local land use planning (Fishman 2000). While our evidence suggests that McHarg may not have anticipated or appreciated the nuanced political dynamics of planning - and may have in fact attempted to plow through them, decision-makers and planners in the region were more attuned to these forces. By working with McHarg’s systematic analysis, regional planners were able to establish a protocol for shaping policy and impacting land use change. Thus, much of the long-standing success of the Met Council might be attributed to the practical lessons planners and policy-makers learned by working with Ian McHarg.

Green infrastructure (GI) is an important tool that can be used to reduce temperatures in an Urban Heat Island (UHI) as well as having many other meteorological, climatological, and ecological co-benefits. Additionally, GI plays an important role in climate adaptation and action plans. The Urban Climate Lab at Georgia Tech developed a high quality and dense urban GI network of sensors that aims to capture the temperature and relative humidity impacts of trees. The network of sensors was set up in urban Atlanta, GA in a greenspace that was primarily grass and bordered with trees that provided a boundary between the greenspace and major roads. Temperature and relative humidity sensors were set up at 2 m high and, starting at the trunk of the tree, were placed every 2 m moving away from the tree. As a control variable, sensors were placed in the middle of the greenspace far removed from any trees. The sensors captured distinct temperature reduction patterns. By understanding how street trees reduce temperature in urban areas, planners and policy makers are better equipped to develop effective environmental plans and design outdoor greenspaces that are not only important public spaces, but are also an essential part of a city's climate adaptation policies.

Planning for urban water conservation requires an understanding of how and where water is used in cities. There is significant evidence that urban water use is related to the characteristics of the residents, housing types, and landscaping patterns (Wentz and Gober 2007; Morales et al. 2011; Randolph and Troy 2008). At the same time, a growing body of research has shown geographic clustering of high or low water use at the neighborhood scale (Chang et al. 2010). This paper explores how the characteristics of neighborhoods influence water use at the parcel scale. We hypothesized that neighborhood characteristics influence water use through social dynamics as well as the physical structure of the neighborhood. Using a dataset for almost 75,000 parcels across 248 neighborhoods in Salt Lake City, Utah, we used multilevel modeling to determine how nine characteristics of neighborhoods influenced parcel-level water use. Almost a quarter (24%) of the variation in parcel-scale water use was explained by neighborhood characteristics. Controlling for key parcel-level drivers of water use, we determined that several neighborhood factors were significantly associated with parcel-level water use. For residential properties, parcels in more homogeneous suburban neighborhoods dominated by detached single family-owned homes and family households used more water than comparable parcels in neighborhoods with mixed housing and household types. Neighborhood effects were more pronounced for residential parcels than commercial, and more for outdoor than indoor water use. We suggest that planning and design strategies at the neighborhood level can contribute to urban water conservation.

‘MANAGED RETREAT’ AS AN ADAPTIVE PLANNING RESPONSE TO CLIMATE CHANGE DISPLACEMENT

Abstract ID: 956
Individual Paper Submission

DONAGHY, Kieran [Cornell University] kpd23@cornell.edu, presenting author

In the coming decades, climate change displacement of residents of coastal communities in the United States and other countries is likely to affect large portions of national populations. Estimates of sea-level

rise are constantly being revised upwards and it is not clear that strategies proposed to make coastal areas more resilient to coastal flooding—including sea walls of various design—will be effective (Goodell, 2017). Flooding and the spread of deadly wildfires are also displacing residents of inland communities as the incidence of extreme weather events (both torrential rains and droughts) increases. Not only physical attributes of communities but also social, political, and economic institutions of communities must be relocated to higher or safer ground. A major concern is that in making current assets more robust to the effects of climate change and in relocating communities—whether partially or totally—a form of ‘climate gentrification’ may be effected and existing inequalities of access to public amenities and safety from extreme weather events may be reproduced or exacerbated (Keenan et al., 2018). Given the failure of climate change mitigation strategies (for a large number of reasons, many of which are political), city and regional planning academicians and practitioners are faced with a number of challenges to effective climate adaptation planning. These challenges include 1) developing reliable projections of sea-level rise, coastal and inland flooding, wild fires and other extreme-weather event incidence; 2) working out social, economic, and environmental impacts of climate-change-related effects, 3) exploring response strategies that are effective in the short run in promoting greater resilience, sustainability, and social equity, but which put communities on the ‘right paths’ in the long run. Response strategies now under consideration include so-called ‘managed retreat.’ Although much legal groundwork has been laid to help communities think through whether and when to initiate managed retreat, or begin planning for the same (see Siders, 2013 and resources from the Georgetown Climate Center), the science informing retreat remains ill-defined and policy discussions complex and contentious. In a previous paper I sketched and demonstrated the workings of a spatial-dynamic model of the effects of sea-level rise, storm-related damage, and climate-change-related displacement and gentrification (Donaghy, 2018). In the present paper I elaborate and implement an integrated assessment model for supporting adaptive response planning over the short- to long-run planning horizons. The model is calibrated with data from New York State communities and introduces to a climate adaptation planning environment applied stochastic optimization appropriate for historical distributions of extreme weather events (Hanson, 2007). I demonstrate how the model may be used to support the practice of retreat management from areas under threat from climate change displacement—to bring about resilient, sustainable, and equitable outcomes—with proof-of-concept stochastic simulations. I also assess the model’s performance properties.

MODELLING THE IMPACTS OF CITY-SCALE “VENTILATION CORRIDOR” PLANS ON INTRA-URBAN PM_{2.5} POLLUTION EXPOSURES

Abstract ID: 976

Individual Paper Submission

LIU, Chao [Tongji University] liuchao1020@gmail.com, presenting author

Chinese cities have proposed varieties of urban plans, strategies and managements in response to severe intra-urban fine particulate (PM_{2.5}) pollution in past years. Among them, city-scale ventilation corridor (VC) is one aggressive but popular proposal. The assumption behind the VC plans is that VCs can alleviate pollution levels by increasing wind velocity and pollution dispersions. However, the influence of VC is ambiguous and has not been well studied. So this study quantifies the impact of VC solutions using City of Shanghai as an example. To develop the study, three VC scenarios were created to investigate the effects of VCs based on Shanghai's existing land use and ecological plan and prevailing wind directions. VC plans differed from the status quo on the city morphology and land uses. Meteorological change before (Base scenario) and after (VC scenarios) urban VC plans was modeled by the Weather Research and Forecasting (WRF 3.9) model incorporating with Single-Layer Urban Canopy Model UCM in this study. Then a hindcast simulation was performed using the Community Multiscale Air Quality (CMAQ) model version 5.0.1. to create hourly PM_{2.5} pollution maps incorporating the meteorology generated with WRF-UCM. Modeling period included the summer time from July 1st to July 15th, 2014 and winter time from December 1st to December 15th, 2014. The results of PM_{2.5} pollution from CMAQ were also evaluated against the same monitors' pollution records. Then each VC scenario was assessed implemented in WRF-UCM and CMAQ to create alternative PM_{2.5} values. Finally, comparison among PM_{2.5} pollution in Shanghai base scenario and VC planning scenarios, the performance of VCs was summarized and analyzed. Modeling results indicated that WRF-UCM showed good fitness with localized parameters. The summer modeled ground-level PM_{2.5} of Shanghai is in the range of 2 $\mu\text{g}/\text{m}^3$ to 45 $\mu\text{g}/\text{m}^3$. The most heavily polluted areas were west suburbs and west city center; the coastal areas were less polluted than the inlands. Results also showed that VC-scenario's summer PM_{2.5} concentrations are higher than the baseline in the downwind areas. The winter modeling PM_{2.5} of Shanghai is in the range of 1 $\mu\text{g}/\text{m}^3$ to 64 $\mu\text{g}/\text{m}^3$. The most heavily polluted areas are the west suburbs and western city center; the coastal areas were less polluted. In general, VCs influencing areas are the VCs and adjacent areas; the affected buffer is roughly double of VCs width. PM_{2.5} concentrations increased within the VCs in both summer and winter in general, yet the upwind concentration decreased in winter. This counter-intuitive result could be explained by changes in surface heat fluxes and roughness heights that decreased planetary boundary layer (PBL) heights, deposition rates, and wind speeds induced by land use and urban height modifications. PM_{2.5} deposition flux decreased by 17% in the VCs, which was attributed to the roughness height decrease for it weakens aerodynamic resistance (Ra) and quasi-laminar (Rb) by caused by roughness height modification. PBL heights within the VCs decreased 15-100 meters, and the whole Shanghai's PBL heights also decreased in general. The modeling results suggest VCs may not be as functional as certain urban planners presumed.

BYAHUT, Sweta [Auburn University] szb0054@auburn.edu, presenting author

ROGERS, Stephanie [Auburn University] s.rogers@auburn.edu, co-author

Research focus: Urban ecosystems are increasingly at risk of being devastated by an ever-expanding city. The rapid expansion of urban areas in coastal communities, in particular, will likely lead to the conversion of undeveloped land into impervious surfaces, which degrades ecosystems, exacerbates flooding, and increases the amount and velocity of stormwater runoff. In order to minimize these negative impacts, some local governments have adopted “green infrastructure” plans and strategies in order to conserve and protect their natural resources, such as greenways, wetlands, and open spaces. This research: 1.) identifies communities that have engaged in green infrastructure planning in the Mississippi-Alabama coastal region; 2) identifies best practices among those communities; and 3) identifies landscape patterns that should be protected with the goal of transferring this knowledge to other coastal communities. This research specifically focuses on the cities of Mobile, Gulf Shores, Orange Beach, and Dauphin Island in Alabama; and Biloxi, Gulfport, Oceans Springs, D’Iberville, and Pascagoula in Mississippi.

Methodology: This research uses both quantitative and qualitative methods in order to examine current green infrastructure planning practices and their outcomes in the Mississippi-Alabama coastal region. Specifically, the comprehensive plans of the 9 cities are analyzed in order to assess if and the degree to which they have incorporated green infrastructure planning strategies. This assessment is based a plan quality scorecard of key indicators related to green infrastructure planning. An online survey and interviews with planners in these 9 cities were conducted in order to understand planners’ experiences and identify which specific factors encourage municipalities to integrate green infrastructure concepts in their comprehensive plans, specifically examining the planning organizations in which these planners work and their capacity in terms of leadership and collaboration, comprehensive planning authority and oversight, and availability of resources. Finally, actual stormwater runoff attenuation is examined, looking at the spatial configuration (e.g., size, shape, isolation, and connectivity) of open and green spaces.

Findings: The majority of municipalities in the Mississippi-Alabama coastal region have not integrated, or have integrated on a limited basis, green infrastructure planning strategies into their comprehensive plans. However, higher levels of planning capacity is associated with higher levels of green infrastructure incorporation. Municipalities that protect the integrity of green infrastructure between developed areas

have a greater capacity to mitigate local flooding and provide quality of life recreational resources to local inhabitants.

Relevance: This research seeks to improve the quality of coastal communities' plans, and the communities' quality of life, by incorporating key concepts of green infrastructure planning in to their planning process and reducing flooding events. It also promotes awareness of and provisions for green infrastructure plans in rapidly growing jurisdictions as to avoid excessive stormwater damage. This research additionally provides practical tools for governmental leaders and planners to assess their current green infrastructure, determine future needs, and develop strategies for closing this gap. This research is funded by the Mississippi-Alabama Sea Grant Consortium.

ABOVE AND BEYOND THE PERIL OF FLOOD ACT: LOCAL MOTIVATORS TO SEA LEVEL RISE ADAPTATION IN TAMPA BAY REGION

Abstract ID: 1000

Individual Paper Submission

HOLMES, Tisha [Florida State University] ttholmes@fsu.edu, presenting author
BUTLER, William [Florida State University] wbutler@fsu.edu, co-author

There are numerous barriers to climate change adaptation planning and action at the local level (Moser et al. 2010; Bierbaum et al. 2010; Hamin et al. 2014; Shi et al. 2015). The literature on these barriers has been developed over the last decade with a focus on discovering what impedes progress on climate change adaptation at the local level. By and large, this literature implies that the presence of inverse conditions will create a context in which local governments are more likely to act. So, with leadership, political will, resources, technical capacity, good quality information, and public buy-in to climate change, climate change adaptation will be more easily accomplished. While this is perhaps obvious, it is also possible to imagine scenarios where there are few barriers, but the motivation to act remains limited and adaptation planning is not undertaken, particularly given the long-time horizons of many climate change impacts such as sea level rise. In this paper, we pose the question, not of how to remove barriers, but rather, how to motivate action.

There has been much less written about motivating climate adaptation action. Risk perceptions and hazard salience have been found to influence whether or not communities are more willing to adopt adaptation

measures. When events happen that lead to physical damage and those hazard events might be attributable to or enhanced by climate change, public perception or political will can shift and adaptation policies are more likely to be adopted (Butler et al. 2016). Moreover, having access to quality and credible planning intelligence such as sea level rise projections and scenarios can facilitate action; however, it is not clear that such information is sufficient to motivate action (Butler et al. 2016). Beyond these structural and contextual variables to motivate action, there remains a major gap in the literature. We seek to respond to this gap by answer the following research question: What are the factors and attributes that motivate local planners to address climate change adaptation?

In this paper, we draw on a study of coastal communities in the Tampa Bay region in Florida to determine what factors and attributes motivate local planners to address sea level rise. This context is relevant for study for two major reasons. First, the Tampa Bay region is on the OECD list of top ten most vulnerable cities in the world to climate change impacts—the issue is salient and relevant to coastal communities in this region. Second, the state of Florida enacted the Peril of Flood Act in 2015 which mandates that communities required to have a coastal management element in their comprehensive plan address a range of sources of flood risk including risks associated with sea level rise. We examined every comprehensive plan from the thirty-six coastal municipalities and counties in the region to determine what actions they were taking and then we interviewed planners where actions went beyond the requirements of the act to determine what motivated more progressive action in these communities.

PREDICTING THE EXISTENCE AND PERFORMANCE OF U.S. WATER QUALITY TRADING PROGRAMS

Abstract ID: 1010

Individual Paper Submission

BENDOR, Todd [University of North Carolina at Chapel Hill] bendor@unc.edu, presenting author

TIMMERMAN, Dylan [University of North Carolina at Chapel Hill] dylantim@live.unc.edu, co-author

Recent years have seen a ground-swell of bi-partisan support for market-based environmental policies, such as water quality trading (WQT). WQT programs include a number of arrangements for redistributing pollution that can increase the efficiency with which polluters can reduce effluent. However, the performance of WQT programs is uneven; while several WQT programs have found frequent use, many experience operational barriers and exhibit low trading activity.

Evaluations of WQT programs have tended to focus solely on a few successful programs, producing little evidence about what sort of program trading structures exist, or even if trades regularly occur. Few studies have sought to understand the abundance of WQT programs (including small-scale programs), where they tend to be established, and where trading actually occurs (as opposed to pilot studies or programs that exist only on paper). Currently, there is little research that attempts to look across geographies and market designs to comparatively study different types of trading programs. Comprehensive analysis is needed to better understand the factors promoting, or detracting from, the viability of WQT as a resource protection strategy and to synthesize policy lessons for improving program design, implementation, and performance.

What are the common inhibitors to implementation WQT programs? Where and why have these programs overcome barriers to become functional and productive and when do these programs frequently become stalled in their implementation?

In this presentation, we present the most complete database to date on WQT programs in the United States. We have compiled program information from numerous data sources over the last two years, creating a geo-database of trading programs. Each program includes separately mapped markets that are specific to separately traded pollutants, distinctive geographic service areas, market designs, and distinct trading mechanisms. Drawing on demographic, political, urban, and environmental co-variables, we use logistic regression modeling to better understand factors associated with the existence and relative operating state of WQT programs. We use this analysis to generate lessons that can inform program design and implementation, as well as improve our understanding of why WQT programs often have limited implementation and performance.

EXAMINING THE ASSOCIATION BETWEEN PHYSICAL CHARACTERISTICS OF URBAN GREEN SPACE AND SUMMERTIME LAND SURFACE TEMPERATURE: A CASE STUDY OF INDIANAPOLIS, INDIANA.

Abstract ID: 1020

Individual Paper Submission

YOO, Sanglim [Ball State University] syoo@bsu.edu, presenting author

The warming trend of US cities became significant since the late 1970s and the rate and magnitude of this trend have become more severe since the late 1990s. According to the National Climatic Data Center, 2012 was the warmest year on record (NOAA, 2013). More frequent occurrences of extreme heat events like those in 2012 have the potential to exacerbate negative public health outcomes and the air and water quality in cities. Heatwave is frequently not considered to be severe or adverse weather condition in Midwest, however, it is a leading cause of weather-related fatalities and also directly linked to poor air quality which is one of the most severe environmental and health concern of the Midwest region (USGCRP, 2016). City of Indianapolis, Indiana, which is the main subject of this study, is one of those U.S. cities where the Urban Heat Islands (UHIs) have grown in largest numbers in recent years (Stone et al., 2012).

The rapid increase of impervious surface and the density of development that accompanies urban growths has reduced the number of green spaces in the urban landscape and increased the land surface temperatures of urban areas. Even though many empirical research identified urban greening as one of the most effective approach to mitigate the Urban Heat Islands (UHIs) effects, there are limited research investigated the most effective and practical green space design for reducing the land surface temperatures (LSTs). This study tries to fill this gap.

This study will explore the most practical urban green space design that can contribute the reduction of the summertime LSTs focusing on following two aspects of urban green space: first, its physical characteristics and second, its functional characteristics. Based on the principles of landscape ecology, the physical characteristics of urban green spaces are defined as shape, size, isolation and diversity (McGarigal, 2002). Using FRAGSTATS software, physical characteristics of urban green spaces will be quantified. The functional characteristics of urban green spaces were measured using land use type of their surroundings, Normalized Difference Vegetation Index (NDVI), and Park Cooling Index (PCI). This study will use Landsat ETM+ images to examine the summertime LSTs and physical and functional characteristics of urban green spaces in Indianapolis, Indiana. The result of this study will provide a practical design guideline for urban green spaces to mitigate UHIs.

DO SQUEAKY WHEELS COMPOUND URBAN TREE CANOPY DISPARITIES?: SPATIAL ANALYSIS OF RESIDENT REQUESTS AND MUNICIPAL FORESTER EVALUATIONS

Abstract ID: 1029

Individual Paper Submission

GEISLAR, Sally [University of South Florida] sgeislar@usf.edu, presenting author
HUFF, Emily [Michigan State University] ehuff@msu.edu, co-author

The benefits that trees provide urban areas range from improved air quality and increased energy efficiency to recreational opportunities and positive emotional effects (Dwyer et al., 1992; Kuo, 2003). Despite the many benefits provided by a healthy urban tree canopy, there are millions of municipally-owned trees that pose hazards or create a nuisance for residents. Unfortunately, many cities have insufficient resources to maintain these trees and often rely on multiple sources of information to prioritize tree maintenance, such as professional arborist inventories and resident requests for maintenance. However, potential mismatch between what residents perceive as a tree care need and priorities as assessed by professional arborists may create or contribute to tensions between residents and their municipality.

The role of municipal forestry operations has yet to be fully examined within this context. In many American cities, urban forestry maintenance priorities are established via citizen requests for tree work (e.g., phone calls, on-line tickets). If citizen requests do not accurately represent the work needed across the population of municipal trees, or requests are received in an unbalanced manner, prioritization of maintenance may not be ecologically sound or may over-represent neighborhoods.

While previous research has shown that there are often disparities in existing urban tree cover and quality by race, income, and owner-status, this is the first study to investigate disparities in resident requests for maintenance and city inventory priorities. Landry et al. (2009) found that low income, predominantly African American neighborhoods may have less tree cover or trees of poor quality. There is also evidence that tree planting initiatives are not equitable, but rather favor neighborhoods with a lower concentration of poor and non-white residents (Watkins et al., 2016). A better understanding of how tree maintenance priorities, resident requests, and socioeconomic factors relate to one another is needed to ensure that urban canopy disparities are not compounded at the stage of prioritizing tree maintenance.

We test three hypotheses using data from professional inventory of tree maintenance needs, resident tree maintenance requests, and socioeconomic variables in Grand Rapids, Michigan. First, we expect that resident requests for tree maintenance do not correlate with the condition of trees based on the city inventory evaluation of maintenance needs as assessed by a professional arborist. Second, we hypothesize that census blocks with residents of higher socioeconomic status are more likely to request tree work. Finally, we expect that census blocks with residents with lower socioeconomic status are more likely to have trees in poor condition.

We will conduct spatial analysis to test these hypotheses. Specifically we will analyze the spatial point patterns of inventory and requests using Pairwise Correlation Function. We also analyze the relationship between spatial position and non-spatial value of each data point (e.g., tree quality) using Geographically Weighted Regression. Results will demonstrate whether two points are related: a tree with a designation of 'needs maintenance' and a tree that has received a 311 request for maintenance.

Municipal foresters stand to benefit from tools that improve prioritization of limited resources, and that increase trust between residents and arborists. This research contributes to the ability of municipal officials to visualize and quantify their tree maintenance needs and to compare the maintenance needs with resident perceptions of maintenance needs. This research also demonstrates a research method and products (e.g., maps) that help prioritize city resources and build trust within possibly disenfranchised neighborhoods. This research aims to build a process that increases transparency and provides opportunities for officials and residents to work together on municipal tree care, supported by objective data and multiple perspectives.

WHERE ARE THE KEY BARRIERS TO CLIMATE CHANGE ADAPTATION? ASSESSING BARRIERS TO SEA LEVEL RISE PLANNING IN FLORIDA

Abstract ID: 1039

Individual Paper Submission

BUTLER, William [Florida State University] wbutler@fsu.edu, presenting author
HOLMES, Tisha [Florida State University] ttholmes@fsu.edu, primary author
MILORDIS, Anthony [Florida State University] amilordis@fsu.edu, co-author

It has been well documented that global warming mitigation is falling short of the necessary pace to arrest many of the significant impacts associated with climate change. Given this reality, climate change adaptation is imperative. Many of the impacts associated with climate change will manifest at local and regional scales through droughts, storms, floods, heat waves, and sea level rise which places much of the adaptation action responsibility in the hands of local and regional planners. Despite this reality, local adaptation planning and action lags the need due to a range of barriers.

The literature on barriers to climate change adaptation is relatively extensive and well developed. Through both qualitative case studies and large-scale surveys, scholars have demonstrated that numerous barriers that can impede climate change adaptation planning and action at the local government level. These include high uncertainty and limited information, insufficient resources and technical capacity, a lack of leadership or political will to invest and act, conflicting priorities and tradeoffs in the face of more pressing concerns, pervasive denial of the salience of the issue, and a lack of mandates from higher levels

of government (Moser et al. 2010; Bierbaum et al. 2010; Hamin et al. 2014; Shi et al. 2015). This literature is less clear on which barriers are the most prevalent, most important, most limiting in impeding climate change adaptation.

This paper seeks to add nuance to this analysis of barriers through a statewide survey of coastal planners in the State of Florida. Florida is on the frontlines of climate change impacts, particularly accelerating sea level rise and tropical cyclone intensification. Sea level rise risk was added as a required consideration in coastal jurisdictions in the 2015 Peril of Flood Act. Thus, sea level rise is generally on the mind of coastal planners in Florida. We have developed and opened a survey that promises to shed light on the question of barriers by asking local planners to assess the types of barriers they experience, the extent to which they experience barriers, and to rank order the barriers they face. Through the survey analysis, we expect to be able to determine whether or not community population, geographical setting, dominant economic industry, tax revenues and other community factors correlate with different types or rankings of barriers. We also expect to be able to assess the relationships between barriers to determine those that are mutually reinforcing or unrelated. These findings will contribute to knowledge on climate change adaptation barriers at the local level, their relative importance based on key community characteristics, and ways that planners can begin to address them in more strategic ways.

REVISITING AFFORDABILITY: INSIGHTS FROM WATER RATE INCREASES IN THE US

Abstract ID: 1043

Individual Paper Submission

SOLIS, Miriam [UT Austin] solis@austin.utexas.edu, presenting author

Since 2010, the average residential water bill has increased by nearly 50%. The rise in water costs is attributed to several factors, including utilities' efforts to generate revenue to pay for infrastructure rebuilding projects. This paper asks, how are notions of water affordability conceptualized? How are increasing water costs linked to the multiple structural and state-sponsored practices that contribute to racialized gentrification and displacement? This paper employs Critical Race Theory's critique of abstract

liberalism (Bonilla-Silva 2015)—including claims of neutrality, objectivity, and equal opportunity—as an analytical framework to answer these questions. It aims to build on the work of Mele (2013) and others who assert the role of race as an ordering mechanism of social and spatial change.

In the United States, water affordability is administratively defined as 2-2.5% of the Median Household Income. This figure, however, was developed in the 1980s and 1990s for the purposes of gauging how a utility might negotiate regulatory compliance, based on its community's financial capability (Teodoro 2018). And when used as a measure of household affordability, the figure lacks theoretical basis. Through a survey of the literature, this paper provides a typology of the consequences of rising water costs, which includes spurring residential displacement. The paper then examines the extent to which affordability is linked to gentrification trends in the country's 25 largest cities. Findings show that high-cost cities tend to also have high water costs, but so do those cities which have experienced economic decline. These different urban contexts provide insights into the limitations of how notions of water affordability are used, as well as the consequences of these uses for the ability of people of color to pay for water services. This paper uses water affordability in Detroit and San Francisco as examples to further explore how notions of abstract liberalism sustain racialized patterns of urban exclusion.

Measures of affordability are a central way by which planners understand, assess, and respond to urban inequality. The concept is particularly prevalent in the area of housing development and preservation (Padley and Marshall 2018; Moos et al. 2018). This paper suggests that measures of water affordability are a site for critical engagement due to their potential to reproduce racialized patterns of urban exclusion. It calls for a better understanding of a growing number of programs that help residents with rising water costs, as well as how planners conceive of affordability more generally.

THE EFFECTS OF LAND USE PLAN QUALITY ON FOREST FRAGMENTATION

Abstract ID: 1053

Individual Paper Submission

GOCMEN, Asligul [University of Wisconsin-Madison] gocmen@wisc.edu, presenting author
ZHANG, Yan [University of Wisconsin-Madison] noorange@gmail.com, primary author

The spatial composition and configuration of forestland have been continuously altered, resulting in significant fragmentation of forestland throughout the United States (Riitters et al. 2002). The fragmentation in forestland has caused loss of wildlife habitat and biodiversity, altered ecosystem

functions, and has negatively impacted timber industry and forestry. Consequently, forest fragmentation has been considered as one of the most serious threats to ecosystems, and thus has become a central concern to policy makers and environmental and conservation planners (Girvetz et al. 2008). By identifying future locations and characteristics of development, land use planning can play an important role in shaping our landscapes and preserving our forest resources (or even accelerating forest fragmentation). Despite such important roles land use planning may play, previous studies on forest fragmentation have frequently neglected to integrate the role of land use planning in their research design. In addition, forest fragmentation studies are rarely conducted at socioeconomically or politically meaningful levels, making it difficult to connect between human related processes and ecosystem functions. These prior studies provide limited information to planners to adopt prompt and suitable strategies to mitigate forest fragmentation in their own local settings.

This study attempts to fill these research gaps by investigating the effectiveness of municipal level land use planning on forest fragmentation dynamics from 2001-2011 in the state of Wisconsin. We argue that the commonly used planning capacity variables in assessing the role of planning practice in sustainability studies (e.g., presence of a comprehensive plan) may not sufficiently explain success in forest fragmentation mitigation. Instead, the quality of a municipal comprehensive plan with regards to forest preservation may play a more important role in mitigating forest fragmentation because it directly reflects the community's attitudes, resources, and policies on forest preservation.

In order to test this hypothesis, we reviewed 28 Wisconsin municipal comprehensive plans. We selected these plans based on a prior statewide analysis that investigated the impacts of a set of socioeconomic, geophysical, and policy factors (see, for instance, Croissant and Munroe, 2002; Radeloff et al., 2005) on forest fragmentation change between 2001 and 2011. These plans represented communities with unexpected forest fragmentation change rate in that period, that is, the community-based socioeconomic, geophysical, and policy factors did not fully explain forest fragmentation in these municipalities. In assessing land use plan quality and conceptualizing its impacts on forest fragmentation, we used a framework developed by Berke and Godschalk (2009).

Findings from our study suggest that municipalities with lower-than-expected forest fragmentation have high quality land use plans that help mitigate forest fragmentation, while those with higher-than-expected forest fragmentation have low quality land use plans that may facilitate forest fragmentation. In other words, this study demonstrates the importance of plan quality on forest protection rather than the mere presence of a local plan prepared as a requirement of the Wisconsin's Comprehensive Planning Law. Study results will help provide forest fragmentation mitigation guidelines to communities that are preparing comprehensive and other land use plans.

THE LANDSCAPE OF SEA LEVEL RISE RESOURCES IN CALIFORNIA: LESSONS FROM ACTION TYPOLOGIES AND BARRIERS

Abstract ID: 1059

Individual Paper Submission

HIRSCHFELD, Daniella [UC Berkeley] daniellah@berkeley.edu, presenting author

HILL, Kristina [UC Berkeley] kzhill@berkeley.edu, co-author

RIORDAN, Bruce [Climate Readiness Institute] bruce@climatereadinessinstitute.org, co-author

Theoretical Context and Questions

As climate impacts are directly experienced and a broader community of organizations and agencies are engaging in climate adaptation, there is a growing urgency to use empirical evidence to guide our theoretical understanding of climate change adaptation (Biagini et al. 2014). Additionally, with limited local capacity there has been an increase in boundary organizations, which work to mediate between scientists and non-scientists (Nordgren, Stults, and Meerow 2016). In sea level rise in particular this is a need to consider the different typologies of actions and how these categorizations can induce or inhibit progress (Hill 2016). In this context our research explores two broad questions. First, what is the connection between theory and practice? We use empirical data to derive critical lessons for theories on climate adaptation broadly and sea level rise theory in particular. Second, we explore the question, are current guidance resources meeting the critical needs of local practitioners? Specifically we check to see that available resources match with the barriers practitioners identify.

Approach & Methods

In this project we address this knowledge gap with special attention to empirical data. Specifically, in our project, we develop a mixed methods approach. In 2017 a research team conducted an analysis of current resources available in California through two interlinked approaches: 1) interviewing local government practitioners to understand their work and the challenges they face; and 2) mapping sea level rise resources in the state of California.

Preliminary Findings and Contributions

By cross comparing empirical data with existing theoretical frameworks and action typologies, a more solid understanding of what sea level rise planning is from a practice perspective has emerged. The insights researchers gleaned from this analysis will enrich both academic discussion and boundary organizations ability to assist local practitioners. Additionally, in this study we demonstrate that significant weight should still be placed on developing resources and on evaluating different action options. This critical step can significantly reduce actions that would lead to maladaptation and can better integrate across competing needs.

SEPTIC SYSTEM DENSITY AND WATER RESOURCE CONTAMINATION: A SPATIAL RISK AND POLICY GAP ANALYSIS IN THE GREAT LAKES REGION

Abstract ID: 1086

Individual Paper Submission

VOWELS, Bradley [University of Wisconsin Madison] btvowels@gmail.com, presenting author
LAGRO, JR., James [University of Wisconsin-Madison] jalagro@wisc.edu, co-author

Septic systems collect and slowly release wastewater back into the natural environment. According to the U.S. EPA, failing septic systems are the second greatest threat to groundwater quality in the United States. If septic systems are not properly installed or maintained, or are clustered at high densities, they can introduce nitrates, bacteria, viruses, and other contaminants into local groundwater and surface water. In Wisconsin, more than 760,000 septic systems have been installed using county-based policies guided by state law. Around 35% of these systems were installed before 1971 when the state began enacting more restrictive septic system policies. Today, little information is available regarding the performance of many older septic systems, but many are still in operation and may be near the end of their functional lives. Permissive land uses policies and recent advances in septic system technology coupled with a transition to a performance-based septic system code in 2000 continues to enable development of non-sewered housing clusters served by private wells and on-site septic systems in southeastern Wisconsin on sites that were once considered unsuitable. And, it is estimated that nearly 33% of Wisconsin's landscapes may be unsuitable for non-sewered development due to natural constraints. These unsewered housing clusters can create "hot spots" of groundwater and surface water contamination that can jeopardize human and environmental health. Studies have indicated that up to 50% of private wells may be contaminated across Wisconsin, but the origins of this contamination are widely disputed. This groundwater contamination may go unnoticed by homeowners, since less than 10 percent of Wisconsin's private well owners test their wells annually.

We conducted a spatial statistical water vulnerability analysis of private well monitoring results collected over the past three decades using a hierarchical regression model to better understand social and environmental characteristics of contaminated well distributions across the region. Our spatial analysis in southeastern Wisconsin identifies septic system clusters that may have elevated risks of groundwater contamination that could be targeted for additional groundwater quality monitoring studies or local policy changes to help protect local water resources. We also conduct a policy gap analysis comparing Wisconsin's state and local septic system policies to the US EPA's septic system policy recommendations and best management practices. We find that Wisconsin policies fall short of many recommendations. Changes in local policies that require larger minimum lot sizes for non-sewered development and foster citizen education initiatives to promote periodic well monitoring and septic system maintenance can help exurban households protect their drinking water. For local governments, mapping installed septic systems and analyzing land use suitability should be integrated into local community planning efforts. This spatial

risk and policy gap analyses can help decision-makers know where and how they may be able to implement stricter land use and septic system policies to protect more vulnerable water resources.

GETTING TO ZERO? PROGRESS ON THE ACUPCC PRESIDENTS' CLIMATE COMMITMENT

Abstract ID: 1096

Individual Paper Submission

WHITE, Stacey [University of Kansas] sswhite@ku.edu, presenting author

Starting in 2006, colleges and universities in the U.S. embarked on momentous efforts to address climate change through a program called the American College and University Presidents' Climate Commitment (ACUPCC). Signatories to this commitment pledged not just to inventory and lower their institutions' greenhouse gas emissions, but to achieve climate neutrality. Perhaps even more dramatic than the extent of this pledge was the sheer number of signatories. Three hundred and seventy-nine institutions signed on in the initial charter period, with hundreds of other schools making later pledges.

An earlier study of the early ACUPCC participants (White, 2009) found that there were no defining characteristics of the 379 charter signatories. Schools from forty-six states, public and private and small and large all committed themselves to these efforts. Now, ten years later, it is appropriate to follow up with an analysis of how these institutions have performed with regard to their pledges. To that end, this paper poses three questions: first, what specific implementation steps did each institution set in order to reach its emissions reduction goals? Second, what is the status of those efforts? Third, what factors appear most influential in the success (or lack of success) in the implementation of these climate commitments?

Policy implementation scholarship examines both compliance with particular policy requirements as well as the quality of that compliance. In other words, both outcomes and outputs are important (Lester & Goggin, 1998; Goggin et al., 1990). In addition, scholars have explained implementation behavior with respect to three characteristics: (1) the environment in which implementation decisions and actions take place; (2) the attributes of the policy; and (3) the implementers and their organizations (Goggin et al., 1990, p. 20). Implementation of the ACUPCC commitment can be examined using a similar framework.

This paper uses a mixed methods approach to address the research questions. Publicly available information from college and university websites will be gathered to describe and assess the progress each early signatory has made. (Part of the ACUPCC pledge is a requirement to publicize the institution's efforts and results.) Data gleaned through this search will inform the development of an electronic survey to send to the person or persons from each institution who the websites indicate are responsible for implementing the pledge. The survey will explore aspects of ACUPCC implementation such as perceived progress and challenges.

Since colleges and universities have taken a leading role in climate action planning, the results of this paper should inform similar efforts at other levels, such as municipal and regional climate plans.

RICE AND CITIES: REFLECTIONS ON WATER SCARCITY IN EGYPT

Abstract ID: 1101

Individual Paper Submission

LASHEEN, eman [DUSP MIT] elasheen11@gmail.com, presenting author

Water scarcity is a critical problem facing many regions of our world today. In recent years, a growing body of scholarship has emerged, examining notions of 'scarcity' and how it is traditionally defined within academic and nonacademic circles. These studies challenge the established understanding of water scarcity as a physical characteristic of a region that is attributed to resource abundance relative to population, and call for a better understanding of the social, political and economic constructions of scarcity. This study furthers the investigation on the origins, making and perceptions of scarcity by examining the case of Egypt's current water scarcity dilemma. Since its inception, Egypt has been a primarily agrarian nation that depends almost entirely on the Nile's fresh water supply. In late 2018, a declaration was made by the country's minister of irrigation that Egypt has officially reached water poverty with an annual deficit of around seven billion cubic meters. Changes to water withdrawal policies ensued, targeting agriculture as the highest consuming sector, with dramatic reductions to rice cultivation due to its extensive use of water. These measures coincide with an ongoing expansion in government owned as well as private urban development with unprecedented investment in new city projects featuring large-scale urban greening. The study uses qualitative methods to analyze a host of policy documents as well as online content to understand the current framing of the water crisis. The analysis is supplemented by semi-structured interviews with local actors as well as observations from visits to rice fields and new city projects. While there's no official evaluation of the water withdrawals for 'urban development' as a distinct sector, the findings of this paper aim to question the general logic of resource allocation under

conditions of water stress, as well as the impacts of unbalanced water management, drawing attention to the need for a better understanding of both urban and rural water loss patterns.

ACCESSIBLE HEAT MORTALITY MODELING AS A FRAMEWORK FOR CLIMATE ADAPTATION PLANNING IN ATLANTA, DETROIT, AND PHOENIX

Abstract ID: 1105

Individual Paper Submission

MALLEN, Evan [Georgia Institute of Technology] esmallen@gatech.edu, presenting author
STONE, Brian [Georgia Institute of Technology] stone@gatech.edu, co-author

Extreme temperatures pose a significant risk to human health, and are projected to worsen in a warming climate with increased intensity, duration and frequency of heat waves in the coming decades. Urban residents are at higher risk of heat exposure due to the urban heat island, a phenomenon in which built materials absorb and retain heat from the sun and elevate urban temperatures. To mitigate heat exposure and protect sensitive populations, urban planners are increasingly using decision support tools like heat vulnerability indices (HVIs) to identify high priority areas for intervention and investment. However, HVIs often capture only proxy heat exposure indicators at the land surface level, not air temperatures that humans experience. Furthermore, HVIs do not allow for numerical estimates of heat mortality, thereby limiting the planner's ability to rationally choose between intervention strategies that show the greatest benefit in lives saved. This gap can be filled using regional climate models like the Weather Research & Forecasting (WRF) model to simulate air temperatures comprehensively over a city, coupled with a heat exposure-response function to estimate heat-related mortality. However, this method is often beyond the capabilities of local planning departments due to limitations in funding or technical expertise to run the model. Fortunately, publicly available air temperature datasets have been developed that may be able to replace the WRF-modeled air temperatures used in the model. This study seeks to answer: to what extent can WRF-driven heat mortality models be replicated using publicly available data sources?

Data & Methods:

This study compares heat mortality results during historic heat wave periods in Atlanta, Detroit, and Phoenix. WRF-derived air temperatures, together with exposure-response functions applied to age and sex cohorts unique to each city are used to quantify spatial distributions in mortality. Then the WRF model is replaced using an airport weather station and Daymet, a spatially comprehensive air temperature model. Total heat mortality and spatial distributions are compared to analyze the accuracy of using the more accessible temperature datasets. Each publicly accessible model is compared to the WRF-derived

mortality within each city using a paired t-test at the census tract scale to test for spatial distribution accuracy.

Results:

Publicly available temperature datasets were moderately successful in replicating the WRF-driven models. While the total mortality counts were similar between all three models, the spatial distribution differed depending on the ability of each dataset to model the urban heat island. Heat mortality was strongly influenced by population, tracking closely with high population centers in each city.

Significance:

In a warming climate, it is increasingly important for cities to adopt strategic plans to protect our most vulnerable populations from heat-related morbidity and mortality. Extreme urban temperatures are a significant problem we are already facing today. Cities must begin to monitor local temperatures now as a first step toward creating a resilient urban environment and population. This information can help urban planners and public health officials improve their emergency response plans and communication strategies for heat mitigation in urban areas by specifically targeting short and long-term responses where there is greatest need. The heat mortality models described in this paper equip planners with a useful and accessible tool to protect vulnerable populations in urban areas effectively and efficiently with minimal public funds. A neighborhood-specific, targeted approach can guide both greening policies for passive cooling as well as emergency heat response planning among sensitive populations. This research utilizes the latest scientific methods to meet contemporary climate change planning needs, and could significantly advance the policies we use to adapt to a changing climate.

SOCIAL VULNERABILITY IN THE MULTI-HAZARD ENVIRONMENTS OF RAPIDLY GROWING METRO AREAS: EXPLORING THE ROLE OF LOW-INCOME HOUSING PROVISIONS

Abstract ID: 1106

Individual Paper Submission

KASHEM, Shakil [University of Illinois at Urbana-Champaign] kashem1@illinois.edu, presenting author

Studies on urban social vulnerability have widely documented how vulnerability to natural hazards vary by socioeconomic characteristics like age, race, income, etc. (Fothergill, 2004; Peacock et al., 1997) and how the patterns of vulnerability changes over time within urban areas (Kashem et al., 2016). But there is yet to have enough study that focuses on the generative process of vulnerability and identify the policy levers which influence that process. This paper adopts the political economic framing of vulnerability production and explores how the current provisions of low-income housing in our cities may influence the process of vulnerability production. Access to affordable housing is one of the key determinants of a household's ability to withstand socio-economic stresses. Prior studies have evaluated the efficacy of low-income housing programs in the US and their effects on households and communities (Goetz 2005; Freeman 2003; Van Zandt and Mhatre 2009). However, very few studies have explored the extent to which these housing programs have affected the hazard exposure of vulnerable populations (e.g., Cutter et al. 2001; Houston et al. 2013). This paper hypothesizes that by ignoring the multi-hazard context of urban areas, subsidized low-income housing programs have failed to reduce the overall hazard exposure of socially vulnerable populations and this pattern is consistent irrespective of the planning and political context of the cities. It evaluates this hypothesis on two rapidly growing coastal metro regions of the US (Boston and Houston). By examining two of the most popular housing subsidy programs, Housing Choice Vouchers (HCV) and the Low Income Housing Tax Credit (LIHTC), this paper explores how these housing subsidies influenced neighborhood social vulnerability between 2000 and 2010. Both natural and technological hazard exposures are measured at the census tract level using publicly available data. It was found that while these programs consider neighborhood socio-economic conditions in some cases, neither of them explicitly requires the housing units to be located away from natural or technological hazards. Both housing programs were found to have contributed to a disproportionately high (relative to the overall population) presence of subsidized low-income housing units in both natural and technological hazard areas. However, the results of the spatial econometric analysis indicate that the supply-oriented subsidy provision of the LIHTC program significantly increases neighborhood social vulnerability when located in technological hazard areas. These findings warrant more critical scrutiny by planners when placing subsidized housing, particularly to evaluate how planning decisions like these may influence the hazard exposure of vulnerable populations and exacerbate environmental injustice. The limitations of market-dependent housing programs that lack adequate safeguards for avoiding hazardous areas are highlighted and potential remedies are suggested.

POST-DISASTER HOUSING RECONSTRUCTION AFTER THE MEXICO CITY EARTHQUAKE: LEARNING FROM THE LANGUAGE AND COMMUNICATION SURROUNDING THE PARTICIPATORY WORK OF NGOS

Abstract ID: 1109

Individual Paper Submission

CONTRERAS, Santana [The Ohio State University] contreras.78@osu.edu, presenting author

Participatory approaches are increasingly emphasized by NGOs engaging in post-disaster housing reconstruction and recovery projects. Latin American cities present one area where questions surrounding participatory efforts of NGOs in housing recovery are particularly relevant. Latin American cities are frequently impacted by seismic activities, which often result in high numbers of earthquake-related housing collapses. In the wake of a major event, these areas may experience a substantial amount of human fatalities and injuries from structural failures, which are often brought on by inadequate construction methods and weak enforcement of building regulations (Kenny, 2012). These large-scale housing losses frequently bring about a multitude of demands and opportunities for local community involvement, leading to increased interest by NGOs of including participatory elements in their recovery activities.

Although there is a growing awareness of the value of incorporating participation, there continue to be questions surrounding the application of this work. This can often be attributed to the frequently wide variations in how external entities may engage local communities in their post-disaster recovery projects, with scholars observing that, at one extreme, community members may be involved in projects only as the labor force whereas, at the other, they may play an active role in decision-making and project management (Davidson, Johnson, Lizarralde, Dikmen, & Sliwinski, 2007).

Evidence of differences in approaches towards participation is observable in the language used by NGOs to portray their efforts towards engaging local communities in their housing reconstruction projects. In referencing their work, NGOs may use jargon, such as being community-based, owner-driven, or focusing on assisted self-help (Lizarralde and Massyn, 2008; Lyons, 2009; Bredenoord and Van Lindert, 2010). However, this terminology may be used to describe varying or similar types of activities, with differing levels of understanding, and towards contradictory goals. Thus, specific details of how NGOs utilize language, techniques, and communication strategies in discussions of their participatory activities remains unclear.

This paper aims to explore these questions surrounding participatory activities through an assessment of NGOs engaging in post-disaster housing reconstruction projects in the wake of the 2017 Mexico City earthquake. This qualitative analysis utilizes available published materials (including websites, organizational reports, and published documents) and interviews with key informants involved in housing reconstruction activities. Findings from this work aim to highlight the important role language and communication surrounding participation play in the work of NGOs and the post-disaster planning process.

EXAMINING THE UNINTENDED EFFECTS OF CLIMATE CHANGE MITIGATION: A NEW TOOL TO PREDICT INVESTMENT-RELATED DISPLACEMENT

Abstract ID: 1132

Individual Paper Submission

JEON, Jae [University of California, Berkeley] jaesjeon@berkeley.edu, presenting author

HWANG, Jackelyn [Stanford University] jihwang@stanford.edu, co-author

ZUK, Miriam [UC Berkeley] mzuk@berkeley.edu, co-author

CHAPPLE, Karen [University of California Berkeley] chapple@berkeley.edu, co-author

California leads the nation in legislation, programming, investments and research to reduce greenhouse gas emissions and mitigate the negative effects of climate change. From coordinated land use and transportation planning, to climate investments made possible by various programs including the Affordable Housing and Sustainable Communities (AHSC), California is investing in a wide range of housing, active transportation, complete streets, and transit in low-income and vulnerable communities. While climate investments have the potential to transform these neighborhoods towards more sustainable land use and transportation patterns, there remains considerable uncertainty over their potential impacts on displacement. If vulnerable residents are displaced due to climate investments, mitigation strategies may not just further disadvantage already disadvantaged populations, but also endanger climate goals if displacement shifts residents to lower resourced neighborhoods with relatively poor accessibility. Furthermore, the potential impacts of different types of investments remain unclear. To the extent that they provide new amenities, climate investments may raise local land values, which could then impact local rent levels and destabilize communities.

Previous studies have attempted to examine investment-related displacement, but with limitations, and thus inconclusive results. Zuk et al. (2018) summarizes the displacement discussion that lacks evidence-based research to draw definitive conclusions about the relationship between gentrification, displacement, and the role of public investment. Two studies of the relationship between transit station proximity and change in low-income households found mixed effects depending on station location within the region (Boarnet et al. 2017, Chapple et al. 2017); these studies were both limited to rail transit and did not examine other types of investments, whether market-rate or public sector. Although the Boarnet et al. study (2017) improved methodologies by looking at individual mobility, it drew upon a Franchise Tax Board dataset that may undercount low-income households. Chapple et al. (2017) did analyze the impacts on affordable housing and market-rate construction, but it lacked individual level mobility data. Thus,

studies to date have not been able to examine the impact of investments on housing stability in many of the disadvantaged communities, raising questions that may contribute to political conflict and impede the passage of legislation.

This study estimates the relationship between climate investments and displacement pressures. Three research questions will be addressed. First, what features of climate mitigation investments are associated with declines in housing affordability in surrounding neighborhoods? Second, what features of climate mitigation investments are associated with displacement of low credit-score households? Third, how can our understanding of the impact of mitigation investments be incorporated into a predictive model? Focusing on the Bay area, we characterize representative investment projects, and generate a typology of climate investments related to infill housing and sustainable community investments. Relying on Zillow data and subsidized housing data from the California Housing Partnership Corporation (CHPC), we develop block-level data of housing developments to explore the unintended affordability impacts of investments. These data sets are then merged with the Federal Reserve Bank of New York Consumer Credit Panel/Equifax (CCP) data, which allows us to examine residential mobility patterns associated with climate investments. Exploring the role of a variety of investments, across diverse geographies with use of fine-grained data on investments, housing, and households, we expect to offer important implications for a better understanding of how to effectively predict and mitigate the displacement impacts of future investments.

OPPORTUNITIES AND CONSTRAINTS FOR SUSTAINABLE DEVELOPMENT IN THE INTERMOUNTAIN WEST: A STAKEHOLDER INFORMED ASSESSMENT MODEL

Abstract ID: 1145

Individual Paper Submission

SLEIPNESS, Ole [Utah State University] ole.sleipness@gmail.com, presenting author

LICON, Carlos [Utah State University] carlos.licon@usu.edu, co-author

OLIVER, Mary [Utah State University] oliverleemary@gmail.com, co-author

This study applies a comparative assessment model to evaluate the sustainable development possibilities for 247 counties in the Intermountain West. It provides planners with new operational tools for applying locally relevant sustainability criteria at the county level, with particular emphasis on rural contexts.

Most current sustainability research privileges urban environments. While urban areas support the majority of the population and built infrastructure, a regional approach to sustainability requires consideration of rural contexts as well (Audirac, 1997). Given that sustainability is affected by context, regional sustainability requires a holistic consideration of a continuum of settlement typologies, from dense urban centers to rural hinterlands that supply food and fiber for burgeoning urban populations. However, most sustainability evaluation metrics favor urban environments due to their higher densities and resulting efficiencies, leaving rural areas labeled as “unsustainable” because of their decentralized growth patterns. Characterized as “not urban,” they fall short of urban sustainability benchmarks (Isserman, 2005). A mixed methods approach of surveys and comparative performance assessment were employed to evaluate dimensions of rural sustainability, illuminating their contribution toward regional scale sustainability.

A selection of 247 counties in the Intermountain West were initially profiled for their demographic, economic, and biophysical characteristics. Next, an electronic survey was sent to 1,200 county-level planning staff, administrators and elected officials in each county. Respondents were provided with 50 social, economic, and biophysical indicators and asked to select which indicators most impact county-level sustainability (Licon & Sleipness, 2018). Selected indicators were used within the assessment model to evaluate different combinations of indicators to produce sustainability scores tailored for each county. County-level sustainability scenarios—visualized through a series of graphs and maps—quantify the interaction of different combinations of indicators, allowing planners and citizens to see the relative impact of various planning prioritization decisions.

Key findings from the model’s scenarios include environmental conditions’ influence on rural sustainable development. In contrast, urban areas, show stronger dominance and variance based on social conditions and built forms. As extraction-based economies have shifted to service and natural amenity-based economies (Winkler, Field, Luloff, Krannich, and Williams, 2007), the model highlights this shifting role of natural resources in rural economies. The model also highlights water’s prominence in driving rural sustainability in the Intermountain West. While many of these findings corroborate previous research, this study provides a deeper examination of which specific indicators drive rural sustainability, and their relative importance in the context of the Intermountain West (Bosshard, 2000). The output of the model defines a benchmark to outline and monitor county planning efforts. The operationalization of sustainability grounds a conceptual definition of sustainable development in measurable features. Additionally, the model’s visual outputs

THIS LAND IS OUR LAND! LAND TENURE AND MIGRANTS' AGENCY UNDER CLIMATE CHANGE

Abstract ID: 1147

Individual Paper Submission

MARIN, Marielos [University of Massachusetts Amherst] marielosmari@larp.umass.edu, presenting author

Studies on climate change have been reported as impacting human migration, considering mostly extreme cases of small island states. Prior research on tenure and decision-making process observe a positive relationship (See seminal work of Hughes and McCormick, 1981; and Krumm, 1983; and Boehm et.al, 1991. And more recent work of Giles and Mu, 2017; and Ma, et al. 2014). Nevertheless, those studies seldom focus on the interaction while facing climate change and the few that consider the effects in migration, consider mostly variations in climate, agricultural yields with migration, and the effects of environmental factors on permanent moves (Feng, Krueger, and Oppenheimer, 2010; Bohra-Mishra, Oppenheimer, and Hsiang, 2014). This research is filling the gap in research by focusing on the relationship between land tenure and migration after a slow onset disaster, considering land property and the decision-making process to migrate in continental areas. I examine whether land tenure affects migration decisions in households after a slow-onset disaster associated with climate change? More specifically, if individuals with insecure land tenure have a higher tendency to push at least one family member to migrate internationally after experiencing a slow-onset disaster in their town.

I use a logistic regression model to understand this relationship, using data from the National Multi-topic Household Survey of El Salvador pooled over the years of 2003-2017 and the DesInventar Database, which provides a detailed disaster loss data for the country. During this period, there was an increase of precipitations and repetitive losses registered nationally. This study allows us to understand the effects of climate change in a longitudinal analysis by using only the types of slow-onset disasters related to flooding.

Furthermore, over the last decades, policies that promote tenure in developing countries have been commonly applied, this reveals the importance of employing the survey ownership data to understand its relationship with the decision of agents to migrate after a slow-onset disaster in El Salvador. The statistical analysis informs about this relationship and the relevance of the predictors related to ownership and land tenure. Salvadoran national multi-topic household survey (EHPM – for its acronym in Spanish) is a household survey that has been carried out nationally in the 14 states of the country.

The empirical findings suggest that variables often affect either positively or negatively ($p < 0.05$) the migration of at least one family member varying by tenure type - owner versus renters –, although the results vary per year. Each year is analyzed individually and observed changes and effects of slow-onset disasters are not revealing a distinctive pattern during this period. Future research should consider two major concerns that arise from this method, first it is necessary to develop a better measurement tool to analyze this relationship; and second, it is necessary to include other types of slow-onset disasters that may significantly play a role in the decision-making process to migrate internationally. Researching the relationship between land tenure, decision-making process, and migration while facing climate change is essential because land tenure – the most positive right in the land – has been considered as a key factor that explains individual and community resilience (Shi, et al. 2018) which has further impact into planning for climate change adaptation.

URBAN HEAT WAVES: A CLIMATE CHANGE INDICATOR AND THE IMPORTANCE OF MINIMUM TEMPERATURES.

Abstract ID: 1150

Individual Paper Submission

HABEEB, Dana [Indiana University] dana@danahabeeb.com, presenting author

KOLIAN, Michael [US Environmental Protection Agency] Kolian.Michael@epa.gov, co-author

Extreme heat events are responsible for more annual fatalities in the United States than any other form of extreme weather [1]. Urban centers are particularly vulnerable to the threats of excessive heat as most cities are home to large populations of lower income individuals who often lack access to air conditioning or adequate healthcare facilities. Urban populations are also more likely to be exposed to extreme heat due to the urban heat island (UHI) phenomenon. Cities are becoming more vulnerable to extreme heat events as a result of global climate change. NASA and NOAA announced that the years 2015-2018 rank among the four hottest years on record.

In this paper, we examine whether heat waves are intensifying in large US cities. This paper is a continuation from an earlier study where we initially examined heat wave trends in the largest 50 cities from 1961-2010 [2]. We extend our previous analysis to the year 2017 and expand our definition of heat waves to include both minimum and maximum temperatures. Specifically, we are examining whether heat waves defined with minimum temperatures are increasing in cities at a faster rate than heat waves defined only using maximum temperatures. At the national level, we find that heat wave season and frequency are increasing across large US cities at faster rate when defined using minimum temperatures as compared to maximum.

Our research highlights the importance of using minimum temperatures as a heat wave metric when analyzing extreme heat events in urban areas. Minimum temperatures have been shown to be a more relevant metric for heat related health effects, are elevated in cities due to the urban heat island effect, and are expected to increase in cities at a faster rate than maximum temperatures due to climate change [3]. As such we identify cities that have the largest min/max differential between heat wave trends and assess whether this differential can be attributed to the development patterns and urban growth patterns of a city.

This work aims to help cities become more resilient to our changing climate by better understanding the changing characteristics of extreme heat in urban environments and the importance that cities play in increasing heat exposures to urban residents. The initial results of this work have been used at the federal level to create a climate change indicator which was released by the US Global Change Research Program, included in the most recent National Climate Assessment Report [4], and will contribute to future discussions on the importance of heat wave measurements specifically in US cities.

COMMUNITY DESIGN IN AN ERA OF CLIMATE CHANGE AND FIRE VULNERABILITY

Abstract ID: 1161

Individual Paper Submission

KIANI, fatemeh [University of Utah] nedakiani1369@gmail.com, presenting author

PROFFITT, David [University of Utah] david.proffitt@utah.edu, co-author

EWING, Reid [University of Utah] ewing@arch.utah.edu, co-author

More than 50 people lost their lives in California fires. This was the news headline for several weeks. The “Camp Fire“, “Woolsey Fire” and “Hill Fire” were only three of which were responsible for 230,000 acres burned and more than 7000 destroyed homes. If we dig more deeply into the past years we would find a growing number of major wildfires in California and other states and a growing cost of wildfire-related damage. All of the Western United States is in danger, including Arizona, Utah, Washington, Oregon, etc. due to the popularity of development in the wildland urban interface (WUI) and also the climate change phenomenon.

We coin the term “fire prevention through environmental design” (FPTED) – an analogue to the long-established idea of crime prevention through environmental design (CPTED) – to describe the approach planners can take when building fire resilience (Schwab, 2005; Ewing, 2016). Fire occurs when there is the right fuel, right weather and a source of ignition for it. Weather and ignition may be beyond the control of planners, but designing communities so there is less fuel at the WUI is something we can affect. The literature from other fields (forestry) focuses on increasing fire resilience at the extremes of spatial scale – either macro-scale improvements to forest management or micro-scale changes to

individual properties. But FPTED focuses on the missing middle of the community scale. We have found two pioneering articles on this subject (Smith et al., 2016; 2018).

Smart growth can be considered a climate adaptation measure. Sprawl is widely defined as low-density, scattered development with poorly connected streets and commercial strips versus centers (Ewing and Hamidi, 2018). Sprawl increases the WUI as compared to compact development. We will use the Ewing-Hamidi metropolitan and county sprawl indices and satellite imagery to estimate how much the interface increases in fire-prone states as development transitions from compact.

Smart growth can be a climate mitigation measure. As California's Sustainable Communities and Climate Protection Act (SB 375) emphasizes, even weather (climate) is affected in the long-run by urban development patterns. The book *Growing Cooler: The Evidence on Urban Development and Climate Change* estimates that compact development will reduce VMT and associated CO2 emissions by 12 to 18 percent by 2050 as compared to urban sprawl.

At the more meso and micro scales, smart growth reduces fire risks. Actions planners have been advocating for decades to make communities more livable will also make communities more fire resilient. Here two examples from APA's Best Development Practices:

Land Use Practice 4: Develop in clusters and keep the clusters small. Cluster developments are built at gross densities comparable to conventional developments, but leave more open space by reducing lot sizes; by leaving open spaces around housing, clusters will tend to protect them from the fire as a defensible fuel break.

Transportation Practice 1: Design the street network with multiple connections and relatively direct routes. More connected streets mean more escape routes from fires for residents and more access routes to individual properties for firefighters.

We will look for each best practice in the built-up areas that have been subject to wildfire devastation in the last season of wildfires.

Other prescriptions for fire resilience include to create defensible space (which is being borrowed from Oscar Newman's book) around communities, avoid steep slopes, and use ignition-resistant building materials such as metal roofing and cement walls.

We believe that the growing importance of addressing drought and other impacts of global warming will make FPTED an important new subfield that has heretofore been unrecognized by planners but is highly relevant to planning scholarship, practice, and education.

ASKING RADICAL QUESTIONS ABOUT SUSTAINABILITY PLANNING: LESSONS FROM SUCCESSFUL PLACES

Abstract ID: 1198

Individual Paper Submission

ROSAN, Christina [Temple University] cdrosan@temple.edu, presenting author
WHEELER, Stephen [U.C. Davis] smwheeler@ucdavis.edu, co-author

Existing ways of planning communities and governing societies are not working. They are not addressing climate change, growing social inequality, the negative impacts of global capitalism, or other urgent needs in a timely manner (Howes et al. 2017; Millard-Ball 2013; Wheeler 2013). A new acronym has emerged—BAU, “business-as-usual”—to denote inadequate conventional approaches. We propose that if we want to move toward sustainability, planners need to ask more radical questions and propose more radical strategies. When our world faces large and growing sustainability problems, we need planners to take the lead and ask big-picture questions, such as “How do we get to carbon neutrality by 2050?” or “How do we have more diverse, inclusive, and affordable communities?” These questions are often radical in the sense that they push people out of their comfort zones. We want to question the BAU model of urban planning and governance and the way we live our lives. Urban planners are often limited in their role, but when we only try to fix the “tail pipe” problem or the “downstream” problem, we necessarily fail to get to the heart of the problem. We argue, that current sustainability problems have developed because societies have not dared ask big-picture questions. Planners, academics, political leaders, and even grassroots activists have assumed that some possibilities were too idealistic or impractical to raise. So the focus instead turned to narrower types of research and policy development which are often useful, but not enough to deal with underlying problems. This research uses a series of cases of planning challenges to the BAU model to highlight ways in which planners can take the lead in asking more radical questions and finding more effective solutions. We highlight examples of cities where planners have initiated change and adopted innovative policies. We find that when planners ask more radical questions, they find more holistic answers to the large-scale challenges we face. Based on an analysis of the cases of innovative sustainability planning, the research proposes a series of lessons that come from asking more radical questions that may inform future planning practice and promote more sustainable solutions.

Accurate microclimate temperature information is a pivotal parameter to explore urban determinants of the urban thermal environment (UTE) associated with extreme heat events and the urban heat island (UHI) effect (Oke, 1981). Many UTE studies use the land surface temperature (LST) retrieved from satellite imagery because of a wide geographic and temporal coverage availability. However, its applicability to the UHI or the extreme heat event studies is limited by a coarse spatial resolution, relatively infrequent temporal resolution and poorer accuracy. Furthermore, only few studies discuss the impact of urban built environment on air temperature (AT) changes with a high temporal resolution from local automated weather stations (AWS) because such big data is rarely available.

This study discusses the usefulness of AWS AT big data to analyze the impact of urbanization on diurnal and nocturnal UTE changes in the Seoul Metropolitan Area (SMA). We collect and compare The Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) data and in-situ climate data, AWS AT big data readings above the ground from 1294 weather stations in SMA during an early summer day. To identify the impact factors on temperature changes, we perform 'Spatial two-stage least squares' regression analysis including a list of variables of natural environment, detailed land use type, the three-Dimensional surface characteristics (aggregated size of 3-D building volume, building materials, height, building coverage ratio), and anthropogenic factors.

We found that the contribution of vegetation, the landscape of different urban development pattern, and the three-Dimensional surface characteristics distinctly between day time and night time. In our analysis, vegetation and the urban built environment variables had a notable effect on the air temperature in the night time. Vegetation (NDVI) and the three-dimensional surface characteristics still remained as good predictors for the air temperature differences between day time and night time in different urban development type; however, the impact on day time temperature showed a mixed interpretation. We also anticipate our finding would provide not only a reliable conversion factor between LST and AT, but also effective UHI mitigation strategies in SMA.

COOL CAMPUS: RETROFITTING EXISTING BUILDING ENVELOPE TO REDUCE GREENHOUSE GAS EMISSION

Abstract ID: 1211

Individual Paper Submission

NATEKAL, Asiya [University of California Irvine] anatekal@uci.edu, presenting author

The main goal of this research is to utilize the campus setting as a living laboratory for reducing greenhouse gas emissions by retrofitting the existing building envelope. One underutilized strategy to decrease greenhouse gases is the retrofitting of existing roofs for “cool roofs.” Cool roofs are highly reflective roof surfaces that maintain a lower temperature than regular roofs (Akbari et al, 2004). This indirectly reduces electricity use in air-conditioned buildings, increases thermal comfort in non-air-conditioned buildings, reduces the urban heat island effect, and has the potential to mitigate global climate change (Akbari et al, 2004; Cool roof toolkit, 2012). The primary purpose of this research is to measure the potential energy savings of cool roofs for the existing buildings on University of California, Irvine (UCI) campus. Using estimates and emission factors from Levinson and Akbari (2010) by zipcode, this study examined the potential benefits of applying cool roofs on the existing buildings of UCI campus. The concept of “Cool roofs” is a potential climate solution that UCI could explore and provide other campus settings with the data to demonstrate the scaling up potential of “cool” design towards climate neutrality.

TOXIC RELEASE FACILITIES AND SOCIOECONOMIC FACTORS IN SOUTH CAROLINA

Abstract ID: 1233

Individual Paper Submission

MASOOMKHAH, Elham [Clemson University] emasoom@g.clemson.edu, presenting author

The Southeast region of the United States produces the most per capita toxic waste in the country. Historically, this is due to lack of regulatory policies that restrict industries in releasing waste in the environment. Many sectors moved to the South to avoid regulations in other parts of the country. On the other hand, numerous studies have found a correlation between health status and vicinity to toxic waste facilities. According to the Environmental Justice mainstream scholars, minorities and less well-off

communities disproportionately suffer from environmental hazards. That is, in general, the more vulnerable population shoulder most of the burden of such environmental disamenities. This research takes a closer look in the state of South Carolina to evaluate the validity of the common assumption in the mainstream Environmental Justice discourse.

South Carolina is one of the least regulated states with regards to environmental policies and toxic waste release in the United States. It has repeatedly scored low in environmental protection and conservation rankings. According to EPA's 2015 report, state of South Carolina is a site for more than 525 facilities that release toxic waste in the environment—which puts it fifteenth among other states with more than 34 million pounds of toxic waste release. This research adds the smaller businesses that do not report to EPA to the analysis. Out of 182,523 total number of businesses in South Carolina, 6,319 were among those that released toxic waste. Approximately 18% of the toxic waste release in South Carolina are linked to some type of cancer. More than 50% of them are known to cause neurological problems — about 38% cause developmental issues in children. Moreover, there are still unknown health impacts for at least 4% of these chemicals.

This research takes a critical realist approach and adheres to the Rawlsian egalitarian theory of justice—hence, framing the problem around the adverse impacts on a specific group of people who are less likely to be heard and weigh in the decision making process. Using ArcGIS Spatial Analyst extension, this study explores the spatial correlation between the location of toxic release facilities and socioeconomic factors of the population of each census tract in South Carolina. In other words, it tests the validity of the common assumption of Environmental Justice discourse that environmental “bads” fall into the backyard of the impoverished, the less represented, and the more vulnerable population. Further, it also looks into the spatial distribution of the smaller toxic businesses which release toxic waste but do not report to EPA. The findings indicate no correlation between the level of toxicity in each census tract and the socioeconomic status of its residents. In other words, none of the independent variables chosen in this study demonstrated any correlation with the amount of toxic waste in each tract. The results show that the level of toxicity--which includes smaller non-reporting businesses--is spatially clustered in Greenville and Charleston metropolitan areas. However, these clusters did not overlap with any of the hot spots of the explanatory variables.

WATER DEMAND OF HOA VS. NON-HOA RESIDENTS ON COLORADO'S GROWING FRONT RANGE

Abstract ID: 1243

Individual Paper Submission

FOLLINGSTAD, Gretel [University of Colorado Denver] gretelfollingstad@gmail.com, presenting author

This research contributes to water resource resilience planning, to increase community scale capacity to prepare, plan, absorb, recover from and adapt to the effects of our changing climate on water supplies (Cutter, Burton, & Emrich, 2010; Romero-Lankao, Gnatz, Wilhelmi, & Hayden, 2016). Acknowledging that increasing population densities in urban areas create greater vulnerability, there is an opportunity for municipal scale changes that can mitigate these impacts (Romero-Lankao et al., 2016). While not all hazard risks can be avoided, mechanisms should be in place to minimize effects (Moser, 2010) of growing populations and warming temperatures. Land use decisions that regulate development based on adaptive water management strategies, have an undeniable and significant effect on sustainable community growth and future water demand.

This research and presentation address the state of knowledge and practice around landscaping regulations for residential developments, specifically, planned special districts and neighborhoods managed by sub-governments such as homeowner associations (HOAs). HOAs are committees or sub-governmental groups that manage the procurement of neighborhood services to maintain common spaces within a development area and ensure its members keep up appearances by mandating the type of landscaping in a neighborhood. These types of residential developments are designed to limit residential yard design with the primary objective of maintaining property values. However, if the managed yard design was xeriscaped (low water design), HOAs could provide a level of sub-governance that enforces the reduction of outdoor water use.

The project will include three municipalities along Colorado's front range, Denver, Aurora, and Castle Rock. The analysis includes comparing different housing developments' that are managed by HOAs and outdoor irrigation of non-HOA residents. Including Castle Rock, CO, one of the West's leaders in promoting xeriscaping and other low water use landscaping, provides a good comparison between a typical green lawn landscape and a xeriscape design. The project will estimate household level outdoor irrigation water consumption, based on regressions of Denver Water, Aurora Water and Castle Rock Water, customer water use data. Then registered HOAs within the respective water utility's service area will be mapped to delineate between HOA and non-HOA residents. The results allow for greater understanding of varied landscape designs' water footprint and clarify the divergences between HOA residents' outdoor water use compared to non-HOA residents. By looking at these diverse irrigation types, policy options to achieve irrigation reductions, including zoning/building codes, incentives and education, can be implemented municipalities and enforced by HOAs. This research helps inform necessary changes to HOA requirement for landscape design. In addition, the effects of these outdoor irrigation reductions on overall supply-demand balance can help communities across the West. While many Western cities have water conservation programs and municipal regulations used in times of scarcity (Mansur & Olmstead, 2012), apart from some arid southwestern cities (Holway, 2009), most urban areas don't have strict landscape ordinances as a water smart tool for resilient cities.

Finally, the research will include a look at what the literature has to say about factors associated with success in these approaches.

COMPARATIVE PERSPECTIVES ON SUSTAINABLE DEVELOPMENT IN POST-INDUSTRIAL CITIES IN THE USA AND FRANCE

Abstract ID: 1265

Individual Paper Submission

FINN, Donovan [Stony Brook University] donovan.finn@stonybrook.edu, presenting author
POIRET, Guillaume [Universite Paris-Est Creteil-Val de Marne] guillaume.poiret@gmail.com, co-author

Sustainable development and urban resilience have become increasingly salient urban planning and policy goals in the US and western Europe in the last two decades and well-resourced cities like Paris, New York City, Portland and Chicago have developed extensive sustainability and resilience agendas (Portney 2013). At the same time, many other municipalities suffer from the effects of economic restructuring that have resulted in deindustrialization, population loss, aging populations, entrenched poverty and other challenges. Many of these places have been labeled “shrinking” or “declining” cities and a growing literature has analyzed this phenomenon and associated challenges and proposed regeneration strategies (Hollander et al 2009). This project connects these two important themes by analyzing approaches employed by shrinking cities that engage sustainability and resilience despite the salience of other challenges or as a mechanism for overcoming economic decline and as a vector for urban regeneration.

The project asks two questions. First, we seek to understand how declining post-industrial municipalities frame and define sustainable development goals and strategies, and assess how these correspond to, or differ from, approaches taken by larger and more affluent cities typically highlighted in the literature on municipal sustainability. Second, we are interested in how approaches to local sustainable development planning in the context of economic scarcity differ between the US and France, which are both advanced capitalist democracies but have very different national contexts regarding economic development, urban restructuring and the role of national governments in local policy and decision-making.

We analyze four cities that experienced strong growth during the industrial era but are now facing challenges of deindustrialization and decline: Dunkirk and Lille in France and Rochester, NY and Baltimore, MD in the US. Fieldwork in the spring of 2019 and continuing through the summer includes interviews with key decision-makers (planners, elected officials, advocates, civic leaders) intended to develop four detailed case studies analyzing how these cities have addressed the intertwined challenges of urban revitalization and environmental sustainability.

Initial fieldwork has helped to generate a set of initial hypothesis that will be analyzed and tested with additional fieldwork in spring and summer 2019 including: 1) local environmental sustainability policies in the French cities have been influenced significantly by national-level policies that are largely absent in

the US cities, 2) advocacy by the non-profit and civic sectors has been substantially more important in the development of local sustainability policies in the US cases, and largely absent in France, and 3) the rationales for addressing sustainability issues and the associated tactics utilized by the case study cities differ in important ways from the approaches more commonly cataloged in the literature on sustainability planning in a growth context, 4) in some cities the uptake of sustainability goals has been done strategically with the hope that sustainability and related strategies and tactics can be a vector for arresting further economic decline or spurring regenerative activity. We seek to better understand the nuances of the differences and similarities among the four cities and inform subsequent research on the utility of sustainability as an orienting framework for planning shrinking cities. Importantly, this research helps move beyond normative prescriptions for how or why sustainability goals should be addressed by declining cities (e.g Schilling and Logan 2008) towards more empirically grounded investigation of how declining cities in the US and western Europe are actually engaging issues of sustainability and resilience, what successes and challenges these types of communities face when focusing on sustainability related issues, and how useful sustainability-related strategies are for achieving other planning goals in a context of scarcity.

BUILDING CLIMATE CHANGE RESILIENCE IN URBAN AREAS: THE DISTRIBUTION OF GREEN INFRASTRUCTURE AND CITIZEN ENGAGEMENT IN PHILADELPHIA AND BALTIMORE.

Abstract ID: 1280

Individual Paper Submission

PRESSLEY, Joyce [Alabama A&M University] Joyce.Pressley@aamu.edu, presenting author

One of the issues in both ecological planning and planning mitigation strategies is that we often don't ask whether or not there is a difference within a jurisdiction in terms of who gets what—as to the type of ecological service system, its magnitude or capacity and its spatial extent. It is important to focus our attention on neighborhood and household mitigation and resilience to climate change impacts. What people can see and what they can be involved with on a daily basis is going to determine how much of the strategies and costs we can expect them to take up.

Massive government expenditure to build extensive mitigation systems for a variety of climate change impacts at the same time in many US metro areas will not be forthcoming quickly enough. Our investment backlog in just new water supply related services is over \$632 billion. (EPA 2017; Council Foreign Relations, 2017) This does not account for repair of existing and ancient systems. The Federal share of cost assistance to a locality is down to 25% which is within a downward trend to expenditures. Thus, because of the magnitude of the numbers effected and the increasing frequency of weather related damage there is a growing need for explicit attention to inclusion, equity and diversity to support our

building resilience to climate change impacts. The old model of post-disaster recovery has proven to be disastrous to people of moderate means. We need only to look at the recovery efforts Hurricane Sandy in 2012 and Hurricane Maria in 2017 and Hurricane Florence in 2018 to name a few. This paper examines and evaluates green and blue infrastructure projects and strategies in two US Cities: Philadelphia PA and Baltimore, MD. Presented is a comparative evaluation in terms of citizen involvement with design, implementation, maintenance and cost sharing on Green Infrastructure (GI) and Low Impact Development (LID) projects. Both of these cities have seen an increase in urban stream, creek flooding in the past ten years. The inventory of GI and LID projects are also examined in terms of the socio-ethno and income characteristics of the neighborhoods where they are located; interrelationships across infrastructure systems; and the magnitude of proposed impact on one or two climate change issues. The problem is can we get them built fast enough, at sufficient density and done with sufficient buy-in to share costs and get behavioral change?

Baltimore's "green" and "blue" infrastructure projects tend to be more disbursed, neighborhood oriented, and participatory. In Philadelphia these projects tend to be centrally directed and administered by the Philadelphia Water Department; in Baltimore they are disbursed across a variety of differently-scaled organizations. This assessment will identify and separate site scale and landscape scale projects. This discussion should also give an opportunity to discuss the spatial distribution of investments and whether or not these patterns are equitable and have more widespread impacts.

MANAGING RETREAT: ASSESSING THE DIFFERENTIAL IMPACTS OF AMERICAN FLOODPLAIN PROPERTY ACQUISITIONS ON COMMUNITIES

Abstract ID: 1294

Individual Paper Submission

KLEIN-ROSENTHAL, Joyce [Earth Institute at Columbia University] jr438@columbia.edu, presenting author

Floods are the costliest type of natural disaster, create the most property damage, and affect the greatest number of people in the United States (Kousky & Walls, 2014). An estimated 41 million Americans live within a 100-year floodplain and are exposed to the risk of major flooding (Wing et al., 2018, p.1). Local

governments are increasingly seeking to reduce the risks of coastal, riverine, and rainfall-driven flooding through climate adaption planning and urban design (Anguelovski et al., 2016).

Since 1999, the Federal Emergency Management Agency (FEMA) has used federal funds to help local governments purchase flood-damaged homes at pre-flood value from willing sellers as part of the Hazard Mitigation Grant Program (HMGP), the largest federal grant program for home “buyouts” following floods. While not building on land susceptible to flooding may be the least-cost option, floodplain buyouts are an alternative to the multiple and costly rebuilding of homes after repeated floods. The public acquisition of flood-damaged buildings, typically owner-occupied residences, and their removal from vulnerable floodplain and coastal areas is an early form of managed retreat.

How do housing values change in neighborhoods with FEMA-funded buyouts? We hypothesize that buyouts have an effect on nearby housing values that differs by neighborhood socio-economic status and measures of local racial homogeneity, ethnic diversity, and segregation, and higher-income and predominantly white neighborhoods will experience greater increases in adjacent property values compared to low-income or communities of color following buyouts. A related hypothesis is that these differential effects may be due, in part, to differences in local land-use following buyouts; e.g., wealthier communities have the resources to develop and maintain new open space amenities on buyout sites, but not low-income areas.

Methods - We examined eight years of completed buyouts of flood-damaged residential buildings during 1999 –2006, a group of 3,838 buyouts in over 500 census tracts located in 21 states east of the Mississippi. Data on completed property acquisitions were provided by Open FEMA.

We used ordinary least square and spatial regression, with the change in median housing values between 2000 – 2016 in census tracts with buyouts as the dependent outcome. The independent variables, based on socio-demographic characteristics, were based on criteria used by local governments to identify environmental justice communities and the literature on social vulnerability to natural hazards (Cutter et al., 2003).

Results - Mean change of housing value in the census tracts with residential buyouts from 2000 -2016 was an increase in \$18,200; with a range from -\$74,420 to \$266,856.

The first hypothesis was supported by regression analysis, as the change in housing values in census tracts with buyouts differed, in direction and magnitude, for low-income and communities of color compared to relatively high income, predominantly white neighborhoods. These results raise essential questions about why this differential occurs and its relationship to buyouts. Is it largely due to long-term structural racism and corresponding disinvestment in the built environment? How are these trends influenced by regional differences, land management practices, and locational effects? To assess land-use and land-cover (LULC) change in places with buyouts, we next use Landsat and Census data to characterize LULC change in these areas, stratify the analysis by region and population density, and incorporate additional buyout characteristics.

Large-scale displacement of human populations is expected this century due to the impacts of a warming climate, and the consequences of current forms of managed retreat must be critically examined. These findings, though nascent, reinforce the call for urbanists to foster public investment that facilitates more equitable social and spatial outcomes. Climate adaptation must avoid reinforcing racial inequalities and offer new pathways to reducing uneven vulnerability (Hardy et al., 2017).

SCIENTISTS' ROLES IN COLLABORATIVE PLANNING AND POLICYMAKING

Abstract ID: 398

Poster

SEO, Hye-jeong [Virginia Polytechnic Institute and State University] seohj@vt.edu, presenting author
 SCHENK, Todd [Virginia Polytechnic Institute and State University] tschenk@vt.edu, co-author

Many planning and policymaking processes involve the use of scientific and technical information. However, this information is frequently questioned by stakeholders, particularly when it contradicts with their opinions and preferences. This study explores scientists' perspectives on their roles in such processes with the aim of gaining insights into how better-informed policies, plans, and management might be achieved through more collaborative science-policy interactions. Integrating scientific knowledge into planning, policymaking and management processes is challenging because of the inherently different purposes, assumptions, and framing of scientific information and policy information (Innes & Booher, 2010). When it comes to environmental issues such as biodiversity conservation and climate change, it is even more difficult to use scientific research to inform decision-making and implementation because these issues are particularly complex in nature, involving uncertainty, complexity, diverse conflicting values and multiple objectives in various sectors; science alone cannot provide simple 'optimal' solutions (Pielke, 2007; Young et al., 2014).

In order to overcome these challenges, prior studies have explored the gap between science and policy. Most of those studies have focused on policymakers' perspectives in light of how they frame complex environmental problems differently than scientists do and concluded with recommendations on what scientists should do to better inform policymakers. This is often through the lens of 'science communication' (van Stigt, Driessen, & Spit, 2015). However, scientists' perspectives have been relatively underexplored in comparison to the body of research on policymakers' perspectives in several areas such as climate science. The role of scientists in planning and policymaking thus remains relatively unclear, other than to better communicate to policymakers. Pielke (2007) presented a typology of scientists' roles in knowledge brokering that has resonated with many scientists, but this typology has been neither empirically tested nor academically established. Although efforts to understand knowledge users or demand-side perspectives have provided valuable insights into how to improve boundary work at

science-policy interfaces, without better understanding scientists' roles and perspectives, those efforts often reinforce the oversimplified assumption that science-policy interactions are a one-sided, simplistic process of transferring neutral facts from scientists to policymakers (Nutley, Walter, & Davies, 2007).

This study aims to understand scientists' perspectives on their roles in planning and policymaking, and how those perspectives are formed early in their careers. More specifically, it examines the development of scientists' sense of expertise and identity through a case study of a graduate education program at Virginia Tech that is designed to promote interdisciplinary knowledge about the multifaceted aspects of global change and environmental threats. An empirical exploration of participants' perspectives on their knowledge brokering roles and boundary work can provide insights into how we can facilitate more effective interactions at science-policy interfaces with implications for scientists, planners and policy-makers, and facilitators of collaborative governance. Better understanding different scientists' perceived roles will help policymakers to more effectively seek and use scientific and technical information and scientists to more effectively participate in policymaking in a goal-oriented manner with clear self-definition and boundaries. Findings from this study will have implications for collaborative governance efforts involving scientists and the knowledge they bring to the table. Insights will benefit planning and policy practitioners such as conveners, mediators, and others engaged in designing and conducting collaborative environmental governance.

While previous studies in environmental equity found a positive relationship between tree canopy and socioeconomic/demographic status of neighborhoods, few examined how changes in tree canopy are associated with changes in socioeconomic/demographic status. We address this gap by examining their

cross-sectional and longitudinal relationships in Atlanta, Georgia. Our analysis confirms that the relationship between tree canopy and socioeconomic status is changing and the hypothesis of inequity cannot be fully supported beyond 2000. While poverty and rentership rates consistently showed inverse associations with tree canopy across different years, areas that had a high proportion of African-Americans are positively associated with an increase in tree canopy during 2000-2009. This trend resulted in a positive association between them in 2013. An interaction effect suggests that the changes in the proportion of African-Americans can have opposite effects on the predicted tree canopy cover depending on the changes in poverty rate. We conclude with how the findings can inform planning and policy decisions.

CHOOSE YOUR OWN ADVENTURE: CAN CLIMATE FICTION READING GROUPS ELEVATE ATTENTION TO EQUITY ISSUES IN CLIMATE ADAPTATION?

Abstract ID: 493

Poster

PENNEL, Penn [University of Kansas] penn@ku.edu, presenting author
LYLES, Ward [University of Kansas] wardlyles@ku.edu, primary author

Motivating mass mobilization to adapt to climate change poses is one of the biggest problems of the 21st century. Communication and activation efforts to date in the United States have largely failed to engage the broader public in critical visioning and planning efforts. Out of the box thinking and approaches are needed. This poster summarizes research linking planning for climate change through expanding imagination (Moser 2006; Sandercock 2004; Collie 2011), personalizing and engaging emotional responses (Moser 2006; van der Linden 2016), using storytelling as a tool for communication (Sandercock 2004; Moser 2006; Collie 2011) and centering people and populations who are most vulnerable to its impacts (Schrock 2015; Reckien 2017). Specifically, the research explores the potential of climate fiction reading groups to catalyze public engagement in local climate adaptation efforts, particularly around issues of inequity.

Fiction can activate imaginations needed to explore possible futures, new ideas for encountering change and difference, and emotionally connect with other people. All of these opportunities arise through the comparative safety of a fictional world. In such ways, this be a useful approach for adaptation planners to spark collective meaning-making that promotes climate action. Recent years have seen a rise in fiction books containing elements of climate change, coining a new term in the literary world: Climate Fiction (e.g. *Flight Behavior*, *American War*, *Orleans*). These 'Cli-Fi' books may help planners working on reducing risks from climate change. Incorporating Cli-fi into public engagement may promote and facilitate conversations that imagine complex future scenarios, especially through emotional stories that humanize climate impacts. The informality of reading groups, as compared to traditional planning

meetings with formal comment periods or large group exercises, can bring people from diverse backgrounds together in more intimate settings. Moreover, readings groups provide a fun and engaging activity that explores the cognitively and emotionally overwhelming topic of climate change. Climate fiction reading groups may provide opportunities for a) exploring how equitable resilience is personally relevant, b) building new connections between readers, and c) enhancing community-wide social capital. Of particular importance is prioritizing writings from authors from traditionally oppressed backgrounds whose characters likely appeal to a broader audience, challenge stereotypes, and even help reduce prejudice, all of which are necessary elements in addressing inequity.

This poster synthesizes findings from an ongoing engaged community reading group process as part of an exploratory research project. We present findings of a multi-stage process working with an innovative public library in a medium-sized Midwestern city. Our project integrates cli-fi novels into multiple reading groups sponsored through the library. Our research design allows for comparison between treatment (cli-fi novel) and non-treatment (non-cli-fi novel) in reading groups focused on social justice and those with a more general focus. Data sources include pre-treatment and post-treatment surveys, focus groups, and participant observation (Hesse-Biber, 2014).

Our findings inform existing literature that has found that by engaging in outreach activities through already existing public library programs, such as book clubs, readers can become planning participants in convenient and comfortable environments (Halvorsen 2001). We offer recommendations for scholars and practitioners alike, who may find cli-fi to open new lines of dialogue and engagement.

SURVEY OF STATE LAND-USE AND NATURAL HAZARDS PLANNING LAWS

Abstract ID: 854

Poster

SHAH, Sagar [American Planning Association] sshah@planning.org, presenting author

The frequency, intensity, and severity of natural disasters is increasing with time (NOAA National Centers for Environmental Information (NCEI) 2019). Natural disasters result in severe damage to

property, built environment, and often lead to loss of life. Governments at all levels (local, regional, state, federal) are looking for new ways to increase community resiliency.

It is necessary to reform the existing state statutes or introduce new legislation for combating the negative consequences of climate change (Platt 2012). Federal Emergency Management Association (FEMA) is at the forefront of working with the communities that are affected by these natural disasters. They appreciate the role that planning laws, primarily related to natural hazards, play in building resilient communities. In this project, which was funded by FEMA, we reviewed legislation from all the 50 states for laws that are intended to require, promote, or encourage local mitigation of natural hazards. We collected data on, 1) State-level planning laws, 2) State planning enabling legislation, 3) State planning-related natural hazards laws, and 4) State building code laws. The emphasis was on the intersection of hazard mitigation and land use in state legislation, and the role of the states in guiding local hazards policy.

To collect the information, we framed questions to explore each of the four categories identified above. The questions were based on the review of the literature and were structured to collect information about specific laws. We did the content analysis of the state legislatures of all the 50 states to answer 25 questions for each state (e.g. Is integration of hazards planning required or encouraged across plans such as local hazard mitigation plan, a hazard-related element of the comprehensive plan, etc.?). Thus, we collected information on a total of 1,250 questions (25 x 50). Each of these 25 questions was further elaborated and defined. For answering the questions, we designed a method to review and scan the state legislation and developed a standardized “answering” (multiple-choice) system for consistency. We also attached notes and inserted links to the specific statutes related to each answer. Then we verified the collected information by contacting the American Planning Association’s (APA) Chapter Presidents and Legislative Liaisons.

It is a challenge to summarize the results of each question, so here are a few examples of what we found. We found that only 40 states required an element related to natural hazards in their local comprehensive. We also found that only the states of California, Florida, Nevada, and Oregon required integration of hazards planning across plans, and only the states of California, Hawaii, and Oregon addressed climate change (directly or indirectly) in their comprehensive plans. Overall, even though there has been more progress in addressing natural hazards through state laws in the last decade, there is much more work needed, especially in states that are not on coasts. These results are consistent with some other work that has not been related to planning (The Pew Charitable Trusts 2018).

Many times, planning is not guided by state laws, largely because planners are not familiar with the laws. This work provides one-stop-shop information to planners working at local levels about state-planning, planning enabling (NOAA National Centers for Environmental Information (NCEI) 2019) legislation, and natural hazards laws. This work can also be used for comparative purposes and could influence the work of states (in terms of policy language, etc.) that want to develop statutes based on the laws that are already adopted in other states. There is also an opportunity to do a more longitudinal study to monitor the changes in state laws over time.

Urban Heat Island (UHI) is a crucial problem for metropolises in the United States. United States Environmental Protection Agency (EPA) defines UHI as an area in a city which is warmer than its neighboring countryside[1]. In fact, UHI reduces the thermal comfort in cities and in some cases, it has a direct effect on Urban Air Pollution (UAP). Hence, mitigating UHI is a challenging dilemma for urban planners who want to enhance thermal comfort and reduce pollution. EPA proposes strategies to mitigate UHI such as Urban Wind Corridor (UWC). Roads and highways are considered the major paths for UWC. Based on the literature, road intersection angle and road direction have a high impact on wind velocity and wind flow. Thus, finding the most efficient direction and pattern to design roads and highways would increase the function of those paths[2],[3].

This study aims to simulate five intersection angles from 90° to 45° with two different road patterns at 30 feet street elevation (upstream) by Computational Fluid Dynamic (CFD) software. In addition, the average air velocity for simulation is 9 mph (based on New York average annual wind speed). The software works based on Reynolds-Averaged Navier-Stokes (RANS) model to analyze the cases and present the results[4]. First, ten patterns are modeled with AutoCAD, then after exporting those models to Autodesk CFD, the simulation was run based on our inputs. The comparison of the ten urban road pattern simulations shows that the closest wind direction to the road direction or the parallel direction of wind and roads would maximize the air flow and air velocity.

The results show the impact of road patterns on urban planning. Planners can use the results of this study for their decision-making process to design the most applicable paths in metropolises. However, this study only considered the upstream level of paths in two different shapes of urban pattern, so additional research is required for downstream and even more with some regular or irregular urban pattern. In addition, it would be helpful for planners to focus on urban heritage sites especially in downtown areas to find the best strategies to enhance the thermal comfort without sacrificing the green spaces and historic districts.

SPATIAL EVALUATION OF URBAN TRIGGERS FOR THE YAMUNA RIVER POLLUTION IN NEW DELHI, INDIA

Abstract ID: 989

Poster

VUPPULURI, Richa [University of Virginia] richa.vup@gmail.com, presenting author

Urban planning & environmental management interventions in complex environments must be responsive to spatial, socio-cultural as well as governance factors. However, it is crucial to root the multitude of responses within the spatial spectrum of urban development through land uses, infrastructure provision, demographic information, etc. The objective of this study is to spatially evaluate the urban condition of the city of New Delhi National Capital Territory (NCT) from the perspective of severe depletion of the Yamuna River. While only 2% (22 km) of the entire river stretch traverses through the city, it picks up 70% of the total pollution load, reducing the river to an open sewer and destruction of the receiving water quality. The central research question is twofold: (1) What are the urban factors of New Delhi identified through a spatial analysis that are impacting the Yamuna river? (2) How does the spatial analysis inform prioritization of interventions for near- and long-term planning of the river restoration?

Primary approach for this project is spatial analysis by GIS, using census and land use data to analyze population density, the impact of specific land use types like industrial sites, and sanitation infrastructure. Secondary sources are used to delineate the floodplain of the river within the urban area, which along with the local drainage network forms the base of the urban analysis.

Key findings:

1. Population Profile: 16% of the total population of New Delhi NCT lives on the floodplain of the Yamuna river. There is a much higher population concentration along the two major drains towards the west of the river, identified as the primary point sources discharging pollutants into the Yamuna river.

2. Landuse: There is significant floodplain encroachment through 26.7% residential use, 6.5% commercial use and 1% industrial. These sites, including cultivated lands, contribute about 46.7% of the total floodplain area. Need to study the non-point pollution discharge from agriculture.
3. Proximity of Industrial sites to the drainage network: 54% of total industrial sites fall within 1000 ft of the river and drainage network, and 85% of entire industrial sites fall within 3000 ft of the river and drainage network; corroborating that industrial effluent discharge could be a significant cause of river pollution.
4. Sanitation Infrastructure: There is a substantial number of households that are not connected to the drainage system this highest at ward level are 65,000 to 100,000 households. A high percentage of households lack individual toilets, highest at ward level is 51% - 94% of households, also showing a strong correlation with households that use open defecation; corroborating that untreated domestic sewage discharge is another major cause of river pollution.

The Yamuna is a seasonal river, and highly engineered. Before it enters the New Delhi city at Wazirabad barrage, almost the entire flow is captured to supply drinking water for 86% of the city population. Beyond this point, the river constitutes of urban discharge from the drains and runoff. It ends up like an open sewer and authorities have failed to maintain minimum water flow to sustain natural river functions. However, during heavy monsoons, the river also heavily floods leading to large-scale property destruction. Therefore, the floodplain analysis is key to capturing the dichotomy of river pollution as well as flooding. It not only identifies development impacting the floodplain but also population and properties under flooding risk. Spatial correlation is a critical tool to guide urban planning and environmental management practice. While there is a high possibility for a direct correlation between urban development and pollution of urban rivers; geospatial analysis can spatially identify areas to focus interventions, programs, and policies by mapping urban trends and infrastructure systems that need attention.

There has been a gradual but steady change in global climatic conditions. These changes have been linked to human activities, from greenhouse gas emissions to deforestation of natural forests to increase in built-up areas (Anderson et.al. 2014). It is inarguable that developments in urban areas have disrupted the natural environment and its ecosystems; real estate developments, highways and roads concrete pavements, and the artificially constructed drainage systems have changed the dynamics of the interaction of nature (Young 2011) This situation is aggravated by water bodies in cities with coastal geographies. The introduction of green infrastructure (GI) into urban ecosystem mimics the behavior of the natural environment, therefore reduce flooding and mitigate climate change. There are currently a number of efforts towards the implementation GI around cities in the United States; similar efforts are also seen in New Orleans.

New Orleans is prone to hazards mostly due its geographical characteristics; impacts of flooding have been heightened due to the use of outdated pumping systems to manage flood waters. This is exacerbated by the fact that New Orleans is a tourist town and witnesses high turnaround of visitors especially during festivals. This study assesses the use of GI in the most vulnerable areas and neighborhoods around the city, to study the impacts of flooding caused by stormwater runoff; then analyze the environmental, social and economic ramifications of implementing green infrastructure in those areas. It also examines the efforts of city government, non-governmental organizations and communities towards GI implementation. The project will achieve this through archival research; qualitative, semi-structured interviews of residence of flood prone areas and city government officials in green infrastructure development.

The triple bottom line approach applies environmental, social, and financial determinants to provide a more holistic way for a cost-effective solution to reduce the impact of flooding in the city. Benefits like social or equity can be deduced through the interview of residence, then making a comparative analysis of the impacts of GI in communities that already have with others that do not have. A compilation of rain data and history in relation to flooding will be collated and analyzed to be able to deduce best GI types can be applicable at each flood prone area. It is expected to see meaningful, however, limited gains due to the implementation of GI in a few areas.

It is our view that a city-wide assessment of such areas will produce new knowledge that can be applied universally. This study will help in making informed policy decision on city planning and also help formulate theories of the social, environmental and economic impacts of green infrastructure development in the city.

Having a better understanding of the value of diversity in the planning academe and workplace is needed, as is more representation and agency of marginalized groups to fill this gap. While planning scholars and practitioners have acknowledged the importance of diversity, the planning academe and practice have struggled to recruit and retain diverse groups and promote cultural competency in programs (Harwood, 2005; Lowe et al, 2016). Across the U.S., there are increased institutional debates regarding how best to support diversity and inclusion within urban planning curricula, within our student and faculty bodies, and work spaces (Edwards and Bates, 2011; Sen et al, 2016). However, there has been limited research that examines how practitioners, students, and faculty perceive or experience diversity within the urban planning field and the steps necessary to bridge planning higher education and culturally competent practices in the planning profession.

This roundtable will discuss the findings from ACSP-POCIGs research team nationwide survey of urban planning students regarding the climate for diversity within their degree programs based on 451 responses and 50 in-depth interviews. The study highlights the experiences students have interacting within the classroom, with faculty, with peers, and with professionals as they prepare to enter into planning practice or academe. Our results show that the majority of students report an overall supportive and positive climate for diversity within their programs, regardless of a student's identity. However, students still report occurrences of bias and discrimination and describe the shortcomings of a lack of faculty diversity and support systems within planning schools. These accounts reflect a major pedagogical challenge to planning education – is doing well here good enough? Student accounts suggest that the answer is no. Overall, there remains much work to be done within our classrooms, the communities at large, which we serve, and how we interact as colleagues. The panel hopes to enable planning educators to prioritize the practice of diversity within our departments and innovate around how we teach and model this practice for our students and the communities we seek to serve.

Panelists will share their insights on four papers that explore the following: 1) Student perspectives on climate for diversity in urban planning programs broadly, 2) Student perspectives on the integration of

diversity and practice-based curriculum, 3) African American and Latino student experiences in urban planning programs and 4) International student experiences with diversity in the planning academe. To that end, the panel will address the following questions: What are the pedagogical and practice gaps in understanding diversity and inclusion in academia? How can planning education enhance student learning in a way that connects the classroom experience with being able to implement skill sets in the real-case scenarios in diverse communities? What are the systemic barriers faced by underrepresented students in planning departments? How is the planning academe and ACSP responding to the needs of underrepresented groups and supporting diversity and inclusion efforts?

TRANSIT CRIME AND SEXUAL VIOLENCE GLOBALLY: EXPERIENCES OF COLLEGE STUDENTS IN 18 CITIES

Abstract ID: 45

Individual Paper Submission

LOUKAITOU-SIDERIS, Anastasia [University of California Los Angeles] sideris@ucla.edu, presenting author

BROZEN, Madeline [UCLA] mbrozen@luskin.ucla.edu, co-author

DING, Hao [UCLA] haoding@g.ucla.edu, co-author

PINSKI, Miriam [UCLA] mpinski@ucla.edu, co-author

Central theme/research questions

The #MeToo! Movement has cast an uncomfortable but necessary lens on sexual harassment. But most attention has been given to the work place environment, and only a handful of studies have examined sexual harassment in public spaces, and particularly transportation environments. This is a significant omission, since media stories and reports around the world indicate that the incidence of harassment on public transit is quite common globally. Indeed, incidents of sexual harassment are being reported on

buses and trains in cities around the world, and ‘transit rapes’ in New Delhi, Rio, Los Angeles and Philadelphia have generated public outrage in the past. But how prominent is sexual harassment on the bus, on the train or at the transit stop, and how does it affect women? What types of harassment (verbal, non-verbal, physical) are most prevalent, and where and when do they mostly occur? Are groups other than women (men, LGBTQI individuals) also affected by harassment, and to what extent? How do victims and bystanders respond to harassers? How common is the reporting of sexual harassment crimes? Are victimization and perceived safety affected by the types of environments people encounter while in transit; if so, how? Where are most individuals afraid of being victimized: on the bus or train, waiting for public transportation or on the way to it? How is harassment and transit crime similar or different in different cities and cultural contexts? Lastly, but importantly, how can cities and their transit operators respond to harassment and other transit crime and make travel by the bus and train safer? These are the research questions which will be addressed in this study that draws from surveys with college students at two university campuses in Los Angeles. The study is part of a larger international study, co-led by the first author, which takes a global look at crime and sexual violence as experienced by college students in 18 cities, in 5 continents.

Approach and methodology

We distributed a 45-question survey to students (male and female) carrying transit passes at UCLA and Cal State, Los Angeles asking, among other things, about their travel patterns, fear of victimization while travelling on public transport, prior experiences with victimization and sexual harassment on transit; spatial and temporal characteristics of feared transit environments, reactions to harassment, and proposed responses. A similar survey was also distributed by collaborating scholars to 17 other cities, in 5 continents. The study will primarily present the findings from Los Angeles, but will also compare them with major findings from other cities. In addition to descriptive statistics, the study will present results from regression models to better understand and explain the differentiation in victimization levels as well as in perceptions of safety among students.

Findings

Our preliminary findings indicate that being female and identifying as LGBTQI are both significant predictors of being a victim of harassment on transit. This finding is consistent across the other international cities in the study, but the extent of harassment varies from one city to the other. Most women take special precautions to avoid harassment, which affect their travel behavior. Underreporting of sexual crimes in transit environments is very significant.

Relevance to planning scholarship and practice

The study will generate new insights on the extent and nature of harassment in transit environments, and how it affects travel behavior among women and LGBTQI riders. These insights will be relevant for practice as they will highlight an issue that affects an important segment of transit riders. Lastly, the study will propose policy recommendations that may have a positive impact on improving transit environments for women riders.

THE ROLES OF FAMILY AND WOMEN IN DECLINING SUBURBS IN JAPAN

Abstract ID: 63

Individual Paper Submission

MATSUMOTO, Naka [Meiji University] nakam227@gmail.com, presenting author
IWASAKI, Masae [Independent] iwasakimasae@gmail.com, co-author

This paper aims to investigate how family ties, especially those of the female second generation (daughters of the original homebuyer) who left the suburbs, affect conditions in declining suburban neighborhoods in Japan.

Japanese suburban neighborhoods were developed throughout the 1960s to 1980s in order to solve the problem of insufficient housing stock in inner cities. The suburban houses with their modern designs and amenities, although located far from the city center, were a dream for middle and upper-middle class families. However, after several decades, those suburban neighborhoods are rapidly aging as younger generations, which include more women in the workforce, leave for more convenient locations. The media have called it the "death of suburbia," showing images of lonely old residents, often living alone in a house and struggling with their daily lives (Soble, 2015). There are several efforts by organizations to assist those remaining elderly citizens, yet the majority of them are still largely reliant on family members for help (Hashizume, 2000; Wallhagen & Yamamoto-Mitani, 2006).

To date, the role of family members in residential choice has been discussed primarily in terms of how the family or individuals move to another location due to complex life events such as marriage, child bearing, and jobs (Clark & Withers, 2009). At the same time, Mulder (2007) points out that the influence on residential choices by family members outside the household is significant. As the provision of care for the elderly by family members is crucial for an aging society such as Japan, examining the residential choices of those who have moved away from their parents' houses and their activities in relation to their parents' suburban location is a critical step in the discussion of the future of declining neighborhoods.

Taking the case of a suburban neighborhood near Tokyo, we conducted 42 semi-structured interviews with adult children of suburban residents to answer the following research questions:

How do the children who have left their parents' houses affect the condition of suburban neighborhoods where their parents remain?

Are there any differences in terms of gender, position among siblings, marital status, and jobs that contribute to the changes in suburban neighborhoods?

We found that daughters tend to live closer to their parents than sons do; however, this was greatly influenced by birth order and marital status. The study concluded that the residents of this suburban town survived due to frequent visits from the family members (mostly adult daughters) who left the town. Strong family connections, especially those of women who feel obligated to take care of both their own and their husband's parents, as well as the tradition that married couples should live close to the husband's parents, persist among younger households. This suburban neighborhood may be slowly dying because of the residential choices of the second generation, but their frequent visits are allowing the older generation to continue living in their isolated suburban houses.

The suburban neighborhood outside of Tokyo was designed exclusively for families with a clear gender-based division of roles—working men and housewives with children. Now, despite changes in family structure such as more women in the workforce, increasing unmarried population, and aging, the neighborhood's deterioration is often delayed by the unpaid and dedicated assistance of female family members far from town. It may not be sustainable to maintain the town itself, however, once the original residents are gone. This paper calls for new strategies to revive suburban towns in Japan such as diversifying the residents, introducing businesses that can ease women's burdens, and coordinating with local organizations and businesses to assist the elderly without relying solely on their daughters and daughters-in-law.

GENDER INEQUALITY IN THE JOURNEY-TO-WORK: INTERACTIVE EFFECTS OF RACE/ETHNICITY AND FAMILY STRUCTURE

Abstract ID: 239

Individual Paper Submission

HU, Lingqian (Ivy) [University of Wisconsin Milwaukee] hul@uwm.edu, presenting author

This research investigates the interactive effects of race/ethnicity and family structure on gender inequality in journey-to-work trips in the United States. I posit that gender inequality in journey-to-work

trips is associated with two additional aspects that have been understood to simultaneously affect gender roles but not jointly examined in women travel literature. The first is race/ethnicity: minority women face double oppression (Crane and Takahashi 2009, Taylor and Mauch 2011). The second is the family structure (Rosenbloom and Burns 1993, Johnston-Anumonwo 1989): an increasing number of women have joined the labor force and consequently gained socioeconomic statuses.

Using the 2017 National Household Travel Survey (NHTS) data, I use interaction terms of gender, race/ethnicity, and family structure to compare gender gaps in journey-to-work trips—measured by commute distance and commute mode—between racial/ethnic minorities and whites, and between single-worker families and dual-worker families. More importantly, I compare the differences in gender gaps between single-worker and dual-worker families across racial/ethnic groups.

The preliminary results paint a complex picture. Gender gaps are larger in whites than in minority groups and larger in dual-worker families than in single-worker families. Additionally, the difference in gender gaps between single- and dual-worker families are the largest in black families but smallest in Asian families.

The results have policy implications. On the one hand, they quantify women's additional tradeoffs in commuting trips in dual-worker families compared with single-worker families. The results suggest that transportation services that serve children's needs can to an extent facilitate women's commuting flexibility and thus their employment. On the other hand, the results suggest additional disadvantages of minority women, particularly blacks, because black women have to balance bread-winning and family responsibilities with limited transportation resources. Providing transportation services in minority neighborhoods is essential for employed minority women.

FROM THE PARK AS STAGE TO THE PARK STAGED: DOES DIVERSITY INDICATE INCLUSIVITY IN DALLAS ART DISTRICT SIGNATURE PARK?

Abstract ID: 385

Individual Paper Submission

GHAFFARI, Nazanin [The University of Texas at Arlington] nazanin.ghaffari@uta.edu, presenting author

Ever since the private sector became accountable for designing, financing, programming and managing a rising number of urban spaces, the meaning of "public space" has become increasingly complex. This

“privatization” has generated criticism for not allowing protests, stifling free speech, Disneyfying, securitizing and commercializing public spaces, therefore, excluding individuals and groups based on race, gender, class, social status, and also beliefs, behaviors, and activities. On the other side, the established geography of events is shifting, and more sanctioned events are being staged in public spaces, including signature parks. Previously, all events took place in public parks were pro bono; they are now being used for several commercial and ticketed events. Urban designers employ events as a tool for animating and diversifying public spaces, though scholars have started to probe this process, exploring eventization of not only our public spaces (Smith, 2016) but also the eventization of our society (Žižek, 2014) and economy (Pine and Gilmore, 1999). The purpose of this paper is to understand the programming factors that contribute to the establishment of exclusionary strategies in a privately-managed signature park in Dallas and to explore how planners, city officials, and even donors contribute to the creation of very well diverse, though an exclusionary public space.

I deploy the “Just City Framework” (Fainstein, 2005) and “Implicit Bias Discourse” (Kahn, 2017) in a signature park in Dallas Art District, complimented by D Magazine as the “city’s most beloved public space” and referred by US Today as “the number one spot for free things to do in Dallas” to evaluate whether diversity means inclusiveness of the park. Fainstein describes diversity as the planning orthodoxy which is not helpful without considering it in the broader concept of just city. Similarly, Kahn, a legal scholar, uses the newly coined term “Recreational Antiracism” and argues that promoting diversity rather than substantive structural change will not create equal opportunity and equal outcomes.

The research methodology includes (1) interviews with the stakeholders; (2) participant observation, and (3) review of web materials, press and social media (Instagram and Twitter) for content analysis. Triangulating the results inform us of how programming and management utilize events to exclude the so-called “undesirables.” For this study, I consider “programs” to be ongoing and recurring activities, as opposed to one-time events in three main categories – commercially-, politically- and community-oriented events - and examined more than 1300 of programs that activated the park from January to December 2018.

The findings indicate that securitization and commercialization as the two principle exclusionary strategies lead to two subgroups: tangible or deliberate vs. symbolic exclusion. The non-profit organization responsible for the operation of the park uses three different mechanisms to exclude unwanted uses and users:

(1) Through private regulations and bylaws that are not posted for public information. Thus, purify the park of difference through exclusion of those who are judged to be defiant, imperfect, and marginal like homeless individuals and groups, punks, skateboarders, unsanctioned journalists, and so on. (2) By closing the publicly-used park for private parties or ticketed events. (3) By not inviting or welcoming unwanted uses and users: (3.a) By not informing unwanted users about the free programs and activities happening on site but advertising ticketed and sponsored events on social media. (3.b) Through failing to represent diversity in computer-generated imageries (CGIs). Also, (3.c) By scheduling free events in a way that unwanted users are not able to participate, such as kid-friendly events on Tuesdays and Thursdays 10 a.m. to 12 p.m., which is just accessible to parents with the luxury of a flexible schedule.

COMMUNICATION BY DOING: URBAN INFORMALITY AS AN EXPRESSION OF NEEDS BY LOW-INCOME IMMIGRANTS

Abstract ID: 433

Individual Paper Submission

DEVLIN, Ryan [The New School] rdevlin@newschool.edu, presenting author

Over the last decade or so, the concept of informality has garnered increasing attention among planning scholars and practitioners in the global North. Much of this work has focused on design interventions advocating for direct, provisional, and reversible interventions in space as a form of relational planning—a way of testing new ideas and inviting discussion and participation (Wohl 2018, Lydon and Garcia 2014). Tactical interventions are conceived of as a tool for planners to plan through provisionality and informality. While this offers an alternative to top-down comprehensive master planning, it does not critically examine who gets to participate, what constitutes “participation”, or the barriers to inclusion that persists in this participatory framework.

In this presentation, I argue for extending the scope of what constitutes participatory planning to informal practices undertaken by low-income immigrant residents to fulfill basic needs like income generation, housing, and transportation—what I have elsewhere called “informalities of need”. Drawing theoretically on scholarship from the global South, I frame informal practice born of need as a mode of urbanization from below (Roy 2005). Two case studies from New York City of conflict over the informal use of space will be used to frame these theoretical arguments. One involves an example of informal vending in a city park that ended with a heavy-handed crackdown. The second example—that of successful campaign to formalize informal basement apartments in immigrant districts, demonstrates the positive social justice outcomes that can result when planners and public administrators the look past myopic focus on regulatory compliance and start to see informal actions as a form of “communication by doing”.

The case studies are guided by a few key research question: how did the initial conceptualization and problem definition of the two examples of informal practices frame responses by administrators and planners? What (if any) alternative forms of participation and listening were employed by public officials to understand why lower income groups turned to informal practice in the first place? How open were public officials to listening to the needs being expressed through practice? How did their openness to listening affect final results of formalization processes? Using in-depth interviews with key stakeholders, analysis of print media, online media, and government documents, this comparison will show how officials in the street vending case were more concerned with legal compliance than needs expressed by vendors, leading to less than optimal results, while in the case of informal housing, city officials were less quick to frame informality as petty rule-breaking and were able to place the issue within a broader context of the need for affordable housing among lower-income immigrant groups.

Through the analysis of these two cases this presentation argues that planners concerned with social justice and inclusion should conceptualize informal practices of low-income immigrant groups as loosely

articulated, often imperfect, sometimes problematic, but always urgent expressions of needs. By listening to needs expressed through informal practice, planners can play a role in opening “spaces of invented citizenship” (Miraftab 2009) where excluded groups can communicate through practice what they need the city to be and to become.

In North America, public transit agencies are often governed by a board of directors, which is responsible for key strategic decisions related to fare setting, project approvals, and long-term planning priorities. The board of directors thus has an enormous impact on the way people move across their communities and regions. It has long been recognized that there is a diversity gap in the representation of women and minorities in the leadership of public agencies as compared to the populations they serve (Johnson and Crum-Cano, 2011; Sandercock and Forsyth, 1992; Bradbury and Kellough, 2011). This research examines how the diversity gap in director representation plays out in terms of unequal participation of women and minorities in transit agency board meetings.

Through a content analysis and interviews, the study analyzes the discourse, the quality of debate, and the perceived experience of the directors in the boardrooms of major transit agencies. The content analysis coded videos from all the 2017 public board meetings of the Metropolitan Transit Agency in New York City, Metrolinx in Greater Toronto, and Translink in Metro Vancouver to identify the individuals speaking, their identities, their level of participation, which topics they participated in, and the manner in which they participate. In addition to the content analysis, in-depth interviews were conducted with board members, chairs and presenters to draw from their perspectives in the boardroom.

The content analysis shows that women and visible minority board members speak proportionately less, are interrupted more, and are less likely to participate in certain topics of discussion related to budgets and major project delivery. Conversely, the interview findings revealed that the board members perceived experiences were different, as women and minority board members do not feel that they were interrupted or participated less than their white male colleagues. The paper concludes by reflecting on the

implications of these findings for the boardroom practices of major public agencies, and the way that the board dynamics impact on key transit investment decisions.

GENDER AND LOCAL GOVERNMENT SUSTAINABILITY: DO DIFFERENT LEADERS PROMOTE DIFFERENT POLICIES?

Abstract ID: 503

Individual Paper Submission

HOMSY, George [Binghamton University] ghomsy@binghamton.edu, presenting author
LAMBRIGHT, Kristina [Binghamton University] klambrig@binghamton.edu, co-author

CENTRAL THEME: Men and women have well-documented differences in leadership style with women tending to be more relational, supportive of colleagues, and democratic than men (Gipson, Pfaff, Mendelsohn, Catenacci, & Burke, 2017). However, the research is mixed about whether those leadership differences translate into different policy outcomes. Some research finds no impact of women leaders on some local government functions such as budgeting or crime control (Ferreira & Gyourko, 2014). Similarly, the impact of women planners on the built environment is not evident and a supposed gender-neutral perspective perpetuates urban planning that privileges men by not taking female needs into account (Greed, 2003) and risks the subordinating planning issues identified as more of a concern to women (Larsson, 2006). On the other hand, corporations with gender-diverse leadership teams tend to be more environmentally friendly (Glass, Cook, & Ingersoll, 2016). And, women elected to office have more years of education than men (Baltrunaite, Bello, Casarico, & Profeta, 2014)—a trait found in the residents of many communities to be correlated with higher levels of sustainability. Given the discrepancy in the literature, we sought to test whether sustainability policymaking is impacted by leadership gender at the local government level. Sustainability sits at the intersection of environmental protection, social equity, and economic development and tends to emphasize values that may map well onto the leadership styles that women tend to possess, such as transformational, collaborative, and democratic.

METHODS: To investigate the question of whether gender differences impact local government sustainability policy adoption, we used the 2015 Sustainability Survey of Local Governments by ICMA (n=793). In addition to asking about the adoption of 80 sustainability policies, we asked whether the highest elected official was a woman or a man. We used a Poisson regression to test whether gender and/or other factors impacted sustainability policy adoption rates. We control for party affiliation as well as other community demographics.

FINDINGS: We find that local governments with women holding the highest elected office are 1.5 times as likely to adopt community-wide energy policies and 1.13 times as likely to adopt social equity policies

as municipalities with men in charge. These are policy areas that may require greater collaboration and therefore may fit better with women's leadership styles. The influence of women leaders is not significant in other areas, such as energy conservation in government operations which save money and therefore may be a priority regardless of gender. Other areas, such as drinking water, are heavily regulated and therefore leaders may have little discretion. Our results suggest that the gender of a leader is another potentially important factor influencing the adoption of sustainability policies by local governments.

TRANS* IN TRANSIT: PUBLIC TRANSPORTATION EXPERIENCES OF PEOPLE WHO HOLD TRANSGENDER IDENTITIES

Abstract ID: 504

Individual Paper Submission

GUY, Tam J. [UCLA] tamjguy@gmail.com, presenting author

Overview of research

Transgender and nonbinary identities are only recently being spoken of and acknowledged by the larger public. Often conveyed through the umbrella term trans*, gender identities beyond the binary assigned at birth include, but are not limited to: transgender, nonbinary, two-spirit, genderqueer, genderfluid, gender non-conforming, pangender, agender, bi-gender, and third gender. It is vital to understand trans* experiences as a part of planning resilient cities, equitable to everyone. The Southern California region, particularly Los Angeles, has been investing heavily in public transit as a part of the solution to reduce greenhouse gas emissions. Yet, not all groups of the public experience transit in the same way. For instance, studies show women as less likely to take transit due to perceptions and experiences of harassment and assault (Hsu, Boarnet, & Houston, 2019; Loukaitou-Sideris & Fink, 2009). Indeed, studies of power dynamics and space often focus on gender (Lubitow et al., 2017). Yet, the experiences of trans* people in public spaces remains understudied, specifically as it pertains to transportation. A 2015 survey in the U.S. by National Center for Transgender Equality (NCTE) revealed that 34% of over twenty-seven thousand people who identify as trans* reported experiencing unequal treatment or service, harassment, or assault on public transit (NCTE, 2015, p. 214). Understanding the experiences of people who identify as trans* can inform policies, processes, and design in transportation planning.

Research question

What is the experience of taking public transit for people who identify as trans*?

Research methodology + data source

This project requires primary data collection. I will conduct semi-structured interviews, approximately 1 hour each, with 10 people. I will get IRB approval prior to recruitment. I will recruit participants at UCLA's LGBT resource center and the Los Angeles LGBT Center (multiple locations). Compensation to participants will be a \$10.00 Visa gift card. Inclusion criteria are that participants use public transit at least once per week and identify within the trans* umbrella. For this sample, I will purposefully seek a diverse array of gender identities and expressions, as well as diverse racial and ethnic identities. As I myself identify as genderqueer and present as masculine-of-center, I will keep a reflexivity journal throughout the process. I will transcribe the interviews. I will code and analyze the data for themes (software assist to-be-determined), ultimately writing a paper on the experiences revealed. The limitations of this study include its lack of generalizability, the possibility of a student-majority sample, and self-selection bias for participants willing to share their experiences.

Findings

Research in progress, paper to be finished by September 22, 2019.

Implications and actionable conclusions

This is a pilot study for my dissertation. Since the transportation experiences of people with trans* identities are understudied, a pilot study will help to generate robust survey and interview instruments as the basis for a larger, mixed-methods study.

I expect the public transit experiences of people who hold trans* identities will highlight issues for this group and its subgroups in the unique public spaces of transit. Knowing what is happening to people and how they deal with it on (or avoid) public transit can inform policies and procedures to make transit equitable in practice. It could inform instruction regarding the use of public space more broadly.

DO MORE ACCESSIBLE AND WALKABLE BUILT ENVIRONMENTS PROMOTE GENDER EQUALITY IN TRAVEL BEHAVIOR? A CASE STUDY IN LOS ANGELES

Abstract ID: 509

Individual Paper Submission

HOUSTON, Douglas [University of California Irvine] houston@uci.edu, presenting author
LO, Ashley (Wan-Tzu) [Tohoku University] wantzu.lo.e1@tohoku.ac.jp, primary author

Previous research has raised concerns that urban sprawl and segregated land uses separate private and public spheres, constrain women to their immediate neighborhoods, and reinforce unequal access to social and economic opportunities between men and women [1]. Gender division of housework and household obligations could lead to differences in travel patterns, which could in turn further reinforce gender differences in household-related tasks [1,2]. Sustainable community design that is more dense, walkable, and accessible, could help address women's social isolation in suburbia and provide greater flexibility for married couples in dividing household out-of-home travel and activities [3,4].

We extend previous studies by examining how regional employment and destination accessibility (REDA) and neighborhood walkability (NW) influence gendered travel patterns. We investigate the following questions: (1) How do married couples respond to built environments differently in terms of travel behaviors?, and (2) Could greater REDA and NW help improve gender equality in daily travel and the gendered division of time dedicated to household-related tasks? We utilize the 2012 California Household Travel Survey to analyze differences in daily travel patterns and activity time for heterosexual married couples in Los Angeles, and examine differences by residential REDA and NW levels. Using propensity score matching to account for residential selection, our multivariate analyses assess the influence of built environments on (i) daily trip number and travel distance by mode and by gender and (ii) gender equality in travel behaviors by mode, after controlling for socio-demographics. Gender equality is defined as the absolute value of the within-household difference in travel patterns for married pairs.

Consistent with previous research [4,5], we found significant gender differences in travel and out-of-home activities. Men on average had greater daily travel distances and automobile trips but walked less than women. We also found that accessibility influenced gender differences in travel behavior. Overall, we found that men and women living in areas with greater employment and destination accessibility (REDA and NW) were likely to walk more, have more daily trips, and travel less by automobile. Multivariate results indicate that, after accounting for socio-demographic factors and residential self-selection, living in an area with greater accessibility was associated with greater equality in daily travel distances, although the effect was moderate.

These patterns indicate that more accessible urban environments are associated with greater sustainable travel overall and suggest that men and women respond to regional accessibility and neighborhood walkability differently in terms of travel behaviors. Findings suggest policies that promote more compact design with greater local and regional accessibility could bring moderate alleviation to gender inequality in travel and access to social and economic opportunities between men and women.

THE DUAL-EARNER HOUSEHOLDS AND GENDER GAP IN COMMUTING TIME

Abstract ID: 533

Individual Paper Submission

LEE, Annie [Rutgers, The State University of New Jersey] a.lee@rutgers.edu, presenting author

As women's educational attainment level and labor participation rate increases, the number of dual-earner household also increases. Research on commuting behavior suggests that women's travel time to work (or commuting distance) is shorter than the men's (White, 1986). The household responsibility hypothesis explains women's dual-role; married women take the prime responsibility of the housework and while they also financially support the family. Since working women have this dual role, they tend to choose a workplace closer to their homes (Johnston-Anumonwo, 1992; Madden, 1981; Turner, 1997).

As the gender gap in employment and education has decreased, women's status in the workplace has improved. But it's unbelievable that the commuting behavior of dual-earner households has changed. In this research, I analyze the commuting behavior of dual-earner households to investigate whether the household responsibility hypothesis still holds.

For the analysis, I use the Census Bureau's 2017 American Community Survey Public Use Microdata Sample (PUMS) 1-year dataset and use a series of statistical models to compare the gender gap across. Dual-earner household types are based on educational attainment level and income levels; (1) Husband's educational level (Income level) > Wife (2) Husband = Wife (3) Husband < Wife. For the comparison, I divide the educational level into five categories (lower than high school, high school diploma, some college or Associate's degree, Bachelor's degree, and Masters/Professional Degree). Income is divided into four quartiles. I compare the standardized coefficients of the gender gap for these six dual-earner household types against those of single-earner households.

I find women still spend less time commuting than men do (both in the single-earner household and dual-earner household). The severity of the gender gap differs across household types. In general, the gender gap for dual-earner households is larger than that for single-earner households. Within the different types of dual-earner household, the gender gap was as might be expected, lowest for Type 3 household (Husband's educational / income level < Wife) and largest in Type 1 (Husband > Wife) household. This suggests women in the U.S. continue to take prime responsibility for the household, despite an increase in their labor market participation. When the wife's educational level/income level is higher or similar to their husband's, their responsibility with respect to housework tends to be lower. This has a diversity of explanations; The husband may participate more in the housework. The household may purchase these services (purchase daycare, eat out, get household labor).

LOCAL IMMIGRANT INTEGRATION STRATEGIES AND CITY NETWORKS: WELCOMING COMMUNITIES TRANSATLANTIC EXCHANGE

Abstract ID: 613

Individual Paper Submission

AY, Deniz [Free University of Brussels] dnzay19@gmail.com, presenting author

The need for management of diversity at the local level has become the basis of various “welcoming” strategies, programs, or initiatives as an urban policy framework for integration. With increasing pressures to ‘manage’ diversity at the city level, some cities came up with formal welcoming plans while others even sought accreditation for their ‘welcomeness’ as a city. There is no single reason why cities want to manage their diversity while signaling a welcoming message with their agenda. Objectives of welcoming programs may range from gaining, or regaining, economic competitiveness with diversity-conscious local economic development agendas (especially for cities that are losing population, jobs, and investment due to changing regional and global economic dynamics) to alleviating political and social tensions that arise with growing diversity within communities. This paper studies how welcoming city strategies are developed both locally and transnationally across cities in the US and Germany by mobilizing a wide range of community partners: What is the role of horizontal knowledge exchanges between cities, both at national and transnational level, in shaping local integration policy? How does a city network focusing on immigrant integration through welcoming strategies impact the existing community development efforts and the solidarity between communities? Empirical focus of this study is an innovative knowledge exchange platform called the “Welcoming Communities Transatlantic Exchange”, which is an initiative led by the Welcoming America, a ‘non-profit, non-partisan organization’ and a movement of ‘communities’[1]. A qualitative case study on selected cities participating the exchange program is conducted to explore the function of the networking within and across the participating cities. By using multiple case study design, this study explores the emerging “best practices” in local integration policy and the “local globalness” of urban policy making with respect to the management of diversity at the city level. Findings suggest that the knowledge exchange facilitated by the city network has immediate tangible outcomes in terms of building new community partnerships and mobilizing innovative ideas on how to become more welcoming. However, the knowledge exchanges tend to be deeper between cities that resemble each other in their strategic positioning with respect to the global economy. Besides the knowledge exchanges between the cities, the involvement with city networks also triggers synergies between the involved community partners at the city level. This paper contributes to the research on local immigration policy and integration practice that has great importance to planning research and education as diversity has become a major force that imply remarkable social, economic, and cultural change in cities. This analysis of the transnational knowledge flows with solid community development consequences shed light on how cities manage their ever-growing diversity while surveying the state-of-the-art in integration strategies in place.

CONSTRUCTING WOMEN'S IMMOBILITY: FEAR OF VIOLENCE AND WOMEN'S CONSTRICTED TRAVEL BEHAVIOR AT NIGHT

Abstract ID: 648

Individual Paper Submission

ZHANG, Mengzhu [Department of Urban Planning and Design, the University of Hong Kong] mengzhu.zhang@pku.edu.cn, presenting author
HE, Shenjing [The University of Hong Kong] sjhe@hku.hk, co-author

Despite rapid advances in ICTs, transport infrastructures and public transits that generally enhance people's daily mobility and travel conveniences in cities, women, as the vulnerable body to sexual harassment, robberies and any other crime in urban context, are still heavily circumscribed by the socially-constructed fear of violence to enjoy the equal mobility as men have. The fear-induced gendered immobility not just aggravates women's disadvantages in job market and narrow down their job choices to near home areas, but also deprives women of other social opportunities for cultivating valuable social networks, and thus substantively, contribute to the social reproduction of gender inequality in a wider aspect.

Albeit noticed very early by feminist sociologists and social geographers, fear of violence as alternative other than gender role and limited access to resources for explaining the gender differences in travel behavior in general, and women's constricted daily mobility in particular has been understudied by transportation researchers and urban planners. This paper aims to fill this void by engaging with Pain's (1997) seminal work on the heterogeneity, spatiality and temporality of women's fear of violence, and theorizing and empirically examining the fear-induced, time-sensitive gendered constricted travel behaviors at night. Through answering the questions on (1) how the fear of violence differently affects women and men when considering travel at night and (2) how gendered fear of violence engenders women's constricted travel behavior at night compared with men, this paper not just contributes to a systematic, quantitative epistemology of the relationship between gendered fear of violence and gendered mobility, but also inform gender-sensitive urban planning and built environment design that seeks to enhance women's daily mobility and mitigate travel-based social exclusion in urban context.

Specifically, with using a large-scale household survey dataset from two Chinese cities, this paper try to (i) firstly, delineate the differences in perceiving fear of violence between men and women in terms of returning home alone at night, and towards different key transport nodes (i.e. outlying bust stations, underpasses and back streets), and examine the demographic and built environment factors that impact women's varying degree of sense of fear when considering returning home alone at night with using Logistic Regression Modelling; and (ii) secondly, to examine the impacts of fear of violence on women's and men's return-home travel behavior at night, in terms of (a) whether to return home at night, (b) when to return home, and (c) travel mode choice for returning home at night with using Structural Equation Modeling.

THE WHITENESS OF POLICE CARE: SECURITY AND PLANNING IN CENTRAL ATLANTA

Abstract ID: 678

Individual Paper Submission

SHERMAN, Stephen [University of Illinois at Urbana-Champaign] sashermin@illinois.edu, presenting author

Plans increasingly integrate urban security measures, though this integration depends on a variety of institutional and political factors. Popular discourse and media largely frame security problems, with discrete and racist effects on urban plans and morphology. Local governance institutions may insert security measures into urban plans, and are more likely to do so at the neighborhood scale (Tulumello, 2017). Yet the growing body of research into security and planning shares a narrow conception of security, mostly examining security vis-à-vis crime and policing. This occurs despite diverse forms of "security" (notably, food security and infrastructure security) assuming increased importance within planning thought. Within my research, I examine how a critical approach to security—inspired by critical race theory and philology—opens up new understandings to planning's role within the racial state. Within this research, I investigate urban security projects as projects centering on care (Hamilton, 2013), and ask how these care projects inform property and urban planning within the racial state (Singh, 2014; Goldberg, 2002; Harris, 1993).

This research, representing an exploratory chapter of my dissertation, investigates policing and planning in and around two of Atlanta, GA's central urban universities: Georgia Tech & Georgia State. This

project's method and design drew upon the geo-narrative approach of Mei-Po Kwan (Kwan & Ding, 2008). Forty-five subjects installed apps onto the phone. For one week the apps logged their movements, and allowed the subject to enter geo-logged text and photographs through which they could narrate their impressions on policing and security within their urban peregrinations. Additionally, the subjects and I bookended their geo-narrative week with two one-hour interactional interviews.

Through these notes and interviews, a salient point emerged: police and crime had a very weak association with security. Even subjects who were not otherwise critical of police did not link police to security or safety; rather, police presence amplified anxiety, and geo-narrative data attest to this in powerful ways. Drawing further on interview data, race emerges as a crucial variable through which to understand the relationship between policing, care, and security. The majority of white and Asian subjects expected police to deliver care, either through healthcare delivery or by protecting the boundaries of their community from outsiders. My research highlights numerous instances of police caretaking practices, and attests to the sense of security most White students felt due to police work at the campus's border. However, all but one Black research subject emphasized the many ways that police presence amplified anxiety and failed to deliver care. They drew on personal history and extensive negative encounters with police. Collectively, subjects' interviews and geo-narratives attest to the powerful, yet oftentimes non-violent, ways that police power shaped urban space through their relationship to care.

Research unearths three related findings. First, I emphasize how police care (and not just violence and arrest) territorializes race within the racial state's urban space. Creating spaces of whiteness through racial banishment (Rothstein, 2017; Roy, 2017) entails violence yet also a series of diverse caretaking practices executed through the state's discretionary power to police. This relates to the second finding: a key aspect of whiteness's property (Harris, 1993) is the expectation of care, delivered through the state's police. This informs the third finding: planning scholarship centralizes planning's relationship to security at the urban scale. Yet, this research emphasizes security's production at two other scales: 1) the nation-state, which propagates racial categories onto which police operate, and 2) the body, which is the site of the anxiety (or care) produced by police. I conclude with discrete recommendations for planning practice.

FROM 'FORGOTTEN NEIGHBORHOOD' TO COMMUNITY ASSET: RECTIFYING THE NARRATIVES OF TERRITORIAL STIGMA

Abstract ID: 767

Individual Paper Submission

REDDEN, Ty [Gettysburg College] tredden@gettysburg.edu, presenting author
DEDENBACH, Laura [University of Florida] laurajd@ufl.edu, co-author
LARSEN, Kristin [University of Florida] klarsen@ufl.edu, co-author
FRANK, Kathryn [University of Florida] kifrank@ufl.edu, co-author

Storytelling is profoundly powerful, capable of traversing cultures and superseding socio-political differences. The daily practice of planning is often an exercise in reconciling the stories of residents' present-day realities with historical development patterns and institutional practices to create narratives. Planners have written extensively regarding their positive role in acquiring a multifaceted perspective that weighs the narratives and vested interests of all stakeholders in development decision-making. Planners both learn the stories of their locales and shape the resulting development narratives, advocating for policies and justifying decisions (Sandercock 2003).

But to what extent have planners used storytelling and narratives to reinforce existing biases and perpetuate hierarchies of social inequality in the built environment? And how could they guard against this in the future? Termed "territorial stigma," social ills are projected on specific urban neighborhoods (and their residents), associating them with persistent narratives that include poverty, racialized minority identity, dilapidated housing, and crime (Wacquant, Slater, & Pereira 2014). In marginalized communities, a vicious synergistic cycle can unfold as development decisions affect neighborhood trajectories and neighborhood trajectories become the basis for future development decisions. As one possible antidote to territorial stigma, narratives can be re-framed and promoted through empowerment planning, which is the use of participatory action research, direct action organization, and education to develop both individual and community capacity to seek beneficial outcomes (Rocha 1997).

Accordingly, this study examines the Porters community, a historically African-American neighborhood located in Gainesville, Florida. Although located near the University of Florida campus, Porters residents have long combated urban disinvestment, infrastructural decay, and biased narratives that have attributed inherent social ills to the neighborhood. The most widely and succinctly articulated narrative in Porters' past was "The Forgotten Neighborhood," which in the mid-2010s was doing nothing to counter the urban redevelopment chipping away at the neighborhood's historic physical, social, and cultural fabric.

Employing historical analysis of planning documents and news articles, and secondary sources, we reveal how and why planners in the Porters case perpetuated territorial stigma through the entrenchment of implicit racial bias in planning culture. To understand the broader planning culture of the times, we apply the literature to mark the evolution of planning and community development practices, including the recognition of diversity and inclusive planning and the eventual identification of empowerment planning as a means to combat territorial stigma (Umemoto 2001). The study contributes insights from a recent 15-month empowerment planning project we conducted with Porters residents and stakeholders, along with interviews of City staff, to create a new, positive neighborhood narrative that identifies the neighborhood as a community asset.

The study advances existing research, asserting that territorial stigma is not simply externally imposed on locales by the general public, but is integrated and reproduced in planning documents and further entrenched through development policy. The study expands the scope of previous examinations, capturing not only the effects of territorial stigma on marginalized communities like the Porters case, but interrogating the role of planners in perpetuating spatial injustice. The researchers affirm the fluid nature of narratives and offer empowerment planning as a means to replace stigma with a narrative of community resilience, and to infuse the new narrative into policy (Howell 2016).

THE DARK SIDE OF LOCAL INTEGRATION POLICIES: THE CASE OF DAY LABORERS IN THE UNITED STATES

Abstract ID: 808

Individual Paper Submission

NICHOLLS, Walter [University of California Irvine] wnicholl@uci.edu, presenting author

Central Themes:

This paper examines local integration policies through the case of immigrant day laborers. The paper suggests that from the 1990s onwards day laborers presented local officials with a “wicked problem” (Rittel and Weber 1973). Most of the laborers were poor and recently arrived immigrants. They often searched for day work in visible locations like busy street corners and parking lots in predominately white suburbs (Valenzuela 2003; Theodore et. al. 2015). As pockets of day laborers flourished, local officials struggled to develop policies to govern the population. This paper examines the principal policies and their consequences.

Methodology

The paper analyzes local battles and policies concerning immigrant day laborers across the country and then focuses in on the Los Angeles suburb of Pasadena. To address local battles across the country, I gathered newspaper articles through LexisNexis searches with the keyword “day laborer”. The resulting database consists of 1,503 newspaper articles, from which 12,652 claims were extracted. The database includes 75 newspapers from different localities. I then coded claims for municipality, stakeholders, types of arguments for and against immigrants, and types of policies.

The paper performs 17 with activists, advocacy organizations, and city officials with direct experience working on day laborer policies in Pasadena. The paper draws on historical archives from four immigrant advocacy organizations in Pasadena and minutes from 14 Pasadena City Council meetings for the period 2000-2010.

Findings

In the 1990s and 2000s, local elected officials across the country adopted various strategies to address immigrant day laborers in their jurisdictions. Two prominent strategies emerged. A punitive strategy sought to govern immigrants through force. Local officials employed established ordinances (loitering, traffic, housing regulations) and created new ones (bans on the public solicitation of work) to criminalize immigrant laborers and make their lives impossible. These efforts aimed to govern this “abnormal” population by banishing it (Foucault 1976). Additionally, a disciplinary strategy sought to govern immigrants by integrating and normalizing them with “worker centers”. Through these centers, immigrants were provided a proper place to look for work and services to assimilate them into the local culture. The case of Pasadena demonstrates the limits of disciplined integration. Many day laborers resisted to seek out labor within worker centers. Their continued presence on the streets resulted in the rollout of increasingly punitive practices to compel “deviant” laborers to conform. The paper therefore conceives both strategies as aiming to achieve a common goal: the governance of a stigmatized and illegalized population.

Relevance

Immigration has become one of the defining features of urban change. While sociology and geography have addressed the issue with great sophistication (Varsanyi 2014), urban planning, with several notable exceptions (Gonzalez 2017), has been slow to examine the effects of immigrants on planning and policy. In a period when immigration is at the forefront of national politics, urban planners must address the issue more than ever.

COLORBLIND RESILIENCY AS RACIAL FORMATION IN URBAN PLANNING

Abstract ID: 812

Individual Paper Submission

BRAND, Anna [University of California Berkeley] annalivia@berkeley.edu, presenting author
BIRCH, Traci [Louisiana State University] tbirch@lsu.edu, co-author

Planning in the last decade has centered narratives about resiliency, sustainable development, and climate adaptation. This is particularly true in the New Orleans region, where Katrina, many planners and policymakers argued, was an opportunity to address the region’s increasing environmental vulnerability and its unsustainable land use and development patterns. In the last decade, wide-ranging and multi-scaled planning efforts have reimagined New Orleans’s future, yet they have largely done so in ways that are blind to deeper racial geographies and inequalities. As a result, urban resiliency and greening efforts

have contributed to displacement, unequal property valuation, and gentrification - causing many already disadvantaged residents to be less resilient rather than more. Thus, despite the fact that New Orleans is viewed by many planners and policymakers as the pinnacle of resiliency planning, planning processes and visions have re-inscribed racialized vulnerability via greening and resiliency processes, ideas and tactics.

Increasingly scholars are bringing focus to the unequal impacts of urban greening and resiliency planning efforts and the ways that they contribute to unequal geographical formation (Davoudi, 2012; Fainstein, 2015; Anguelovski, Connolly and Brand, 2018). Indeed, as Hardy, Milligan and Heynen (2017) argue, “colorblind adaptation planning” ignores the deep and unequal histories of racial-geographic formation, perpetuates racial inequalities in climate adaptation landscapes and creates new experiences of displacement, erasure and invisibility. As Safransky (2014) notes, greening the urban frontier hinges on processes of erasure and narrating “empty” landscapes as those in need of being revitalized, raising critical questions about how settler colonialism is at work in resiliency planning efforts, despite their normative commitments to environmental justice. While planners are committed to generalized ideas of green justice, the meaning and use of the spaces created through such planning efforts differ radically depending on which side of the racial-geographic divide you are on.

In this research, we ask how planning praxis perpetuates urban inequalities in the context of urban greening and how, upon further investigation, resiliency planning efforts re-inscribe unequal racial geographies. We examine how conceptualizations of resilience in urban planning are rooted in colorblind racism. Drawing on content and discourse analyses of resiliency planning in the New Orleans region, as well as interviews and observations, we examine the content, visions, processes and emerging repercussions of major planning efforts such as the New Orleans Water Plan, LA SAFE and the New Orleans Resiliency Plan. From our findings, we argue that rather than promoting a more resilient community for all, the colorblind approach has led not only to undemocratic planning processes, but also to the development of projects that further exacerbate issues of racialized inequality. In this paper, we analyze how concepts of resilience contribute to racial formation in shaping the region’s future through the lens of urban planning. This research contributes to planning scholarship by critiquing how concepts of resiliency, as deployed in planning practice, heighten vulnerability for communities of color and, from this analysis, we offer theoretical insights as to the limits and possibilities of addressing both racial and environmental justice.

LIVING WITH DEMENTIA IN SUBURBAN PUBLIC SPACES: UNDERSTANDING NEIGHBOURHOOD EXPERIENCES TO IDENTIFY ENABLING AND DISABLING BUILT ENVIRONMENT FEATURES IN ORDER TO BUILD MORE INCLUSIVE COMMUNITIES

Abstract ID: 860

Individual Paper Submission

BIGLIERI, Samantha [University of Waterloo] samantha.biglieri@uwaterloo.ca, presenting author

The World Health Organization calls dementia the leading cause of dependency and disability among older adults, and globally, the number of people living with dementia (PLWD) will rise from 47 to 115 million by 2050. Contrary to popular belief, most PLWD live in the community as opposed to congregate living settings, however research on the accessibility of public spaces and the impact of the neighbourhood for this population is nascent (Biglieri, 2018). The influence of place, neighbourhood and context are recognized as some of the most important determinants of wellbeing (Corburn, 2009), and this is more acute for older adults (Ghani et al., 2018). Further, suburbs have been shown as having a negative impact on the mobility of older adults and their ability to live well (Kerr et al., 2012). This is problematic considering that the vast majority of older adults in North America live in suburbs and have expressed a desire to age in place, and PLWD deserve to age in place like their peers. This research investigates how PLWD experience their suburban neighborhood's public spaces as enabling/disabling by examining (1) PLWD's perceptions of their neighborhood and mobility prior to diagnosis, in the present, and in the future and (2) their mobility patterns and interaction with local environment.

This exploratory nested case study examines the neighbourhood experiences of seven individuals self-identifying as community-dwelling with mild/moderate dementia, living in suburban Waterloo, Canada. Multiple methods including in-depth interviews, two go-along interviews, and two-week GPS tracking and travel diaries were used to provide deep insight into individual experiences of their neighbourhoods, as well as examining similarities across cases. Go-along interviews were geocoded, with quotes being represented in space with corresponding visual images of the physical locations, and in-depth interviews were transcribed verbatim, then both analyzed using a grounded theory approach to elucidate enabling and disabling features in suburban spaces for PLWD. GPS data and travel diaries were used to expand and complement the enabling/disabling factors.

While this research highlighted barriers for participants, their suburban neighbourhoods were often perceived as enabling in diverse ways, highlighting the need for more nuanced understanding of everyday life in suburban settings. Enabling built environment features fit into three categories: landmarks for orientation (e.g. street signs, commercial stores, natural areas); street designs, micro infrastructure, and architectural features that produce feelings of comfort, familiarity, and safety; and proximity of amenities. Disabling features split into two themes: street designs that produce feelings of fear, discomfort and unease; and a lack of proximity of amenities. GPS and travel diary data expanded understandings of enabling/disabling by identifying independent and dependent mobility patterns, the distance and times traveled from home, and the most frequent types of trips. Further, when comparing perceived and lived mobility (hand-drawn maps and interviews with GPS and travel diary data), there was often an incongruence – both in overestimating and underestimating travel outside the home.

In pursuit of the just city, it is vital to understand what an enabling environment looks like for marginalized groups like PLWD. This research provides a fuller picture of the mobility and experiences in suburban neighbourhoods for PLWD, and the identification of enabling/disabling features can provide guidance to planners and policymakers on creating more inclusive suburban places. Further, it contributes to the larger project of theorizing suburban space in terms of everyday life and socio-spatial supports for/barriers to wellbeing for vulnerable populations (Lo et al., 2015).

WHITE PRIVILEGE, PLANNING PRACTICE, AND CITIZEN PARTICIPATION: UNPACKING BARRIERS TO SOCIAL EQUITY

Abstract ID: 945

Individual Paper Submission

YIN, Jordan [Alabama A&M University] jordan.yin@aamu.edu, presenting author
ERICKSON, Emily [Alabama A&M University] emily.erickson@aamu.edu, co-author

In her classic work on a “A Ladder of Citizen Participation,” Arnstein (1969) observed that efforts to promote citizen participation typically fail to result in community-controlled initiatives that effectively address the needs and desires of disadvantaged communities. Decades of subsequent research and practice have continued to address this unresolved and problematic issue. While there are many factors and practices that influence the relationship between planning and citizen participation, the role of white privilege in planning practice as a significant barrier to citizen participation has not been fully articulated or explored.

This paper examines the basis of white privilege in planning practice and develops a model for examining the barriers to citizen participation that are posed due to white privilege. As conceived by McIntosh (ca. 1989) and others, white privilege is unearned and conferred due to structural biases and inequities. Therefore, white privilege is an influence on planning practice that exists whether or not a planner intends to knowingly benefit from their privilege. In this sense, the presence of privilege provokes a constantly shifting dialectical context for planning and the paper examines the structural characteristics that confer white privilege to planners.

The paper develops a conceptual model of the relationship between the privilege of planners and citizen participation examining how the influence of white privilege is typically actioned through behaviors of exclusion, discounting, certainty, and asymmetry (Kendall, 2002) across the various stages of the citizen participation process (see Bryson, Quick, Slotterback, & Crosby, 2013) to impose specific barriers to meaningful citizen participation.

The paper concludes by considering how various approaches to unpacking the privilege of planners as both a responsibility of the profession and an individual-level professional competency for practicing planners (Thomas, 2008) could resolve existing barriers to citizen participation and promote greater social equity in planning.

THE INFLUENCE OF MICROAGGRESSION ON MUSLIM WOMEN'S WALKING BEHAVIOR

Abstract ID: 1052

Individual Paper Submission

MOHEBBI, Mehri [University of Cincinnati & Planning Communities] mohebbmi@gmail.com, presenting author

CHIFOS, Carla [University of Cincinnati] , co-author

LINDERS, Annulla [University of Cincinnati] annulla.linders@uc.edu, co-author

PALAZZO, Danilo [University of Cincinnati] danilo.palazzo@uc.edu, co-author

During the last two decades, emphasis on social components of walking behavior has created an emerging discussion in walkability discourse. The socioecological model of walking behavior is one of the models, which determines social factors impacting walking behavior. This model discusses life-cycle circumstances at the individual, group, and regional level, which impact one's decision to walk or not walk in an urban neighborhood (Alfonso 2005; see also Mehta 2008). The present research study explores social components of urban accessibility and the influence of those factors on walking behavior of a culturally cohesive disfranchised group, Muslim women, in the Detroit Metro Area. This research determines whether a higher level of walkability in an urban neighborhood encourages walking for Muslim women or social factors impact Muslim women's walking behavior more effectively than built environment components. The socioecological model of walking behavior introduced by Alfonso was used to determine the impact of Muslim women's life-cycle circumstances at individual and group level.

Detroit Metro Area hosting one of the highest concentration of Muslims in the U.S. is a good study area for the present research. This area also represents one of the most diverse Muslim communities within urban America due to their countries of origin, religious affiliations, language skills, and years of living in the U.S. This considerable diversity among Muslims in the area provided us with an insightful perspective on Muslim's cultural values and the roles those values play in Muslim women's social life experiences. The present research tends to answer three questions of (1) does fear of others (non-Muslims) diminish

Muslim women's presence in studied public spaces (e.g. walking trails and sidewalks), (2) would living in urban neighborhoods with the majority of Muslims as residents promote Muslim women's walking behavior, and (3) what kind of barriers do community planners face to engage Muslim women in planning processes. This paper presents the outcomes of qualitative research conducted from early 2013 to late 2016 to answer those three questions. A set of research activities were completed in this period from several participants observations in walking trails and urban parks, to semi-structured interviews with 122 Muslim women as participants.

This study revealed that four factors impactfully influence interviewed Muslim women's walking behavior: 1) fear of otherness, 2) social acceptance within Muslim community, 3) cultural differences with non-Muslims, and 4) built environment components. Fear of otherness was the most impactful factor mentioned by study participants, which includes sub-factors such as micro-aggression. Microaggression has long been mentioned as an impactful factor influencing urban population's social experiences (Wing Sue 2010). This paper introduces a model for walking behavior based on interviewed Muslim women's experiences, highlighting the phenomenon of microaggression and its overarching impact on Muslim women's social lives in the Detroit Metro Area. Results of this research will also provide community planning experts with the knowledge they need to communicate with this minority group and provides a new lens through which urban planners could see Muslim minorities' priorities and limitations related to their level of urban accessibility.

MAKING LESBIAN SPACE AT THE EDGE OF EUROPE: QUEER SPACES IN ISTANBUL

Abstract ID: 1072

Individual Paper Submission

ATALAY, Ozlem [Florida State University - DURP] oa17b@my.fsu.edu, presenting author

DOAN, Petra [Florida State University] pdoan@fsu.edu, co-author

Although it is explicit that there is an increase in the visibility and rights of LGBTQ+ community in Western world cases, there are still place-based struggles for LGBTQ+ individuals to cope with discrimination in housing, public accommodations, and access to safe public spaces. The level of struggle roughly corresponds to the overall visibility of LGBTQ populations as well as the racial, class and gender background of LGBTQ individuals across geographies. Moreover, this struggle is compounded by cross-cutting urban issues such as gentrification, and urban redevelopment practices that leave out the interest of marginalized and underrepresented groups.

There is a limited body of research regarding queer spaces in Turkey, and almost nothing concerning lesbians. In general, women in Turkey have struggled to have an active public presence, but public

attitudes about homosexuality have created even more difficulties for lesbians. Accordingly, lesbian spaces have been more embodied and even less explicitly visible in public spaces than in the west.

This study aims to make the invisible more visible by examining the space-making strategies of the lesbian community during the late 20th and early 21st century when LGBTQ activism reached a high point in Turkey. The 1990s saw the establishment of the first Turkish LGBTQ organizations, and 2003 saw the first pride parade. During the 1970s when the LGBTQ movement was gaining visibility in the US, that activism shaped the physical and social arena of queer life. In this paper we examine a similar situation at the edge of Europe and Asia, though at a later time period. To explore this topic we use in depth interviews gathered through snowball sampling of lesbian women who lived in Istanbul during the turn of the century, participated in the lesbian scene, and were involved in community activism. We also analyze the archives of two important LGBTQ organizations in Turkey; LAMBDA Istanbul and KAOS GL as well as review relevant newspaper coverage of LGBTQ activism.

Through our research, we trace the “invisible” power of lesbians in the queer space making in the Beyoglu neighborhood of Istanbul. We see three different strategies employed by lesbians in their creation of safe spaces. In the first strategy, we found that lesbians established/opened their own businesses such as restaurants not only to welcome the lesbian clientele but also to host the other sexual minorities. Thus, LGBTQ+ individuals could socialize without fear of harassment and discrimination in such areas. A second strategy used by lesbians was to utilize domestic spaces such as homes to socialize and to push for lesbian activism. Finally, some lesbians were able to appropriate gay and heterosexual dominated spaces such as gay bars, and women’s organizations to carve out safe spaces. Since there was not an evolved visibility of the lesbian community yet, they were not the target of pervasive hate crimes or harassment as long as they managed gender performativity and did not reveal their sexual orientation. These strategies made effective use of a trade-off between visibility and being safe.

Further work will explore later time periods of queer spaces in “New Turkey” through gentrification and urban planning implementations under the governance of Justice and Development Party.

GENDERED TRAVEL AT EVERY AGE: TRIP FREQUENCY AND PURPOSE AMONG CHILDREN, ADULTS, AND SENIORS IN THE STATE OF GEORGIA

Abstract ID: 1112

Individual Paper Submission

KASH, Gwen [Georgia Institute of Technology] gwenkash@email.unc.edu, presenting author
MOKHTARIAN, Patricia [Georgia Institute of Technology] patricia.mokhtarian@ce.gatech.edu, co-author

Gender profoundly influences how we travel and what we use those trips for. However, the effects are not the same across all ages and life stages. How can researchers best understand the interrelated effects of gender and age? Previous studies have found that young girls are given less leeway to travel independently (McDonald 2012). Adult women have more complex trip-making patterns than men, and are disproportionately responsible for household-serving travel (trips made to maintain the household or its members) (Taylor et al 2015). Elderly women are likely to give up driving sooner than men, and suffer disproportionately from being immobile or housebound (Loukaitou-Sideris et al 2018). All of these effects can reduce women's quality of life, but many of them remain hidden if researchers do not incorporate age, gender, and the interactions between the two into analysis.

This study examines trends in mobility and trip purpose by gender and age through analysis of the Georgia subsample of the 2017 National Household Travel Survey. Daily trip-making is modeled as a function of gender and age using a count model for total quantity of trips made. Multivariate probit analysis is then used to examine differences in trip purpose. Even for age cohorts where there are not significant gendered differences in the quantity of travel, analysis of trip purpose suggests that female travelers may be deriving fewer benefits from their trips. For example, while adult women do not travel significantly less than men, their trips are more likely to be devoted to household obligations. This discrepancy in trip purpose starts in childhood and is readily evident among teenagers. Despite making fewer trips overall, we find teenage girls are more likely than teen boys to make trips devoted to transporting other household members. These findings reveal how structural inequalities, including discrepancies in the allocation of household tasks and gendered stereotypes about responsibility and vulnerability, are inscribed on day-to-day travel behavior. Unless we attend to these broader social forces, improvements to women's mobility may not realize their full potential to improve women's access to opportunity and community.

Taken together, the findings indicate that, while the specific effects vary by age, gender pervasively shapes travel behavior from childhood through old age. Female children, teenagers, and older adults are less mobile than their male counterparts. Female adults are as mobile as men, but more of their trips are devoted to household labor. The specific policies needed to promote equitable transportation vary by age group, but this study reveals one constant: a gendered lens is critical when planning for the needs of travelers of every age.

MANSPLAINING STILL THE NORM: GENDER DYNAMICS IN PLANNING WORKPLACES

Abstract ID: 1119

Individual Paper Submission

TURESKY, Marisa [University of Southern California] turesky@usc.edu, presenting author
WARNER, Mildred [Cornell University] mew15@cornell.edu, co-author

Planners' workplaces are diversifying with respect to gender, but office culture and policies do not always reflect such change. We use a 2015 national survey, conducted with the American Planning Association's Women and Planning Division, to assess if planners' perceptions regarding workplace culture and benefits differ by gender and organizational characteristics of the planning office. Regression model results indicate that women were less likely to feel heard in their workplace or perceive equal opportunity, but the gender of management was a statistically significant predictor of sensitivity to gender issues, support for flexible benefits and equal opportunity for pay and advancement. Building from theories on role congruity, expectation states, representative bureaucracy, and transformational leadership, we argue management and communication dynamics are key to improving the gender dynamics of planning workplaces.

THREE PILLARS OF GENDER SENSITIVE PLANNING

Abstract ID: 1204

Individual Paper Submission

SARMISTHA, Uma [University of Florida] uma.sarmistha@gmail.com, presenting author

The recent urbanization report (UNDP, 2014) states that almost 55% of the world population is living in urban areas. Rapid urbanization, especially in developing nations, along with less than adequate infrastructures and resources is creating multidimensional problems of deprivation, poverty, and gender violence (see Beall and Fox, 2009) and many other planning challenges. Gender-based Violence is widely prevalent and occurs in both public and private realms. According to the United Nations, up to 35% of women experience some kind of violence in their lifetime. Over the last few decades, issues of violence have evolved as a primary concern in many societies around the world. Both the threat of its occurrence and its actual incidence curtail women's freedom, affect their ability to realize and fulfill their potential, and hinders their effective participation in the development process (Panda and Agarwal, 2005). Numerous studies have also explored the reasons for violence against women and girls and blamed it to the failure of urban planning in understanding the needs of women (Sassen, 2016). Studies have also discussed the need for inclusion and safety measures in urban planning to make the city safer for women and girls.

In India, the current model of development lacks the essential linkages between gender sensitive planning and safety, equal access to amenities and good governance. With this background, the paper will focus on exploring the reasons for the failure of planning in creating gender-neutral public space.

This paper discusses the failure to achieve safe urban spaces for women even after many positive measures taken by policymakers such as more police. This paper also explores the reasons behind the increase in incidences of violence against women and girls in urban India. This study utilizes primary data collected in 2017 from four states in India (Bihar, Jharkhand, Himachal, and Haryana). The preliminary findings suggest that the lack of basic amenities like street lights, water facilities, bathrooms, etc followed by lack of policing and poor governance at the local level is leading to public space violence against women and girls. This phenomenon is especially omnipresent in the second and third tier cities of India.

As per UN-Women report on safe city (2010), "A safe city is one that promotes the elimination of gender-based violence, while at the same time promoting equal opportunities for men and women in all the spheres of social, economic, cultural and political life", the paper argues that only planning for safety provisions is not enough to curtail public space violence. We need more inclusive gender sensitive urban planning that will stand on three pillars: safety, good governance and equal access to amenities.

MEASURING SOCIAL DIVERSITY DYNAMIC U.S FROM 2010 TO 2015 AND HOW IT IS ASSOCIATED WITH THE LAND USE PATTERN

Abstract ID: 1244

Individual Paper Submission

CHEN, Yan [University of North Carolina at Chapel Hill] yanc@live.unc.edu, presenting author
SONG, Yan [University of North Carolina at Chapel Hill] ys@email.unc.edu, co-author

Since the 1970s, economic inequality has grown, resulting in socioeconomic polarization and spatial segregation, especially in urban areas. Therefore social diversity has gradually become a central value in urban planning. In this study, we applied an innovated diversity entropy measure based on a study last year (Chen & Song, 2018) to identify the social diversity performance in places using the ACS 5-year estimates data from 2010 to 2015 within all U.S metropolitan statistical area at census block group level. The new measure mitigated some critical issue that not properly addressed by the original “Shannon entropy” by combining the accessibility, location quotation, and entropy measure together, therefore, become much more valid with the spatial and regional context consideration and much more applicable for small spatial study unit such as census block group. After identifying the performance of social diversity, then we use an multi-year land use dataset compiled from previous study (Chen & Song, 2018) with same scale and resolution to explore how land use mix pattern is associated with social diversity change and compared the result with previous studies in similar topic to see how the application new measure will affect the validity of the study.

THE NEXT TIER OF THE DIGITAL DIVIDE? TOWARD A MORE INCLUSIVE FRAMEWORK OF COMMUNITY REPRESENTATION AND IDENTITY ON SOCIAL MEDIA

Abstract ID: 1261

Individual Paper Submission

CRUZ-PORTER, Annie [Purdue University] acruzpor@purdue.edu, presenting author

The concept of representation and identity on social media suggests that it serves as a space where participants may freely align themselves with chosen values, politics and emotions (Ellison, 2007, Schwartz and Halegoua, 2014). Social media interactivity is conceived as a process, which in turn, influences the perception of status, reputation and credibility. In this paper, I explore the twin concepts of representation and identity among Sheffield's public housing, professionals and elites. Establishing friends, liking posts or sharing information are all activities which may reinforce a feeling of belonging which is constantly validated and perpetuated by a mediated process. Representation and identity figures prominently in how an individual conveys voice and visibility; in addition to who and what is trusted.

Individuals using social media become ambassadors of their employers, their educational establishment/history, their political/social causes and even their cultural tastes within a public sphere. For example, a Sheffield resident may 'like' the Arctic Monkeys or the Sheffield International Documentary Film Festival on Facebook and this online association indicates a way to promote not only their city and their tastes, but also themselves. In order to understand this phenomena and the ways it contributes to identity and representation, I delve into the ways that Sheffield City citizenry denoted community belonging through relational ties. The evidence collected included archiving tweets and analyzing network structures to understand ways representation and identity manifested in social media conversations and to reach an (un)intended audience.

In an age when civic leaders and e-government proponents frequently look to social media platforms as a way to engage with the public, how may diverse voices be heard and communities seen above the din clamoring for attention? The digital divide, however, means that Sheffield's public housing residents do not engage in building relational networks outside of their family unit. This paper explores the concept of representational identity and influence in the social network. Processes on social networks are based on three factors (Shalizi and Thomas 2011): homophily, social contagion, and the causal effect of an individual's covariates on network behaviour. Hence, the collective experience of belonging in the City of Sheffield, while perpetuating a shared love of the City, may also unintentionally reinforce issues of status and hierarchy through relational ties, influence, and network behaviours. Among public housing resident, a perceived lack of societal position and home ownership also influenced community identification linked to perceived limits to authority and actual access to network resources (Knapp, 2004). Elites, on the other hand, were observed cultivating a model of thought leadership and authority. This study will help inform policy on how planners, city officials and public leaders may best engage with a diverse public online.

FROM HAROLD WASHINGTON TO LORI LIGHTFOOT- A CULTURAL INTERPRETATION OF LOCAL GOVERNMENT TRANSFORMATION IN CHICAGO

Abstract ID: 1291

Individual Paper Submission

MANGCU, Xolela [George Washington University] xolelamangcu@gwu.edu, presenting author

Lori Lightfoot's election as the first black woman gay mayor of Chicago is reminiscent of an earlier historic precedent – Harold Washington's election in 1983 as the city's first black mayor. While it is not yet clear whether Lightfoot will be as progressive as Washington, their respective elections constitute important cultural moments in the history of the city. They both emerged as charismatic figures who challenged the old-style, racist and corrupt machine that governed Chicago for decades. They also

suggested the possibility of an alternative form of what Max Weber called legitimate authority.[1] This cultural achievement was often lost in the overly economistic assessments of the Washington administration. These assessments presented the administration as either a local economic development success story or a failure because it did not transform the material conditions of poor people.

However, a broader angle of vision would suggest that there is more to the desires of black and poor people than economic development. As J.Phillip Thompson argues, the economic approach is blind to the peculiar challenges that face black and minority communities- “state repression, racial segregation, and culture.” [2]

But as Weber argued, in order to have a lasting impact on institutions of government, charismatic authority has to be transformed into rational-legal authority.

The second part of the paper thus discusses Washington’s use of the rules and rituals of state formation to change the culture of City Hall.[3] More than any department, the law department carried the banner for racial empowerment. The changes initiated by the law department thus constitute the core empirical section of the paper.

The third and final part argues that while these cultural achievements were reversed during the long reign of Daley’s son, Richard M Daley, their memory endured in the public mind. As Albert Hirschman argued about the long-term effects of social movements, “the social energies aroused during the course of a social movement do not disappear when that movement does. They are kept in storage but become available to fuel later and sometimes different social movements.” [4]

In my dissertation on Washington, I suggested that Washington’s greatest legacy would be found in the inspiration he provided to a new generation of leaders in Chicago. I did not know then that he also inspired first African American president of the United States, Barack Obama. As Obama put it, “I originally moved to Chicago in part because of the inspiration of Mayor Washington’s campaign.”[5] Senior White House advisors such as David Axelrod and Valerie Jarrett were also inspired by Washington. Washington became a magnet for a new leadership corps and a new energy in the city.

Lightfoot was similarly influenced by Harold Washington. As she put it in a recent interview, “I moved to Chicago in the middle of the second Washington campaign. I have never seen such energy and enthusiasm regarding a political movement.[6]

The memory of the city’s experience under the first black and progressive mayor might be an important cultural resource in navigating its racial, political and policy challenges.

CRY AND DEMAND: A DRAMATIC INTERPRETATION OF IRANIAN WOMEN’S URBAN PRAXIS TOWARD THE RIGHT TO THE CITY

Abstract ID: 138

Poster

GOHARIPOUR, Hamed [Kansas State University] hgohari@k-state.edu, presenting author

Public spaces are the renditions of the power symmetry within the social setting it resides in, and are both controlling and confining of power. Since the Revolution of 1979, Iranian public spaces have been reshaped to both reflect and produce ideals of modern Islamic citizenship as understood by various political actors including the central government, the municipality, and other authorities. The urban component of these policies has been extremely brutal, particularly for those who do not fit into normative understandings of the dictated spatial behavior (Sham, 2013), including a significant proportion of women, especially among the newer generation who has not adapted to the mental atmosphere of top-bottom norms and demands more democratic urban spaces. Under these conditions, as well as the historical lack of inclusive urban design in Iran, ideals of urban identity, citizenship, and belonging, already threatened by the spreading malaise of the political and cultural ethic, become much harder to sustain.

Although there are different sociological, political, and cultural theories based upon which the problematics of women and urban spaces have been addressed, this study aims at interpreting the lived space of Iranian women based on the Lefebvre’s widely accepted concept of “The Right to the City.” The person who is a total human, Lefebvre argues, dwells in a lived space of the imagination and moments which has been kept alive and accessible by the arts and literature (Shields, 2001). Given the impossibility of purely theoretical knowledge, 'total human' is thus best captured with reference to 'art' (Kipfer, 2009). As much the science of the city, art and the history of art are part of a meditation on the urban which

wants to make efficient the images which proclaim it. Art brings to the realization of urban society its long meditation on life as drama pleasure (Lefebvre, 1996). Cinema, then, frames this study's lens of interpretation to see why urban life for Iranian women has yet to begin. Cinema provides urban planners and designers not only with artistic and dominant but also residual and even excluded meanings and interpretations of the space. This is particularly important for Iran, whose cinema covers a significant number of urban issues, and it has attracted international attention for its content and artistic qualities. The *Girl in the Sneakers* (Sadrameli, 1999), *Offside* (Panahi, 2006), and *Subdued* (Nematollah, 2017) are three influential and popular Iranian movies made in three different decades, representing women's praxis (social practice) toward the realization of the right to the city.

From a critical interpretive position, using a qualitative approach, this research takes advantage of the dynamic Interpretativeness of Charles S. Peirce's triadic model of semiotics to interpret Iranian women's right to urban life.

Based on Peircean terminology, the 'representamen' in this study is any image-sign (a shot, sequence, scene, or any group of shots) that conveys meaning; 'object' stands for the real-world urban space/phenomena represented by the image-sign; and 'interpretant' refers to what the interpreter, according to Lefebvre's theory, makes sense of the praxis represented in the movie. Findings of this study reveal Iranian women's challenging praxis to meet what Lefebvre refers to as their needs and expectations, including the need for security and opening, certainty and adventure, the predictable and the unpredictable, as well as the needs to accumulate energies and to spend them, even waste them in play, the need to see, to hear, to touch, to taste and the need to gather these perceptions in a 'world.'

TRACK 6 – HOUSING

TRACK 6 – PRE-ORGANIZED SESSION SUMMARIES AND ABSTRACTS FOR THE SESSIONS

HOUSING INSECURITY AND DISPLACEMENT –NO GENTRIFICATION NEEDED

ID: 2

Pre-Organized Session Summary

Includes abstracts: 28, 29, 30, 85, 103

Large numbers of households lose their homes each year when they cannot pay their mortgages, rents, or property taxes. These households experience high housing-cost burdens although no gentrification affects their neighborhoods. Papers in this session look at the extent of household displacement in weaker housing markets where rents and purchase prices are not high and at the results of programs that have aimed to provide affordable housing or prevent displacement in such places.

Objectives:

- Explain the reasons for failure of programs to prevent housing loss
- Communicate the scale of housing loss in weak markets with lower rents and purchase prices

'I WOULDN'T BE FACING THIS FORECLOSURE': BARRIERS TO TAX RELIEF AND FORECLOSURE PREVENTION IN DETROIT, MICHIGAN

Abstract ID: 28

Group Submission: Housing insecurity and displacement--no gentrification needed

DEWAR, Margaret [University of Michigan] medewar@umich.edu, presenting author

EISENBERG, Alexa [University of Michigan] alexae@umich.edu, primary author

MEHDIPANAH, Roshanak [University of Michigan] rmehdipa@umich.edu, co-author

All U.S. states permit local governments to recover unpaid property taxes through a tax lien foreclosure process. Tax relief policies can reduce household tax burdens and prevent the foreclosure of owner-occupied homes, but little is known about their use and effectiveness. Like other cities, Detroit, Michigan, experienced a rise in tax foreclosures following the mortgage foreclosure crisis and deep recession. Michigan law allows cities to exempt low-income homeowners from their property tax obligation. Only a small fraction of homeowners eligible for the exemption receive it. This research tracked the experience of applicants whose income qualified them for the exemption and who applied for it. Implementation of the policy, the Poverty Tax Exemption, failed to protect many low-income homeowners from dispossession through tax foreclosure. State-mandated and locally determined procedures placed the burden of learning about and applying for the exemption on financially stressed homeowners, many of whom had limited mobility, and therefore restricted widespread access to this critical tax relief. Eliminating institutional barriers to tax relief can more effectively prevent owner-occupied tax foreclosures, especially in cities where a high need for tax relief occurs under local conditions of governmental fiscal austerity.

FOUNDATIONS OF SAND: DEMOBILIZATION IN THE CONTEXT OF CURRENT EVICTION AND HISTORIC DISPOSSESSIONS IN RICHMOND, VIRGINIA

Abstract ID: 29

Group Submission: Housing insecurity and displacement--no gentrification needed

HOWELL, Kathryn [Virginia Commonwealth University] klhowell@vcu.edu, presenting author
TERESA, Benjamin [Virginia Commonwealth University] bfteresa@vcu.edu, co-author

In 2018, the release of a nationwide dataset revealed that the eviction rate in Richmond, Virginia was greater than 11% for more than 16 years, making it the second highest rate of cities across the country. These data masked neighborhood variations. Majority white neighborhoods, for example, had rates below 5%, while African American and Latinx communities had rates that, in some cases exceeded 20% or even 30%, threatening the stability of not just individual families, but entire communities. We understand eviction to be about more than the individual moment when a family receives a notice, loses in court or is removed from a home. Rather, we understand eviction as an indicator, result and a cause of direct and indirect issues. Eviction is an indicator of larger structural problems within the region, specifically, historic patterns of racial discrimination in the housing market and race-based dispossession of housing and community in Urban Renewal, redevelopment and highway projects throughout the 20th century. These patterns have resulted in a population with little access to property, opportunity communities and political power. While eviction has played a critical role in the currently landscape of instability, dispossession of housing and, ultimately, of the right to the city as a cause and a result, has been a trend stretching back to slum clearance, Urban Renewal and highway construction projects that targeted African American communities in Richmond.

Housing instability has greater implications for civic engagement. While research has argued that community engagement originates from homeownership, newer research argues that this is due to the stability and control conferred through homeownership, rather than ownership itself (Lindblad and Quercia 2015). Because households that have been displaced or expect to be displaced have to overcome the concurrent challenges of finding and keeping housing, accessing jobs, catching up in school and maintaining mental and physical health, they are unable keep up with voter registration (Squire et al 1987) much less engage in community organizations, local advocacy or political organizing. Thus,

housing unstable households, regardless of tenure, are often unable to collectively advocate for changes in their buildings, neighborhoods or cities.

The consequences of “serial forced displacement” (Fullilove and Wallace, 2011)—the recurring patterns of involuntary movement from urban neighborhoods that concerted public and private action produce—are myriad, affecting individuals, families, and groups. Racial segregation frequently precedes displacement which then produces new segregation. These processes are as much a threat to health and well-being as they are a potent political tool, historically wielded to displace Black people and people of color from positions from where they could exercise political power and build political capacity. Most obviously, physical displacement from home and community can strain and sever relationships that sustain organizing. Beyond the difficulty distance creates, having a sense of place is important for identity, claims-making, and for challenging the conditions that produce urban inequality (Good, 2017; Martin, 2007).

This paper uses content analysis, observation and theory to interrogate the historic patterns of housing dispossession in Richmond, Virginia. It further explores the theoretical and practical implications of this history for the current eviction crisis and its impact of communities of color. We argue that this dispossession is cyclical, meaning that the housing instability created through previous iterations of eviction and forced displacement have placed barriers to mobilization to address basic housing needs, community engagement and organizing that might operationalize a right to the city through political advocacy. We further argue that breaking this cycle will require the creation of physical and social spaces in which to engage, as well as legal supports that facilitate control and stability in the lives of low- and moderate-income renters.

THE FEDERAL HOUSING ADMINISTRATION (235) PROGRAM IN NEWARK, NJ

Abstract ID: 30

Group Submission: Housing insecurity and displacement--no gentrification needed

NEWMAN, Kathe [Rutgers] knewman@rutgers.edu, presenting author

The Federal Housing Administration was created in the 1930s to expand jobs by encouraging investments in housing. For many years it did this though efforts to expand supply mostly of single family homes but also of multifamily housing. Over time Congress added programs to make single and multifamily housing more affordable to lower income residents. FHA’s Section 235 program created in 1968, for

example, was intended to expand single family home ownership by increasing access to credit for borrowers who lacked it. The implementation of the program ran into a number of problems and many homes went to foreclosure (Bratt 1976; Fox Gotham 2000). Bradford (1979) explains some of these effects as the result of an easy ability to sell the insured mortgage loans into the secondary market. In this paper I consider the assemblages of human and nonhuman actors who were involved in the FHA 235 program in Newark, NJ. I consider the infrastructure for home mortgage lending, the experience of borrowing and homeownership, and the effect of the 235 program on surrounding housing and community. Academic literature, Congressional reports and hearings, administrative reports, plans and data and news reports inform the analysis.

SHIFTING TAX LEVY BURDENS IN GENTRIFYING CHICAGO: BALANCING AFFORDABLE HOMEOWNERSHIP PRESERVATION AND WEALTH CREATION IN COMMUNITY LAND TRUST PROPERTY ASSESSMENTS

Abstract ID: 85

Group Submission: Housing insecurity and displacement--no gentrification needed

PROCHASKA, Natalie [University of Illinois Urbana Champaign] prochask@illinois.edu, presenting author

The community land trust (CLT) model is a central strategy for providing long-term opportunities for affordable homeownership and household wealth creation. The CLT model provides moderate household level wealth-building through home value appreciation capitalization upon resale, among other traditional benefits of market rate homeownership. Higher in areas that have experienced large increases in home values, successful individual resale capitalizations hinge on sustaining a manageable tax burden relative to income over the holding period to prevent cost-based CLT homeowner displacement. One overlooked area of CLT analysis in demonstrating successful resale equity capitalization involves the role that fair market value property assessments in rapidly gentrifying neighborhoods play in their associated tax burdens on residents, particularly relative to the average household income of CLT homeowners. In this paper, I examine the assessments and associated tax bills of CLT properties in Chicago over the last two assessment cycles (2014-2019). Rising property taxes are increasingly implicated as a factor inducing cost-based displacement of homeowners, particularly in rapidly gentrifying areas (Brown-Saracino, 2009; Immergluck, 2009; Martin & Beck, 2018; Vigdor, 2002; Zukin, 1987). Similar to previous work on the protective effects of rent regulation against displacement in gentrifying areas (Freeman & Braconi, 2004; Wyly, Newman, Schafran, & Leez, 2010), it is vital to examine whether CLTs are an effective strategy preventing cost-based residential homeowner displacement in these same areas.

In the last four years, Chicago's primary CLT, the Chicago Community Land Trust (CCLT) has seen significant increases between market rate residential property assessments and the affordable formula-

based caps on property valuation set in their deed restrictions at the time of sale. Since 2014, the City of Chicago has seen an overall 6.3% average increase in residential property tax bills, and 1.6% average tax rate increase on residential property. Chicago's property taxation has been found to be "variable and regressive," with residential property in Chicago bearing more of a burden than commercial and industrial property in citywide assessments. There was a 12.8% average tax bill increase on residential property in 2015, and CCLT homeowners are receiving tax bills higher than they can afford, because many properties are located in areas with rapidly escalating home values. High tax bills for low-income homeowners may produce compounding negative financial outcomes and higher cost-based displacement pressures, as lenders' escrow analyses re-assess and increase mortgage payments over subsequent years, regardless of assessment appeal outcomes. This paper traces scattered CCLT property assessments and tax bills over the last assessment cycle to test for pre- and post- appeal assessment valuation regressivity in CCLT properties compared to surrounding neighborhood units, and evaluates tax bill increase-driven displacement pressures. I also compare CLT properties to households of similar income living in neighborhoods not experiencing rapidly escalating housing price appreciation. I question whether the claim that CLTs may slow cost-based residential displacement based on property tax increases holds true in the City of Chicago. These findings hold important implications for optimizing coordinated responses to gentrification forces in currently transitioning neighborhoods, and evaluating the effectiveness of the CLT model as a model that both prevents cost-based residential displacement and guarantees positive homeowner equity appreciation.

BUILDING THE EVICTION ECONOMY: SPECULATION, PRECARITY, AND EVICTION IN DETROIT - TO MOVE

Abstract ID: 103

Group Submission: Housing insecurity and displacement--no gentrification needed

SEYMOUR, Eric [Population Studies, Brown University] eseymour@umich.edu, presenting author
AKERS, Joshua [University of Michigan-Dearborn] jmakers@gmail.com, co-author

Evictions have gained attention as a problem of crisis proportions. The Eviction Lab at Princeton University estimates one million tenants are evicted each year, equal to the number of owner-occupant households displaced through foreclosure during the mortgage crisis. Scholars frequently focus on evictions in high-cost cities where home prices and rents greatly outpace wages for low-income earners and the supply of affordable housing is inadequate and dwindling. Desmond (2016) shows evictions are

also a persistent feature of low-income neighborhoods with weak housing markets. Older buildings are costly to maintain and landlords may charge higher rent in anticipation of property damage and vacancy (Greif 2018). Landlords operating in distressed neighborhoods therefore charge rents only slightly less than area averages. In cities where jobs for low-skilled workers are scarce and wages low, many households encounter difficulties consistently paying rent. Landlords in low-income neighborhoods often withhold investment in their properties, e.g., by deferring maintenance, to insure adequate returns. Low-income tenants thus pay rent not far below the area average - accounting for a large and unaffordable share of their monthly income - but are forced to endure inadequate and often unsafe housing conditions. Tenants regularly tolerate these situations as their housing options are deeply constrained, but may face eviction as they withhold rent or deduct the cost of necessary repairs.

While the broad contours of these landlord-tenant dynamics were documented decades ago, researchers have recently turned their attention to the behaviors of landlord-investors purchasing large numbers of properties in the wake of the foreclosure crisis (Raymond et al. 2018). Private equity firms purchased tens of thousands of single-family properties in Sunbelt cities hit hard by the foreclosure crisis, converting them to rentals. But in distressed housing markets where home prices and income remain low, investors follow a different model for generating profit, purchasing large numbers of low-cost properties and either renting them without making additional investment or selling them via high-cost land contracts (Akers & Seymour 2018).

This paper examines the relationship between investment in distressed properties and evictions. Net of income and housing costs, we hypothesize neighborhoods where investors have acquired single-family homes through foreclosure sales have a greater number of evictions. Inadequate and irregular income make it difficult for low-income households to pay rent. But based on prior research and discussions with anti-eviction activists, legal aid attorneys, and investigative journalists in Detroit, we also expect investors' practices create unsafe housing conditions leading tenants to withhold rent or contact building inspectors. Both cases likely lead to eviction, as the legal system is tilted toward landlords. Further, land contracts shoulder buyers with the responsibilities of homeownership but few of the protections of a traditional home purchase agreement. Contract sellers often remove buyers through eviction courts, though not the appropriate channel, to accelerate repossession.

This study draws on eviction filings and real estate transaction records in Detroit, Michigan since 2005 to examine the relationship between investor acquisition of properties repossessed for delinquent property taxes and evictions. We examine these relationships at both the property and neighborhood level. Using a longitudinal negative binomial regression model, we find a distinct, direct relationship between eviction filings in single-family residential neighborhoods and county sales of tax-reverted properties in prior years. This relationship persists for at least three years, indicating elevated eviction filings are linked to ongoing owner-tenant dynamics and failed land contracts, not simply investors taking control of properties after acquisition.

DISPLACEMENT, EVICTION, AND HOUSING MARKETS

ID: 6

Pre-Organized Session Summary

Includes abstracts: 134, 200, 205, 449

In 2018 the Princeton University Eviction Lab released a national eviction dataset that demonstrated pattern of widespread and long-term eviction across the US. We know less about the local factors and causes at play in eviction. This session includes papers that address the underlying causes and the effects of displacement, including eviction. The papers draw on theory and empirical research to explore the neighborhood context of evictions, the role of "serial" eviction filings in the displacement process, and the segmentation of housing markets as both a cause and consequence of evictions. The research these papers are based on come from a diverse set of urban contexts. The session will help understanding about the eviction crisis, and in particular, shed light on the local contexts of displacement.

Objectives:

- Understanding the role of neighborhood context, eviction, housing markets in displacement.

EVICTION AND SEGMENTED HOUSING MARKETS IN RICHMOND, VIRGINIA

Abstract ID: 134

Group Submission: Displacement, Eviction, and Housing Markets

TERESA, Benjamin [Virginia Commonwealth University] bfteresa@vcu.edu, presenting author
HOWELL, Kathryn [Virginia Commonwealth University] klhowell@vcu.edu, co-author

This paper examines the relationship between housing market segmentation and eviction in Richmond, Virginia. Eviction is a local phenomenon that varies dramatically at the urban scale. The variegated geography of eviction suggests that a range of factors affect eviction rates, including neighborhood characteristics, ownership structure, and management practices. Specifically, research indicates that Black and non-white neighborhoods experience higher eviction rates than White neighborhoods (Teresa, 2018), larger property owners evict at higher rates than smaller-scale owners (Raymond et al., 2018 and Immergluck, 2019). These factors define housing markets so that eviction is much more likely in particular neighborhoods where specific owners operate.

Due to historical patterns of racial and class segregation in urban regions, these factors are also likely the dimensions along which segmented housing markets are defined and through which they operate to produce differential housing outcomes for tenants. Housing market segmentation theorizes that instead of a unitary regional housing market that responds to supply and demand constraints, but rather several distinct submarkets that operate independently of each other to different extents (Rothenberg, et al., 1991). Segmentation is typically defined by different groups of housing quality, which consumers pay for at different rates. From a different research tradition, segmented housing submarkets are produced by property owners and financial institutions by structuring scarcity within restricted geographical areas, creating the conditions for capturing absolute or class-monopoly rent (Harvey and Chatterjee, 1974).

In this paper, we examine what actors produce housing segmentation and with what practices, and how tenants navigate and are corralled into different submarkets. We identify high-evicting market submarkets in Richmond through describing their geography and ownership structures, and narrate the pathways and

lived experiences of tenants in those submarkets. To do so, we rely on an original large-building database for 120 multifamily buildings with more than 25 units that we created using city assessor data, recorder of deeds records, court eviction filings, and city housing code violation data. We pair this dataset with qualitative interviews with 25 tenants who have experienced at least one eviction. Our findings confirm a highly segmented housing market in Richmond, which not only restricts non-white, poor and working class tenants to the poorest quality and most unstable housing submarkets but also directs them into progressively poorer quality housing until their eviction records and credit scores are used by landlords to effectively shut them out of the private rental market. Short-term housing such as motels, informal housing, and homelessness become the submarkets of last resort.

FINANCIALIZATION AND RACIAL CAPITALISM OF HOUSING AFTER THE CRISIS: DISTANCE AND FORGETTING

Abstract ID: 200

Group Submission: Displacement, Eviction, and Housing Markets

FIELDS, Desiree [University of Sheffield] d.fields@sheffield.ac.uk, co-author

RAYMOND, Elora [Georgia Tech] elora.raymond@design.gatech.edu, presenting author

In this research we place the financialization of housing since 2008 in the broader context of racial capitalism. By mobilizing the black radical tradition, which emphasizes race as a crucial precursor to and organizing logic of capitalism, and centering the housing struggles of marginalized groups, we relate contemporary racialized displacement and dispossession to settler colonialism and the plantation. The production of racial difference that Du Bois stressed as a crucial element of economic subordination in a divided and racially tiered labor force extends to the real estate profit cycle: the devalorization of non-White bodies, places and property hastens dispossession, making way for revalorization and successive rounds of accumulation. Since 2008, the U.S. racial divide in housing outcomes has widened. The recovery has been uneven, with clustered, prolonged negative equity, the rise of institutional investors in the single-family rental space, and the resurgence of predatory forms of lending targeted at black borrowers. Neighborhoods exposed to predatory subprime lending have seen foreclosures segue into evictions. As Park (2016) and McKittrick (2011) remind us, such processes are rooted in the violence of the plantation and of settler colonial expansion; that is, they are normal and recurrent features of the U.S. economic system of subordination. Understanding the financialization of home in terms of racial

capitalism is an epistemological move that counters abstraction with history and context, suggests the importance of interventions like reparations, and ultimately foregrounds homes as shelter and sites of human relations, rather than “bifurcated systems of possession and dispossession” (McKittrick, 2011).

THE NEIGHBORHOOD CONTEXT OF EVICTION

Abstract ID: 205

Group Submission: Displacement, Eviction, and Housing Markets

LENS, Michael [UCLA] mlens@ucla.edu, presenting author
GROMIS, Ashley [Princeton] ashley.gromis@gmail.com, co-author
NELSON, Kyle [UCLA] kyle.robert.nelson@gmail.com, co-author
KUAI, Yiwen [UCLA] xavierk@ucla.edu, co-author

The largest metropolitan areas in the United States are in the midst of affordable housing crises. Costs of living are increasing relative to stagnating wages, rent burdens continue to rise for the poorest Americans, and supplies of subsidized and affordable housing are dwindling while more and more renters compete with each other to call them home (McCue 2018; Marr 2017). As a result, increasing numbers of renters nationally are at risk of receiving an eviction notice (Desmond et al. 2018). Despite once being labeled the “hidden housing problem” by (Hartman and Robinson 2003), Matthew Desmond’s (2016) landmark research and a growing national media focus (e.g., Badger and Bui 2018) have brought increasing policy attention to the nationwide eviction crisis. Most recently, San Francisco and New York City enacted laws providing low-income renters a right to legal counsel in eviction proceedings, and Los Angeles and Philadelphia look to follow in their footsteps (Capps 2017). As policymakers increasingly look to eviction prevention as a means of ameliorating the housing crises gripping American cities, existing research unfortunately reveals as many questions as it provides answers.

We examine two types of evictions: court-processed evictions and evictions filed through the Ellis Act, which is a California law providing owners of rental property a pathway to exit the rental market and evict existing tenants without cause. For court-based evictions, we use a dataset of eviction case filing addresses compiled by American Information Research Services, Inc. (AIRS) in five Southern California counties between 2005 to 2015 to analyze the spatial patterns of eviction cases. For Ellis Act evictions, we rely on data from the Los Angeles Housing and Community Investment Department (HCID), which has generously supplied addresses for every application for a no-cause eviction from 2000 to 2017. We then append data on neighborhood housing and demographic characteristics from the U.S. Census’s American Community Survey and data on residential construction permits from the LA County Assessor’s Office to assess the relationship between new construction on eviction rates (in LA County only), addressing policy debates over new construction’s role in eviction and displacement.

Preliminary analysis points to links between concentrated disadvantage, gentrification, and eviction rates. Through these analyses, we develop a model that describes the determinants of eviction rates in neighborhoods, cities, and counties in Southern California that can be used to comparatively evaluate eviction's spatial dynamics.

Evictions and eviction filings cause substantial harm to lower-income families and neighborhoods. We examine multifamily eviction filings in the five-county metropolitan Atlanta area with a rich data set of eviction filings, property characteristics, and ownership information. We find that eviction filings include many "serial filings," in which landlords file repeatedly on the same tenant. The literature suggests that serial filings are aimed less at removing the tenant and more at disciplining the tenant through state-sanctioned threat of removal. We analyze serial and nonserial filing rates at the property level, and the share of a property's filings that are serial filings (serial share). Regressions on building, location, and neighborhood characteristics reveal important factors associated with higher serial and nonserial filing rates and serial share. We then examine the owners of the largest number of multifamily properties in the region and identify those that exhibit high or low serial filing rates after controlling for building, neighborhood and location characteristics. We find that the largest owners and larger buildings tend to have high serial shares. We also find that, while properties in Black neighborhoods have higher nonserial filing rates, their serial shares are also higher than otherwise similar properties. A key result is that sales in the prior three years have a significant, nontrivial positive effect on the nonserial filing rate, suggesting that building sales are significant predictors of rising evictions. Finally, those few large owners that do have low serial filing shares tend to be located in neighborhoods that are significantly less Black than the average building. We discuss implications for policy and further research.

POST-DISASTER HOUSING RECONSTRUCTION AND REDEVELOPMENT: CASE STUDIES FROM THE PHILIPPINES, PUERTO RICO, FLORIDA, AND TEXAS

ID: 12

Pre-Organized Session Summary

Includes abstracts: 168, 169, 170, 171, 176

This panel studies human interactions with the built environment in communities impacted by disasters through examining decisions in reconstruction and development. All four studied in this session are focused on housing issues after disasters using case studies in the Philippines, Puerto Rico, Florida and Texas. These studies identify leverage points to expedite and encourage safe reconstruction and redevelopment. These leverage points will be analyzed in international and the US regulatory and normative environments. With increasing severity and frequency of disasters that disproportionately affect low-income communities, this panel will discuss impacts on those most vulnerable groups. This is critical not only for improving the current situation in these communities, but also to prevent future housing failures when another natural hazard occurs. The current institutional challenges can lead to a cycle of informal reconstruction or abandonment which is not limited to our case studies; states across the US have attempted policies to encourage regulatory and code compliance and discourage abandonment and informal construction.

Objectives:

- By identifying barriers to safer and formal reconstruction and redevelopment, decision makers can implement comprehensive programs and policies geared at redevelopment of vacant buildings and implementation of building codes and formal reconstruction.
- Understanding the leverage points to expedite and encourage safe reconstruction and redevelopment.

RESETTLEMENT OF INFORMAL COASTAL RESIDENTS AFTER TYPHOON HAIYAN: COMMUNITIES' PERSPECTIVE FROM A FIVE-YEAR ETHNOGRAPHIC OBSERVATION

Abstract ID: 168

Group Submission: Post-disaster Housing Reconstruction and Redevelopment: Case studies from the Philippines, Puerto Rico, Florida, and Texas

IUCHI, Kanako [Tohoku University] kxiuchi@gmail.com, presenting author

Informal settlements are often located in highly vulnerable areas and directly exposed to adverse environmental change (UN Habitat, 2015). With an internationally shared notion of reducing future disaster risk in the recovery process, various rebuilding programs have begun to address hazard-sensitive land use and better resettlement of informal residents through relocation to reduce risk (see UNHCR,

2014). While informality of land tenure is reported as one of the greatest hindrances to rebuilding, such settlements continue to dominate and reemerge in poorer societies where land titling systems are either malfunctioning or nonexistent (Reale & Handmer, 2010). Concerns regarding informal settlements in rebuilding have increased over the past decade, yet studies on informal settlers' perspectives on relocation-related housing remain scarce (Barenstein, 2017).

Using post-disaster recovery from 2013 Typhoon Haiyan (local name Yolanda), Philippines, as a case study, this paper unpacks the resettlement processes of informal residents by shedding light on their decisions and actions with respect to resettling in permanent housing. The overarching question asks how and why households rebuild on informal land devastated by disasters, regardless of government housing support with relocation. Specifically, this study seeks to understand: i) who, after disasters, choose to informally reside on vulnerable land; ii) how and why residents decide to live on restricted land; and iii) how residents react to government-provided relocation programs. Data collection included annual fieldwork trips to the Leyte region of the Philippines from 2014 and 2018. In addition to collecting and analyzing housing and resettlement documents locally and nationally, residents from five communities located along Cancabato Bay in Tacloban City were interviewed once a year for four years. With the aid of students/interpreters who speak Warai (local language), 40 responses to open-ended questions were collected during each of the four years using an opportunistic sampling method.

In response to the coastal devastation caused by the storm surge, Tacloban City adopted a 40-meter "no-build (dwelling) zone" to proactively minimize loss of coastal residents from a future catastrophe. To accommodate residents who owned houses in the no-build zone pre-disaster, the City planned a two-step housing relocation program in sites far from the coast: residents would first move into temporary housing to wait for the permanent housing, and then to permanent housing when the units are ready. While relocation began relatively quickly, multiple actors in the relocation process, various options for beneficiaries, political decisions, and limited resources for housing development slowed and muddled the process (Iuchi & Maly, 2017). Five years later, houses continue to occupy the no-build zone along Cancabato Bay.

Ethnographic interviews and observations suggest that there was a shift in attitudes about relocation over time. Almost all coastal residents in the early stage of rebuilding had returned to or at least near to their original residential location. Residents were aware of their informality but indicated that they were returning as there was "no other places to go". However, residents did show concern about living along the shore, as respondents were willing to receive a new housing unit and relocate inland once ready. Over time, however, there was a greater mix of residents' housing status along the no-build zone – some continued waiting for their permanent units, some rented spaces, and others purchased existing coastal units from former owners. More importantly, an increasing number of residents began owning two units – one in the relocation site and the other back in the coastal community. These residents justified this dual-residency as important for their family's continued work and education. For them, the houses provided in the relocation sites are important assets but are not yet completely suited to their lifestyle.

INFORMAL AND FORMAL HOUSING RECONSTRUCTION IN PUERTO RICO AFTER HURRICANE MARIA

Abstract ID: 169

Group Submission: Post-disaster Housing Reconstruction and Redevelopment: Case studies from the Philippines, Puerto Rico, Florida, and Texas

HAMIDEH, Sara [Iowa State University] shamideh@iastate.edu, presenting author

TALBOT, Jessica [Iowa State University] jtalbot@iastate.edu, primary author

POLEACOVSKI, Cristina [Iowa State University] poleacov@iastate.edu, co-author

Hurricane Maria resulted in significant devastation to Puerto Rico—approximately 400,000 houses are in need of reconstruction and repairs which represents a third of the 1.2 million houses on the Island (Brown, 2018). The recovery process has been strained and issues like inadequate funding have affected many communities especially where institutional support and resources are scarce (De La Rosa, 2018). Only 40% of Federal Emergency Management Agency (FEMA) financial assistance applications have been approved (Acevedo & Pacheco, 2018) and 80% of appeal cases are either pending or denied (Acevedo, 2018). As a result, many households and communities have relied on their own resources and efforts to reconstruct their houses (Portal, 2018; Viglucchi, 2018). This kind of self-reliance has widespread precedents in pre-Hurricane Maria informal reconstruction in Puerto Rico. Housing units considered ‘informal’ are more common in rural communities where residents often sell or inherit properties through informal agreements, subdivide land without completing the title transfer process, occupy government-owned land to build homes, or build a house without completing the construction permit process (akin to colonias or informal settlements commonly found in the southern US). Informal reconstruction is defined in this research as design and construction actions carried out by community members in establishing temporary and permanent features of housing (e.g. design decision, physical labor) without following formal construction procedures and codes. Estimates of informally built houses range from 260,000 to 700,000 homes—the latter constitutes 60% of total homes in Puerto Rico (Brown, 2018; Florido, 2018). Structures built using informal reconstruction, which do not necessarily comply with building codes, are expected to be less reliable and vulnerable to disasters (Burby, May & Paterson, 1998). Hence, there is a critical need to address the continuing and widespread informal reconstruction practices in Puerto Rico in order to address present and future built environment vulnerabilities to disaster exposure. This research seeks to identify the contributing drivers to informal reconstruction and barriers to formal reconstruction, as well as the interactions between these drivers/barriers that lead to this emergent informal reconstruction behavior. We posit that this emergent reconstruction behavior of interest arises out of a multiplicity of simple interactions and drivers or barriers (Sturmberg 2014), and can only be understood by looking at the residential construction process/system as a whole (Dyson 1997). Preliminary results from our research in Puerto Rico indicate that institutional factors—e.g. costs, complexity of the formal process—and socioeconomic characteristics of a household play a critical role in

shaping informal-formal reconstruction behavior (Talbot, Poleacovschi & Hamideh 2018). Using these preliminary results about the intersection of human systems with disasters and the built environment, this research pursues to identify various types of institutional and social factors that increase the likelihood of decisions to pursue informal reconstruction as opposed to formal reconstruction at the household level after Hurricane Maria. The authors have collected preliminary semi-structured interview data (N=30) in three communities (Barranquitas, Utuado and Adjuntas) and survey data (N=350) in two communities (Pueblo and Loiza) during Summer and Winter of 2018. Preliminary results indicate the importance of the community relationships and links with recovery organizations as key components for reconstruction (Talbot, Poleacovschi, & Hamideh, 2018). Additionally, the preliminary results show that costs and complexity of formal construction are the top factors for pursuing informal.

“DEFERRED MAINTENANCE”: SOUTH TEXAS COLONIAS AND THE FIGHT AGAINST FEMA

Abstract ID: 170

Group Submission: Post-disaster Housing Reconstruction and Redevelopment: Case studies from the Philippines, Puerto Rico, Florida, and Texas

RIVERA, Danielle [University of Colorado Boulder] danielle.rivera@colorado.edu, presenting author

Recent concern about the intersections between environmental and social injustices has allowed planning researchers to more directly investigate post-disaster marginalization (Bullard & Lewis, 1996; Jacobs, 2018; Jon & Purcell, 2018). One such issue is perceived urban informality; in post-disaster situations, researchers note both the possible positive (Parthasarathy, 2015) and negative (Rumbach, 2014) effects of urban informality. This paper seeks to build upon these studies to ask, within a U.S. context: how is perceived urban informality affecting access to equitable disaster reconstruction?

This paper expands upon a case report, funded by the Lincoln Institute of Land Policy, which examined the legal case LUPE vs FEMA. The case study examines post-disaster Hurricane Dolly, which made landfall on July 23, 2008 in the Rio Grande Valley, a tri-county region of South Texas that is one of the poorest areas of the United States. Following Hurricane Dolly, residents of the colonias, the poorest communities within the Rio Grande Valley, noticed a disturbingly high rejection rate for FEMA assistance from the Individuals and Households Program (IHP). Most IHP applicants in the Rio Grande Valley were rejected due to “deferred maintenance,” or a determination that house damages were pre-existing and not attributable to a disaster event. However, FEMA does not clearly define “deferred maintenance” in its IHP policies. As a result, a civil lawsuit was initiated by residents and representatives of South Texas colonias challenging the uncertain definition and implementation of FEMA’s “deferred

maintenance” policy, as the residents and their representatives stated: “The high repair denial rate in the Rio Grande Valley results from FEMA’s unpublished and vague rule requiring the rejection of housing repair applications in cases of substandard housing — a rule that institutionalizes economic discrimination” (Preliminary Injunction, p. 2).

From the residents’ victory in that lawsuit, it is evident that FEMA is not upholding its congressional mandate to not bias against low-income communities. Through the ill-defined policy of not funding deferred maintenance, FEMA biases against those subject to the housing disinvestment common throughout low-income neighborhoods. This is a significant consideration for post-disaster urban planning — it provides concrete evidence that low-income communities are systemically being withheld important funding necessary to rebuild after disasters. This is also corroborated by other low-income communities rebuilding after disaster, like Puerto Rico and areas of Houston. This structural inequality is, potentially, a significant indicator of why other post-disaster phenomena, such as displacement and disaster gentrification, are so commonplace.

POST-IRMA HOUSING RECONSTRUCTION IN THE FACE OF RISING SEAS: CASE OF MONROE COUNTY, FLORIDA

Abstract ID: 171

Group Submission: Post-disaster Housing Reconstruction and Redevelopment: Case studies from the Philippines, Puerto Rico, Florida, and Texas

KURU, Omur Damla [Florida International University] okuru003@fiu.edu, co-author

MARR, Matthew [Florida International University] mmarr@fiu.edu, co-author

GANAPATI, N. Emel [Florida International University] ganapat@fiu.edu, presenting author

What are the factors that people take into account as they decide whether or not to rebuild their homes in communities that are affected by a disaster? If their community is also vulnerable to sea level rise, to what extent do long-term risks associated with sea-level rise contribute to their relocation or rebuilding decisions? Despite a growing literature on post-disaster housing reconstruction, our understanding of factors that affect housing reconstruction decisions in communities vulnerable to sea level rise remains limited. To fill this gap in the literature, we examine these factors in the context of Monroe County (Florida Keys), which was affected by Hurricane Irma in 2017. Our data collection methods include in-depth interviews (n=23), one focus group (n=5), participatory site observation, and review of secondary sources. Based on an NVivo analysis of our data, we suggest that displaced homeowners’ focus is on their

short-term, immediate housing reconstruction needs, especially receiving the necessary permits and the financial assistance (e.g., through insurance companies and/or the federal government) in a timely manner and finding qualified contractors and construction workers, and higher insurance premiums. The key priority of displaced renters, on the other hand, is finding affordable housing compatible with their limited income, a problem which was exacerbated after the disaster. Long-term environmental risks associated with sea-level rise have little to no direct influence on affected homeowners' or renters' relocation or rebuilding decisions. The study suggests that planners and policy makers need to find the optimum period to act on sea-level rise adaptation and mitigation in the aftermath of a disaster, after affected populations' immediate needs are addressed and before these population's collective memory of the disaster is forgotten.

HOW CAN ABANDONED PROPERTIES IN SAN JUAN, PUERTO RICO BECOME OPPORTUNITIES FOR AFFORDABLE HOUSING PROJECTS IN THE POST-MARIA RECONSTRUCTION ENVIRONMENT?

Abstract ID: 176

Group Submission: Post-disaster Housing Reconstruction and Redevelopment: Case studies from the Philippines, Puerto Rico, Florida, and Texas

GARCIA ZAMBRANA, Ivis [University of Utah] ivis.garcia@gmail.com, presenting author

About 360,000 housing units in Puerto Rico were affected by Hurricane Maria and 70,000 were completely destroyed (FEMA 2018). It is estimated that reconstruction would cost about \$33 million (Puerto Rico Department of Housing 2018). Under the first 1.5 billion allocation for the Action Plan of CDBG-DR funds, one billion was allocated for new construction, rehabilitation, or reconstruction of housing for homeownership or rental assistance to low-income individuals and families.

The housing crisis in Puerto Rico already existed and it was only aggravated by Hurricane Maria. Compared to the U.S., the Island has the highest number of vacant homes that any state of the union and the value of the properties has decreased by about 10 percent since the hurricane (Center for Puerto Rican Studies 2018). The population has shrunk due to massive outmigration along with the income of families due to deindustrialization (Birson et al. 2013). According to the 2017 ACS, about 26 percent of housing units in the municipality of San Juan are vacant.

Yet, San Juan is the perfect place to redevelop. First, from the perspective of sustainability, concrete structures embody energy that could be preserved (Jackson 2005). Second, according to the Action Plan, these areas are far away from flood zones and are ideally the place to rebuild to increase resiliency given

that hurricanes are a frequent natural phenomenon in the Island. Third, currently these abandoned structures only contribute to blight and deter any kind of economic development in the central city—from housing to businesses, they also affect safety and quality of life (Accordino and Johnson 2000).

All that being said, these abandoned buildings could provide housing choice options if they were rehabilitated. Although to the naked eye it seems that these abandoned building are a great opportunity to develop affordable housing projects in dense, urban areas, that are close to transportation and amenities (García 2018), it is very hard for developers to access these buildings without state intervention and the enforcement of tax-collection, code violations or the use of eminent domain.

This article will outline the various laws in Puerto Rico dealing with abandoned and public nuisance properties to show that there is not an efficient or primary course of action for developers to actually be able to acquire these properties. This study will look specifically to the legislative and procedural land use obstacles at the local and state level. The presentation will first provide a macro perspective of abandonment in San Juan and then provide case studies of properties to illustrate the inefficiency of the different law mechanisms that have contributed to the massive abandoned property problem.

The research method employed is Participatory Action Research (Forester 1999). The author spent six months helping an affordable housing developer to find properties. In the quest of finding properties she created an inventory of possible buildings to redeveloped and investigated its legal standing as well as contacted the agencies involved in the case including the Property Registry, the Tax Collection Agency, the Public Nuisance Department, the Land Use Agency, the Mayor's Office, and the Housing Development Authority to understand how the property could be acquired for redevelopment. The author interviewed and engaged with community groups dedicated to advocate for the redevelopment of properties including Casa Taft, CAUCE, among others, to understand community efforts being taken to combat the problem and steps taken in light of the federal funds coming for the redevelopment of the Island. At the end, the author will present some recommendation to address the issue of abandoned properties for the development of affordable housing projects in the context of the post-Maria reconstruction environment.

NEIGHBORHOOD INEQUALITIES IN HOMEOWNERSHIP

ID: 23

Pre-Organized Session Summary

Includes abstracts: 288, 289, 290

Homeowners often have access to privileges that renters lack: security of tenure, a savings and investment mechanism, and entry to neighborhoods that frequently contain minimal rental housing. But access to homeownership can be uneven by neighborhood, particularly for minorities and low income households. And the Great Recession precipitated changes in local housing markets and the geographic distribution of residential opportunities. The papers on this panel explore spatial dimensions of tenure both within metros and across them. They examine the geographic components of minority-white homeownership gaps and whether the transition of many single-family homes into rental after the Great Recession have facilitated access to neighborhoods of opportunity for renter families.

Objectives:

- To understand how tenure opportunities vary by geography.

TRENDS IN HISPANIC HOMEOWNERSHIP AND SUBURBANIZATION, 1990-2017

Abstract ID: 288

Group Submission: Neighborhood Inequalities in Homeownership

SANCHEZ-MOYANO, Rocio [University of California, Berkeley] rsanchezmoyano@berkeley.edu, presenting author

Homeownership is the primary form of wealth accumulation for American families, in addition to serving as a point of entry for advantaged neighborhoods, school districts, and social networks. As a result, gaps in homeownership and different homeownership experiences exacerbate socioeconomic inequality, both in the present and among future generations. Previous research on the gap in homeownership between Hispanics and whites has focused on differences in financial, demographic, and immigration characteristics. But the location of a home will affect many of the risks and benefits associated with homeownership, and understanding Hispanic-white homeownership inequality should also include analysis of where homeowners live.

Suburbanization and homeownership among Hispanics both surged in the 1990s (Belsky & Duda, 2002; Massey & Tannen, 2017), but it is unclear whether the new suburbanites purchased homes or rented, and if the new homeowners owned in the suburbs or in the city. Though city-suburb dynamics are shifting, suburbs generally retain a higher status than urban areas (Airgood-Obrycki, 2019), and Hispanics may be trading off suburban neighborhood amenities with the opportunity to own a home. Research indicates that much of the increase in suburban Hispanics was affected by the expansion of affordable rental housing opportunities in many suburbs (Hardwick, 2008; Howell & Timberlake, 2014), suggesting that movements to the suburbs were made by renters rather than by homeowners.

This research examines trends in both Hispanic homeownership and suburbanization from 1990-2017 using the decennial censuses and the 2013-2017 American Community Survey for the 100 largest metro areas where differences between cities and suburbs are most distinct. By looking at the interaction of homeownership and location, this research can begin to answer the question of whether moves into homeownership by Hispanics have been coupled with moves to opportunity in the suburbs, and whether suburbanizing Hispanics are able to capture the benefits of residential stability and wealth-building through homeownership in suburban neighborhoods. This paper will then go beyond cities and suburbs to examine how the presence of existing Hispanic communities affects Hispanic homeownership in urban

and suburban areas by analyzing both ethnic enclaves at the neighborhood level and regional Hispanic settlement patterns.

As planners and policymakers continue to advocate both for access to homeownership for Hispanics (and other minorities) and the expansion of affordable rental housing in the suburbs, it is important to consider to what extent improving equity along one measure results in stratification along the other. Suburban moves may be less successful if not accompanied by tenure security and asset-building. And homeownership may come with additional risks or more limited benefits if happening in urban, majority-minority neighborhoods. This research begins to shed light on the relationship between tenure and location for Hispanic households and what areas are more successful in achieving equal outcomes between Hispanics and whites.

THE LOCATION OF SINGLE-FAMILY RENTAL AND IMPLICATIONS FOR AFFORDABLE HOUSING

Abstract ID: 289

Group Submission: Neighborhood Inequalities in Homeownership

HANLON, Bernadette [Ohio State University] hanlon.42@osu.edu, presenting author
AIRGOOD-OBRYCKI, Whitney [Harvard Joint Center for Housing Studies] whitney_airgood-obrycki@harvard.edu, co-author

Single family rental housing (SFR) have increased in recent years largely as a result of the conversion of single-family detached homes from owner-occupied to rented (Eggers and Moumen 2011). Following the foreclosure crisis, owners opted to rent rather than attempt to sell. In addition, investors purchased foreclosed homes to rent, taking advantage of the availability of vacated properties at a steep discount and the weak homebuying market (Fields, Kohli and Schafran, 2016). The number of SFRs increased from 9 million to 12 million from 2004 to 2013, a 35 percent rise over this time period (Drew, 2015). By 2017, there were 16.6 million SFRs in the United States, accounting for about 39 percent of the rental housing market nationally.

In this paper, we examine the spatial location of SFRs. We identify regional variation in the proportion of SFRs across the United States, ascertain the types of neighborhoods where SFRs are clustered, and

examine changes overtime. There is a sense that the growth in SFRs is a positive development since it offers affordable rental housing, particularly for larger low-income families, in areas of opportunity across the metropolitan region. Similar to Immergluck (2018), we find that there are more SFRs available in neighborhoods where the foreclosure crisis was severe and the housing market recovery is slow. We also find that these neighborhoods that are located in the suburbs tend to be inner-ring suburbs that have lower incomes than other suburbs. We do find that SFRs are being utilized by low-income families with children in many cases. We discuss the implications of our findings for planning and policy.

EXPLAINING THE BLACK-WHITE HOMEOWNERSHIP GAP

Abstract ID: 290

Group Submission: Neighborhood Inequalities in Homeownership

CHOI, Jung [Urban Institute] JChoi@urban.org, presenting author
GOODMAN, Laurie [Urban Institute] lgoodman@urban.org, co-author
MCCARGO, Alanna [Urban Institute] AMcCargo@urban.org, co-author

Existing studies (McCargo, Strohach, 2019) have found consistent black-white homeownership gap across U.S. cities. The black homeownership rate fell significantly following the Great Recession, and now is at the same rate as it was in 1968 when the Fair Housing Act was signed (Goodman, McCargo and Zhu, 2018). Due to the uneven impact of the financial crisis, the racial homeownership disparity in the United States has widened during the past decade. The black-white homeownership gap exists in all US cities, but the size of the gap differs substantially across the country. For example, among the top 100 MSAs with the largest black population, Minneapolis-St. Paul-Bloomington, MN has the largest black-white homeownership gap of 50 percent while Killeen-Temple, TX has the smallest gap of 14 percent.

The differences in the black-white homeownership gap across US cities spark the question of why these gaps persist, what local factors impact the differences, and how can progress be made to reduce the racial gaps. Using various data, including American Community Survey and HMDA, we will examine what factors explain the gap in the black-white homeownership rate. We will employ regression analysis and Oaxaca decomposition method to estimate which factors – e.g. demographic composition, labor market conditions, housing costs, and residential segregation – contribute most to the homeownership gap and how the relative contribution differs across cities. This analysis will also help to further identify which cities to dive deeper into. For example, we could look closely and drill down in 10 MSAs with the

greatest homeownership gap and 10 MSAs with the smallest gap, and examine how these cities differ in what drivers that contribute to the black-white homeownership gap

While our research quantifies key factors driving the racial homeownership gaps across US cities using existing data can explain the black-white homeownership disparities, it is likely that some will remain unexplained. Historical legacies, policies (Rothstein, 2017), and financing practices (Baradaran, 2017) at the national and local level would have also played an important role in widening or reducing the homeownership gaps; however, these factors are difficult to quantify. The results from our research will guide us on where to consider a deeper dive with further research and analysis to understand additional local factors and policies that lead to strikingly different homeownership outcomes. Our research will also help inform cities to effectively design local solutions and policies specifically to meet their unique conditions and needs. The research will assist in formulating the theory of change for how some cities might enhance housing strategies and policies locally to specifically address the racial homeownership gap.

PRE-ORGANIZED SESSION - AGING OUT OF PLACE: RESIDENTIAL MOBILITY AMONG OLDER ADULTS

ID: 24

Pre-Organized Session Summary

Includes abstracts: 411, 412, 413, 414

While aging in place has received a great deal of attention in planning research, many people move later in life. Older adults move for a variety of reasons: to live near family and friends, to downsize to a smaller home, to experience a more favorable climate, to enjoy the amenities and support of a retirement community. For some, retirement enhances their freedom to choose where to live. For others, financial constraints, health problems, and functional limitations precipitate or prevent moves, and restrict their housing options. The papers in this session investigate the factors that affect older adults' decisions to move, and their choices about where to live. Each study uses geocoded survey data to trace older adults' residential locations, paired with contextual data to understand the types of places - both neighborhoods and regions - where they move. The analyses focus on questions of housing tenure, location, and inequality in later life, and draw out implications for the future of housing demand.

Objectives:

- Understand the patterns of residential moves in later life.
- Explain the broader impacts of changes in where older adults live.

HOUSING AFFORDABILITY AND RESIDENTIAL MOVES IN LATER LIFE

Abstract ID: 411

Group Submission: Aging Out of Place: Residential Mobility Among Older Adults

MAWHORTER, Sarah [University of Southern California] smawhort@usc.edu, presenting author

AILSHIRE, Jennifer [University of Southern California] ailshire@usc.edu, co-author

Since the 1990s, US home prices have swung up and down and then back up again, in a dramatic cycle of boom, bust, and recovery. Rents have risen without interruption. At the same time, housing prices in prosperous urban areas have pulled away from those in declining urban and rural areas.

Older adults are more likely to be affected by increases in housing prices: older homeowners on fixed incomes may not be able to afford rising property taxes (though they benefit from increasing home equity), and older renters are especially vulnerable to rising rents. The divergence of housing prices in different areas of the country may also affect the places where older adults can afford to move. Older adults living in places with high and increasing housing prices face pressures to move towards less expensive places, while older adults living in places with lower housing prices may be unable to move towards more expensive places.

In this paper, we investigate two main research questions. First, how have changes in housing prices during the 2000s housing boom, bust, and subsequent recovery altered housing affordability constraints for older renters and homeowners? Second, has the divergence in housing prices between various areas of the US affected inter-regional residential mobility among older adults? We examine housing affordability and residential mobility patterns for adults over age 50 living in high-cost, mid-cost, and low-cost areas from 2000-2016, using household-level data from the Health and Retirement Study, combined with county-level contextual data from the US Census and American Community Survey, as well as the US Department of Housing and Urban Development 50th Percentile Rent Estimates and the Zillow Home Value Index.

We find that both homeowners and renters living in high-cost areas remain in place at higher rates compared with those living in mid-cost and low-cost areas. Among those who move, older adults living in high-cost regions move towards mid-cost and low-cost regions more often than the reverse. The differences are particularly pronounced for renters. The overall outcome is a net movement of older adults away from high-cost areas towards mid-cost and low-cost areas. These shifts have direct consequences for the well-being of older adults and broader implications for housing markets where reduced turnover worsens housing shortfalls. The findings suggest that economic and spatial inequalities between renters and homeowners are exacerbated in later life, especially in the context of rising housing prices. This research contributes a new perspective to the literature on housing affordability and inter-regional moves, which mainly focuses on working-aged adults, and offers insights for planners working to find housing solutions for an aging population.

UNDERSTANDING OLDER ADULT MOBILITY DECISIONS: THE ROLE OF CHILDREN

Abstract ID: 412

Group Submission: Aging Out of Place: Residential Mobility Among Older Adults

BEGLEY, Jaclene [Fannie Mae] jbegley@nyu.edu, presenting author

CHAN, Sewin [NYU] sewin.chan@nyu.edu, co-author

Despite the importance of housing and location characteristics to the wellbeing of older households, we know surprisingly little about their residential choices and the primary factors that drive their decisions to move. The majority of older households are homeowners, and many of these households have a substantial share of their wealth invested in their home. Older households are also often out of the labor force and therefore have lower incomes and may be more likely tap into their housing wealth. Even without lower incomes, older adults are entering a period of life changes, which may make them more likely to move as they enter retirement, experience health problems, or simply prefer to reduce their housing consumption. Understanding the likely behavior of older adults over the coming decades has important implications for local housing markets. Whether older adults will be more likely to downsize and relocate to urban areas, remain in their long-time homes, or relocate to be near children all have important implications for housing supply and demand during the coming years of population aging.

Our goal in this paper is to further the understanding of residential housing and location choices as we age, and to highlight the key factors that drive moving and housing decisions for older adults. We focus specifically on how the mobility choices of adult children also influence the moves of their parents. Ultimately, these findings will inform potential policies that could increase the likelihood of households living in aging-appropriate homes and communities.

We explore the following facets of older adult mobility:

1. Mobility patterns: Who moves? How do age, retirement, and other life events affect moving decisions?
2. Distance from children: To what extent are people moving closer to their adult children?
3. Age-friendly moves: What are the post-move housing and neighborhood characteristics? How do these compare with their pre-move characteristics, and those of households who stay? Is post-move housing more aging appropriate?

To answer these questions, we use data from the geocoded version of the Health and Retirement Study (HRS), a large, biennial, nationally-representative panel survey of older adults that began in 1992. In addition to detailed information on individuals and their homes from the survey, we use the geocodes to match on a variety of neighborhood and location attributes. We are also able to use the geocoded information on respondents' children coupled with questions about child co-residence, grandchildren, and proximity to children to explore how the location of children influences mobility.

With our rich dataset, we explore the role of individual, family, housing, and neighborhood characteristics in residential mobility and location choice. We explore the role of proximity to children and caregiving in moving decisions. Finally, for those who move to another home, we compare the old and the new home and neighborhood along a variety of dimensions.

NEIGHBORHOOD LIVABILITY AMONG OLDER ADULT HOUSEHOLDS

Abstract ID: 413

Group Submission: Aging Out of Place: Residential Mobility Among Older Adults

LEE, Hyojung [Harvard University] hyojung_lee@harvard.edu, presenting author
AIRGOOD-OBRYCKI, Whitney [Harvard University] whitney_airgood-obrycki@harvard.edu, co-author
MOLINSKY, Jennifer [Harvard University] jennifer_molinsky@harvard.edu, co-author

With the aging of the baby boomers, persons age 50 and over now represent more than a third (114 million) of the US population. The number of households headed by someone age 65 and over has also risen, and is projected to increase, from 37.2 million in 2015 to 72.4 million in 2035 according to the Harvard Joint Center for Housing Studies. At the same time, geographic and housing tenure choices of older adults households have been gradually changing. Older adult households are becoming increasingly concentrated, with growing number of senior-majority neighborhoods (50 year and older); while homeownership rate among households age 50 and over declines over time, the black-white homeownership gap among the older households has become among the largest in the history. Some of these neighborhoods have services and amenities to help older adults age comfortably in place, others not. Given all these changes, this study examines the residential mobility, housing tenure, and location choices among older adult households, focusing on the differences across demographic and socio-economic groups in housing and neighborhood qualities.

The AARP Livability Index enables us to identify disparities in neighborhood livability for older adults. We use the Livability Index to create five quintile categories of neighborhood age-friendliness and then describe the geographic locations and socio-economic characteristics of these neighborhoods. Next, we examine the links between household characteristics and neighborhood livability using American Community Survey restricted-access microdata. Using the data, we conduct binomial and multinomial logistic regressions to investigate the household- and neighborhood-level determinants of residential mobility and location choices for older adults. The independent variables include demographic and socio-economic characteristics of old adult households such as age, race/ethnicity, income, education, tenure, and household composition, and neighborhood characteristics such as age structure, racial composition, housing prices. Lastly, we analyze whether there are different patterns across race/ethnicity, income, and tenure status.

Our findings show that livable neighborhoods tend to be located on the periphery of urban centers, in where single-family owner-occupied homes are prevalent. The households living in them tend to be non-Hispanic white owners and have higher incomes than those in low-livability neighborhoods. Ultimately, the findings of this study will contribute to discussions on how to create healthy, sustainable, and livable communities for the nation's growing older population.

AGING AND HOUSING TENURE TRANSITIONS

Abstract ID: 414

Group Submission: Aging Out of Place: Residential Mobility Among Older Adults

ZHU, Linna [University of Southern California] linnazhu@usc.edu, presenting author

This paper examines the determinants for delayed transitioning out of homeownership among the elderly and explores the consequences of aging in place on housing supply. The United States is experiencing rapid aging of its population: more than 20 percent of the population will be over the age of 65 by 2029. In this rapid aging context, housing, the most important asset in households' portfolios, plays a vital role in post-retirement life. How do older generations make housing tenure transitions and when do they transition out of homeownership are having profound impact on housing market. Previous literature has shown that health status, marital status and child proximity play vital roles in elderly housing tenure transitions (Painter and Lee, 2009; Lee and Painter, 2014). Motivated by the findings[1] that compared to

AHEAD cohort, more recent senior generations (HRS and Baby Boomers Cohorts) show delayed timing of transitioning out of homeownership, this study aims at 1) investigating how the interplay of detailed health status (both physical disability and cognitive declines), household financial fragility, child proximity and intergenerational wealth transfers fastens the trend of aging in place, and 2) exploring how this trend of aging in place shapes the geographical mismatch between housing demand boomed by millennials and Gen Xers) and housing supply held up by baby boomers and elderly cohorts. This research will further shed light on how elderly housing tenure transitions can have an impact on unequal intergenerational housing wealth distributions especially in MSAs with tighter housing supply.

This study takes advantages of the RAND HRS data, sampling the period from 1992 to 2014. RAND HRS dataset and the restricted geocodes data are ideal datasets to examine this research question. RAND HRS data contains extensive information on individual and family characteristics, including detailed health status, financial and housing wealth, income information and intergenerational wealth transfers. All those variables are crucial factors determining elderly housing tenure decisions. The detailed cohort information helps this study investigate heterogeneous transitional patterns across HRS, Children of Depression, War Baby and Early Baby Boomers. Moreover, the longitudinal data structure enables us to better control for unobserved time-invariant factors affecting households' housing wealth consumption portfolios. Most importantly, the unique detailed health data helps this study disentangle the impact of cognition decline from physical disability.

The empirical model in this study employs proportional hazard model and multinomial logistic regression to examine the determinants for housing tenure transitions after controlling for households' demographic and socioeconomic characteristics as well as post-retirement income level. The dependent variable will be a constructed categorical variable indicating the tenure choice set based on self-reported value of primary residence and mortgages, reverse mortgages take-up, and the residential location indicated by zip-codes (restricted data). Independent variables of interest include detailed health status (functional, mental, cognitive and health conditions), financial fragility (indebtedness level measured by LTV on primary residence), probability of leaving a bequest, housing value/wealth, cohort, health insurance type, expectations of mortality, inter-generational wealth transfers and demographic and socioeconomic factors.

HOUSING VULNERABILITY AND LOSS

ID: 25

Pre-Organized Session Summary

Includes abstracts: 428, 429, 430, 431

What happens to housing in precarious conditions? What are the consequences for the people who live there? The papers in this session consider mobile home parks after a natural disaster, rental units with code violations, housing facing demolition, and informal settlements outside the reach of legal standards and city services. The authors develop new techniques using parcel- or unit-level administrative data to study types of housing that are difficult to observe. After analyzing patterns of housing vulnerability and loss, the papers go further, to ask what such housing conditions mean for their residents. For people living in mobile home parks, what happened when flooding threatened their homes? In substandard rental housing, will code enforcement improve living conditions, or simply raise rents so that residents can no longer afford to live there? How do demolitions affect the housing available for people living in poor or declining neighborhoods? Informal settlements may provide much-needed housing, but what do they offer in terms of living conditions for their residents?

Objectives:

- Understand the patterns of housing in precarious conditions.
- Describe the consequences for residents.

BEYOND THE OWNER-RENTER DIVIDE IN DISASTER PLANNING: A GEOGRAPHICAL ANALYSIS OF MOBILE HOME PARK DAMAGE AND RECOVERY AFTER HURRICANE HARVEY

Abstract ID: 428

Group Submission: Housing Vulnerability and Loss

RUMBACH, Andrew [University of Colorado Denver] andrew.rumbach@ucdenver.edu, presenting author

SULLIVAN, Esther [University of Colorado Denver] esther.sullivan@ucdenver.edu, co-author

MAKAREWICZ, Carrie [University of Colorado Denver] carrie.makarewicz@ucdenver.edu, co-author

Mobile homes are a significant, but often unacknowledged, part of our nation's affordable housing supply. Mobile homes are the single largest source of unsubsidized affordable housing in the United States. An estimated 2.9 million mobile homes are located within mobile home parks (MHPs), which are unique land-lease communities where households own their housing unit but rent the land underneath. The population living in MHPs is predominantly low-income and includes many elderly, disabled, non-white, and non-English speaking individuals. Mobile home parks are frequently exposed to hazards and disasters. In 2017 alone, floods, hurricanes, and wildfires triggered disasters in Texas, Florida, and California, the three states with the largest populations living in mobile homes. The limited scholarship on affordable housing and disasters has focused almost entirely on site-built housing, however, and largely overlooked MHPs. Because of the unique characteristics of MHPs – their mixed tenure arrangements, park ownership structure, and treatment under local laws and regulations – we hypothesize that MHPs are exposed to, and recover from, disaster events differently than other affordable housing types.

In this paper we utilize a mixed-methods research design to study the geography of exposure and recovery of MHPs in the Houston MSA after Harvey. Texas, Hurricane Harvey, and the Houston metropolitan area present a unique nexus to study the vulnerability of mobile home parks to disasters, across different geographic, demographic and governance contexts. Texas, the state with the largest mobile home

population, also outranks all other states in deaths, injuries, and property loss resulting from floods. The largest share of Texas' roughly 1.9 million mobile home park residents (17.7%) lives in the Houston Metropolitan Area, throughout 134 cities, towns, and jurisdictions.

First, we locate all MHPs in the 9-county region using tax record and parcel data. Next, we overlay Harvey flood models to estimate the extent, and magnitude, of flood exposure. Third, we use pre-Harvey remotely sensed imagery to count the number, and type, of mobile homes in each park and use flood data to estimate the level of damage and unit loss for each park. Finally, we review local development regulations related to mobile home parks and flood recovery. These findings represent the first-time, comprehensive and comparative analysis of the exposure and recovery of the mobile home park housing stock of a major metropolitan area following an extreme event. They allow us to understand which parks, in terms of their physical location, ownership structure, and treatment under local laws and regulations, are most likely to suffer damage and to recover after loss. These findings will help planners to more accurately account for vulnerability in the affordable housing stock and design more effective hazard mitigation or community resilience plans and strategies.

CODE ENFORCEMENT AND AFFORDABILITY: WILL BETTER HOUSING RAISE THE RENT?

Abstract ID: 429

Group Submission: Housing Vulnerability and Loss

MUELLER, Elizabeth [University of Texas at Austin] ejmueller@austin.utexas.edu, presenting author

In the early 1970s, as part of debates over the focus of urban renewal, scholars debated the impact of enforcing housing standards (whether through the implied standard of warrantability or local code enforcement) on rents. In recent years, rents have risen despite stagnation in housing quality (Super 2011). One side, led by legal scholar Ackerman, argued that if standards were enforced across the board the impact on rents would be minimal. The other, led by Komesar, argued that higher standards would result in rents beyond the reach of those living in housing in need of improvement. According to Desmond, the outcome of the scant empirical research on the topic was indeterminate. Since that time, little new research has tried to resolve the issue. In this paper, I attempt to revive the discussion, by examining the impact of a targeted code enforcement initiative in Austin, Texas, on rents and housing quality. After the failure of an initiative to require all rental housing to register with the city, as a first step

toward systematic code enforcement, the city established the Repeat Offender Program (ROP). Under the ROP, buildings receiving repeat violations during a two year period are repeatedly inspected and targeted for various types of enforcement. Since 2014, when the program was established, 121 properties, containing over 10,000 units have been subject to enforcement under the program. To date, reporting on the program and anecdotal evidence suggests that enforcement has been weak, allowing owners to avoid compliance. In some cases, owners have negotiated down the fines associated with code violations upon sale of the property. Little is known about the impact of the program on housing quality and affordability for low-income tenants. I hypothesize that both the strength and speed of enforcement and the desirability of the property location affect the impacts for tenants. Since enforcement has improved over time, I hope to be able to see evidence of improved enforcement outcomes using code inspection activity data. Using proprietary data available from a local company that regularly surveys rental housing in buildings of 50 units or more, I will attempt to assess the relationship between code enforcement and rents, controlling for citywide trends in class c properties. I conclude with a discussion of the original question—does pushing for improved conditions result in rents beyond the reach of low-income renters? How do changes in rents for targeted properties vary based on other factors, such as location? What practices appear to work best (or worst) for tenants

DEMOLITION AND NEIGHBORHOOD CHANGE IN CHICAGO

Abstract ID: 430

Group Submission: Housing Vulnerability and Loss

ROHRET, Danielle [University of Louisville] danielle.rohret@louisville.edu, presenting author
KINAHAN, Kelly [University of Louisville] kelly.kinahan@louisville.edu, co-author
MAWHORTER, Sarah [Syracuse University] sarah.mawhorter@gmail.com, co-author

Demolition is often studied as an urban redevelopment strategy employed to deconcentrate poverty and ‘clear the way’ for new development in prime real estate locations (e.g. Goetz, 2003). Many communities have been ‘twice-cleared’, first during midcentury urban renewal followed by the demolition of public housing through the HOPE VI and Choice Neighborhoods programs (Vale, 2013). Demolition is also pursued as a stand-alone strategy to regenerate communities through the reduction of disorder and crime, particularly in cities that have experienced widespread population loss (Stacy, 2018), and as an economic response to urban austerity under neoliberalism (Rosenman & Walker, 2016). In fact, research shows that in some cities, these ad hoc, scattered site demolition practices led to more housing loss than in the urban renewal period (Hackworth, 2016). Yet, scattered site demolition is an understudied component of the broader housing market. What are the housing-, parcel-, and neighborhood-specific determinants of

housing demolition? Using fine-grained administrative data on building characteristics and city demolition permits, combined with American Community Survey neighborhood measures, we employ a multilevel survival analysis to analyze the residential building stock in Chicago, IL across the 2006-2018 time-period. We then assess the implications of ad hoc demolitions for neighborhood change, in terms of the housing available for rent or sale, housing prices, housing affordability, and residential mobility of existing residents and newcomers. This research complicates the idea that demolition is a straightforward response to structural deterioration of housing – demolition can also be pursued to pave the way for redevelopment and new construction – and begins to quantify the ways in which demolition can have both helpful and harmful impacts for neighborhood residents. The findings serve to inform planners about the larger scale impacts of the increasingly prevalent practice of ad hoc demolition, and will help planners devise strategies to protect vulnerable residents living in both declining and gentrifying neighborhoods.

BUILDING FOOTPRINT-DERIVED LANDSCAPE METRICS FOR THE IDENTIFICATION OF INFORMAL SUBDIVISIONS IN SOUTH TEXAS

Abstract ID: 431

Group Submission: Housing Vulnerability and Loss

DURST, Noah [Michigan State University] noahdurst@gmail.com, presenting author

HUANG, Huiqing [Michigan State University] huiqingh@msu.edu, co-author

HOGUN, Park [UC San Diego] hopark@ucsd.edu, primary author

CANGELOSI, Elena [Michigan State University] cangelo3@msu.edu, co-author

Substantial research has examined the challenges posed by the proliferation of colonias, low-income informal subdivisions located along the U.S.-Mexico border, where the lack of water and waste water service and widespread self-building of the home has contributed to severe health and safety risks for residents (Ward, 1999). Although recent research has illustrated that informal subdivisions are more widespread across the country than typically acknowledged (Durst, 2018; Durst, 2016; Ward and Peters, 2007), the time-intensive nature of identifying these subdivisions through the analysis of satellite imagery and property records necessarily limits the systematic study of these communities. This paper uses big data to develop landscape metrics capable of identifying the location of informal subdivisions across the country. We use a data set of building footprints developed by Microsoft and released publicly in 2018 to measure the size, type, orientation, placement, and uniformity of housing in more than 2,000 residential neighborhoods Hidalgo County, Texas, where more than 1,000 informal subdivisions have been documented by prior research (Durst, 2016). We use cross-validation to test the ability of these landscape

metrics to distinguish between three neighborhood types: informal subdivisions, mobile home parks, and formal subdivisions. We then illustrate how these landscape metrics data can be paired with data from other sources to examine issues of housing vulnerability and loss. We conclude by describing the methodological steps necessary to identify and systematically study informal subdivisions across the country.

PERCEPTION MEETS REALITY: SUBJECTIVE ASSESSMENTS OF HOUSING AND NEIGHBORHOODS

ID: 26

Pre-Organized Session Summary

Includes abstracts: 338, 339, 340

People's feelings about their homes have concrete impacts on their lives. This session explores how housing and neighborhood characteristics affect perceptions, and how those perceptions influence residents' well-being. The connection between perceptions and the built environment is difficult to observe. In survey responses, subjective assessments are often embedded in objective observations, and vice versa. The innovative, mixed-methods studies in this session solve this problem by using separate data sources to measure perceptions versus characteristics. The researchers link survey or ethnographic data on perceptions with datasets that provide fine-grained measures about the respondents' homes and neighborhoods. The papers reveal the importance of housing design, size, and condition for residents' happiness. At the neighborhood level, they uncover tensions between social cohesion and envy of neighbors. The authors also investigate how tenure affects the relationship between residents and their homes and neighborhoods, illuminating the divergent experiences of renters and homeowners living in similar types of places.

Objectives:

- Understand the connection between built environment characteristics and residents' perceptions.
- Explain the implications of housing and neighborhood perceptions for residents' well-being.

ASSESSING THE EFFECT OF NEIGHBORHOOD CONTEXT ON RESIDENTS' HOUSING SATISFACTION

Abstract ID: 338

Group Submission: Perception Meets Reality: Subjective Assessments of Housing and Neighborhoods

CHARLES, Suzanne [Cornell University] slc329@cornell.edu, presenting author

KUHLMANN, Daniel [Iowa State University] dok@iastate.edu, co-author

This study examines the effect that neighborhood context has on suburban residents' satisfaction with their houses and neighborhoods. Veblen (1899) identifies the need in a consumer-oriented society to outwardly express success through what he terms "conspicuous consumption"—expenditures on goods and services that are motivated by the public display of wealth and status. Hirsch (1976, p. 2) identifies these conspicuously consumed goods as "positional goods," which he defines as those for which satisfaction depends not only on individual consumption but on consumption by others as well. Housing is a powerful symbol of wealth and prestige and is widely considered a positional good (Charles, 2018; Solnick & Hemenway, 2005). What one considers to be a large house is very much dependent upon the house's context. The concept of positionality in housing satisfaction research is compelling because it contradicts neoclassical economic principles that prioritize absolute consumption—the overall square footage of the house—over other considerations such as relative consumption. Yet it makes intuitive sense: the physical and social contexts in which housing consumption takes place are important to individuals as they assess their satisfaction with their houses and their neighborhoods.

When the higher relative housing consumption of neighbors negatively affects the utility of an individual's house, it is described as "envy" (Easton & Eswaran, 2003). But individuals may also gain from their neighbors' relatively higher housing consumption. "Basking in the reflected glory" is a behavior when individuals emphasize their connections with successful people and gain esteem through those associations (Cialdini et al., 1976). Thus, one may value the relatively higher consumption of their neighbors because they view their status as enhanced by their proximity to those higher status households. It follows then that envy and reflected glory may affect individuals' assessments of their houses and their neighborhoods differently—those living in houses that are relatively smaller and older than their neighbors may report lower ratings of satisfaction with their house but higher ratings of satisfaction with their neighborhood. Envy and reflected glory are important yet understudied concepts affecting individuals' housing satisfaction. The overarching question addressed in this study is: how do the physical qualities of surrounding single-family houses affect one's subjective assessment of their house and neighborhood?

The study begins with an online survey of suburban residents' subjective assessments of their houses and their neighborhoods. Survey respondents are first asked for their current address and whether they own or rent their home. Then, after a series of demographic questions, the survey asks respondents to measure their satisfaction with their house and their satisfaction with their neighborhood on a Likert-type scale. Next, we match the street addresses provided by the respondents to property record data to determine the physical characteristics of each respondent's house and neighboring houses (reference group). We identify all neighboring houses within the viewshed of each respondent's house—defined as houses that are located on the same street and within 100 meters. The physical characteristics of houses within the viewshed are used to calculate relative measurements of each respondent's house compared to their neighbors' houses. Using this dataset, we examine the association between the objective characteristics of housing within the viewshed of each respondent's house and their subjective assessments of their house and neighborhood quality. And we test whether these associations differ whether one owns or rents their house. The study will contribute to the literature on factors affecting housing satisfaction and will influence our understanding of why households choose to remain in or leave neighborhoods undergoing gentrification pressures.

Key Words: housing satisfaction, positional goods, single-family housing, suburbs

HOUSING & HAPPINESS: AN EXPLORATORY ANALYSIS

Abstract ID: 339

Group Submission: Perception Meets Reality: Subjective Assessments of Housing and Neighborhoods

PFEIFFER, Deirdre [Arizona State University] deirdre.pfeiffer@asu.edu, presenting author

There is growing awareness about how decisions made about the built environment may affect health. Most existing research focuses on the link between health and the qualities of infrastructure and open spaces, such as walkability and access to parks. Relatively little is known about how the design and use of buildings may affect health, including the most important kind of building in the built environment: the home. This research helps to fill this gap by using a rich survey data set from the Phoenix region to explore how the design of the home—whether the home is oriented to the car or not—and the tenure of its occupants relates to one aspect of health, happiness.

To start, I will use descriptive statistics and econometric modeling to investigate two often-cited assumptions about housing design, tenure, and wellbeing. The first assumption is that people who live in more human-, rather than automobile-, centric homes are happier. The features of the home that comprise a human- vs. automobile-centric design, including the location and size of the garage and driveway, the presence of a porch, and the visibility of the front door and windows from the street, will be captured through a windshield survey of participants' neighborhoods. The second assumption is that people who own their homes are happier. Participants' tenure is self-reported in the survey data. I will attempt to isolate these relationships by accounting for other individual and neighborhood characteristics that likely relate to happiness, such as income and age. I also will partly control for self-selection bias, or the tendency for happier people to live in communities with particular qualities, by accounting for participants' satisfaction with the quality of housing in their neighborhood.

Next, I will examine the role that two intervening factors—perceived social capital with neighbors and identification with one's neighborhood—may play in the relationships among housing design, tenure and happiness. I expect to find that people who live as owners in more human-centric homes are happier, because these qualities may encourage them to engage and invest more in their neighborhood, which may lead them to have higher social capital with their neighbors and identify more strongly with their neighborhood.

Overall, this research stands to build on emerging research on the link between housing and health by offering new insights on whether and how the design and tenure of the home may affect happiness, which could have broad implications for how local governments regulate housing development.

DISPARATE DISCRETION: BUILDING INSPECTIONS AND THEIR CONSEQUENCES FOR HOMEOWNERS AND RENTERS

Abstract ID: 340

Group Submission: Perception Meets Reality: Subjective Assessments of Housing and Neighborhoods

BARTRAM, Robin [Tulane University] rbartram@tulane.edu, presenting author

Who has the power to decide what counts as decent or substandard housing, and how do these decisions matter for residents? My mixed methods study of municipal building inspections in Chicago connects on-the-ground interpretations of building conditions to city-wide patterns in housing inequality, tracing the intentions of inspectors and the ramifications of their actions. I draw on an ethnography of building inspections in action and observations in housing court, coupled with statistical analyses of housing and rental market data.

My research shows that building inspectors in Chicago bend the rules for low- and moderate-income homeowners by not levying fines and not insisting they make repairs, or by recommending how to fix issues cheaply and still pass an inspection. On the other hand, inspectors target professional landlords, wealthy homeowners, and speculators by nitpicking and dragging them through red tape. The white, working-class background of most building inspectors means that they have an affinity for the little guy for whom the odds are stacked against, and contempt for exploitation; in their work that means the struggling homeowner, and the negligent landlord, respectively. However, their actions backfire. Landlords raise rents in response to inspectors' punitive allocation of violations and fines, low-income homeowners lose value on their homes when inspectors do not mandate that they make repairs, and inspectors often go easy on gentrifying newcomers because they are homeowners. Inequality prevails - albeit through different mechanisms for renters and homeowners - due to the structure of the housing market.

TRACK 6 – INDIVIDUAL ABSTRACTS

DOES NEIGHBORHOOD SOCIAL MIX LEAD TO CROSS-GROUP SOCIAL INTERACTION? A CASE STUDY ON THE ISLE OF DOGS, LONDON, UK.

Abstract ID: 17

Individual Paper Submission

LEE, Yeonhwa [University of Pennsylvania] yeonhwa@design.upenn.edu, presenting author
ARBACI, Sonia [University College London (The Bartlett)] s.arbaci@ucl.ac.uk, co-author

As seminal works drew attention to residential segregation and concentrated poverty (Wilson, 1987; Massey and Denton, 1993), countries around the world, including the US and the UK, adopted social mix policies, or policies that promote socio-spatial integration by diversifying levels of income and forms of tenure in an area, to counter negative neighborhood effects. Mixed communities, or mixed-income and mixed-tenure neighborhoods, have been theorized to confer benefits more commonly enjoyed by higher-income groups to lower-income groups, such as social capital and upward mobility, thereby improving their welfare and life chances. However, such theorizations are predicated on the assumption that people of different social groups, when placed to live in proximity, will socially interact, form relationships, and exchange information. There is relatively little literature on whether this assumption holds true.

In order to address this gap, this paper poses the following questions. Does residential proximity create social interaction potential, as measured by spatio-temporal joint accessibility of everyday activity spaces (Farber et al., 2014)? Do residents living in mixed communities take advantage of the opportunities for cross-group social interaction? Why or why not, and what are the implications for planning and housing policies going forward? To answer these research questions, the paper devises an innovative methodological framework that triangulates quantitative analysis of the 2011 census, spatial analysis of 39 residents' activity spaces, and qualitative analysis of the same residents' reported experience of social interaction in the case study area—a mixed community neighborhood on the Isle of Dogs, London, UK.

The paper has three key findings. First, a mixed community remains difficult to define in terms of composition, concentration, and scale (Galster, 2010). A multi-scalar analysis of census data reveals a number of mixed communities, some more mixed than others, at varying geographical units in the case study area. Second, proximity in the residential space does not necessarily increase social interaction potential. Residents belonging to dissimilar social groups use different spaces for their everyday needs, living somewhat of parallel lives within the neighborhood. Third, proximity in the residential space and even increased cross-group exposure do not necessarily reduce social distance. Some limited social interactions occur in the shared spaces, but most respondents are less than enthusiastic about social interaction in general, while some demonstrate strong perceptions of different social groups as 'the other'.

The paper adds to a growing body of literature that explores the relationship between mixed communities and social interaction and, in particular, makes a methodological contribution by putting forth a unique research design involving triangulation of quantitative, qualitative, and spatial analysis methods. Furthermore, the findings have important implications for planning and housing policies; they challenge the theorized social-interactive mechanism of positive neighborhood effects and more broadly the ‘mixed communities consensus’ (Arthurson, 2012), especially in light of the emerging criticisms of social mix policies for their costs to the poor and the marginalized (Bridge et al., 2012).

THE EFFECTS OF HOME PURCHASE RESTRICTIONS ON LOCAL HOUSING MARKETS IN CHINA

Abstract ID: 22

Individual Paper Submission

WANG, Rui [Johns Hopkins University] email.rui@gmail.com, presenting author

China’s central government introduced home purchase restrictions (HPR) to cities with high home price levels in 2010 to reduce speculative demand and improve affordability. Widely believed as one of the country’s harshest housing market interventions, the HPR policy was first implemented in Beijing in April 2010, followed by most major cities. Previous studies treat HPR as an exogenous demand shock but find inconsistent effects on home prices across cities. In particular, studies using micro data discover opposite price effects of HPR between Beijing and Guangzhou. We believe there has been a misconception of the policy process of HPR, which should be considered as an exogenous demand shock only in Beijing, with the national effects of HPR compromised by the strategic reactions of the local governments in other cities. Specifically, we hypothesize that the rational response of buyers and sellers permitted by the strategic local implementation of the HPR policy produced housing market effects different from what happened in Beijing. Using aggregated monthly housing market data from a panel of major cities during 2009-2016, we confirm the different price effects of HPR in other cities from those in Beijing. Moreover, local governments strategically timed the implementation of HPR, which assisted the rational responses by buyers and sellers and at least temporarily counteracted the policy goal of the central government. Policy makers could learn from this in order to design future policies that minimize unintended consequences.

INSTITUTIONAL PERSPECTIVES AND HOME-OWNER OUTCOMES FROM THE CHICAGO HOUSING AUTHORITY'S CHOOSE-TO-OWN (CTO) PROGRAM

Abstract ID: 24

Individual Paper Submission

BALACHANDRAN, Sowmya [University of Illinois at Urbana-Champaign] sowmyab2@illinois.edu, presenting author

GREENLEE, Andrew [University of Illinois at Urbana Champaign] agreen4@illinois.edu, co-author

Low-income home ownership facilitation has received little space in academic debates since the housing crisis of 2008. If anything, research has advocated against ownership as the risks associated with owning are thought to increase intrinsic vulnerabilities of low-income and minority families owing to their income volatility, housing and labor market downturns, and most importantly lack of assets to rely upon (Reid 2013, Kingsely, Smith and Price 2009, Wolff 2001). Mortgage market discrimination (Bocian et al. 2011) and spatial inequities (Galster and Sharkey 2017) further exacerbate these risks.

However from a social justice and public policy stand point, provision of a conducive policy and institutional environment for low-income families to benefit from ownership, continues to have the potential of being an important anti-poverty intervention, one that holds the promise of reducing racial wealth gaps in the United States (McCargo and Strochak 2018). More importantly the poor and minorities continue to associate homeownership with upward mobility, achievement and full citizenship (Drew and Herbert 2013; Grinstein-Weiss et al. 2011; Reid 2014; Rohe and Lindblad 2014). Evidence from projects like the Community Advantage Program (CAP) show that a well-designed mortgage product, along with appropriate subsidy and handholding, substantially increase chances of success at building equity and leveraging of benefits from homeownership for low-income and racial minority families (Quercia, Freeman, and Ratcliffe 2011; Manturuk, Lindblad, and Quercia 2012).

This paper employs a mixed-methods program evaluation framework to examine institutional processes and outcomes from another such program – the Chicago Housing Authority's (CHA) voucher based Choose-To-Own (CTO) program. Utilizing the HUD family report dataset from 2002 to 2016 for the city of Chicago and institutional interviews with CHA and its partners, we explore the following research questions. How does the CHA and its partners work to reduce low-income risk over the 15 years of facilitation? Does the program reduce propensity for tenure-transitions and foreclosure risk? We answer these questions by examining the structure of pre-purchase, post-purchase and post-program support offered by institutions; and by assessing longitudinal variations in family assets, liabilities; and by constructing future ownership trajectories.

CHA reports suggest that 1/4th of the program participants have assumed full mortgage responsibility and have moved out of the program. The CTO program could thus have demonstration value not only in fostering innovative partnerships and multi-faceted support (Rohe and Stewart 1996), but may also serve to show that sustained long-term facilitation (Elugardo and Klein 1998) can help even ‘very low-income families’ (50 to 80% of area median income) on the path to residential stability and upward economic mobility.

HOW DO HOUSING AFFORDABILITY AND TENURE TYPE IMPACT AN INDIVIDUAL’S RISK OF EXPERIENCING HOMELESSNESS? EVIDENCE FROM NEW YORK CITY

Abstract ID: 47

Individual Paper Submission

HAUPERT, Tyler [Columbia University, GSAPP] th2675@columbia.edu, presenting author

In many housing markets around the world, rent and home prices have increased to unprecedented levels and become unaffordable, particularly for low income households. This lack of affordable housing supply and options has significant implications for access to housing and is often cited as a key contributor to substantial recent increases in homelessness (O’Flaherty, 2004). While the link between housing market fluctuations and trends in aggregate homelessness levels is well-established in the public health and urban economics literature, a compelling body of evidence exploring how an individual’s housing context relates to their risk of becoming homeless does not exist. To address this gap, this article advances a ‘multistate’ econometric approach to measuring the relationship between homelessness and housing tenure type, affordability, and assistance level over time. This approach is applied to data from The New York City Longitudinal Survey of Well-Being, a representative panel of New York City adults surveyed at three-month intervals over the two-year period between 2013 and 2015. A series of multilevel multinomial logistic regressions are specified to analyze the interrelationship between states of housing insecurity, including homelessness, and different housing tenure types such as homeownership, voucher-

assisted renting, and public housing occupancy. Results will inform planners' and policymakers' efforts to target scarce government resources toward reducing homelessness by strategically increasing housing security and affordability for those who are most vulnerable.

This research contributes to our understanding of the link between housing and homelessness by addressing several substantive and methodological gaps in the literature. First, existing studies assessing the relationship between housing and homelessness typically observe links between metropolitan- or city-level housing market characteristics and aggregate levels of homelessness (e.g. Hanratty, 2017) and thus fail to identify specific housing-related mechanisms contributing to an individual or family's path to homelessness. This article overcomes this limitation by utilizing panel data including a rich array of participants' housing characteristics, enabling inferences about the relationship between an individual's housing arrangement and their risk of homelessness. Second, the few other studies using panel data to assess predictors of homelessness at the individual level are beset with methodological and theoretical limitations. Research in this vein (e.g. Shinn et al., 2007) commonly relies on stepwise regression models applied to samples of already-homeless individuals which results in challenges interpreting statistical outputs and the limited generalizability of findings. The present study brings a more sophisticated econometric design to bear on data representative of the entire New York City adult population. Third, despite increasing evidence that neighborhood characteristics often relate to housing and health outcomes in important ways (Desmond & Kimbro, 2015), few empirical studies of pathways to homelessness investigate the interrelatedness of neighborhood characteristics, housing quality, and homelessness. Because the panel data used here include participants' locations, this study is able to incorporate several neighborhood covariates which inform inferences about whether various neighborhood characteristics impact housing's link to homelessness and reinforce notions of homelessness' multidimensionality (Somerville, 2013). In summary, this article's longitudinal, multistate approach, individual-level data, and neighborhood covariates enable a nuanced analysis of the roles housing tenure type, affordability, and assistance level play in the path to homelessness, thereby providing valuable information to policymakers seeking to prevent homelessness with housing-oriented interventions.

“I DIDN’T RAISE YOUR RENT, THE MARKET DID”: HOW PROFESSIONAL AND AMATEUR LANDLORDS SET RENTS IN SMALL RENTAL PROPERTIES

Abstract ID: 96

Individual Paper Submission

DECKER, Nathaniel [UC Berkeley] ndecker@berkeley.edu, presenting author

Rental affordability is a serious problem across the US. Renter cost burdens remain at historically high levels with approximately 47% of renter households paying 30% or more of their income on housing. While much of the rising cost pressures on renters can be attributed to economic and demographic shifts there have also been substantial changes in who owns rental properties and how they are managed that might contribute to rising rents.

The upper boundaries of rents are usually determined by market forces. Lower boundaries are usually determined by the expenses of owning and managing a property. Within these boundaries owners and managers set rents, but how they do so is poorly understood, particularly in the stock of 1- to 4-unit properties. Many of these properties are owned by amateurs, with small portfolios and full time employment that is unrelated to real estate. Scholars have theorized a number of reasons, from the economic to the personal, why amateur owners might set rents at lower levels than professionals (Downs, 1983; Gilderbloom & Appelbaum, 1988). However there is only limited evidence that this is the case, largely due to a lack of data on rents and rental property ownership (Ellen, Been, & Gross, 2013; Stegman & Sumka, 1976).

To discover how different owners set rents I designed and conducted a large survey of small rental property owners. The survey asked owners and managers what factors they considered in setting rents and asked about current and past rents for their units. The survey provides data that are used to show the link between the factors used in rent setting and specific rent outcomes. The survey was conducted on a stratified random sample of over 30,000 owners in the top 150 metro areas in the US.

The objective of this paper is to determine (i) whether there is a generalizable difference in the rent outcomes for professionally-owned units relative to units owned by amateurs and (ii) if there is a difference, whether the difference is attributable to the owners themselves. The paper presents results examining the connection between ownership and two specific rent outcomes: whether an owner knowingly sets rent at below-market levels and the “stickiness” of rent, i.e. the decision to not change rents over a two-year period. I categorize owners using a few of the definitions that have been used to distinguish professionals from amateurs including: portfolio size, the use of corporate entities to hold property, and the proximity of the owner’s residence to their rental property.

1- to 4-unit properties collectively provide about half of the nation’s rental housing stock. Because these properties tend to have larger units than units in multifamily buildings, they are disproportionately the homes of renter families with children. Understanding how rents are set in these properties is important to understanding the drivers of cost-burdens for renter households, particularly renter households with children.

ADDRESSING CHALLENGES POSED BY THE YEAR-15 TRANSITION IN LOW-INCOME HOUSING TAX CREDIT PROJECTS: LESSONS FROM DETROIT

Abstract ID: 152

Individual Paper Submission

DENG, Lan [University of Michigan] landeng@umich.edu, presenting author
DEWAR, Margaret [University of Michigan] medewar@umich.edu, co-author
BLOEM, Melissa [University of Michigan] mlubbers@umich.edu, co-author

Central Themes

This study examines the year-15 issue for the Low-Income Housing Tax Credit (LIHTC) Program, the country's largest affordable housing production program. Under the LIHTC program, investors who have made equity investment in affordable housing projects in exchange for tax credits must ensure affordability is maintained for 15 years. After year 15, most investors would seek to transfer their ownership interest to general partners or third parties. Ownership restructuring is thus common at year 15. While projects are required to maintain affordability for another 15 years, the federal government provides no oversight or funding to support this. Ensuring that LIHTC properties can continue to operate as decent affordable housing after year 15 has largely become a state and local responsibility.

Only three studies have examined the outcome of the year-15 transition for LIHTC projects (Schwartz and Meléndez 2008; Meléndez et al. 2008; Khadduri et al. 2012). All were conducted at the national level and all are a decade old. No studies have examined what specific challenges the year-15 transition may pose for LIHTC properties at the local level. Consequently there have been no writings on what efforts can be made at the state and local level that would help address those challenges.

Approach and Methodology

For over three years, we have been working with city leaders and LIHTC industry stakeholders including nonprofit developers and syndicators in Detroit to examine the year-15 challenges for LIHTC projects in Detroit and what could be done to address them. Our research approach includes meetings with community partners to identify research needs, collection and analysis of data from a variety of sources, and interviews of LIHTC industry experts both inside and outside Detroit. At last year's ACSP conference we presented data and analysis to identify the specific challenges in Detroit. This paper focuses on examining the efforts that have been made in Detroit to address them. In addition, we have also identified year-15 practices from other localities that are relevant to Detroit. We summarize what we have learned from these different sources and offer recommendations for housing policymakers and practitioners on what could be done at the state and local level to help produce a positive outcome for the year-15 transition, which is critical for LIHTC projects to continue operating as decent affordable housing for the next 15 years and beyond.

Findings

Due to the complexity of the LIHTC development financing, we find that the first task for the state and local actors who are interested in preserving LIHTC housing after year 15 is to bring together all the key stakeholders associated with those projects. Identifying the role and responsibility of each stakeholder and how they are likely to change after year 15 is important in developing coordinated strategies to address the challenges that year 15 may bring.

We also find that one critical component in the year-15 efforts we studied is to develop technical capacity for data collection and analysis so that all parties could have an accurate assessment of the conditions of the LIHTC projects approaching year 15 and the risks they face.

With the risk assessment, the core task of the year-15 efforts involves identifying resources to address the potential risks. Risks can vary among individual projects, ranging from financial needs to organizational capacity issue as well as changing market conditions that may lead to the conversion of some LIHTC projects into market housing.

Due to the constraint of resources, we find that prioritizing resource allocation is often needed. But this can cause difficulties for some LIHTC projects and may result in neighborhood disinvestment in the future.

INVESTIGATING SERIOUSLY DELINQUENT MORTGAGES IN MEXICAN NEIGHBORHOODS IN METROPOLITAN STATISTICAL AREAS IN THE UNITED STATES

Abstract ID: 225

Individual Paper Submission

ANACKER, Katrin [George Mason University] kanacker@gmu.edu, presenting author

While many scholars have extensively discussed the relatively high foreclosure rates in Hispanic/Latino neighborhoods in the United States, few have focused on the differences among neighborhoods with Mexican subgroups. This manuscript analyzes publicly available NSP 3 data from the U.S. Department of Housing and Urban Development and 2005/2009 American Community Survey (ACS) data from the U.S. Bureau of the Census. Based on descriptive statistics and Weighted Least Squares (WLS) regressions, it investigates rates of seriously delinquent mortgages in Census tracts for all Metropolitan Statistical Areas (MSAs) in the United States. Results show that neighborhoods with Mexican Census tracts had relatively high rates of seriously delinquent mortgages compared with other groups.

PROPERTY TAXES AND ELDERLY HOUSING

Abstract ID: 228

Individual Paper Submission

KIM, Jinyhup [University of Maryland, College Park] jinyhup.kim@gmail.com, presenting author

As the giant baby boomer generation born between 1946 and 1964 has been a dominant force across many sectors of the housing economy in the United States, there have been considerable interests in the housing choices made by the elderly, which generally suggest several reasons for expecting homeowners to make the transition to rental status or downsize to smaller homes during retirement. This study attempts to shed light on the reasons why the elderly make a downward transition from homeownership, especially focusing on the significance of property taxes on elderly mobility. This study uses the six waves of the Health and Retirement Study (HRS) survey from 2004 through 2014. In addition to the public HRS data, I obtained restricted access to household level geographical identifiers. These identifiers allow me to identify the residence location for each household at the time of each survey interview. The identifier is crucial because it links households to several variables to capture the housing and labor market. Methodologically, the research adopts the competing risk framework of leaving homeownership and estimate the effect of renting and downsizing simultaneously. The competing-risks survival regression provides a useful alternative to Cox regression in the presence of one or more competing risks. Renting and downsizing are considered competing risks because, when the elderly are likely to consume their home equity in the retirement, they preclude action on the other. This study seeks an assessment of the affordable housing needs of seniors under rising property taxes, providing insight into understanding seniors' housing tenure decisions that lead to becoming renters or downsize to smaller owned homes before, during, and after the Great Recession. As the baby boomers start to retire, the evidence for old adults is growing in importance. Estimates of the elasticity of elderly mobility with respect to property taxes will help state and local government design fiscal policies that retain and attract elderly homeowners in their jurisdictions.

ASSISTING RENTERS: LANDLORD AND TENANT EXPERIENCES OF A RENT SUPPLEMENT PROGRAM IN MANITOBA, CANADA

Abstract ID: 238

Individual Paper Submission

COOPER, Sarah [University of Manitoba] sarah.cooper@umanitoba.ca, presenting author
HAJER, Jesse [University of Manitoba] Jesse.Hajer@umanitoba.ca, co-author
MAES-NINO, Christina [Manitoba Non-Profit Housing Association] execdir@mnpha.com, co-author
MCCRACKEN, Molly [Canadian Centre for Policy Alternatives - Manitoba] molly@policyalternatives.ca, co-author

Manitoba's Rent Assist supplement program pays the difference between 30 percent of a household's income and 75 percent of median market rent directly to the household. It is available to any household below a given income threshold, including those receiving welfare. The low-cost end of the rental housing market in Canada is primarily made up of private rental housing. While public, nonprofit and cooperative housing certainly play an important role, there is simply too much demand and not enough of these kinds of housing to address housing need through nonmarket means (Suttor, 2016). Rent Assist is intended to support households in creating housing security and stability for themselves and their families in both social and private market housing. As such, it offers a way for tenants to find housing that meets their needs, and for housing providers to provide better quality housing.

It is expected that private market landlords would be pleased with Rent Assist, as it provides their low-income tenants with greater incomes—and thus greater capacity to pay rent—than they would otherwise have had. As a program universally available to those below a certain income cut-off, Rent Assist has the potential to eliminate affordability-based housing need. However, it doesn't necessarily address other aspects of housing need. Low-income tenants may face barriers to housing that cannot be fixed with a simple infusion of cash. At 75 percent of market rates, rents may be too low to allow landlords to maintain their units in good condition. Low vacancy rates, increasing rents, and a decline in the number of rental units make it difficult for many tenants to access housing (Brandon, 2014). Many tenants' access to housing is also limited by other barriers, including racism and a lack of adequate identification or credit. Increased income is unlikely to resolve these issues.

This paper explores the impact of Rent Assist on the private rental market in Manitoba. Through focus groups and interviews with tenants and landlords in urban, rural and northern areas, it examines the advantages or barriers for access to housing with Rent Assist, as well as the gaps in both the Rent Assist policy and in the broader housing system that need to be addressed to enable universal access to good quality housing. It considers how Rent Assist support tenants' access to housing in reality, not just in theory, as well as how it may affect the capacity and willingness of private market landlords to continue to provide low-cost housing.

By exploring the tenant experience with Rent Assist, this research expands the definition of housing need beyond affordability. It also contributes to the relatively small body of qualitative research that explores the role and experiences of landlords in low-cost housing provision (e.g. Desmond, 2016, Aubry et al. 2015; Allen and McDowell, 1989). As such, this research has the potential to inform rent supplement policy in Canada. As the National Housing Strategy's new Canada Housing Benefit—which is intended to provide up to 300,000 households with a portable rent supplement—is developed, learnings from Rent

Assist may contribute to a policy and program that are more directly responsive to both tenants' and landlords' needs.

OVERCROWDING AND LEARNING IN THE CITY: SHANGHAI'S BED SPACE RENTALS FROM A LIFE-COURSE HOUSING PERSPECTIVE

Abstract ID: 265

Individual Paper Submission

HARTEN, Julia [USC] jharten@usc.edu, presenting author

China's ongoing urbanization is the physical expression of millions of people wanting to be part of the country's flourishing urban economies. With post-industrialization, jobs increasingly concentrate in urban areas and the "urban pull" has intensified. Cities are centers of services and employment. But the benefits of being in the city are priced into urban land, making cities increasingly unaffordable. While planners struggle to re-imagine the absorptive capacities of cities, people –and urban newcomers especially– are reconfiguring space in the city to work for them.

I study the housing consumption of highly educated migrants that are "transitionally poor" and come to Shanghai to "learn in the city". Neglected by official policy making, and with low starting salaries, rural high-skilled migrants live in illegal, overcrowded dormitories as a means to afford expensive urban living and to get a foothold in the city's highly competitive labor market. This niche informal market for just a bed that caters to this overlooked demographic is distinctive from conventional wisdom about informal housing: recent graduates live here temporarily and in locations with good access to jobs and opportunities, integrated in the formal build environment.

To study this housing phenomenon I draw on a mixed methods research design that synergizes the opportunities of critical digital data analysis with ethnography. I scraped, cleaned, analyzed, and mapped more than 33,000 geocoded online postings advertising bed spaces for rent in Shanghai and field-verified the internet data with market surveys. Additionally, I spent this past summer living in one of the crowded units, conducting interviews with my fellow renters, landlords, and policy analysts.

I found that bed space rentals cluster at the edge of the inner city. Typically, three bedroom co-ed apartments house an average of 24 tenants. The spatial pattern is owed to the fact that renters trade-off personal space for access: as newcomers to the city and the labor market they need to locate close to their jobs, but starting salaries don't allow them to pay high downtown rents. Long hours prevent them from paying for more personal space with their time. Delayed returns to education are the result of China's higher education policy and make them "transitionally poor". For these high skill, low income migrants a job in the big city is a human capital investment. Aspiring to upward mobility, they see their living situation as a stepping stone, a necessary, but temporary means to building a career.

The findings have implications beyond the Chinese case. The particularities of this market reflect the China context, but the trends of "emergent adulthood", changing renter demographics, and increasing labor mobility are felt globally. However, the spatial outcomes have received little academic or practical consideration. To design more efficient and equitable land uses in growing cities, we must understand how these trends translate into housing needs and act accordingly. Studying the existing informal solutions and renters' tradeoffs can inform new, practical models of denser, less private urban living.

THE FALLACY OF FILTERING DOWN: A CRITIQUE OF THE YIMBY MOVEMENT AS A FORM OF HOUSING FILTERING

Abstract ID: 278

Individual Paper Submission

MILLER, Camden [University at Buffalo, SUNY] camdenmi@buffalo.edu, presenting author

The housing market and the processes within are extremely complicated due to the fact that it is impossible to distinguish problems associated with housing allocation from issues regarding economic growth. One process that works within both spheres is filtering. Simply put, filtering is the process in which housing is passed down from one income group to a lower income group as a result of declining market prices (Ratcliff 1945). This would then allow for substandard housing to be freed up and taken off the market. While this complex concept is approximately one hundred years old and is used amply, there is still much that remains to be understood about how this process operates and what policies need to be in place in order for it to truly provide benefits for people at each and every income level or housing market strata. This paper will delve into a deep understanding and critique of the filtering process as described by Ratcliff's 1945 seminal piece, "Filtering Down and the Elimination of Substandard Housing." Some of the issues with this theory that are critiqued include the conflict with efforts of historic preservation, filtering up due to gentrification, and the inability for the mechanism to successfully operate within a capitalist society.

Based on the critique of the Ratcliff's process of filtering down, this paper then turns to the YIMBY ('Yes In My Backyard') movement discourse that has become prominent over the past decade. The YIMBY movement, which formed out of pro-development groups, focuses on lowering rising housing costs by supporting the new production of housing, especially near jobs and transit. This paper critiques the objectives and philosophies of the YIMBY movement as well as what it has accomplished in order to examine this movement as a form of housing filtering and to see if it is successful as a method of filtering down (removing substandard housing from the market and providing affordable housing within the US neoliberal, capitalist society).

In 1945 when Ratcliff published his seminal piece, he seemed hopeful that the dynamic of filtering down, under the right conditions and with policies in place, would be a process to cure the substandard housing ills. The fact that we are still left positing the question of whether filtering down will work 74 years later also explains why there have been substantial disagreements within housing literature regarding the notion of filtering (Baer and Williamson 1988). Unless there are drastic interventions in the process of filtering, the theory will remain flawed in being able to provide affordable housing for the poor and removing substandard housing from the housing market.

RIGHT TO THE CITY: HOUSING AFFORDABILITY FOR MIGRANT WORKERS IN CHINA

Abstract ID: 294

Individual Paper Submission

XU, Zhumin [LATTS] xuzhumin@gmail.com, presenting author

Over the last two decades, scholars from sociology, political science, economics and urban planning have questioned for housing security system for migrant workers, in terms of urban housing provision (Wu 2004), invisible migrant enclaves (Huang and Yi 2015), and urban village redevelopment (Liu and Wong 2018). The general disadvantage experienced by migrants has much of its root in the institutional restrictions associated with the hukou system that outweigh the combined effects of socioeconomic factors (Wu 2004). There is a dual land system in China, with rural land owned by rural collectives, and urban land owned by the state. The recent reform on urban governance and housing policy in China have tremendous impacts on the living conditions of migrant workers, especially in the context of the current implementation of the regulations on housing rental market. This study argues that firstly the lack of "security housing for all" has pushed migrant workers to live in informal housing. Second, elimination of

informal housing caused eviction of migrant workers. Third, standardization of informal housing led to gentrification; it further worsen the situation that migrant workers cannot find a place to stay on their original site which is close to their job locations. This study is built on field research trip between 2017 and 2018 in Shenzhen, Shanghai and Wuhan investigating government subsidized housing system and the living conditions of low-income migrant workers. This research suggests that city government, enterprises, and village should work together to renovate “urban village” and include it into affordable housing system. The study of right to the city in housing affordability in China adds to the state-capital discussion.

FINDING COMMUNITY WHEN HURRICANES HIT HOME: DISASTER DISPLACEMENT FROM PUERTO RICO IN THE AFTERMATH OF HURRICANE MARIA

Abstract ID: 308

Individual Paper Submission

SCHWALLER, Nora [UNC Chapel Hill] nschwall@live.unc.edu, presenting author

NGUYEN, Mai [University of North Carolina at Chapel Hill] co-author

Hurricane Maria struck the island of Puerto Rico on September 20, 2017 as a Category 4 hurricane. It was the worst storm to hit the island since 1928. The storm tracked across the island with a northwest trajectory, causing widespread flooding, mudslides, billions of dollars in damage, and the destruction of essential infrastructure (Meléndez and Severino 2017). Hundreds of thousands of individuals fled in the aftermath of the storm, leaving the island and settling across the mainland United States. The literature discussing the reasons for displacement is well established, with intuitive findings. However, there is scant research on where individuals go when they are displaced and what aspects of their destinations influence their decisions to remain or to return.

This paper uses a proprietary data set aggregated from cellphone data to track the movement of populations between counties in the mainland USA and Puerto Rican municipios from the date of the hurricane to six months after, at monthly intervals. The data tracks over 400,000 individuals who left Puerto Rico for the mainland USA, and over 200,000 who subsequently returned to Puerto Rico. Using this dataset, we examine the characteristics of counties on the mainland where disaster migrants settled to address two questions: 1) Are disaster migrants displaced to areas with comparatively low-levels of vulnerability? And 2) Do patterns of settlement by post-disaster migrants resemble pre-disaster migration trends?

The first question builds off of previous literature focused on housing opportunity and residential mobility in the context population shifts that occurred in the aftermath of Hurricane Katrina. Previous work has shown that a comparatively high number of households were able to use Hurricane Katrina as a catalyst to

leave disadvantaged neighborhoods (Graif 2016). Our hypothesis posits that, to the extent that displaced individuals have sufficient choice (supported by appropriate information and funds), they will select areas with more resilient community indicators and better socio-economic characteristics. Further, complimenting the existing literature that shows that more vulnerable populations are less likely to return (Peacock et al. 2014), we argue that those who succeed in settling in more resilient communities will be more likely to remain long-term.

Second, this paper asks if the patterns of individuals and households leaving disaster-affected areas replicate existing pre-disaster migration patterns (Black et al. 2011). Our hypothesis posits that the presence of mainland Puerto Rican populations may be indicative of extended social networks that could reduce the social and economic costs associated with migration, and therefore provide insight into destinations with better opportunities. Our initial findings suggest that previous migration patterns are highly significant in identifying initial post-disaster destinations, while their importance diminishes in explaining whether individuals remain in destination locations or return to Puerto Rico. This may indicate that the social support is more valuable initially, but that economic factors become more important in the decision to stay.

To demonstrate these findings, we use a multi-level regression model across two geographic levels to compare the impact of variables rooted in different theoretical perspectives in a manner designed to better integrate the existing literature. This leverages our findings to influence both the migration and housing mobility fields, with consideration for both economic and community development. Additionally, because our initial findings strongly suggest that understanding pre-disaster migration patterns can predict post-disaster migration trends, this work will have significant policy implications. Understanding pre-migration trends across different racial and ethnic groups can allow planners and policymakers to prioritize where resources and support should be allocated in the aftermath of major disaster events.

HOUSING RELOCATION AND DEPRESSION: UNRAVELING THE MENTAL HEALTH OUTCOMES OF HOPE VI HOUSEHOLDS

Abstract ID: 310

Individual Paper Submission

JARAMILLO, Atticus [University of North Carolina at Chapel Hill] atticusa@live.unc.edu, presenting author

ROHE, William M. [University of North Carolina at Chapel Hill] brohe@unc.edu, co-author

WEBB, Michael D. [University of North Carolina at Chapel Hill] webbmd@unc.edu, co-author

Planners are increasingly interested in creating communities that foster positive mental and emotional health outcomes (Pfeiffer & Cloutier, 2016). Some scholars suggest that housing relocation and neighborhood mobility programs can help advance this goal, as these programs help participating families exit distressed, high-poverty neighborhoods (e.g. Alegria, Perez, & Williams, 2003; Leventhal & Brooks-Gunn, 2003). However, there is still limited knowledge of how various compositional (e.g. age, race) and contextual (e.g. housing quality, social support) factors mediate the impacts of housing relocation and neighborhood mobility on mental health (Osypuk et al., 2012; Popkin, Levy, & Buron, 2009).

In response, this paper analyzes changes in depression symptoms among a small panel (N=75) of low-income households displaced from distressed public housing in Charlotte (NC) through the HOPE VI program. Although small, this panel provides for a powerful analysis because we can analyze changes in depression symptoms across three critical time periods: (T1) six months prior to relocation; (T2) two years after relocation; and (T3) five years after relocation. Thus, we can control for a variety pre-relocation factors that may mediate post-relocation mental health outcomes and distinguish between the short- and long-term effects of housing relocation on mental health.

The specific goals of this study are to (1) classify subgroups of “relocatees” who experienced similar trajectories of depression across the study-period and (2) identify what factors predict relocatees trajectories of depression. We accomplish these goals using a three-stage, mixed-method research design:

Stage 1: Using Optimal Matching (OM) and K-mean cluster analysis techniques, we identify subgroups of relocatees that experienced similar trajectories of depression symptoms across the study period. We then conduct a descriptive analysis of the demographic makeup of each subgroup to determine whether members have any common attributes.

Stage 2: Using OLS regression, we analyze how relocatees’ perceptions of their former public housing community and compositional characteristics are associated with their depressive symptoms at T3. This allows us to examine how relocatees’ pre-relocation circumstances are associated with their post-relocation outcomes.

Stage 3: Based on stage 1 and 2 findings, we analyze relocatees post-relocation interview transcripts to identify: (1) what aspects of HOPE-VI relocation residents described as most stressful; and (2) how, if at all, residents co-associate their relocation experience with their mental health. The goal of this stage is to contextualize and clarify the differences in relocatees' trajectories of depression symptoms.

We have already completed stage 1 and stage 2 of our analysis. Our initial findings indicate that relocatees who exhibited depressive symptoms prior to relocation reported substantial changes – both positive and negative – following relocation, and that relocatees who perceived their pre-relocation public housing community as “very unsafe” experienced significant reductions in depressive symptoms. We also find that elderly households experience significant mental health benefits from housing relocation.

ADVANCING CHOICE IN THE HOUSING CHOICE VOUCHER PROGRAM: SOURCE OF INCOME PROTECTIONS, USAGE RATES, AND LOCATIONAL OUTCOMES

Abstract ID: 325

Individual Paper Submission

ELLEN, Ingrid [New York University] ingrid.ellen@nyu.edu, presenting author

O'REGAN, Katherine [New York University] katherine.oregan@nyu.edu, co-author

The Housing Choice Voucher program is the largest source of federal rental assistance in the country. A key aim of tenant-based vouchers is to expand the housing (and neighborhood) choices of recipients. Yet two key criticisms of the voucher program relate directly to choice namely that a sizable share of voucher recipients fail to successfully lease housing with their voucher, and that those who do, tend to be concentrated in a limited number of neighborhoods that are highly disadvantaged.

A key hurdle is landlords. The voucher program is unusual among social programs in that take-up requires both tenant and landlord participation. A recently commissioned HUD audit study of landlords in five different markets reports alarmingly high denial rates, ranging from 78 percent in Fort Worth, Texas to 15 percent in Washington, D.C. (Cunningham et al., 2018). A few excellent qualitative studies shed some light on the landlords who choose to participate in the voucher program. Based on interviews with 127 landlords in Baltimore, Dallas and Cleveland, Garboden et al (2018) report that voucher landlords appreciate the reliable rent payments and low turnover among voucher tenants. Yet many are still wary of serving voucher holders because of their pre-existing stereotypes about how they will behave as tenants. Further, landlords complain about burdensome inspection systems and other bureaucratic impositions.

Source of Income (SOI) protection laws are often lauded as a possible solution, but the existing empirical evidence yields mixed results (e.g., Freeman 2012; Freeman and Li 2012). This paper extends earlier work by assessing a broader set of impacts at a lower level of geography, including directly assessing whether new landlords enter the program after the adoption of SOI laws. We draw on a combination of datasets, including longitudinal HUD data on the universe of voucher holders across the country, PHA data on voucher utilization, and a rarely used HUD dataset on voucher landlords. We employ a difference-in-difference approach, comparing voucher holder outcomes in jurisdictions before and after SOI protections are adopted to voucher outcomes for nearby public housing authorities (PHAs) but in jurisdictions without such protections. We begin by looking at voucher usage, captured by both PHA

utilization rates and, where data permit, success rates (or the share of voucher recipients who successfully lease up). We also examine changes in the composition of new voucher recipients, as well as changes in a range of neighborhood characteristics (including the quality of nearby schools) of new voucher recipients, and those of existing recipients who move, separately by race and family composition. Finally, going to a finer grain of geography and exploiting the HUD data on landlords, we test whether SOI protections appear to expand the number of buildings and landlords that accept voucher households.

OPPORTUNITY WITHOUT ACCESS: ASSESSING CONFLICTING LIHTC SITING STRATEGIES

Abstract ID: 351

Individual Paper Submission

AZHAR, Awais [The University of Texas at Austin] awais.azhar@utexas.edu, presenting author
KARNER, Alex [The University of Texas at Austin] alex.karner@utexas.edu, co-author

The Low-Income Housing Tax Credit program (LIHTC) is one of the largest affordable housing programs in the United States in terms of the production of new units and the preservation of existing units. While the program is funded federally, states guide the allocation of tax credits and individual project selection through “Qualified Allocation Plans” (QAPs) that outline eligibility requirements and competitive scoring criteria.

In preparing QAPs, policymakers typically set requirements and criteria so that resultant projects best provide housing to low-income residents and lead to long-term improvement in their quality of life. On the one hand, policy has aimed to locate LIHTC housing in high-opportunity areas characterized by low poverty rates, high social cohesion, and an abundance of nearby opportunities. Research has shown that residents of low-poverty areas, particularly children, have better economic, health and educational outcomes compared to their peers in high-poverty and low opportunity areas (Chetty, Hendren, & Katz, 2016). On the other hand, policymakers have focused on providing housing with better public transit connectivity to reduce household transportation costs and increase job access (Nedwick & Burnett, 2015; Sanchez, 1999).

In many cases, these two goals have proven to be contradictory. LIHTC housing is generally located in high-poverty areas with poor access to labor markets, and environmentally degraded neighborhoods with

poor performing schools but with better transit opportunities (Ellen, Horn, & Kuai, 2018). A report published by the Poverty and Race Research Action Council showed that LIHTC housing in neighborhoods with good transit connectivity tends to be located in low-opportunity areas. In addition, transit stations are more likely to be built in neighborhoods with existing affordable housing as opposed to the construction of new affordable housing units being located near existing transit stations (Zuk, 2015).

Whereas, the literature on moving residents to high opportunity areas and connecting residents to transit separately show substantial benefits for the residents in terms of accessing employment, education and higher incomes over their lifetime, there is a gap in the literature connecting the two. It is important to further assess what effect these two competing location priorities, access to opportunity and connection to transit, have on travel times for LIHTC and other affordable housing residents using transit to get to major job centers. This study evaluates whether residents of LIHTC housing constructed in high opportunity areas in major cities in Texas spend more time traveling to job centers using transit than residents in low opportunity areas.

In the study, LIHTC housing in Texas cities is mapped against their location's opportunity designation, where opportunity areas are identified based on the definition used by the Texas Department of Housing and Community Affairs. Using geographic information system methods to calculate public transit travel times, the study assesses the time penalty paid by residents of LIHTC housing living in high opportunity areas as compared to their counterparts in low opportunity areas when accessing jobs by public transit. It is important to address this conflict between access to transit and opportunity in order to inform the development of policies that guide the location of LIHTC properties, allowing policymakers and housing advocates to better understand the impact of such policies on regional economic productivity and resident quality of life. It is important to balance opportunity and fair housing goals against resident needs as they relate to transit use to access employment.

ACHIEVING CULTURAL COMPETENCE AND RACIAL INCLUSION IN NEW URBANIST COMMUNITIES

Abstract ID: 369

Individual Paper Submission

JACKSON, April [Florida State University] ajackson5@fsu.edu, presenting author

Planners are tasked with working collaboratively to develop plans that foster equity and inclusion. Further, major changes in the demographics of the U.S. elevate the importance of organizations and professionals who can effectively address the needs of a diversifying population. In short, an increasingly diverse society requires planners to prepare for building bridges and resolving conflicts in the communities they serve in order to limit disparities and effectively implement the values of equity and social justice in their mission delivery. New Urbanism seems to have a hard time delivering on these objectives (Talen, 2010; Trudeau & Kaplan, 2016; Markley, 2018). While, new urbanism is most identified with green fields, or new communities such as Seaside, Florida; Kentlands, Maryland; and the Disney town of Celebration in Orlando, Florida, new urbanist principles have also been used to revitalize urban brown field sites, comprehensive plans, regionally based transportation networks, and inner city redevelopment via the Department of Housing and Urban Development's (HUD) HOPE VI program and now Choice Neighborhoods Initiative (Choice). Moreover, although the Congress of New Urbanism (CNU), through HOPE VI and Choice aims to provide a broad range of housing types and price levels to bring people of all ages, races, and incomes into daily interaction in an effort to promote a sense of community – achieving diversity, particularly racial diversity in its projects, continues to be a challenge (Vale, 2013, Smith, 2002).

Choice builds on the HOPE VI program by continuing mixed-financing and public-private partnerships to replace low-income housing. Choice now extends eligibility to privately owned subsidized developments, and provides funding for projects to broaden revitalization efforts to the surrounding neighborhood through more comprehensive support services, education, and economic development activities. As part of Choice, there are three key components focused on housing, people, and the neighborhood. These transformation plans are much more comprehensive than those of HOPE VI in an effort to expand neighborhoods of choice for low-income residents. HUD has issued 79 Choice planning grants and 22 Choice implementation grants between 2010 and 2017.

Strategies for promoting more diversity in new urbanist developments have tended to focus on changing regulations or looking for more creative methods of financing. But what can be done to foster a more inclusive approach in the planning process itself? In this paper, I argue that new urbanism needs better insights about how an inclusive planning approach to building walkable, diverse neighborhoods might be achieved. Specifically, we need research that explores the ways in which cultural competency and racial inclusion might be cultivated. To answer this question, I present an example of how this research might be conducted, what it might show us, and how future research endeavors might be able to add to and solidify a growing knowledge base for cultural competency and racial inclusion in new urbanism. I do this through the lens of Yesler Terrace (Yesler), a Choice project in Seattle, WA, in which 23 interviews and archival document research were conducted. Using evidence from Yesler, this paper highlights how cultural competency in its various dimensions (e.g., knowledge, awareness, skills) were integrated into the community engagement, design, and community building process.

Findings illustrate that incorporating culturally competent planning practices can bolster diversity and social equity outcomes. Furthermore, I discuss how emphasizing a commitment to cultural competency can encourage better planning for mixed-income new urbanist communities, and I offer suggestions for future planning practice, CNU systems change, and research agenda. This research also provides insights on Choice, which will inform approaches to implementing affordable mixed income housing and promoting broader neighborhood revitalization in a way that promotes equity and racial inclusion.

WHO BENEFITS FROM SHARED LIVING AND WHO DOES NOT? SOCIAL DYNAMICS AND POTENTIAL EXCLUSION IN SHARED HOUSING

Abstract ID: 375

Individual Paper Submission

OH, Jihun [Ulsan National Institute of Science and Technology] wlgnsdl414@unist.ac.kr, presenting author

KIM, Jeongseob [Ulsan National Institute of Science and Technology] seobi78@gmail.com, co-author

Background: Shared living among young adults has been increasingly widespread way of life in the world, yet little is known about their social dynamics (Clark et al., 2018). Since those non-kin households are in a wide range of socioeconomic backgrounds, their personal relationship is the key to whether their shared living wanes or flourishes (Heath et al., 2017). The previous research bridges how the experience of shared living connects to various social outcomes like increased social capital or sense of community (Cho et al., 2019). Here, this study extends the bridge by figuring out which residents of the shared housing benefit from the social outcomes and which residents do not. Specifically, this study explores whether there is a potential exclusion of certain residents in shared housing due to their socioeconomic backgrounds rather than their personal traits or residential conditions.

Method: To confirm the positive impacts of shared living in terms of social dynamics and identify the potential exclusion among the residents of shared housing, we conducted a survey on 800 young single households who lived in Seoul, Korea. Among them, 300 residents lived in shared housing. The survey items include the personal traits, socioeconomic backgrounds, residential conditions, and social dynamics of the residents. We measured the social dynamics in various aspects such as acceptability with socioeconomically different people, social relationship, and social activity. With this data, to verify the positive social outcomes from shared living, we first examine the baseline differences in social dynamics between the residents of shared housing and other housing types. Then, to identify a potential exclusion among the residents of shared housing, we divide them into several groups based on their socioeconomic backgrounds (e.g. income level, gender, occupation, birthplace, etc.) and investigate how their social dynamics differ by each socioeconomic group.

Result: Our preliminary finding reveals that the residents of shared housing are more likely to have a 'healthy' life in terms of social dynamics than the residents living in other housing types. For example, they show higher satisfaction with their social relationship and participate in social activities more frequently. However, when we divide their socioeconomic group by monthly income level, the low-

income group show less satisfaction with their social relationship and participate in social activities less frequently than the high-income group. It indicates the possibility that there can be a potential exclusion of certain socioeconomic group in shared housing. We will investigate a structural link for how their socioeconomic backgrounds connect to the potential exclusion of them.

Implication: While there is a growing interest in shared housing as one of the solutions for providing affordable living place to young single households in Korea (Woo et al., 2019), we detect a sign of potential exclusion of certain residents in shared housing. To mitigate the potential exclusion and make the shared housing to be both affordable and equitable housing option for young adults, we intend to suggest several guidelines on the management of shared housing.

UNDERSTANDING THE SHARE HOUSING SECTOR: A GEOGRAPHY OF GROUP HOUSING SUPPLY IN METROPOLITAN SYDNEY

Abstract ID: 392

Individual Paper Submission

ZHANG, Yuting [University of Sydney] yzha5040@uni.sydney.edu.au, presenting author
GURRAN, Nicole [University of Sydney] nicole.gurran@sydney.edu.au, co-author

Share housing, once considered a transitional form of accommodation on the ladder to family formation and home ownership, has become increasingly important, particularly in high-cost cities (Maalsen, 2018). Share and group housing arrangements extend the capacity of private rental supply, but are difficult to monitor and research, hidden within different formal or informal tenancy arrangements (Vacha & Marin, 1993).

The rise of online platforms for advertising and finding rental accommodation, such as 'Craigslist' or 'SpareRoom', appear likely to have enabled and facilitated the share housing sector, but may also offer a critical window into its operation (Boeing & Waddell, 2017). This paper presents research on the share housing market in Sydney, Australia, drawing on listings data scraped from primary share housing platform 'Flatmates.com.au' (N= 3391 in 2016 and N= 5164 in 2018), as well as the wider housing market and urban indicators. The paper sought to determine the scale and distribution of shared housing vacancies in Sydney, in relation to the city's wider housing market. The share listings data collected in December 2016 broadly corresponds with the national 2016 Census survey – providing an opportunity to compare the scale and characteristics of share vacancies listed on the Flatmates platform with census data

on group households more widely. The scale and spatial distribution of share advertisements was examined in relation to dwelling characteristics, household characteristics and cost.

The study found that: data contained in online listings for share accommodation aligns with census data on the spatial distribution of areas of group households in Sydney; full-time workers advertising for roommates live in areas of dense job concentration; while students advertising share vacancies locate primarily around major universities. This alignment suggests that online listings data can offer useful insights into the poorly understood share housing sector – extending five yearly census data sources on group households through additional and time-sensitive information about share vacancies, rental costs, and occupancy arrangements. Delving deeper into the online listing data sets, the study revealed a marked increase in Sydney’s share vacancies advertised through the online platform between 2016-2018, expanding the supply of lower-cost rental housing near work locations. It also found that besides larger, stand-alone houses, apartments are also a strong supply source for share vacancies; and that inner city share homes are often accommodating much larger households than dwellings overall, with evidence of extreme overcrowding in some segments of the market. As an important source of low-cost rental housing, the share housing sector needs to be monitored, and broader responses to affordable housing need to be developed to ensure that city housing markets offer appropriate accommodation for people across the income spectrum.

WHY PEOPLE ARE WILLING TO PAY MORE FOR GREEN BUILDING? THE PRICE PREMIUM AND THE WELL-BEING BENEFITS OF GREEN BUILDING

Abstract ID: 394

Individual Paper Submission

ZHANG, Danlei [National University of Singapore] danniezhang0609@gmail.com, presenting author
TU, Yong [National University of Singapore] tuyong@nus.edu.sg, primary author

The past decade witnessed a rapid development of green buildings (GB) worldwide and arose heated discussion on how green building economically and socially perform. In the economic strand, a bunch of literature has shown different evidences on the price premiums of green buildings, demonstrating that beyond being environmentally friendly, green buildings can be more economically beneficial and productive than other comparable ordinary buildings. But little evidence has been provided to explain why such price premium exists. In the social strand, the existing literature validates the benefits of green buildings from the human aspects, like better thermal comfort, better indoor environmental quality (IEQ) and health and productivity improvement. However, the findings are less comprehensive as the evidences are mostly focused on IEQ, are centered on the non-residential buildings and are mostly qualitative research rather than quantitative research, calling for further research.

Standing across these two strands of literature and focusing on the Singapore context, this paper aims to answer two research questions: (1) Does GB fetch price premium? (2) Why people are willing to pay more for GB? Presented hypotheses are as follows:

Hypothesis 1: GB fetches market-driven price premium.

Hypothesis 2: People are willing to pay more for GB because green building has better quality.

Hypothesis 3: People are willing to pay more for GB because GB can provide a more favorable living environment to their residents and contribute more to residents' subjective well-being compared to their non-green counterparts.

The main data sources are the complete transaction data of private housing between January 2005 and December 2017 and the survey data from an on-site household survey. To test hypothesis 1 and 2, we employ hedonic pricing method to examine the existence of green price premium, the change of price premium in the process of building decay and the role of building quality in the persistence of green price premium over ages. The empirical results demonstrate that GB fetch higher price than non-green building at the resale stage when price premium is mainly market driven and more possibly capture buyers' willingness to pay for the "green" benefits. Such premium can last as they physically decay and the building quality is a major factor in such persistence of price premium over ages.

In order to test hypothesis 3, employing the survival model, we firstly find that owner occupiers of green building have longer residence duration, which may be attributed to the better living environment in a green building. Further, through the on-site household survey, we find that residents in a green building are more satisfied with their living environment and that they are less likely to move and have higher subjective well-being, explaining why residents have longer residence duration in a green building. Greenery, ventilation, building quality, orientation, indoor temperature and waste disposal are the main contributing green features to the residents' subjective well-being, while energy saving plays a minor role.

Our study provides new quantitative evidence on both the economic and social performance of green building, empirically explaining why people are willing to pay more for green building. We also empirically develop a conceptual framework which connects the built environment with human subjective well-being in green building context. These findings have some practical implications for the green building industry in ways that would contribute to the future design solution along the way of green building towards human well-being. The industry needs to shift their attention to the greenery, indoor environment, maintenance and provision of waste disposal facilities, from energy efficiency, to better promote the subjective well-being of residents living in green building and to maximize the values of green building.

SPILOVER EFFECTS IN NEIGHBORHOOD CHANGE: A SPATIAL ANALYSIS

Abstract ID: 400

Individual Paper Submission

JUN, Hee-Jung [Sungkyunkwan University] tuttle6@gmail.com, presenting author

Neighborhoods are not isolated areas but rather components of complex urban systems. Thus, a neighborhood may decline because nearby neighborhoods decline. Indeed, Jun (2017) finds that neighborhood change is spatially dependent and thus economically improving and declining neighborhoods form clusters with nearby improving and declining neighborhood, respectively. However, Jun's (2017) study does not examine what 'specific' neighborhood attributes lead to spatial dependence in neighborhood change. In particular, racial/ethnic composition has been found as a major factor affecting neighborhood change and it is expected that the presence of blacks and Hispanics affect not only the host neighborhood but also surrounding neighborhoods through spillover process.

This study aims to examine spillover effects among neighborhood attributes in neighborhood change. I analyze the Neighborhood Change Database that contains the decennial census data at the census tract level in the largest US 100 metropolitan areas and in the 1990s and 2000s. Neighborhood change is defined housing value change at the census tract level and factors affecting neighborhood change consist of housing, racial/ethnic, and socio-economic characteristics. To examine spillover effects among neighborhood attributes, I create a spatial weight matrix and run a spatial-durbin analysis that allows examining both direct and spillover effects among neighborhood attributes. The empirical analysis clearly shows that neighborhood attributes have spillover effects in neighborhood change. More specifically, the absolute magnitudes of spillover effects are greater than those of direct effects for racial/ethnic composition variables. Also, the spillover effects of socio-economic characteristics are less dominant compared to racial/ethnic and housing characteristics.

The audience will learn what specific factors cause spatial dependence in neighborhood change.

DO CALIFORNIA RENT DISPUTE RESOLUTION ORDINANCES WORK?

Abstract ID: 452

Individual Paper Submission

CHRISINGER, Benjamin [University of Oxford] benjamin.chrisinger@spi.ox.ac.uk, presenting author
VEAZEY, Helen [Tenants Together] hmveazey@berkeley.edu, co-author
SCHOTTENFELD, Lisa [Tenants Together] lschottsy@gmail.com, co-author
LINCK-FRENZ, Sara [Tenants Together] sara@tenantstogether.org, co-author

In the face of a widespread and worsening housing affordability crisis, California municipalities have enacted different local housing policies to protect residents from potential harms, including unreasonable rent increases. In more recent years, a subset of policies have sought to address rent-related landlord-tenant issues in mediated processes, called “rent dispute resolution” (RDR), whereby tenants may request to meet with a landlord who has proposed a legal rent increase. Similar kinds of alternative dispute resolution (ADR) models have been previously used in other housing matters, such as foreclosure proceedings and cooperative board disputes, as a means of avoiding the costs to time, money, and emotion that are often associated with courtroom proceedings [1-4].

In California, some RDRs include mandatory provisions which may compel a landlord to attend such a meeting or arbitration, while others are entirely voluntary, and none require landlords to adhere to any agreements made through a RDR process, which is a noteworthy distinction from previously-studied ADR processes [1,5]. In the case of California, RDR has also often been proposed as an alternative to market intervention policies, such as rent control or just cause protections, and are viewed by tenant organizers and advocates as ultimately ineffectual in protecting tenants. To date, no evaluation research has been conducted on RDR programs in California.

This research has three main aims: First, we use document review and content analysis to understand the origins, intents, and advocacy surrounding RDR ordinances in California, and identify an appropriate set of evaluation measures to determine their efficacy. Second, we evaluate the impact of RDR on local housing markets based on appropriate indicators identified in Aim 1, using a difference-in-differences approach. Finally, we use semi-structured qualitative interviews with individuals who have participated in rent dispute resolution processes to understand exactly how these policies are experienced in practice. The project has completed Aim 1, is currently preparing datasets for Aim 2, and will begin recruiting participants for Aim 3 in April 2019.

Beyond addressing the immediate and policy-relevant question of RDR efficacy, this research project also speaks to broader discourses on the use of alternative dispute resolution in housing policy, especially as a mechanism for avoiding courtroom proceedings, facilitating communication between disputing parties, and improving access to just outcomes.

DEVELOPING COMMUNITY IN NEW YORK CITY PUBLIC HOUSING: A PRAGMATIC APPROACH

Abstract ID: 463

Individual Paper Submission

STAHL, Valerie [Columbia University] valerie.stahl@columbia.edu, presenting author

In 2015, the New York City Housing Authority (NYCHA) introduced NextGeneration NYCHA, a 10-year proposal intended to help fill the agency's \$32 billion capital budget shortfall and revitalize the city's distressed public housing through a series of predominantly privately-financed initiatives. The most controversial aspect of the plan, called NextGeneration Neighborhoods, includes leasing 'underutilized' land adjacent to existing public housing to private developers, who will be responsible for constructing and managing mixed-income 'infill' developments. In my dissertation, I conduct a holistic, pragmatically-oriented case study on the implementation of NextGeneration Neighborhoods at two pilot mixed-income sites. I namely ask, how do stakeholders—most importantly, existing tenants—define, defend, or resist the infill plan? And to what extent does plan implementation influence residents' understanding of their community's present and future?

I conduct a holistic case study with two embedded units of analysis that evaluates the NextGeneration Neighborhoods mixed-income plan pragmatically. Evaluating plans pragmatically takes a normative approach to considering the various networks involved in influencing a plan, all while centering on the lived experiences of those most impacted by its outcomes (Hoch, 2002). In this project, such an approach involves evaluating tenants' engagement experience not only through 'traditional' forums for social planning hosted by NYCHA, but also through adjacent community organizing efforts in resistance to the plan, as well as through a more thorough understanding of residents' sentiments regarding the physical and social redevelopment of their community (Sites, Chaskin, & Parks, 2012). Data collection methods include participant observation, interviews, and a review of primary and secondary materials relevant to the plan.

This paper focuses on the efforts to redevelop two public housing communities through a series of interviews with tenants, policymakers, and private developers, as well as through participant observation in community meetings and actions hosted by non-profits and local elected officials. Using discourse analysis, the results: a) show how residents' long history of distrust of the housing authority complicates participatory processes and drives residents to outlets beyond NYCHA's engagement strategies, b) shed light on resident fears of secondary displacement resulting from the prospect of new residents moving to their long-neglected public housing campuses, and c) demonstrate how policymakers and developers invoke fiscal crisis to legitimize moving the plan forward while tenants and select elected officials do so to slow the plan down.

The results of this project contribute to planning theory and practice in three primary ways. First, the project adds to a growing literature that considers the importance of evaluating the implementation of public housing redevelopment schemes (Vale, 2019), as well as tenant resistance to such transformations

(Goetz, 2016). Further, by looking beyond deliberative and linear definitions of ‘formal’ participatory processes, it contributes to expanding definitions of participation to include alternative, transgressive voices, therefore complicating consensus-driven narratives in community planning (Thorpe, 2017). Finally, throughout the project, I have attended meetings hosted by non-profits, conducted research with advocacy organizations, presented information at an elected official’s office who has proposed suing the mayor over the infill plan, and attended protests and a day of action lobbying for additional NYCHA funding at the state level in Albany, NY. Taken together, such actions not only show how I have become a stakeholder in resisting the plan, but they also further reflect upon the pragmatic methodological approach I have brought to the research.

RENDON, Maria [University of California, Irvine] mgrendon@uci.edu, co-author

ARROYO, Diego [University of California, Irvine] diegoa1@uci.edu, co-author

Through one case study of a colonia in Arizona we renew attention to the ill infrastructure and poverty conditions American citizens and residents, most of Mexican descent, live with along the U.S./Mexican border. Through qualitative interviews and participant observation, we shed light on how the lack of infrastructure and public services complicate everyday tasks for colonia residents and compromise their wellbeing and life prospects. At the same time, we call attention to their allure, highlighting their promise as viable communities where families can raise their children and prosper, or, retire with dignity. We highlight the tenacity of colonia residents and practices of mutual support that make these communities resilient and far from deficient as they are often depicted. Social capital in the colonias is mostly made up of social support given by kin and fictive kin and often has an unrecognized outward projection as residents attempt to negotiate for better infrastructure and public services. These communities are socially and politically neglected. Colonia residents have set root in these communities worthy of concern and investment and we contend they ought to be folded into the larger conversation of poverty concentration, segregation and housing needs in the United States.

EXPANDING LANDLORD PARTICIPATION IN HUD'S HOUSING CHOICE VOUCHER PROGRAM

Abstract ID: 483

Individual Paper Submission

ROHE, William M. [University of North Carolina at Chapel Hill] Brohe@unc.edu, presenting author
WEBB, Michael [University of North Carolina] webbmd@unc.edu, co-author
JARRAMILLO, Atticus [University of North Carolina] atticusa@live.unc.edu, co-author

The Housing Choice Voucher (HCV) program aims to provide low-income families with a choice about where to live. In doing so, it relies on private market landlords to rent safe and decent housing to voucher holders. In many places, however, voucher recipients cannot find suitable housing in opportunity neighborhoods (those with low rates of poverty, good schools, etc.) or, in the worst cases, in any neighborhoods because landlords will not participate in the program. Despite their importance to the success of the program, however, research on landlord participation in the HCV program is limited.

The paper we will present at the ACSP Conference will build on studies conducted by Greenlee (2014), Varady et al., and Garbonden et al. (2018). Those studies involved interviews with landlords, public housing authority staff, to understand why landlords rent or do not rent to voucher holders and what challenges housing authorities face in recruiting landlords to program. We will go beyond prior research by probing how landlords respond to various incentives to encourage their participation in the voucher program, such as higher payment standards, streamlined inspection processes and/or reduced inspection frequency, tenant pre-screening, risk mitigation funds, and the like. We will also speak to HCV households who recently moved to provide learn about their relationships with landlords and their role in relocation decisions.

This paper will address the following research questions:

- Under what circumstances do landlords choose to rent, or not to rent, to HCV households?
- How do landlords differentiate their experiences working with HCV and non-HCV households?
- How do program regulations shape landlords' decisions to participate, or not participate, in the voucher program?
- How do landlords respond to potential incentives to encourage participation in the voucher program?

This research will be conducted in Charlotte, North Carolina where we will interview with the following groups:

- Charlotte Housing Authority staff involved in administering the voucher program and other key stakeholders including key leaders in the Greater Charlotte Apartment Association;
- landlords and property managers currently participating in the voucher program
- landlords and property managers not currently participating in the voucher program (If possible, we will include some landlords who previously rented to voucher holders but are not currently doing so.)
- HCV voucher holders who relocated within the past three months

We plan on interviewing a total of 60 individuals. We will interview both landlords who own small and large rental portfolios and we will interview landlords in higher-opportunity areas. Interviews with residents who recently moved will allow the research team to better understand how the availability of rental housing—or lack thereof—impacts HCV households. To understand how landlords respond to incentives to participate in the program, we will both consult with CHA staff and review Annual Plans of other Moving to Work agencies to identify potential incentives to discuss with landlords. These interviews will begin in early April and will be completed by mid-summer, giving us time to write a paper for presentation at the conference.

The results of this research will be of interest to academics, policy makers and practitioners interested in expanding housing opportunities for lower-income families. Based on our findings we will develop a set of recommendations for expanding landlord participation thereby expanding housing opportunities for lower-income families.
