We will conduct field research in the summer of 2025 in Kampala and Kiwumu (a peri-urban community near Kampala). Since 2021, Kiwumu has been successfully operating a 40kWp mini-grid with a battery capacity of 140kwh enough to power 300 homes and 60 businesses. The grid also enables productive use of energy through electrification of community maize milling and drying facility, along with other micro-enterprises. This case offers a unique opportunity to assess the long-term social and spatial impacts of decentralized, community-managed energy systems. In Kiwumu, we will conduct interviews and focus group discussions to investigate the downstream effects of mini-grid operation, such as community and 'prosumer' (producer + consumer) understanding of energy potential and resulting shifts in social dynamics and interactions. In Kampala, we will interview institutional actors involved in the upstream of grid installations, such as financing, policy implementation and creation of national agendas. Insights from diverse actors will allow us to identify any discrepancies between intentions of project providers and actual experience of end-users, thus offering insights for more responsive and inclusive energy planning.

Rural Attractiveness in China: A Multi-Source Data Analysis of Spatiotemporal Pattern and Mechanism

Abstract ID: 1844.0.0.608.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Ni Yan [Tsinghua University] yannimail2024@gmail.com, presenting author

Song Han [Tsinghua University] hs18thu@gmail.com

Zhengxu Zhou [Tsinghua University] zhouzhengxu@tsinghua.edu.cn

While urban areas have developed by attracting in-migration, rural areas have declined due to persistent out-migration. Globally, rural decline presents particularly severe challenges in developing countries, leading to expanding urban slums and deteriorating rural conditions (Liu & Li, 2017). In China, the rural population correspondingly declined from 82.08% to 33.84% since the 1980s, which threatens the sustainability of rural livelihoods (Long et al., 2012). Recognizing this crisis, China's Central Committee has consistently prioritized rural revitalization through its No.1 Policy Document for seven consecutive years since 2017.

Even as rural-to-urban migration remains dominant, a counter-trend is emerging - increasing rural in-migration across China (Cheng et al., 2024; Qi et al., 2022). According to the "2024 China Township Comprehensive Competitiveness Report," approximately 70% of the top 100 townships have achieved net population inflows. Systematic research on the attractiveness mechanisms of these in-migration-receiving rural areas is crucial for understanding new trends in rural population mobility and exploring the potential for rural development. Classic migration theory suggests that specific attractiveness factors must exist to draw migrants to destination locations (Massey et al., 1993).

However, existing studies on rural attractiveness in China have focused on micro-level analyses of single cases and overly relied on static national census data, failing to capture the dynamic nature and macro-level patterns of rural attractiveness. To address this gap, this research addresses a fundamental question: How can we precisely analyze the influencing factors and mechanisms of rural attractiveness in in-migrant-receiving rural towns across China?

Methodologically, this study combines census data with mobility big data for rural township-level analysis. We identify in-migrant-receiving rural towns using the Seventh National Census (2020). Baidu daily population flow data is then utilized to construct multi-temporal rural attractiveness indices. We analyze temporal trends using STL decomposition, spatial patterns through Moran's I statistics, and employ Random Forest models with geographical detector methods to reveal interactions among environmental, economic, social-cultural, and institutional factors across different regions.

Our research reveals spatially uneven and temporally dynamic patterns of rural attractiveness in China. Long-term attractiveness is primarily driven by economic opportunities and institutional factors, while short-term attractiveness is closely linked to natural amenities, including climate. Eastern rural areas, particularly in the Yangtze River Delta and Pearl River Delta regions, exhibit higher and more stable attractiveness compared to other regions. These findings underscore the complexity of rural population mobility and emphasize the need for differentiated revitalization strategies in China. This study advances theoretical understanding of rural attractiveness mechanisms in the Chinese context. It also offers practical experiences and methodological innovations applicable to other transitional economies, ultimately supporting more sustainable rural development strategies worldwide.

Seeing from the Ground: Meso-level Land Use Planning in Metro Seoul, San Antonio, and Guadalajara

Abstract ID: 1844.0.0.286.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Elizabeth Steward [Rutgers University] es1110@scarletmail.rutgers.edu, presenting author

Bernadette Baird-Zars [Rutgers University] b.bz@rutgers.edu

Soo Yeon Lim [Bloustein School, Rutgers University] sooyeon.lim@rutgers.edu

Land use practice rarely happens according to plan or plans. Similarly, the 'rules' of land use, such as zoning, while under increased attention from scholars, are never followed in full and are always negotiated. This essay examines a component of the land use negotiations as it plays out in public offices where municipal employees review applications for development, drawing on interviews and observation, embedded ethnography and our own firsthand experience as employees of, zoning offices in metropolitan Guadalajara, Seoul, and a major city in the American South. The essay argues that the land use staff weave patterns of practice that can help them navigate the morass of threads of regulations, values, political pressures and expectations. Because the patterns are can be predictable and have structured expectations - and outcomes - of urban development, they are unwritten institutions.

To answer planners' mandate to make values explicit and advance equity, institutional analyses of daily practices must move beyond organizational, policy, and neo-institutional analysis to endogenize critiques of uneven power relations that permeate daily work and institutions (Bourdieu, 1990; Leffers and Wekerle 2020; Linkous and Skuzinski 2018). This paper suggests the term gray institutions to signal how institutions inherit and mostly reproduce inequalities, as well as to highlight the particular interstitiality of these repeated practices as they fluctuate along spectrums of legality, formality, and permanence. Grounded in the tradition of examining everyday actions among public-facing government administrators (Lipsky 1980; Zacka 2017), this article places utilizes a sociological institutionalist lens that places the array of sites (e.g. offices), actors (e.g. staff), materials (papers, spreadsheets) and actions(e.g. phrases and phones) as irrevocably embedded in the broader network of actors and discourses (González and Healey 2005; Healey 2018). The article argues that gray institutions are improvised-yet-lasting expressions of planning values, knowledge and power. More immediately, gray institutions offer an arena for planners to enact tangible, feasible shifts in what they do in ways that can compound or -ideally- eke away at systemic injustices.

Tax Equity and Legitimacy: An Experimental Survey of Property Taxes in Mexico City

Abstract ID: 1844.0.0.314.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Aurora Echavarria [Florida State University] aechavarria@ucla.edu, presenting author

Land and the structures on it agglomerate significant wealth in cities. Property taxes represent an important mechanism for local governments to tap into this wealth to fund essential services and infrastructure. Yet levying this tax effectively requires accurately assessing the value of property. This prompts its own set of challenges since it not only calculating an unrealized value, but also constantly updating it to ensure that it captures changes in the market. Cities throughout the world have developed unique strategies to effectively calculate value. However, these often encounter technical and political limitations which may undermine tax efficiency and citizen trust in government processes. In this study, I ask: Does evidence of property tax inequity affect people's perceptions of government and its legitimacy to tax property? I address this question using a mixed-methods approach, involving three focus groups, elite interviews with government officials, and an experimental survey of 1,202 residents fielded in 120 neighborhoods of Mexico City. Results demonstrate that exposure to inequities in property tax calculation processes have small, but significant effects in shifting people's perceptions of government's legitimacy to tax property. For example, I find that individuals exposed to horizontal inequities in property tax calculation processes are eight percentage points more likely to view government's right to tax as illegitimate. Findings from this study contribute to scholarship on property tax inequity and offer experimental evidence that inconsistencies and inequities in administrative processes are consequential for how people perceive the legitimacy of taxation.

The Dual Impact of Competition in Rural Development Projects: Social Capital and Spillovers

Abstract ID: 1844.0.0.881.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Mina Kim [Portland State University] kimmin@pdx.edu, presenting author

This study empirically investigates whether income-generating projects introduced under the Saemaul Official Development Assistance (ODA) program in 100 villages across Myanmar and Cambodia enhance residents' social capital—specifically trust, cooperation, and solidarity—and reduce poverty through improvements in living conditions, income, and capabilities. It examines not only the direct effects of these projects but also potential spillover effects on neighboring communities. Implemented by the Korea International Cooperation Agency (KOICA), the Saemaul ODA combines a top-down, government-led approach with self-help principles, resident participation, and competitive elements to accelerate rural development (Schwak, 2023). However, whether competition actually fosters cooperation and trust (Hutter et al., 2011), and whether project benefits extend to nearby villages (Su et al., 2022), remains contested. Prior studies also highlight the limited capacity of government-led support and local leadership alone to build strong community cohesion and sustainable social capital (Wahid et al., 2017).

To explore these dynamics, this study poses two main research questions: (1) Do villages that perform well in competitive income-generating projects also demonstrate higher levels of trust, cooperation, and solidarity? (2) Do their positive outcomes spill over into adjacent communities, improving local social capital and reducing poverty indicators such as living conditions and income? To answer these questions, I compiled a dataset based on field surveys and administrative data from Saemaul ODA agency in Myanmar and Cambodia. The dataset of this study includes each village's project performance (as the key independent variable), multiple indicators of social capital and poverty (dependent variables), and relevant control variables—such as population size, education levels, government support, and geographic characteristics.

Methodologically, this study develops and applies a Difference-in-Differences (DID) spatial regression framework to estimate both the direct impacts of these ODA projects (treatment) and their spillover effects on neighboring villages. By integrating a spatial lag term that captures interdependencies among geographically proximate communities, the analysis explicitly accounts for possible cross-village diffusion. Specifically, the empirical specification includes a treatment indicator (reflecting whether a village participates in the ODA project), a post-intervention time indicator, and their interaction. This setup isolates the direct effect of the intervention while simultaneously considering how changes in adjacent villages could feed back into each focal community. By estimating the model using Maximum Likelihood or similar methods, the study disentangles inherent policy impacts from broader diffusion dynamics arising from spatial clustering or cross-border externalities.

This research makes three key contributions. First, it provides empirical evidence that competition, within a government-supported, self-help-driven model, can enhance social cohesion. Second, it shows how successful project outcomes can diffuse through spatial village networks, underscoring the need for better planning to leverage these spillovers. Third, it offers practical insights for policymakers and practitioners on how to design rural development programs that effectively combine government support, resident participation, and strategic competition. In doing so, the study highlights how the Saemaul ODA model—by uniting top-down leadership with bottom-up engagement—can foster both social capital and poverty reduction across broader regional contexts.

The Immediate Impact of an Integrated Resilient Development Project in Accra, Ghana

Abstract ID: 1844.0.0.527.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

HsiChuan Wang [National Cheng Kung University] andrewwang@wustl.edu, presenting author

Urban projects featuring resilient development have become popular, whereas limited studies have been invested in evaluating the impacts of these projects, especially regarding those that rely on bilateral/multilateral partnerships to enable their implementation. This paper addresses this research need by conducting an assessment regarding the impacts that the Greater Accra Resilient and Integrated Development Project (GARID), supported by the World Bank, has led. Two surveys were conducted in 2022 and 2024, respectively, to capture the baseline and midline of GARID's implementation. The paper proposes an assessment centering on resilience enhancement and inclusive growth with a Difference in Difference (DiD) design to demonstrate the changes occurring in the intervened neighborhoods in contrast to the comparative counterparts. The findings suggest that, since the initiation of GARID's interventions on the ground, it has significantly facilitated project transparency and stimulated notable bottom-up commitments to neighborhood improvements. Unexpected results have also emerged, such as learning that the residents' living satisfaction has declined during the assessing period; yet, these results are understandable, considering that the actual interventions have been delayed and the implementation is still in progress. GARID is found to conditionally enhance Greater Accra's regional resilience based on its immediate impacts thus far, and an optimistic view is promising regarding the upward outcomes that GARID will result in later. The project will benefit from expediting certain interventions to avoid temporal contestations, maintaining its extensive participatory activities, and initiating early discussion around sustainable operations and maintenance mechanisms. The experiences of GARID could provide fruitful lessons for other cities to advance their resilience investments.

Civil society, or the third sector, plays a range of pivotal roles in improving local urban planning, governance and management efforts. This paper attempts to map the evolving landscape of urban civil society in Indonesia since reformasi — the fall of the authoritarian New Order era in 1998 — primarily through a nationwide survey of urban civil society organizations (CSOs). This unique inquiry, which we believe is the first of its kind (and part of a multi-method qualitative study), seeks to explain the types of urban CSOs, their activities, their approaches and functions, how they support themselves, their impacts, and their evolving challenges and relationships to key planning and governance stakeholders. The sudden shift to democracy and extensive decentralization reforms made Indonesian civil society blossom. In the two ensuing decades democracy matured, and a series of decentralization iterations transformed the institutional arrangements for local governance and planning. In this new landscape of localized planning, urban CSOs increasingly assumed unprecedented roles as activists, advocates, intermediaries, and innovators working with hitherto disenfranchised communities and local governments. CSOs' involvement is making cities in this fast-urbanizing nation more livable — by being more inclusive of informality and more equitable in providing services, and more efficient and resilient by being more collaborative and technology-oriented. However, the CSO landscape is poorly appreciated and understood. A weak regulatory structure governing civil society and a yet diffuse, less organized third sector make for scarce data on CSOs. As a modest attempt to fill this void, our effort itself represents a collaborative endeavor between a local CSO and an academic institution bridging the Global South and North. Our nationwide survey of 84 CSOs that responded (120 contacted) was conducted, online and telephonically, in two phases — 48 in 2023, and 36 in 2024. Respondents were asked to suggest other CSOs. Analyzing the initial 40 responses snowballed to 48, and prompted the second phase. Those surveyed include CSOs from 19 cities and seven islands, and included think tanks, voluntary organizations, established and new non-governmental organizations (NGOs), informal associations, community-based organizations (CBOs), and grassroots organizations (GROs). We also conducted in-depth interviews with 14 CSOs. Descriptive and inferential statistics indicate that local civil society action is positively altering public discourse and sentiment; structural and contextual factors can impede the missions, longevity, and growth of CSOs; and CSOs are innovating with technology and collaborative arrangements to sustain themselves. For continued progress, we call for state and private sector stakeholders alike to promote local multistakeholder coalitions involving CSOs. We find that the national government's role is critical for creating space and much-needed support for civil society; local leadership can transform the third sector space; and CSOs are uniquely poised to respond in innovative ways.

Trading Bricks for Iron Sheets: Analyzing a Rebound Phenomenon in a Slum Upgrading Project in Kenya

Abstract ID: 1844.0.0.617.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Carlos Lopez-Ortiz [Cornell University] cal382@cornell.edu, presenting author

Tackling the housing and services crisis in cities across Sub-Saharan Africa is a global priority to reduce poverty, yet it remains unclear how to achieve this goal. The United Nations (2024) estimates that the urban population living in slums in Sub-Saharan Africa grew at the fastest rate globally between 2017 and 2022, with an annual growth rate of 4.52%. This group made up over 53% of the urban population in Sub-Saharan Africa in 2022, the largest proportion in any region worldwide. These demographic trends indicate that the demand for improved housing and infrastructure in Sub-Saharan Africa will continue growing in the foreseeable future. Governments and international development organizations have explored strategies to improve the spatial conditions in slums, with slum upgrading being among the most widely accepted approaches today (Brakarz & Jaitman, 2013; Núñez Collado & Wang, 2020).

Although governments and international agencies have spent billions of dollars on slum upgrading projects worldwide (Werlin, 1999), studies have found that, in some projects, beneficiary households decided to move back to slums (Koster & Nuijten, 2012). This ‘rebound phenomenon’ (Debnath et al., 2019) questions the effectiveness of slum upgrading to improve residents’ living conditions in slums. Aiming to contribute to a better understanding of this phenomenon, I ask: What are the underlying causes of some beneficiaries’ decision to move back to slums? How does this decision impact their living conditions? What can urban policymakers learn about low-income households’ housing preferences by analyzing their decision to move back to slums?

I analyze the causes of the rebound phenomenon by examining the Kenya Railways Relocation Action Plan (RAP) in Nairobi, Kenya. RAP is a government-led housing program in Nairobi that provided subsidized rental housing to 4,700 households illegally occupying the railway reserve area in two of Nairobi’s largest slums. Ten years after its implementation, around 33% of the original beneficiaries decided to rent out their housing units and move somewhere else. I conducted semi-structured interviews with beneficiaries (n = 25) and key informants (n = 10) to identify beneficiaries’ main reasons for moving out from the upgraded units. Preliminary findings show two dominant reasons for renting out: (1) the mismatch between households’ expectations and housing characteristics and (2) an opportunity to secure a stable income. This paper challenges the commonly accepted assumption within the international development community that improved access to affordable and decent housing automatically translates into improved well-being for low-income households.

Urban Displacement: Innovative and Inclusive Data Collection Approaches in the Global South

Abstract ID: 1844.0.0.807.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Timothy Berke [The University of Michigan Ann Arbor] tberke@umich.edu, presenting author

The global challenge of population displacement has continued to increase over the past few decades, with approximately 123 million people—or about 1.5% of the global population—currently displaced, according to the United Nations High Commissioner for Refugees (UNHCR). This includes internally displaced persons, asylum seekers, and refugees. The factors driving this increase are predominantly political conflicts and the adverse impacts of climate change. Furthermore, 76% of these displaced individuals reside in low-income countries, where resources to accommodate and support them are often limited. As cities increasingly become destinations for displaced populations, urgent attention must be directed toward developing adaptive and accurate data collection methods, including household surveys, to inform effective urban planning and policymaking.

Traditional data collection methods often rely on pre-crisis census data and consequently fall short in capturing the realities of populations in flux. The needs and demographic makeup of a community can drastically change following and during a crisis. Additionally, due to problems in accessing changing communities that may include “hidden” members who may be subject to political constraints, some conclude that randomization is not possible and that convenience or non-random samples may be necessary. I agree that in many communities, conventional randomization techniques for data-gathering are not possible, especially if administrative boundaries are not well defined and governance is limited. However, I argue that new methods can help ensure representative samples. But I also argue that other data best augment these samples.

I worked with community members to develop innovative sampling techniques tailored to communities hosting displaced populations. These techniques were applied in a case study in Juba, South Sudan. Collaborating with local chiefs, we documented informal urban area boundaries and implemented a strategy to randomly select households for a comprehensive survey, sampling 240 households across four distinct urban residential areas that include both internally displaced persons (IDPs) and host community residents. To augment the quantitative survey data with qualitative insights, we conducted approximately 75 semi-structured interviews and five focus group discussions (FGDs). Furthermore, these surveys and interviews were complemented by periods of participant observation within the community, engaging with local authorities, NGO staff, and community members. This multi-method approach, conducted over four timeframes from 2022 to 2025, was designed to provide a holistic understanding of the needs, challenges, and dynamics within these urban settings.

The problem of displaced populations is escalating at an alarming rate. The number of displaced persons, driven by conflicts and natural disasters, continues to rise dramatically. Over the past decade alone, this number has doubled, underscoring the severity of the crisis. The trend shows no signs of slowing down due to the increasing pressures of climate-related disasters, ongoing conflicts, and a glaring lack of sustainable long-term solutions for those uprooted from their homes. It is crucial that urban planners and policymakers rethink assessment methodologies to better inform strategic interventions. By reconceptualizing data collection processes, my research aims to guide the development of initiatives capable of serving both established residents and newcomers effectively. These initiatives require a nuanced understanding of urban displacement’s impacts on different community stakeholders.

Urban Land Values in Santiago: Effects of the so-called “Chilean Miracle” on over-Appreciation

Abstract ID: 1844.0.0.301.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Clemente Larrain [University of California, Los Angeles] clementelarrain@ucla.edu, presenting author

This paper examines the persistent rise in urban land values and its impact on housing affordability and wealth distribution, with a focus on Santiago de Chile. Chile, a country characterized by high inequality and recurring challenges in housing access, experienced significant land value increases in the 1990s. This period coincided with extensive demand-side housing subsidies, whose effectiveness may have been undermined by rising land costs. As a result, low-income households faced increasing difficulty accessing land, leading to smaller, less accessible, and sometimes informal settlements—a trend observed across Latin America.

This study has two primary objectives: (1) to construct a novel set of long-term, geographically controlled land value indices for Santiago de Chile and (2) to empirically test predictions from urban land rent theory regarding the impact of macroeconomic factors. The analysis focuses on the "Chilean Miracle" period (1990–1997), investigating how rapid land value appreciation contributed to housing unaffordability and social inequality.

Methodologically, the paper develops two distinct quarterly land value indices for Gran Santiago covering 1983Q4 to 2016Q2: the Índice del Precio del Suelo en Santiago (IPSS) and the Índice de Precio de Oferta del Suelo de Santiago (IPOSS). Both indices use a Laspeyres estimator based on land market offer data from a long-standing real estate consultancy. To ensure spatial comparability and temporal consistency—and to address biases related to arbitrarily defined zones (Modifiable Area Unit Problem)—a geographic spatial clustering approach (Automatic Zoning Procedure, AZP) is applied, consolidating the original 206 zones into 60 statistically robust clusters. The IPSS weights price variations by geographic surface area (approximated via property counts from the previous period), while the IPOSS weights variations by the number of market offers per zone, capturing market activity more dynamically. To analyze the short- and long-term relationships between land values and macroeconomic factors, the study employs Vector Error Correction (VEC) models, incorporating key determinants: economic activity (proxied by an economic development index and employment levels) and the real interest rate.

The theoretical framework is grounded in urban land rent theory, which posits that land rent is a residual value derived after accounting for production costs, reflecting locational advantages and metropolitan economic growth. Land value is conceptualized as the capitalization of this rent flow, discounted by the interest rate. Two core hypotheses are tested: (H1) metropolitan economic performance positively influences land values, and (H2) interest rates negatively affect land values.

Empirical findings confirm these theoretical predictions: the VEC models indicate that both IPSS and IPOSS are significantly affected by economic activity (positively) and interest rates (negatively). Additionally, land values in Santiago grew at a faster-than-expected rate during the "Chilean Miracle," even after accounting for macroeconomic fundamentals. This pattern aligns with literature linking this period to worsening housing affordability and socio-spatial inequality. Furthermore, the indices themselves show minimal causal influence on macroeconomic variables, supporting their interpretation as residual land values.

This study contributes to urban economics by introducing long-term, high-precision land value indices for a major Latin American city. These indices facilitate robust causal analysis of the relationships between land values and macroeconomic dynamics, offering valuable insights into urban development, housing markets, and inequality—particularly during Santiago's rapid economic transformation.

Urban Spatial Transformation Induced by Shadow Education in China: A Case Study of Nanjing

Abstract ID: 1844.0.0.737.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Yunhong Xiao [Southeast University] nuageshaw@foxmail.com, presenting author

Shijie Sun [Southeast University] sun_shijie@seu.edu.cn

Over the past two decades, China has experienced extensive infrastructure expansion, particularly in office space construction. However, due to excessive supply and the economic downturn exacerbated by the COVID-19 pandemic, office vacancy rates in major Chinese cities averaged 30% by 2021, reaching up to 50% in marginal urban areas. In the post-pandemic era, the rapid proliferation of shadow education institutions has emerged as a significant driver of office space reutilization, influencing both the material and functional transformation of urban areas (Bray, 2023).

Shadow education, commonly referred to as private tutoring, comprises informal privately operated educational services that complement formal schooling (Zhang & Bray, 2021). In Nanjing, a megacity with over ten million residents, the intensification of educational competition compels families to enroll their children in supplementary tutoring to enhance academic performance. This growing demand has driven the expansion of shadow education, with the number of related points of interest (POIs) increasing from 1,910 in 2014 to 4,196 in 2022 (Liu et al., 2021). Since shadow education is not formally classified within China's land-use system, such institutions frequently repurpose existing built spaces—particularly vacant office buildings—thereby contributing to the adaptive reuse of underutilized urban infrastructure (Sun & Wang, 2021).

This study investigates two core research questions:

1. Spatial dynamics of shadow education: How has the spatial distribution of shadow education institutions evolved in Nanjing between 2014 and 2023? What spatiotemporal patterns differentiate various types of shadow education (e.g., youth-focused vs. adult-oriented tutoring)?
2. Mechanisms of spatial transformation: Which types of built environments have been favored by shadow education institutions (commonly vacant office spaces)? What are the spatial conversion processes, key actors, and sustainability implications of such transformations?

Methodologically, this study employs a spatiotemporal analysis based on large-scale location-based service (LBS) data from 2014, 2017, 2020, and 2023 to map and analyze the evolving spatial structure of shadow education institutions in Nanjing. A multivariate geographically weighted regression (MGWR) model is applied to examine the key determinants shaping their spatial distribution, incorporating variables such as land-use characteristics, real estate values, proximity to schools, and accessibility to public transit. Furthermore, bivariate spatial autocorrelation analysis is employed to investigate the interactions between shadow education expansion and broader urban spatial factors.

In the second phase, this study statistically analyzes the original land-use functions of sites now occupied by shadow education institutions, revealing a predominant transition from office spaces to tutoring centers. Two representative areas—Nanjing Library and Jishan Software Park—are selected as in-depth case studies, where clustering of shadow education institutions has not only facilitated office space reutilization but also stimulated adjacent service industries. Through historical policy analysis, stakeholder interviews, and field surveys, this

research explores the driving forces, transformation timeline, institutional actors, and spatial mechanisms underpinning this urban evolution.

By integrating spatial analysis, land-use adaptation, and educational geography, this study provides a novel perspective on the role of shadow education in shaping urban spatial transformation. Findings contribute to theoretical discussions on educational urbanism and offer empirical insights for policymakers seeking to optimize vacant office space reuse and urban renewal strategies.

Women's Work in the Indian Platform Economy: A View from Bangalore

Abstract ID: 1844.0.0.290.2025

Track 7: International Development Planning

Individual Paper Presentation Submission

Amrita V. Nair [Massachusetts Institute of Technology] amritavn@mit.edu, presenting author

In India, despite accelerating economic growth and rising per capita income, women's participation in paid work has been markedly low. At the same time, the rise of the digital economy and the proliferation of digital platform firms have led to platform work being touted as a solution to this gender gap due to its promises of spatial and temporal flexibility and autonomy. My project critically examines these narratives through the study of gig workers and home chefs in the platform economy of Bangalore. Using a relational comparison approach based on interviews, ethnographic observation, and critical discourse analysis, I ask: (1) What are the motivations for women to participate in the Indian platform economy? How are they related to the extant conditions of social reproduction and to women's socioeconomic positionalities? (2) What are the avenues for resistance and agency that are provided or prevented by platforms and platform-mediated work?

In this project, I analyse the workflows and experiences of platform workers to posit that paying attention to the spatiality and temporality of women's socially reproductive work on platforms reveals them as sites where the divisions of caste, class, and gender are reproduced, reinforced, and facilitated. Paying particular attention to women workers' care contributions during the COVID-19 pandemic and beyond, I argue that belying their promises of flexible work, platforms are rendering women as flexible workers and as a reserve army of labour. Additionally, I find that through algorithmic control and surveillance, platforms are depriving gig workers even of forms of subaltern and everyday resistance. On the other hand, home chefs, due to their socioeconomic privileges are able to instrumentalise platforms to find avenues for agency and resistance through platform work. Based on these findings, I argue for reimagined solutions to the gender gap in paid work that centre women, for platform configurations that prioritise people over profits, and for increased attention from platform scholars and planners to the spatiality of women's work.

The Informal Armatures Approach as a Non-Standard Planning Toolkit: Potential Applications in China

Abstract ID: 1842.0.0.1001.2025

Track 7: International Development Planning

Research-in-Motion Presentation Submission, Research currently in process

Shiqi Ming [The Architectural Design and Research Institute of Zhejiang University Co., Ltd. (UAD)] maggie-ming@live.cn, presenting author

Honglei Bao [Tianjin University Research Institute of Architectural Design and Urban Planning Co., Ltd] gulongdejiu@live.cn

Since its introduction in 2019, China's National Territorial Spatial Planning (NTSP) system has been gradually implemented with a top-down approach, integrating multiple parallel systems to resolve conflicts. This has led to more efficient planning, sustainable growth, and improved long-term territorial and urban development. However, as a rapidly developing, multi-ethnic country, China faces complex and dynamic territorial, environmental, urban, socio-economic, and cultural conditions that are constantly shifting. After years of rapid economic growth, urban development in China has reached a point of saturation, requiring more nuanced responses to design contexts that differ from previous centralized and highly homogeneous urbanization models. The system has also been less effective in addressing immediate challenges faced by local communities.

The concept of Informal Armatures (IA), introduced by Professor David Gouverneur in applied research, offers a promising alternative toolkit for contexts experiencing fast-paced urbanization in countries with emerging or fluctuating economies. This approach effectively addresses the complex, interrelated environmental, urban, and socio-cultural challenges in a simple yet adaptable manner.

This research explores two central questions: From a technical perspective, how can the IA Approach contribute to planning and design practice in China? What does the IA Approach offer in terms of research methods and theoretical frameworks for exploring urban development and industrial operation models?

A multipronged methodology underpins this study, combining an in-depth review of the Informal Armatures concept, comparative analyses between China's socio-cultural and economic contexts and those of other developing nations, theoretical analysis of China's NTSP system, ethnographic observations, and semi-structured interviews with design institutions, local authorities, NGOs, and community members through past and ongoing design projects.

This paper argues that the IA Approach, while primarily focused on addressing challenges in developing countries, can offer valuable insights for China's newly implemented NTSP system. It serves as a supplementary non-standard planning toolkit, responding to China's evolving economic landscape and sustainable development goals. As an applied research model, IA can provide significant contributions in the following areas: a) addressing current environmental, urban, and socio-economic conditions at various scales, b) recognizing site-specific factors, c) offering flexibility in the face of change and uncertainty, d) fostering community engagement in the planning, design, implementation, and management of urban habitats, thereby alleviating the managerial and economic burdens on governments at all levels, e) acknowledging the nation's rich cultural diversity, f) supporting new settlers with spatial and managerial strategies, and g) facilitating rural revitalization. Additionally, the IA Approach

systematically identifies the main factors shaping urban and rural development. Its theoretical framework offers a valuable reference for Chinese planning professionals and scholars as they adapt to new development models and transition from executing top-down strategies to serving as communicative nodes within a complex, interconnected planning system.

Women, Work, and Mobility: Navigating Urban Infrastructure in Mumbai's Platform Economy

Abstract ID: 1842.0.0.1093.2025

Track 7: International Development Planning

Research-in-Motion Presentation Submission, Research currently in process

Mansi Kumar [Georgia State University] mkumar10@student.gsu.edu, presenting author

Women have more options to work due to the quickly growing platform and gig economy in urban India (NITI Aayog, 2022), particularly in major Indian cities like Mumbai. Despite the fact that these platforms provide flexibility and alluring economic opportunities, their potential to benefit from their labor is usually linked to the worker's ability to move within the urban fabric (Vecchio et al., 2022). Mobility for women engaged with platforms is influenced by a web of limitations created by various factors, including uneven urban infrastructure, socio-cultural norms, and platform rules and regulations that determine how far, freely, and under what circumstances women can move. Women have unique difficulties as independent workers in cities like Mumbai, where transportation can be unreliable and public spaces are frequently gendered (Phadke et al., 2011). Research on digital platforms has grown, primarily focusing on economic instability, and labor precarity and rights. However, focus on mobility is limited, and studies on digital platforms frequently overlook women platform workers and their specific spatial challenges (Bauriedl & Strüver, 2020). This study fills these gaps by examining the impact of urban infrastructure on the mobility of women platform workers in Mumbai and identifying planning strategies to address their mobility issues. The research employs a qualitative approach, utilizing semi-structured interviews and participant observations of women working at Urban Company, a digital platform with one of the largest female-dominated beauty and salon verticals. This study's Mumbai setting adds much more depth and significance by situating the research within one of India's dynamic and most densely populated urban centers, where intersections of class, caste, gender, and rapid urbanization shape women's spatial (im)mobility and experiences in the platform economy (Kuttler, 2022; Phadke et al., 2011). To build a more equitable urban environment for all, this study emphasizes the importance of planning interventions that consider the specific mobility needs of female platform workers.

Experts, Friends and Enemies: Networks in Decisionmaking and Disputes

Abstract ID: 1840.0.0.1106.2025

Track 8: Land Use Policy and Governance

Pre-Organized Session Summary

Session Includes: 1844.0.0.294.2025, 1844.0.0.749.2025, 1844.0.0.484.2025, 1844.0.0.368.2025, 1844.0.0.1087.2025

Joseph Weil Huennekens [Columbia University] jsh2228@columbia.edu, organizer

Networks of decisionmakers and advocates have long been theorized as critical in paradigmatic land use disputes. These networks can be spaces of negotiation, opportunity and improvisation, or simply closed arenas for regimes of elites, owner-advocates, and developers. Yet amidst the growing understanding of 'gray' legalities at the intersection of housing, environment and land use action, and the increasing importance of social analyses for land use processes, how can careful study of cases trace ways in which networks and relationships interact with land use outcomes? This panel will draw on in-depth cases of contested land use, highlighting some of the specific alliances, tactics, coalitions, and mobilizations of official planning documents, regulations and judiciaries that are used to intervene in contested development.

Learning Objectives:

- Audience members will learn about housing justice struggles, land use conflicts, and environmental disputes through the specific lens of planners-in-action.
- Audience members will learn about case-study as a methodology suited for close empirical study of how planning policy and contestation is enacted on-the-ground.

'Gray' Densification: Incremental Multifamily Approvals in New York

Abstract ID: 1844.0.0.294.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Joseph Weil Huennekens [Columbia University] jsh2228@columbia.edu, presenting author

Most scholarship on densification considers either formal or informal processes. Formal densification typically consists of zoning reforms: rule changes which allow denser buildings over a large territory (Kazis 2023). Informal densification typically consists of conversions: the unpermitted addition of new units in existing homes (Wegmann and Mawhorter 2017). Yet, a wide array of practices exists in-between the two poles of formal/informal, including practices of housing production (Fawaz 2017).

Building on what Yiftachel (2009) labels “gray space” and what Baird-Zars (2023) calls “gray institutions,” this paper attends to “gray” densification. Specifically, “gray” densification describes one-off, site-specific approvals that accrete to eventually constitute an informal change in land use policy. Using a case study research design, the paper documents two cases in New York where a significant number of new housing units have been created through a different practice of “gray” densification: area variances in the suburban town of Ramapo and half-block rezonings in the urban neighborhood of Harlem.

In the first case, the suburban town of Ramapo, New York, thousands of new units have been facilitated through case-by-case variance exceptions, which allow for construction beyond the requisite zoning envelope. In the second case, the Central Harlem neighborhood of New York City, hundreds of new units have been facilitated through small half-block rezonings, usually developer initiated. Drawing from archival resources (plans, environmental review documents, agendas), permitting data, and a self-constructed database of land use approvals, the paper highlights how these one-off approvals form precedents which eventually accrete to become a “shadow” zoning code.

These two examples of “gray” densification serve as “black swan” cases, showing that – at least in some political and institutional contexts – site-specific approvals actually help facilitate housing production. This finding is in contrast to much of the planning literature, which tends to argue that discretionary approvals contribute to the supply crisis. The paper ends by considering the implications of “gray” densification on land use governance and planning outcomes, noting the diversity of approaches that exist between the binary of formal and informal.

Relationships to Action: Fair and Accountable Flood Adaptation in US Coastal Frontlines

Abstract ID: 1844.0.0.749.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Bernadette Baird-Zars [Rutgers University] b.bz@rutgers.edu, presenting author

Paul Gallay [Columbia University] pag57@columbia.edu

Hoi Nam Hellas Lee [Columbia University] hl3735@columbia.edu

Amelia Ying Ding [Barnard College] ayd2110@columbia.edu

Annel Hernandez [Rachel's Network] annelmhernandez@gmail.com

Victoria Sanders [New York City Environmental Justice Alliance] victoria@nyc-eja.org

Frontline communities demand and deserve protection from flooding, along with repair from past harms, celebration of strengths, and fair planning processes (Morris et al. 2024). While large-scale investments are necessary for coastal flood adaptation, advocates emphasize the importance of integrating the strengths of residents and community-based organizations alongside governmental agencies (ibid). Yet relatively little research to date has foregrounded the specific components of the networks and initiatives that have protected frontline communities beyond formal plans, which frequently lag in participation and 'justice issues' (Rekien et al. 2023).

Addressing this research gap is urgent: urban flood adaptation epitomizes many of the built-in challenges of equitable action, with complex and compounding factors that are highly contextual at the physical and social scale, block to block, and creek to creek (Sun et al. 2024); and which are particularly sharp for frontline and environmental justice communities (Liao et al. 2019). Nevertheless, equity remains amorphous in most adaptation plans (Angelo et al. 2022), and coastal adaptation processes continue to prioritize short-term, hierarchical relationships and transactional exchanges (e.g. USACOE 2025).

Building off a multi-year co-produced research project led in partnership with an umbrella environmental justice organization, this project examines the experiences of 22 leaders in these spaces nationwide, across state agencies, consultancies, local government and community-based organizations. Through using snowball sampling to select participants and conducting multiple rounds of long-form interviews, which were then analyzed and refined in collaboration with participants, we explore how local networks enable fair and accountable spaces for decision-making and problem-solving. We define these spaces as those that marshal the resources of the many entities involved and simultaneously advocate for the protection and inclusion of groups historically left out of formulas, investment, and protection in coastal adaptation planning.

Our initial findings suggest that equitable actions stem from long-term relationships and networks of respect underpinned by values, such as the understanding that everyone engaged brings valuable knowledge and experiences. Further, we identified key roles and arenas for action that dynamically interplay to foster equitable planning processes. These roles - facilitators who connect people and resources, educators who foster knowledge exchanges, mediators who create spaces for diverse stakeholders, defenders who advocate against injustices, and mentors who guide communities to long-term empowerment - collectively inspire new modes of action and lay the foundation for successful, relationship-centered planning.

“Good cause” or “just cause” eviction laws (GC) are regulations barring landlords from evicting tenants unless they have a specific allowable reason. Although some versions of good cause laws have existed in various parts of the U.S. since the 1970’s, the specifics of these laws vary across states and municipalities (Urban Law Annual, 1981; Vasquez and Gallagher, 2022). Many of these differences regard the housing stock that GC laws cover. GC laws have spread across New York State in the past few years, evolving to cover different stock with each new iteration and network of supporters, contenders, and decision-makers (Been et al., 2024; Card et al., 2025).

A few municipalities passed local-level laws starting in 2021, but legal challenges from landlord groups led to courts requiring New York to pass state-level enabling legislation. This requirement led advocacy groups and policymakers to develop a multi-scalar policy approach to GC with a state-level enabling policy that would govern New York City’s GC, while also allowing other municipalities to adopt their own versions. After the state passed GC in its 2024 budget, 13 municipalities have passed GC ordinances.

This case study examines the New York State landscape of GC laws, assessing the ways in which municipal GC ordinances came to align and differ as well as the details of what segments were determined by the state versus left to the municipalities. In the process of these laws being passed, ruled against, enabled by the state, and then passed or re-passed by municipalities, a complex network of decision-makers shaped and re-shaped the specifics of each ordinance, changing what housing stock is covered and what is exempt. Who comprised these networks of inter- and intra-municipality actors? What stock did these different actors aim to cover, and what stock is covered today? In addressing these questions, this paper provides insight on how the multi-scalar regulation of housing stock is composed, contested, and reconstructed.

Deepening Injustice: How Climate Adaptation Undermines Communities' Adaptive Capacity

Abstract ID: 1844.0.0.368.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Sauvanithi Yupho [Department of Geography, Rutgers University] s.yupho@rutgers.edu, presenting author

Several climate adaptation scholars have analyzed adaptation plans, highlighting their failures and negative consequences—such as how development policies and practices have created uneven vulnerabilities or failed to mitigate climate risks and introduce new challenges for affected communities. Scholars have argued that climate adaptation and land-use planning must center on climate justice and be fully integrated into planning processes to prevent the reproduction of vulnerabilities, and some advocate for prioritizing justice first and climate later. However, there is a lack of studies that critically examine how these adaptation efforts actively undermine the adaptive capacities of communities that have historically been well-equipped to cope with environmental challenges.

This study addresses this gap by offering a different perspective that enhances our understanding of climate adaptation, focusing on deeper political dynamics, development discourse, and socioenvironmental injustices. The study examines the riverside community in Bang Ban, Ayutthaya, Thailand. Ayutthaya has historically thrived with a water-based way of life for 400 years. Today, the city has transformed into a typical land-based urban area, but remnants of its water-based lifestyle remain. Several riverside communities maintain aspects of this way of life, such as building elevated houses to withstand seasonal floods and using boats for secondary transportation. Despite being well adapted to floods, the Bang Ban community is experiencing increasingly prolonged and severe flooding each year. I hypothesize that climate adaptation plans in Thailand are undermining their adaptive capacity by using flood management strategies to prioritize capital accumulation at their expense.

I demonstrate their capacity to be proactive despite their challenges by asking Who gets to adapt (from water-based to land-based). What are communities adapting to? How can climate adaptation be socially just? This study draws on political ecology and discursive institutionalism to untangle the interplay between climate adaptation plans, flood management strategies, and the situation on the ground. It employs a mixed-methods qualitative approach, including semi-structured interviews with government officials, policymakers involved in floodwater management, local NGOs, scholars specializing in flooding in central Thailand, politicians, and residents of the Bang-Ban community. Interviews were conducted in Thailand from June to August 2023, including 15 participants. Additionally, the study analyzes governmental floodwater management plans, irrigation strategies, and provincial comprehensive plans, supplemented by news articles and media coverage.

We find that government officials and policymakers, particularly in the water sector, impose flood protection infrastructure such as dikes, diversions, and water gates not only to manage water but also to amass political power and sustain their status quo. The water sector employs governance schemes that integrate climate-protective infrastructure, flood zoning, and flood management strategies into the daily governance of the Bang-Ban community. However, rather than enhancing resilience, these strategies undermine the community's adaptive capacity and normalize their suffering under unjust practices. The findings contribute to the literature on historical institutionalism in planning by extending beyond the concept of path dependence to examine the recursive practices of promoting discourses, ideas, and projects that sustain institutional persistence. Additionally, this study sheds light on infrastructure and climate adaptation scholarship, moving beyond the notion of maladaptation to highlight how adaptation strategies actively erode the adaptive capacity of communities that have long lived with

floods. The overarching goal of this study is to emphasize the urgency of embedding socioenvironmental justice into development practices.

Knowledge, Space, Power - The Relevance of Territory in Understanding the Caribbean

Abstract ID: 1844.0.0.1087.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Elizabeth Alvarez [Columbia University] ema2200@columbia.edu, presenting author

This paper advances a theoretical framework for understanding housing as a spatial technology through which borders, sovereignty, and governance are produced and contested. At the intersection of urban planning, political geography, and critical race and Indigenous studies, I argue that housing cannot be fully understood without accounting for the spatial logics of partition, border, and camp—three formations that illuminate how racialized and colonial power operates at the edge of state control and within the domain of planning.

By examining the architecture and logic of the partition, I trace how spatial division—whether through national boundaries, settler-colonial land regimes, or redevelopment projects—functions as a violent tool of disaggregation and displacement. The border emerges not only as a geopolitical line, but as an apparatus that prefigures housing conditions—determining who may dwell, under what conditions, and with what claims to space, land, or recognition. Finally, I theorize the camp as an increasingly normalized housing typology for the stateless, the racialized poor, and those cast outside formal planning paradigms. Camps, whether in the form of refugee settlements, encampments of the unhoused, or temporary labor housing, reveal how the state orchestrates both inclusion and abandonment through spatial containment.

Situating this inquiry within transnational planning contexts, I show how these spatial forms do not exist outside planning, but are often its unspoken infrastructure. From the demolition of public housing to the proliferation of gated tourist enclaves and informal settlements, planning becomes visible not as the agent of equity, but as a participant in the bordering and partitioning of life. Through this lens, housing becomes a critical site where power circulates—through policy and absence, through mapping and unmapping, and through the shifting terrain of legality and informality.

By reframing housing as a political, ontological, and epistemological site rather than a mere policy output, this paper contributes to debates on planning's role in reproducing—or resisting—the architectures of coloniality, racial capitalism, and displacement. I call for a renewed theorization of planning as a field of networked action—where borders and sovereignties are made and unmade—and argue that our understanding of housing must extend beyond shelter to include the spatial and historical conditions that delimit who gets to dwell, and who is rendered perpetually out of place.

The Role of Political Intermediaries in Urban Governance in the United States

Abstract ID: 1840.0.0.560.2025

Track 8: Land Use Policy and Governance

Pre-Organized Session Summary

Session Includes: 1844.0.0.269.2025, 1844.0.0.458.2025, 1844.0.0.235.2025, 1844.0.0.498.2025, 1844.0.0.155.2025

Irene Farah [University of Illinois, Urbana-Champaign] irenef@illinois.edu, organizer

Urban governance increasingly relies on intermediaries who navigate between elected officials, bureaucratic structures, and civil society. These intermediaries, ranging from street-level bureaucrats to nonprofit organizations, play crucial yet understudied roles in shaping policy implementation, resource allocation, spatial form, and community participation in planning processes. As cities face mounting challenges related to employment, migration, and housing affordability, the role of these intermediary actors has become more significant in determining how policies translate into practice and how community needs are represented in decision-making arenas.

Learning Objectives:

- Understand how bureaucrats and nonprofit organizations exercise discretion in translating urban policies into practice, often transforming outcomes in ways not anticipated by formal planning processes.
- Examine the mechanisms through which political intermediaries negotiate between elected officials, bureaucratic structures, and civil society to shape resource allocation and community participation in decision-making arenas.
- Explore theoretical frameworks and methodological approaches for assessing how intermediary actors either advance or impede equity and justice in urban planning and governance.

Professional Discretion and Diverse Property Claims After the 2022 Hermits Peak / Calf Canyon Fire

Abstract ID: 1844.0.0.269.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Renia Ehrenfeucht [The University of New Mexico] rehrenfeucht@unm.edu, presenting author

Marla Nelson [The University of New Orleans] mnelson@unm.edu

Networks of assistance providers help residents navigate complex disaster recovery processes. These include FEMA staff members alongside state program, nonprofit agency and foundation staff. Those interacting directly with residents can exercise discretion in ways that influence recovery outcomes (Jerolleman et al, 2024; also see Lipsky, 2010). In FEMA claims processes, claims navigators are instrumental in helping residents access recovery aid and document their losses although they may not demographically represent the impacted communities (Rivera, 2016). FEMA has widened the range of documentation allowed to access recovery aid for land and property, and yet residents continue to face challenges obtaining this aid (Flordio, 2022). Residents from places impacted by disasters take jobs in the recovery to help their communities. While these local recovery professionals have knowledge about local specificities, they also face constraints from the state apparatus (Scott, 2020). This project seeks to answer the following questions: What authority and discretion do intermediaries have who work directly with impacted residents in the post-disaster recovery environments? Does the authority and discretion differ for locals who accept jobs in the recovery apparatus? This project draws on a case study about the 2022 Hermits Peak / Calf Canyon Wildfire recovery efforts in New Mexico, utilizing interviews, news coverage, and documents produced by FEMA and the State of New Mexico Department of Homeland Security and Emergency Management. This project contributes to planning practice and theory by exploring how local professionals and street-level bureaucrats aid in the unique situations inherent to local community differences.

Who Represents Whom in the Planning? A Case of Political Alienation in Boyle Heights California

Abstract ID: 1844.0.0.458.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Walter Nicholls [Urban Planning and Public Policy UC Irvine] wnicholl@uci.edu, presenting author

Ashley Hernandez [UNC Chapel Hill] ashleych@unc.edu

Boyle Heights, a historic Latino barrio in East Los Angeles, presents a puzzling contradiction. Despite decades of systematic dispossession and a celebrated tradition of Chicano activism, the neighborhood experienced prolonged political quiescence following the movements of the 1960s-70s. This paper examines a fundamental contradiction in urban governance we term the "representational paradox": how growing political representation of marginalized communities paradoxically diminishes their political voice.

Drawing on analysis of media records, campaign finances, and political communications (1986-2015), we demonstrate how this paradox manifests in Boyle Heights' urban planning politics through five interrelated mechanisms. Class difference and ethnic identity function as complementary forms of symbolic capital enabling specific community members to gain recognition as legitimate representatives. Politicians like Jose Huizar leveraged professional credentials to gain external legitimacy while employing cultural authenticity to maintain constituent support, creating what Bourdieu terms a "cleft habitus."

As interests diverge between voters and external supporters, power increasingly favors the latter. Campaign finance analysis reveals Huizar's 2015 campaign raised nearly \$950,000, with 42% from real estate interests—showing structural dependence on forces threatening constituents' spatial security. Representatives develop sophisticated legitimization strategies: delivering symbolic policies over substantive ones; intensifying cultural identification to obscure class divides; and controlling communication channels to monopolize legitimate discourse.

When recognized as legitimate, representatives penetrate constituents' conceptual spaces and establish control over legitimate discourse. In Boyle Heights, Huizar transformed opposition to gentrification into cultural celebration while facilitating Downtown's \$20-25 billion transformation. This creates profound misrecognition, where residents cannot coherently identify sources of their dispossession.

By conceptualizing territorial dispossession across material, conceptual, and subjective dimensions, we demonstrate how dispossession from conceptual space represents an equally significant form of alienation as physical displacement, explaining prolonged political quiescence despite ongoing threats to spatial security.

Nonprofits as Intermediaries: Street-Level Organizations in the Mission District of San Francisco

Abstract ID: 1844.0.0.235.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Irene Farah [University of Illinois, Urbana-Champaign] irenef@illinois.edu, presenting author

This paper develops a theory of political intermediation by examining nonprofits (street-level organizations) in San Francisco's Mission District. Using ethnographic fieldwork and interviews with nonprofits, local officials, and residents, I analyze how these organizations function as crucial mediators between government and communities in the context of state devolution and administrative decentralization.

I advance three interconnected arguments: First, I demonstrate how nonprofits create a landscape of selective representation, where their varying degrees of representational legitimacy determine which community voices influence planning processes, raising critical questions about democratic accountability in decentralized governance. Second, I argue that these organizations simultaneously embody characteristics of civil society, but have also function as quasi-governmental bureaucracies, developing unique forms of discretion that differ from traditional street-level bureaucrats when interpreting and implementing policies. Third, I examine competitive collaboration dynamics among nonprofits, revealing how funding ecosystems place nonprofits in paradoxical positions that shape their intermediary roles. In particular, by forming strategic coalitions to increase political leverage while differentiating approaches to secure resources.

The Mission District case illuminates how street-level organizations navigate these tensions while mediating between formal policies and community needs the implementation of a street vending ordinance. This research challenges traditional conceptualizations of bureaucratic structures by revealing how the boundaries between state and non-state actors have become increasingly porous in contemporary urban governance. Understanding this complex landscape is essential for developing more nuanced theories of urban governance that account for the increasingly prominent role of nonprofit intermediaries in planning processes.

Informal Management: Flexible State Practice and Co-Production of Public Space in Queens, NYC

Abstract ID: 1844.0.0.498.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Ryan Devlin [Temple University] rtdevlin@temple.edu, presenting author

During the summer of 2020, at the height of the COVID-19 pandemic, street vendors transformed a small plaza in the New York City neighborhood of Corona, Queens into a bustling marketplace, offering a variety of Latin American food and all sorts of goods, from masks and hand sanitizer to toys, artisanal crafts, and clothing. In addition to providing the neighborhood with affordable goods and food, the market, which at its peak was home to over 100 vendors, served as an important source of livelihood for immigrant residents suffering from the pandemic-induced economic downturn. But the Corona Plaza vendor market, integral as it was to the neighborhood's social and economic resilience, existed for years in a legal limbo. Vendors at the market lacked street vending permits and licenses and the plaza itself was technically off-limits to street vending of any kind.

For three years, the market emerged as an example of bottom-up planning, as vendors organized themselves to self-manage the public plaza. This process of informal spatial management by vendors is documented in other work by the author. For this paper and presentation, I focus on the role of the state during this process. The state was by no means absent from this example of self-management. Caught between what at the time were two politically, operationally, and ethically unacceptable poles – expel vendors from the plaza in the midst of the pandemic or officially endorse what was technically illegal behavior – planners and policy makers managed the situation through a mix of flexibility, forbearance, and creative policy practice that often worked the edges of legality, utilizing the space between laws/policy as written and practiced to create conceptual and physical space for ongoing discussions about the future of the plaza.

This paper presentation seeks to answer three major questions. First what specific mechanisms and strategies, both formal and informal, were used by planners and public administrators to open space for flexible management and negotiation of the informal use of space at Corona? Second, how did the decisions and values of individual bureaucrats shape the approach to managing the plaza? Finally, what lessons can be drawn from this exceptional moment, when, in the midst of the pandemic, planners and administrators embraced informality to co-produce a more inclusive approach to public space management?

Drawing on theorizations of the grey spaces of plans and policy (Yiftachel 2009), this paper presentation argues that planners can and should embrace a more “fluid” form of governance (Certomá et al. 2020), leaning into the space opened for negotiation at the level of policy implementation (Lipsky 1980) to work in and through values of temporariness, incrementalism, and flexibility, positing the informal as a productive epistemology of planning rather than as a deviation from norms in need of correction (Roy 2007, Bhan 2020).

Representations of Substandard Housing in the Media

Abstract ID: 1844.0.0.155.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Danna Gutiérrez Lanza [Michigan State University MSU] gutie241@msu.edu, presenting author

Communication scholars have examined how media coverage of housing has the potential to shape the public's perception of housing needs or problems and preferences regarding policy responses. Following the literature of social constructivism, Martin (2021) argues that "housing problems are not simply objective facts [...]. Rather, decisions to focus on particular housing issues reflect the outcome of contests among policy makers, advocates, experts and the general public about which issues are worthy of time and attention and the nature of these issues" (Martin 2021, p.361). Other than underscoring the generally negative outlook of the media on urban problems, most of this work has also highlighted the recurrence of matters of habitability, social order and the deservingness of residents when constructing framing of housing issues in the media.

While previous work has focused on selecting newspapers with contrasting ideological viewpoints/ political slant (Nello-Deakin, S. (n.d.)), our work here focuses on sampling different socio-spatial and housing contexts: constrained geography, minimally regulated or unconstrained growth or widespread vacancy (Herbert et al., 2022), which play out differently according to the existing growth pattern of a city (stagnant, shrinking, growing cities, etc). Particularly, this project examines one aspect of housing issues in the media: substandard and non-compliant housing.

We ask how newspaper articles in Los Angeles, CA, Houston, Tx, Boston, MA, and Baltimore, MD between 2000 and 2024 construct a portrait of housing affordability and quality and its relationship to code enforcement by identifying those actors responsible for the causes and solutions to substandard or non-compliant housing?

We gather newspaper articles for the metro areas and time periods listed above through the database NexisUni, from a list of keywords refined for their ability to call up items of interest. With each news article as a unit of analysis, we follow Entman's framework, and code them to identify five framing elements: how the problem is defined, actor responsible for causes, possible solutions, actors responsible for the implementation of the solutions, and moral evaluation of the problem. Given the focus of our work, we additionally code housing type. We then analyze the frequency of references to particular housing types, conditions, actors, and policy solutions into a quantitative content analysis (Matthes, 2009, p.351) that lets us estimate the prevalence of some actors and solutions represented in the media. Finally, we count and graph the connections between the values across elements to analyze the different framings of substandard housing.

We find that the type of housing brought to the spotlight by the media as substandard – and in need of attention – varies across context. On the other hand, the actors deemed responsible for these conditions and its solutions vary less and continuously portray an image of personal responsibility for conditions of substandard housing while calling for improved, although not always increased, oversight from local government and code enforcement.

This study provides insight into how media narratives can influence political responsibility and policy and resource allocation (White & Nandedkar, p.214) by examining representations of substandard housing as matters of personal failings as opposed to structural deficiencies in the provision and regulation of housing across different contexts.

Understanding the Centrality of Land Development: Exploring Methods and Conceptual Lenses

Abstract ID: 1840.0.0.508.2025

Track 8: Land Use Policy and Governance

Pre-Organized Session Summary

Session Includes: 1844.0.0.268.2025, 1844.0.0.277.2025, 1844.0.0.162.2025, 1844.0.0.370.2025, 1844.0.0.432.2025

Soo Yeon Lim [Bloustein School, Rutgers University] sooyeon.lim@rutgers.edu, organizer

We are witnessing the centrality of land development to how local governments build, fund, and govern cities, as well as how we live our urban lives. Land questions continue to configure key issues in municipal finance, urban inequality, and spatial production. How land has been governed and developed has fundamentally shaped access to resources, opportunities, and political power within cities. Land is embedded in socio-political relations, and studying land involves engaging with various actors, planning practices, techniques, histories, and institutions. This session invites researchers to explore the centrality of land issues through various methodological approaches—from mapping, geospatial analysis, ethnographic observations, and interviews to other creative methods—and conceptual lenses. Through this panel, we aim to examine how these approaches shed new light on processes of exclusion while also exploring how land can be re-embedded socially to make cities more inclusive.

Learning Objectives:

- To learn about global land development practices and engage with emerging debates on methodological approaches and conceptual frameworks for understanding the politics of land development.

The City That Has Said Yes: Mapping the Workings and Spatiality of Density Tools in New Taipei City

Abstract ID: 1844.0.0.268.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Mi Shih [Bloustein School, Rutgers University] mi.shih@ejb.rutgers.edu, presenting author

Yu Wang [Bloustein School, Rutgers University] yw1111@scarletmail.rutgers.edu

Ying-hui Chiang [Department of Land Economics/National Chengchi University] yinghui@nccu.edu.tw

Since the 1990s, New Taipei City has had an active and speculative land and property development market, leading to the growing construction of residential buildings as well as a worsening housing affordability problem in the city. In this paper, we focus on a set of zoning-based density tools that municipal planners and government officials have deployed to enable, accelerate, and intensify urban land development. Our goal is to pry open the workings of these density tools to shed light on how they have deepened the treatment of land as an investment target by real estate capital even though these tools are couched in public interest discourses promoted by the local authority. We map out how these tools work technically and the spatial outcomes they produce. To make sense of the material and spatialized consequences of these density tools, we engage scholarship on the politics of land development in general and the regulatory techniques of planning tools in particular. Recently, housing affordability crises in American cities have spurred the “city of yes” movement – a set of discursive and regulatory practices that aim to expand housing construction by relaxing zoning restrictions and granting higher density. Yet, planning scholars and community organizers continue to debate whether the so-called “yes in my backyard” movement is an effective fix to the housing affordability challenge or merely a supply-side dressing that cloaks the deepening hold of real estate capital over urban spaces. For example, there has been a call to “unlock” the right to build as a part of the land value capture strategy to address housing shortage and affordability challenges (Furman Center, 2014). Yet, there remains a strong critique that the “city of yes” movement lacks an understanding of how financialization works to monetize land and housing while producing too little affordable housing to make a meaningful difference in equitable development (Rodríguez-Pose and Storper, 2020; Curren, 2021; Sclar, 2019; Shih and Chiang, 2024). This paper builds on and contributes to this important and growing body of debates by examining three major density tools in New Taipei City: density bonusing, TDR, and rezoning. Density bonusing grants developers additional buildable floor area in exchange for privately funded public facilities, such as providing open spaces, or on condition that certain planning requirements, such as using green building materials, are met. TDR is a technique of fungible air rights. It allows developers to produce taller, bulkier, and larger-scale projects if they purchase air rights from land parcels that are reserved for public facility uses under the city’s zoning regulations. Rezoning changes industrial land or farmland to a residential zone that permits higher-density property development. Working in tandem, these three regulatory techniques have ushered in large-scale land development as well as infill-style urban redevelopment. We combine three major data sources: meeting minutes from the Municipal Urban Planning Review Committee, the city’s records of TDR cases, and the national government’s land and housing sales registrar. Our analysis sheds important light on the quantity of buildable density granted by these tools, where they are built and in what type of development, and the neighborhood changes that they have enabled.

Governing the Public Realm: Negotiating Air, Light, Mobility, and Property Rights in East Midtown

Abstract ID: 1844.0.0.277.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Bridget Fisher [Rutgers University] bcf54@scarletmail.rutgers.edu, presenting author

Kathe Newman [Rutgers University] kneuman@rutgers.edu

When entrepreneurial local governments sponsor land development projects in partnership with private interests in a context of global competition for investment, they increasingly negotiate taking on project risk in exchange for public benefit. To better understand how the public private negotiations shape public outcomes, we explored the East Midtown rezoning in New York City. Through an analysis of planning documents, the project's financial instruments and projections of future revenues, and a set of strategic interviews, we center how the public private relationship was negotiated. Of particular interest is the negotiation between the public provision of land use rights through rezoning and air rights along with public capital expenditure, tax breaks, and risk sharing to produce anticipated public benefits. These public benefits can take a variety of forms including increased property tax revenue, private investments in public infrastructure, overall economic growth, and affordable housing. We describe these negotiations and consider land development as a strategic tool to produce public benefits. We conclude the paper with a consideration of equity. As public benefits are negotiated through the process of public/private land development, a critical concern for planners and society is who gets to decide what public benefits emerge as well as the management of resulting negative externalities.

Redevelopment, Property Rights, and the Right to the City: The Political Implications in Seoul

Abstract ID: 1844.0.0.162.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Euna Kim [Cornell University] ek683@cornell.edu, presenting author

Scholars have proposed the existence of a distinct culture of property in Singapore, Hong Kong, Taiwan, and Korea, with some hinting that such a strong inclination toward property ownership may be sustaining and reproducing speculative urbanization (Haila, 2017; Hsu & Hsu, 2013; Ley & Teo, 2014; Shin & Kim, 2016). However, these studies often lack empirical evidence or critical analysis of the roots of this propensity. To address this gap, further research is needed that critically examines the various manifestations of a culture of property in these regions, focusing on the origins, conditions, and mechanisms of such a culture (Haila, 2017). This study contributes to this line of inquiry by investigating the manifestation of a culture of property in Seoul, South Korea. Drawing from discourse analysis of interview data and historical analysis of legislation and the institutional framework that governs redevelopment, this study demonstrates the deep entanglement between redevelopment, property rights, and rights to the city. I argue that the property rights-oriented redevelopment system in Korea, established in the 1970s, effectively marginalizes renters as secondary citizens while rendering redevelopment a “private matter” concerning only property owners. This perception shapes the urban landscape differently from the West, where concepts like “the right to stay put” and “the right to the city” are championed by renters, empowering them to challenge displacement and advocate for more inclusive urban futures (Marcuse, 2009; Newman & Wyly, 2006), while in regions with a dominant culture of property, the emphasis on property ownership limits the political possibilities and poses challenges for imagining alternative urban futures.

The paper first traces the history of redevelopment engaging with Korea’s developmental history. Particular focus is placed on understanding the sociopolitical factors, institutional framework, and legislations that have governed and facilitated large-scale redevelopment in Seoul, South Korea. By doing so, the paper highlights how property rights have become seen as the only legitimate interest in redevelopment, entrenching the exclusion of renters as key stakeholders in urban transformation. The paper pivots from this historical perspective to provide a more contemporary, in-depth examination of the mechanisms in which a culture of property is sustained. Drawing on 36 interviews with residents, both property owners and renters, and government officials, I demonstrate how the internalization of a property rights-oriented mind normalizes displacement, eviction, and exclusion. In the end, I argue that a culture of property, which positions property rights as the paramount determinant of whose voice is heard in shaping cities, leads to significant and consequential political outcomes.

From Flower Farms to High-Rises: Reading Peri-Urban Land Transformation in Greenbelts, South Korea

Abstract ID: 1844.0.0.370.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Soo Yeon Lim [Bloustein School, Rutgers University] sooyeon.lim@rutgers.edu, presenting author

This paper examines how peri-urban flower farms in the greenbelts of the Seoul Metropolitan Area (SMA) have been made 'developable' for state-led urban development through technical, regulatory, and discursive planning tools. Cities have sought to control urban growth by restricting development around their perimeters through greenbelts, which are widely implemented in places such as London, Baltimore (Maryland), Toronto, Seoul, and Beijing. Globally, greenbelts face persistent pressures for deregulation, often justified by the need to expand urban housing capacity. The South Korean government has been at the forefront of greenbelt deregulation, developing high-rise residential buildings on the peri-urban SMA. Initially introduced in the 1970s, greenbelts were a land-use regulation prohibiting large-scale urban development, densification, and housing production for three decades. Since the 2000s, however, greenbelt land development has become the primary mode of housing production in the SMA, South Korea.

Among the more than 20 official land use categories in South Korea, greenbelt housing developments primarily target peri-urban farmland, which has long been home to flower farmers. As a result, ten of the SMA's 34 flower farming communities have either disappeared or are facing imminent displacement as high-rise buildings take over low-rise floriculture communities (J. Choi, 2014, pp. 40–53). Local communities emphasize that greenbelt development has become a zero-sum game against them. In contrast, official planning rhetoric highlights that the development is for the greater good, using 'low-value' land damaged or used in undesirable ways. The images of flower farmers' polytunnels—greenhouses made of plastic covers and steel pipes—are communicated as an example of inappropriate peri-urban land use in policy discussions and media reports. However, the rationales, as well as the counter-rationales behind the politics of land development, have not been sufficiently explored.

Peri-urban land developments have been central sites where contemporary urban dynamics unfold globally (Caldeira, 2017; Keil, 2017). Informed by scholarly discussions that view land as a social relation and a political-economic process (Balakrishnan & van Maasakkers, 2021; Li, 2014), this paper examines how peri-urban flower farms in the SMA are made 'undesirable' and, therefore, 'developable' for housing projects in greenbelt land regimes. I explore this issue through a case study of Gwacheon City, where over 90 percent of the city's land is designated as greenbelt and has a high concentration of flower farmers. In my analysis, I examined the greenbelt land grading system and the evolving peri-urban land use regulations. Furthermore, I conducted ethnographic observations and 41 semi-structured interviews with land development experts, local floriculture communities, and former staff at the municipal government.

The resulting content analysis of interview scripts, documents, and photographs demonstrates that flower farms have been marginalized in official land use planning narratives through socio-political and aesthetic claims about peri-urban ideals. The socio-political narrative positions high-rise residential developments as the ultimate planning goal for societal progress, diminishing greenbelts' potential to accommodate alternative land uses, livelihoods, and opportunities in the peri-urban SMA. The aesthetic claims, which are often framed as environmental issues, focus on the exterior appearance of flower farmers' polytunnels and portray them as unsightly structures that make greenbelts appear 'white' rather than 'green.' By examining multiple entry points to interpreting the land—land use categories, the materiality of built structures constituting the landscape, and the lived experiences of local

residents—this paper situates the peri-urban land development within the broader landscape of contemporary urban politics in South Korea.

Externalities and the Logic of Public Development Planning in New York City

Abstract ID: 1844.0.0.432.2025

Track 8: Land Use Policy and Governance

Pre-Organized Paper Presentation

Laura Wolf-Powers [Hunter College] aw2416@hunter.cuny.edu, presenting author

James DeFilippis [Rutgers University] jdefilip@rutgers.edu

Planners and policy makers have increasingly relied on market logics and market rationales in how they think and act. This is particularly true when it comes to land use planning and land development. The critique of the centrality of “highest and best use” in land use planning has a long history (Fainstein, 1991, Swanstrom, 1997, Wolf-Powers, 2005). Few scholars, however, have explored the extent to which planners have abandoned the obligation to address market failures introduced by the existence of externalities. Economic externalities have long played a role in justifying planning (see Klosterman, 1985), and even the most anti-interventionist of theorists, such as Hayek (2007), see a role for planning when it comes to dealing with both negative and positive externalities (as well as public goods). Land use planners in New York City, however, have forgotten even this narrowly economic justification for planning.

This paper presents the case of the Brooklyn Marine Terminal (BMT) project on the Brooklyn waterfront as an example of planning that is uneconomic even from the perspective of the most orthodox economists. BMT is a freight infrastructure project that will benefit the entire New York City region, but its planning process has erased those benefits to the larger region. A properly functioning set of piers at the BMT would yield more efficient freight movement via water and thereby fewer trucks on the road (and the congestion, pollution, accidents, and road wear and tear that come with those trucks). In spite of clear positive externalities, the planning for this project is being conducted within a conceptual framework that requires infrastructure costs incurred in stabilizing and modernizing the piers to be paid for by revenues generated on site. We assert that planners in New York City, in arguing that development on public land must somehow “pay for itself,” have erased from their thinking the concept of the public sector’s obligation to correct market failures by facilitating the internalization of negative externalities and the capture of external benefits. We make this argument not because we believe that planning should be constrained to solely addressing issues of externalities and public goods (as per Hayek), but to say that planning has shrunk in its logics to an even more conceptually reduced form than even free market idealists have advocated. New York City planners and economic development officials maintain that they are acting pragmatically; we argue for a different definition of pragmatism (Healey, 2008); for the incorporation of social rationality into public decision-making (Friedmann, 1987); and at the minimum for a restored adherence to the uncontroversial premise that the internalization of market externalities is an appropriate role for government.

Track 8 Roundtables

Resident Engagement in Housing Reform: What difference does it make?

Abstract ID: 1843.0.0.562.2025

Track 8: Land Use Policy and Governance

Roundtable Submission, Topical Discussions

José Meléndez [University of Oregon] jmelende@uoregon.edu, organizer

Anaid Yerena [University of Washington, Tacoma] yerena@uw.edu

Rachel Berney [University of Washington, Seattle] rberney@uw.edu

Damian Pitt [Virginia Commonwealth University] dpitt@vcu.edu

This roundtable will feature Pacific Northwest scholars studying public engagement in local housing reform efforts. They will discuss what impact different engagement strategies have—whether they lead to meaningful change or simply draw the same participants and preserve the status quo.

Typically, housing reform conversations and research focus on zoning reform policies and outcomes, while providing little or no attention to how the public was engaged during the creation and implementation of said policies. This may be due to housing reform traditionally being taken up by legislative bodies or housing/planning commissions, both of which commonly only offer public comment periods as their public engagement method. However, as housing policy reform has become more urgent, more methods are being taken up by jurisdictions to engage residents in these efforts.

Dr. José W. Meléndez will highlight insights from an ongoing project investigating the public engagement efforts in addition to the development code revisions and update process in response to Oregon, in 2019, becoming the first state to push middle housing zoning changes at the state level (HB2001). The research team completed a comprehensive inventory of 11 cities public engagement methods, in addition to interviewing planning staff in 10 of the 11 cities that were involved in the HB2001 implementation. He will share both the innovative coding scheme used to code cities efforts that was based on democratic goods that are essential in democratic institutions that engage lay members of the public and the resulting typology.

Dr. Anaid Yerena, will highlight insights from when the City of Tacoma implemented the Home In Tacoma zoning and development standards package in November of 2023—a bold policy shift aimed at increasing housing options, promoting affordability, and advancing equitable urban development. In this roundtable describe the key changes introduced through the new Urban Residential zones, including expanded housing typologies (e.g., backyard cottages, rowhouses, and townhomes), updated parking regulations, flexible lot standards, and requirements for tree preservation. The conversation will also highlight the City’s innovative Housing Equity Champions program, a grassroots initiative designed to ensure underrepresented communities have a meaningful voice in shaping Tacoma’s housing future.

Dr. Rachel Berney will highlight insights from the Equitable Development Zoning (EDZ) project, which aims to align land use policies with equitable development goals by removing regulatory barriers that hinder community-led projects, particularly those combating displacement and enhancing cultural networks. In July 2023, the City Council adopted zoning code changes to facilitate these objectives. Additionally, Seattle introduced policies in 2021 to support faith communities in developing affordable housing on property they own or control. This initiative (the

Religious-Organization Owned Property ordinance (ROOP)) grants religious organizations more flexibility to redevelop their land with long-term, income-restricted affordable housing, thereby contributing to the city's efforts to address the affordability crisis and support community-driven development.

Finally, Dr. Damian Pitt is a member of the citizen advisory commission for the current zoning rewrite process in Richmond (VA), which like many other jurisdictions is tackling all of these issues in real time, including allowing for much more missing middle housing. Dr. Pitt will provide initial commentary on how the efforts undertaken in the PNW can be taken and applied elsewhere in the country, while also highlight relevant issues that may be regionally/context dependent. He will moderate the discussion between researchers and participants.

Track 8 Individual Paper Presentations

Are Plans and Policies Integrated for Community Flood Resilience in Indigenous Communities?

Abstract ID: 1844.0.0.465.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Siyu Yu [Texas A&M University] syu@arch.tamu.edu, presenting author

Kin Long Lei [Hazard Reduction and Recovery Center, Texas A&M University] kl934@tamu.edu

Michelle Annette Meyer [Texas A&M University/ Hazard Reduction & Recovery Center] mmeyer@arch.tamu.edu

Maria Koliou [Texas A&M University] maria.koliou@tamu.edu

As a manifestation of weather extremes, various types of natural hazards are rising in many parts of the world. These include extreme heat, wildfire, and – in the case of many coastal communities – flooding. For instance, the infamous Mississippi River Flood of 2011 has caused an economic loss of over \$2.8 million in the state of Louisiana (National Oceanic and Atmospheric Administration, n.d.). Similarly, in the summer of 2021, southern Louisiana experienced a heavy thunderstorm, which brought one foot of rainfall within merely 24 hours (Di Liberto, 2021). This strong rainfall led to severe flash floods, which many communities were left with no means to cope with (Di Liberto, 2021). While the impacts of flooding are devastating, they are more concerning since their burdens tend to fall disproportionately on populations that have been historically disenfranchised. Indigenous communities are oftentimes one of these communities being disproportionally impacted (Colchester, 2004; Robertson, 2015).

The physical environment in which a community is embedded plays a substantial role in shaping its resilience to natural hazards. As an important force behind the physical environment, urban planning is thus an activity with much potential to promote resilience. This is particularly so when planning policies are coherently oriented toward this purpose. However, when the policies are not integrated, as empirically found to be commonly the case, they can instead weaken resilience. Recognizing this, several studies have been conducted in recent years to evaluate plan integration. Nonetheless, no study has touched on the context of Indigenous communities. We pioneer in this study to adopt and apply the Plan Integration for Resilience Scorecard-TM (PIRS-TM) (Berke et al., 2019; Yu et al., 2023; Malecha et al. 2019) – a well-established method for plan integration evaluation – to an Indigenous community and its surrounding localities in the southern United States. We illustrated this method in the reservation and addressed the following research questions:

1. Is the plan network integrated in promoting community resilience to flooding?
2. Is the plan network paying enough attention to the Indian reservation when promoting community resilience to flooding?

We find that the land-use / development plans are integrated overall in promoting community resilience for current and future flood risks, particularly the former. By comparing the results between the reservation and the surrounding communities, we also assess if the plans are prioritizing the tribal community when promoting resilience – the more fundamental policy reasons behind such are also highlighted. These findings can directly contribute to refining the plans being examined. The methodology demonstrated has an even broader significance as it illustrates the approach to evaluate plan integration that other Indigenous communities can utilize.

Such knowledge is significant for planning practitioners since it enables the continuous tracking of their performance regarding plan integration for resilience. It also allows for identifying policies contributing to the integration and those working against it. These conclusions can, in turn, help practitioners refine their plan ecosystem to more effectively support the community's hazard resilience.

Compactness in Shrinking Cities: Rethinking Density for Urban Adaptation

Abstract ID: 1844.0.0.603.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Putu Indah Adnyani [Ulsan National Institute of Science and Technology] putu.indah@unist.ac.kr, presenting author

The compact city model, widely promoted as a sustainable urban development strategy, emphasizes densification, mixed land use, and transit-oriented growth (Kikuchi et al., 2022). Previous studies have found a significant contribution of compact city policies to sustainable urban development in high-density cities (Bardhan et al., 2015). This is true for such land-use planning approaches that were primarily designed to regulate and direct urban growth, but often proven inadequate in shrinkage scenarios (Galster G., 2019). However, its application in shrinking cities, where areas are of low density, presents a fundamental paradox: while compact city strategies rely on pro-growth planning, shrinking city solutions often align with degrowth principles, advocating for de-zoning, adaptive reuse, and managed contraction.

This study argues for a nuanced land-use framework, leveraging densification where compact urban forms persist while allowing for strategic de-zoning in areas undergoing long-term decline, as a more effective response to shrinking city conditions. In doing so, it addresses how compact city strategies and urban shrinkage spatially intersect in small and medium-sized cities, what built environment characteristics define compactness, and how densification can be aligned with urban decline to better serve existing residents. To capture this complexity, we develop a comprehensive compactness metric that integrates traditional urban form indicators, such as density, land use mix, and accessibility, with computer vision-derived data from street view images. With the advancement of computer vision, street view images may provide new data of both subjective and objective variables of an urban scene. Advances in computer vision enable the extraction of both subjective and objective variables from urban scenes, allowing us to incorporate perception-based attributes like safety, beauty, and vibrancy alongside built environment features such as vegetation, buildings, roads, and pedestrian activity (Naik, et al., 2017; Zhang et al., 2018). We apply principal component analysis (PCA) to synthesize these variables, distinguishing between compact and dispersed urban patterns. Using a spatial clustering approach, we classify urban areas into distinct typologies, differentiating compact urban forms from areas experiencing decline, as well as transitional spaces that exhibit characteristics of both. Our study focuses on small and medium-sized South Korean cities (populations around 100,000), providing an empirical foundation for understanding spatial adaptation in shrinking urban environments.

Findings reveal distinct spatial zones where compact city principles remain viable mainly concentrated in the city center area, contrasted with the outer parts where urban shrinkage. This suggests different planning approaches are needed for cores and peripheries. Rather than treating compactness and shrinkage as mutually exclusive, this study proposes a hybrid land-use framework: targeted densification in urban cores while facilitating strategic de-zoning in peripheral areas. By redefining compactness as a concept adaptable to shrinkage rather than growth, this shifts viewing city centers not as engines for economic expansion, but as attractive living environments that prioritize well-being of the existing residents. This study contributes to land use policy discussions by offering a spatially explicit evaluation of compact city feasibility in shrinking urban contexts, bridging the gap between smart growth ideals and shrinking city realities.

Individual Paper Presentation Submission

Youjung Kim [University of South Florida] youjungkim@usf.edu, presenting author

Restricting development in flood-prone areas is essential for long-term flood risk management. However, many U.S. cities continue to permit development in vulnerable coastal and riverine areas (Highfield et al., 2013; Hino, 2023) due to population growth, the appeal of waterfront living, and low flood risk perception (Akhter et al., 2021). Many U.S. floodplain communities, including New York, NY; Houston, TX; and Tampa, FL, have permitted floodplain development in accordance with building codes—such as freeboard requirements, which mandate elevating structures an additional height above the Base Flood Elevation (BFE)—established based on the guidance of the Federal Emergency Management Agency (FEMA) (Aerts & Botzen, 2012; City of Houston, 2018). Although these measures have been widely implemented, empirical evidence on their effectiveness remains scarce, largely due to difficulties in monitoring flood damage and in precisely assessing first-floor elevations.

This study examined the effectiveness of first-floor heights in mitigating flood risk on Davis Islands in Tampa, Florida, in the aftermath of the 2024 flooding caused by Hurricanes Helene and Milton. The research questions are: (1) How has first-floor height changed over time on Davis Islands? (2) How do different elevation measures (ground elevation, relative first-floor height, and absolute first-floor height) influence the likelihood and extent of flood damage? (3) What is the critical first-floor height threshold that significantly reduces the likelihood of flood damage? This study uniquely utilizes first-floor elevation data, captured through mobile LiDAR, to accurately represent flood risk exposure in terms of height. Additionally, it incorporates ground-truth flood damage data, combining the author's windshield survey with storm damage assessments from the City of Tampa. To answer the questions, this study employs a combination of descriptive analysis, regression modeling, and predictive visualization to examine ground elevation, and relative first-floor height, and absolute first-floor height influence flood damage on Davis Islands.

The findings of this study underscore the crucial role of elevation in mitigating flood damage. The scatter plot of first-floor height and year built reveals a clear shift in first-floor height trends before and after 1980, reflecting changes in construction practices and elevation standards over time. In the regression results, both ground elevation and relative first-floor height significantly reduce the likelihood of flood damage. However, ground elevation exerts a slightly stronger protective effect per foot, suggesting that site selection (i.e., choosing higher terrain) may be as important or even more important than elevating structures alone. The regression result of absolute first-floor height also demonstrates a strong negative relationship to flood damage, with higher elevations significantly lowering the probability of flood damage. Furthermore, the predicted probability curve shows a steep decline in flood risk for buildings elevated up to 10–12 feet, after which the risk stabilizes at near-zero levels.

These findings contribute to a deeper understanding of the relationship between first-floor elevation and flood damage, offering critical insights for policymakers and urban planners seeking to strengthen flood resilience in coastal communities. Additionally, the findings support FEMA's guidance on elevating buildings' first-floor height above the BFE for floodplain development. This research highlights the importance of data-driven evaluation of building code regulations in mitigating flood impacts amid increasing climate-related hazards. It also underscores the role of advanced technology, showcasing how building elevations obtained through mobile LiDAR can serve as empirical indicators of flood damage.

Do New Towns Have Lower Carbon Footprint? A Case from South Korea

Abstract ID: 1844.0.0.338.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Jungyoon Seol [Korea Advanced Institute of Science and Technology] jungyoon@kaist.ac.kr, presenting author
Albert Tonghoon Han [Korea Advanced Institute of Science and Technology (KAIST)] albert.han@kaist.ac.kr

The Paris Agreement's emphasis on global greenhouse gas reduction and carbon neutrality has prompted various countries and cities to propose and implement carbon neutrality policies, with South Korea, for example, establishing its 2050 Carbon Neutrality goal in 2020. Decarbonizing cities are essential since energy use in urban areas account for about 71% of global carbon dioxide emissions. Existing research examined how urban land-use structure, continuity, and shape complexity affect carbon emissions. Since the 1990s, South Korea has built New Towns outside Seoul to manage population growth and housing shortage. These towns feature large parks, community facilities, public transit, and stringent building codes for enhancing energy efficiency. Analyzing these urban features is crucial to understanding their effectiveness in reducing energy and carbon footprints.

Master-planned New Towns in Korea present an opportunity to test whether various emerging urban planning concepts such as sustainable development, Smart City, and net-zero city have yielded their intended effects. The first phase of the new town development primarily focused on addressing housing shortage problems creating bedtowns around the city. The second phase focused on large-scale urban planning to prevent haphazard development and promote sustainable development, incorporating green transportation, public transit systems, and ecological parks. The third phase of new town development emphasized increasing green space, transit-oriented infrastructure, and smart city technologies. New towns are evolving their plans to develop into sustainable cities by expanding from merely addressing housing issues to incorporating new technologies to address carbon neutrality.

In this research, we analyzed whether the planning elements for decarbonization including energy efficient buildings, public-transit system, and large park system functioning as carbon sinks have contributed to reducing the carbon footprints of New Towns. We first analyzed the association between carbon emissions and various urban and environmental factors including variables representing 1st, 2nd, and 3rd phases of New Towns at the administrative district dong level in Seoul Metropolitan Area consisting of city of Seoul, the city of Incheon, and Gyeonggi Province. As New Towns were developed in phases, the analysis period was set to years of 2000, 2010, and 2020 during which each phase of New Town developments were completed or nearly completed. To isolate the carbon reduction effects of New Towns, we divided administrative districts in the SMA with similar residential areas as the comparison group.

Our preliminary findings suggest that New Towns built in later phase with energy efficient buildings and large park systems slightly reduce carbon emissions in the comparison group. Environmental factors such as the park area and green area have always negative correlations with carbon emissions in every analysis. As the number of vehicles was a significant variable correlated with carbon emissions only in the 2020 analysis, this suggests that the farther New Towns in later phase were built from Seoul, the greater the dependence on automobiles.

From these findings, we may be able to identify which of the planning factors (e.g., land use pattern, density, and transportation) could effectively reduce carbon emissions in large residential development projects like New Towns. Although this study focused on the Korean cities, the planning implications derived from this study could shed

insights into developing effective decarbonization strategies for large-scale residential development projects in other countries.

Do Smart Growth Policies Lead to More Compact Residential Subdivision Patterns?

Abstract ID: 1844.0.0.1012.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Samto Wongso [University of Wisconsin-Madison] swongso@wisc.edu, presenting author

Aslıgül Göçmen [University of Wisconsin-Madison] gocmen@wisc.edu

Land use policies in local zoning and subdivision ordinances of U.S. planning jurisdictions have largely favored automobile-dependent, low-density development by capping residential density, restricting allowable land uses and housing types, and prioritizing automobile infrastructure over infrastructure for other modes of transportation. To create more sustainable development patterns, planning scholars and smart growth advocates have urged local jurisdictions to amend their ordinance texts and maps to integrate smart growth policies that promote high densities, diverse land uses, interconnected streets, accessible destinations, and nearby transit (Talen, 2012). As local governments have gradually reformed or are considering reforming their ordinances, empirical evaluations on the extent to which the prescribed ordinance changes have resulted in more compact development are necessary to inform and improve future land use policies.

In this study, we seek to fill knowledge gaps regarding the relationship between smart growth policies and development outcomes. Studies in this area include Song's (2005) spatial analysis of subdivision design following the implementation of smart growth instruments, in which she observed some positive changes in subdivision design following the implementation. Song's (2005) analysis provided valuable results, but she did not establish direct links between specific local policies and the observed spatial patterns. In the past few years, relevant assessments have primarily investigated the impacts of zoning reforms on housing densities and diversities (e.g., Dong, 2025; Huennekens, 2023). These studies have generally documented positive changes while also acknowledging the influence of other factors, such as market forces, socio-demographic characteristics, and fiscal policies, on development outcomes. In other words, the planning literature has yet to provide adequate empirical evidence on the effectiveness of many of its prescribed smart growth policies, especially those intended to promote land use mix, street connectivity, and accessibility for non-auto users.

Our study seeks to answer whether planning jurisdictions that have adopted certain smart growth policies have indeed developed more compact residential subdivisions than those that have not. Our sample is 13 Wake County planning jurisdictions that have integrated smart growth principles into their ordinance texts and maps at varying levels. To address the question, we created an inventory of land use regulations and zoning districts for each sample jurisdiction and conducted a spatial analysis—using metrics adapted from Song's (2005) study—to measure density, land use mix, housing diversity, and internal street connectivity in subdivisions developed between 2011 and 2022. We then examine whether the results of the subdivision spatial analysis are associated with the presence of certain relevant land use policies.

Our preliminary analysis indicates that subdivisions with higher street connectivity and greater housing density are located in jurisdictions that have included additional regulations promoting street connectivity and larger zones for higher-density or multi-family housing. However, jurisdictions that permit a wider range of housing types and select commercial uses in residential zones have not necessarily developed new subdivisions with greater housing or land use mix. The limited number of subdivisions with mixes of single-family, multi-family residential, and commercial uses appears to be primarily the result of planned unit developments (PUDs), with some enabled by traditional neighborhood development (TND), conditional zoning, or mixed-use district regulations. This finding echoes David's

(2015) conclusion that municipalities in Michigan were more successful in achieving compact development patterns through PUDs than through other land use regulations.

Geographies of Transfer: Building Data Systems for TDR Management

Abstract ID: 1844.0.0.773.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Todd BenDor [University of North Carolina at Chapel Hill] bendor@unc.edu, presenting author

Joanne Chen [University of North Carolina at Chapel Hill] joannec@unc.edu

Transfer of Development Rights (TDR) is a much-discussed, but comparatively rarely used, land use planning tool whose use in the US has reflected the popular shift towards market-based policies (Linkous, 2016). Under TDR programs, development rights are transferred from sending sites—often historic or environmental protection areas—to receiving sites. In addition, local governments have adopted TDR tools for urban growth control or enable special projects under increasing development (Chiodelli & Moroni, 2016). However, despite significant attention, few studies have analyzed transaction-level details, such as limited data on credit prices and lack of transparency (BenDor et al., 2022; Linkous, 2017).

This study seeks to determine how TDR programs collect, manage, and distribute data on program operations. Using TDR program data, we also seek to understand how transfers shift development rights spatially across jurisdictions (and neighborhoods with defined socio-economic characteristics). Based on these evaluations, we also seek to establish a flexible and extensible data model that would allow a wide range of TDR programs to improve their operations and outcomes.

We rely on the TDR program database constructed by BenDor et al., (2022), which consists of 375 programs across 39 States. We contacted all 375 programs and received 20 responses (18 useful for analysis and 7 with location identifiers) that included some form of data on transactions within TDR programs. Mapping the sending and receiving sites of these 7 programs onto US Census Tracts, we performed paired Wilcoxon tests to compare the neighborhood socio-economic characteristics of sending or receiving sites.

We assessed the organization of collected data using entity-relationship (ER) model in database design (Chen, 1977), mapping out common relationships between attributes and entities in even the most complex programs. We applied normalization techniques to structure a data model that collected data necessary for TDR program monitoring and evaluation, as well as for reducing redundancy and improving data integrity. Finally, we created a master ER diagram – a conceptual map for understanding data needed to track transactions and programs – depicting this data model.

Our results suggest widespread data scarcity – either in what was collected or distributed – in TDR programs. We found that TDR transactions are typically recorded in scattered formats, such as tables, permits, and deeds, rather than in unified databases. Most TDR programs record acres transferred, approval dates, site entitlements, zoning, location, and transaction status, while credit fees and calculation details appear less consistently. Additionally, ad hoc notes often clarify merged cases or special program conditions. Overall, TDR program operations reflect a many-to-many relationship between sending and receiving sites, whereby credits can flow through a variety of transfer pathways. Transfers are complex, often occurring in phases across repeated transactions, with calculations tailored to match sending site capacity with receiving site demand.

We propose a data model that connects sending and receiving sites, which each can represent hierarchical objects consisting of parcels or groups of parcels, to TDR credit “banks” – accounts representing amassed TDR credits that have yet to be fully transacted to receiving sites. These connections occur through transactions. The transaction

table connects the other three tables, respectively, with a primary key for sending site ID, receiving site ID, and a composite key for sending bank ID and receiving bank ID.

The proposed database allows the systematic tracking of TDR transactions, which is flexible for program adjustments or changes. This academically supports transparency and reproducibility in research and bridges theory and practice, practically performs advanced program evaluation, and reveals institutional constraints and governance issues.

How Just is TOD? The Incorporation of Transit-Oriented and Just City Planning by Brazilian Cities

Abstract ID: 1844.0.0.803.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Natalia Arruda [Arizona State University] narruda@asu.edu, presenting author

Brajesh Karna [Arizona State University] brajesh.karna@asu.edu

Transit-oriented development (TOD) is a worldwide approach that aims to achieve compact and sustainable urban growth, relying on zoning overlays and high-quality transit systems. While the TOD model has been associated with increased transit ridership, creating mixed-use, and mitigating greenhouse gases, it has also been criticized for spurring gentrification and displacement. The model has evolved in the academic field and planning sector to incorporate inclusivity and equity concerns into proposed frameworks. However, there is much to learn about how local agencies articulate the TOD concept and theoretical ideas of justice in their plans, especially comprehensive plans. This research helps address this gap by evaluating the relationship between transit-oriented planning and just city planning. It builds on a preliminary analysis of 39 comprehensive plans from all Brazilian cities with an operational rapid transit system (BRT, LRT, and Metro). It draws on an exclusive database that expands the analysis of comprehensive plans to the 145 most populated Brazilian cities, therefore allowing for enough variation. It aims to answer the research question: Which Brazilian cities have the most transit-oriented plans, and how does transit-oriented planning relate to just city planning?

We apply a range of advanced natural language processing techniques to this end. In particular, we use semantic network analysis - Word2Vec embedding - and dictionary analysis to capture the contextual relationship of the two concepts (Just City and TOD), their prevalence, and networks, with the data analysis expected to be completed by May 2025. Three different dictionaries are adopted to capture the TOD concept and its nuances based on distinct frameworks: the 6-D framework developed by TOD scholars, which is well-established in the literature, and the TOD frameworks developed by the ITDP and the WRI, which have been applied in the Brazilian context by academics and practitioners. To capture theoretical ideas of justice in the planning documents, we build on the Just City theory, proposed by Susan Fainstein.

The hypothesis is that cities with a more TOD-oriented general plan are more likely to embrace values that promote justice in urban planning. We anticipate similar results from our preliminary study: a disparity in adopting the TOD model across different cities. Despite the growing interest in TOD as a framework for achieving sustainable urban mobility and development, we anticipate a significant gap between the acknowledgment of TOD principles and their effective implementation. Despite the TOD principles' presence in the planning documents, land use and transportation integration goals remain fragmented. This study will provide exploratory findings with policy implications.

How Useful Can a Land Use Planning Approach Be in Mitigating Coastal Vulnerability?

Abstract ID: 1844.0.0.986.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Seongyeong Lee [Pusan National University] 2018525255@pusan.ac.kr, presenting author

Climate change is no longer considered preventable by human intervention. Studies show that even with rapid carbon neutrality, global warming and sea-level rise are inevitable. Thus, adapting to climate change and disasters has become crucial. Coastal cities, in particular, must address these challenges.

Coastal areas hold high value as tourist and residential zones, leading to extensive development and continued demand. This increases coastal vulnerability and complicates adaptation efforts. South Korea, a peninsula with limited land and mountainous terrain, faces heightened risks of coastal disasters and land loss due to sea-level rise.

Assessing vulnerability and verifying urban planning's role in mitigation are essential. This study employs the Coastal Vulnerability Index (CVI) and a land-use planning approach to analyze (1) current and (2) future vulnerabilities under sea-level rise. Five land-use scenarios are then applied to highly vulnerable areas to assess mitigation effects.

The InVEST Coastal Vulnerability Model was used, integrating climate change scenarios into CVI while allowing easy visualization. This model evaluates coastal vulnerability considering regional characteristics. With growing concerns over worsening vulnerability, it is crucial to examine changes over time. After assessing present and future vulnerability, land-use scenarios were applied to high-risk areas. This aligns with the idea that land-use planning supports long-term disaster prevention.

Scenarios were applied within 500m of the shoreline and included: (1) full development, (2) preservation of ecologically valuable areas while continuing planned developments, (3) preservation with minimal development in low-ecological-value areas, (4) full preservation of valuable areas with no planned developments, and (5) complete conservation. Land cover maps were reconstructed based on urban planning data to observe changes in vulnerability. Unlike previous studies that simplified scenarios, this study explicitly incorporated development plans and ecological value.

Results showed high vulnerability in two regions: Kkotji Beach (west coast) and Wonpyeong Beach (east coast), both exceeding a 3.7 vulnerability score pre- and post-sea-level rise. Scenario applications revealed:

Kkotji Beach exhibited significant differences in vulnerability across scenarios due to concentrated planned developments, high exposure to sea-level rise, and clustered ecologically valuable areas. In contrast, Wonpyeong Beach had few planned developments and evenly distributed ecological value, leading to minor vulnerability changes except in the full development scenario.

South Korea lacks systematic policies for coastal vulnerability mitigation. Most measures focus on structural approaches, with limited vulnerability assessments. While structural solutions offer short-term benefits, unintended consequences have increased advocacy for non-structural approaches.

This study contributes by comprehensively assessing coastal vulnerability and empirically demonstrating the effectiveness of non-structural approaches. It also highlights land-use planning's potential to shift policies away from structural responses.

Comparing Kkotji and Wonpyeong Beach, findings indicate that while preserving natural areas is crucial, restricting development in high-risk zones should be a priority to mitigate coastal vulnerability effectively.

Instagrammable Neighborhoods, Youth, and Revitalization of HUA: An Individual Perception Analysis

Abstract ID: 1844.0.0.713.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Jiahui Liu [Southeast University] 1683944232@qq.com, presenting author

Xiaosu Ma [Southeast University, School of Architecture] maxs@seu.edu.cn

Historic urban areas (HUA) are currently facing an unsustainable threat to urban vitality due to the pressures of an aging population. In response to the Chinese government's initiative to promote youth-friendly cities, local authorities are exploring diverse strategies aimed at attracting young adults to reside in HUAs. At the same time, social media platforms, such as RED note, have a growing impact on young people's activity preferences and daily lives. And the prevalence of social media has led to the emergence of instagrammable neighborhoods, enabling traditional residential districts to adopt new-era urban functions. In fact, despite the aging population, outdated infrastructure, increasingly noisy living environments, these neighborhoods exhibit vibrant rental markets with relatively lower rents. It may appeal to the young generations who are seeking affordable entry points into big cities. Therefore, it is both a challenge and an opportunity of neighborhood revitalization.

This study selects a representative instagrammable neighborhood, i.e. Kexiang in Nanjing, China, as its empirical case study, which is identified through 7862 RED note posts. The built environment and vitality characteristics are captured by clustering 246 panoramic videos of public spaces in the HUA from a pedestrian perspective. A stated-preference (SP) questionnaires is further designed to collect the activity preferences and intentions of various public spaces. Anonymous participants were required to provide information on their socioeconomic background and current activity habits in the public space. Furthermore, participants made sequential choices, including binary public space preferences and ultimate residential selections between scenes selected from the aforementioned clustered panoramic video samples. An SEM-logit model was then applied to capture both tangible and intangible factors that influence activity decisions, e.g. visual and auditory perception, historical-cultural as well as vitality atmosphere. From the influencing factors and participants' residential choice between two scenes, it identified peoples' preferences regarding public space activities and residential choices, evaluating the feasibility of youth inhabitation in these neighborhoods and propose improvement strategies.

The model results demonstrated distinct preference patterns for different public space scenarios among different demographic groups. And it would reveal potential correlations between existing vitality characteristics, environmental attributes, and behavioral patterns, which helps to assess the risk of unsustainable vitality, such as over-commercialization or cultural homogenization. The preliminary analysis indicated that social media significantly shapes young people's choices public spaces and accommodations, as they show strong interest in visiting online-viral public spaces and consider online recommendations when selecting settlement cities. Moreover, newly renovated environments and supporting facilities accompanying internet popularity in trendy neighborhoods are particularly significant for youth. These internet-tailored changes meet their entertainment and social needs. It further offers valuable insights for urban planning and policy decisions. Since local governments could have several potential urban renewal strategies for these neighborhoods, including converting existing residential properties for commercial redevelopment aligned with current viral trends. Alternatively, they could focus on preserving residential functions and attract new residents through targeted improvement of residential environments. Our research provides a framework to identify neighborhoods suitable for commercial development versus those better maintained as residential communities. This long-term perspective helps prevent short-sighted commercial transformations driven by uncertain internet trends that may undermine original community values.

Interlinking Transit-Oriented Development and Zoning Reform: A Comparative Study of Four U.S. Cities

Abstract ID: 1844.0.0.117.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Zekun Li [The Ohio State University] li.12350@osu.edu, presenting author

Bernadette Hanlon [The Ohio State University] hanlon.42@osu.edu

Cities are complex systems shaped by the interplay of policies and the dynamic interactions among urban elements. Zoning reform and transit-oriented development (TOD), as two important tools for improving accessibility, housing affordability, and sustainable development, have attracted significant scholarly and policy attention (Freemark, 2023; Mathur and Gatdula, 2023). However, there is still a limited understanding of how these policies interact with each other in theory and practice, and how their coordination impact urban dynamics. To bridge this gap, this study conducts a comparative case analysis of New York, Minneapolis-St. Paul, Seattle, and Miami.

First, I draw on two major strands of academic literature to build a theoretical framework that understands the relationship, complementarities, and potential tensions between the two policies: (1) zoning reform as a prerequisite for TOD, including tools like upzoning, mixed-use allowances, and parking requirement reductions, to set the conditions for TOD success (Ibraeva et al., 2020). (2) TOD projects as a catalyst for zoning reform, by impacting density, parking ratio, and housing affordability (Soliz et al., 2024).

Then I chose New York, Minneapolis–St. Paul, Seattle, and Miami for in-depth comparative study based on their diverse geographic, demographic, and political contexts, as well as their active engagement in both TOD initiatives and zoning reform efforts. The case study integrates content analysis (zoning code changes, TOD projects, plans, reports and local policies) and spatial analysis to trace the implementation pathways and temporal-spatial coordination between TOD and zoning reform.

Preliminary findings suggest that cities where zoning reform preceded TOD implementation, such as Minneapolis-St. Paul, tended to exhibit stronger regulatory alignment and land use readiness, facilitating more cohesive and equitable TOD outcomes. Seattle also demonstrates strong coordination, with zoning updates and reduced parking minimums closely tied to TOD goals, enhancing walkability and mixed-use development. In contrast, cities like Miami, where TOD efforts preceded substantial zoning reform, often faced barriers such as restrictive land use patterns and community resistance, limiting the transformative potential of TOD investments. Similarly, New York is undergoing rezoning after TOD to address concerns about compatibility with existing neighborhoods and commuting patterns. These results contribute to a more nuanced understanding of how TOD and zoning reform can be strategically integrated. Planners and policymakers can draw on these actionable insights to maximize the potential of TOD and zoning reform in achieving sustainable and equitable urban development.

Land use configuration and its synergistic effects on heat island: roles of urban functional zones

Abstract ID: 1844.0.0.106.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Junheng Qi [Southeast University] junhqi@seu.edu.cn, presenting author

In the context of the growing urban heat island (UHI) effect, mitigating high land surface temperatures (LST) has become a key goal in urban planning. Identifying the key drivers of LST, especially the role of land use spatial configuration, is crucial for optimizing urban spatial layouts. Existing studies tend to focus on individual factors, such as building density, often overlooking the mechanisms of land use spatial configuration and its interactions with other key factors influencing LST. These gaps hinder a comprehensive understanding of LST drivers and limit the guidance for optimizing functional zoning in urban planning. To address these gaps, this study focuses on urban functional zones in the central city of Nanjing, using a LightGBM model combined with the SHAP (SHapley Additive exPlanations) framework to systematically analyze the nonlinear and synergistic effects of land use configuration on LST. The findings show that spatial configuration significantly affects LST, with distinct impacts across different functional zones. Moreover, strong interactions between spatial configuration and other key factors were identified, particularly between agglomeration and building form, fragmentation and the natural environment, as well as patch density and human activity factors. These innovations provide a refined methodology for high-precision analysis of spatial configuration and offer theoretical support for optimizing functional zoning in urban planning.

Local Land Use Governance & the Energy Transition: How Ordinances Shape Solar Development

Abstract ID: 1844.0.0.15.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Lina Moe [Rutgers University] mkm213@scarletmail.rutgers.edu, presenting author

One challenge of the climate crisis is that even a successful energy transition will catalyze waves of new infrastructure development and transform great swathes of the physical landscape. Building out renewable energy sources, particularly cost-effective, ground-mounted, utility-scale solar projects, will use large tracts of land to generate electricity, particularly affecting residents in areas with high solar radiation and cleared land near transmission lines. Yet, while the U.S. has set ambitious energy transition goals to meet its stated policy ambitions of zero CO₂ emissions by 2050, land use is largely shaped by local ordinances and zoning rules.

This study investigates how local ordinances influence solar development, examining the growing prevalence of zoning restrictions that facilitate, constrain, or outright block new development, addressing 1) What types of local ordinances are being adopted to regulate solar energy development, and how have they evolved over time? 2) How do we distinguish between reasonable local governance and unreasonable restrictions? 3) What factors predict the adoption of restrictive local solar ordinances?

By analyzing these questions, this study contributes to planning scholarship at the intersection of land-use regulation, energy infrastructure siting, and climate policy in a decentralized governance system. Utilizing a database of local ordinances and solar capacity growth by county, this study classifies land-use regulations as supportive, neutral, or restrictive, distinguishing between ordinances that impose moderate development conditions (e.g., setbacks, screening) and those that function as de facto bans (e.g., moratoria, excessive buffer zones). Second, using an event study analysis, I study whether counties with increasing solar capacity are more likely to pass restrictive ordinances. Following this, I use a difference-in-differences model to investigate what local political, economic, and geographic factors predict adoption of reasonable regulations compared to policies so restrictive they function as proxy bans. This approach distinguishes local governance choices that shape responsible solar development from those that act as barriers to decarbonization.

Preliminary findings indicate that the number of local solar ordinances has increased significantly in the past decade and their content varies widely, with a growing number instituting strict permitting barriers that function as bans compared to ordinances that impose workable setbacks or other siting requirements. Counties with rapid solar capacity growth appear more likely to pass restrictive ordinances, suggesting a reactive regulatory response. Additionally, the political misalignment between local and state governments—where the local majority party differs from the state—appears to predict ordinance adoption, highlighting tensions in governance structures.

This study builds on a growing body of work quantifying how local land-use regulation shapes energy transitions. As states seek to accelerate renewable energy permitting and siting, understanding how local rules act as regulatory guardrails or as obstacles to progress is critical. For practitioners, the study offers evidence on the types of local regulations regulating solar energy development. For scholars, this study contributes to multi-level governance research about how decentralized regulatory power affects the feasibility of national and state climate policies.

Preservation or NIMBYism? Tension Between Historic District Designation and Zoning Reform in Seattle

Abstract ID: 1844.0.0.780.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Sunho Choi [University of Washington] sunhoch@uw.edu, presenting author

Manish Chalana [University of Washington] chalana@uw.edu

Many American cities continue to experience housing affordability challenges due to housing shortage and rising prices, leading to the Yes In My Back Yard (YIMBY) movement and zoning reforms aimed at increasing residential supply. However, these supply-focused solutions frequently trigger significant opposition from residents who utilize various tactics to defend their neighborhoods (Einstein et al., 2020). Within the ongoing affordability crisis, the role of historic preservation remains controversial as to whether it limits housing supply or provides affordable housing (Cheong, 2020). Nevertheless, recent evidence suggests that historic district designations may be strategically utilized to resist change and maintain the status quo within higher-income and predominantly white neighborhoods (Choi et al., 2025).

In order to explore how tensions between historic preservation and housing affordability are reflected around zoning reforms, this research examines Seattle's case of three newly designated National Register Historic Districts and the recently legislated upzoning plan under the Mandatory Housing Affordability (MHA) program. A case study using various archival and document sources allows us to investigate how the procedures of historic district designations and upzoning plan development intersect and mutually influence each other. We also conducted a semantic network analysis of letters of interest submitted during the designation process of the three historic districts, aiming to identify various stakeholder perspectives and central themes of their narratives. This network approach maps the relationships between words, enabling the identification of prevailing topics and frames by revealing structural patterns in textual data (Segev, 2021).

The case study reveals that the designation of Mount Baker Park and Ravenna-Cowen North historic districts during the zoning reform process resulted in their exclusion from the City's final upzoning ordinance. This finding implies that the designation of a National Register Historic District, despite its honorary status, may serve as a de facto barrier to upzoning initiatives, especially in single-family zoned neighborhoods. In addition, the case of the Wallingford-Meridian Streetcar historic district with the semantic network analysis demonstrates contrasting narratives between opponents and supporters of historic district designation, highlighting significant tensions between neighborhood preservation and housing affordability. While opponents resist historic district designation, arguing that it can worsen housing affordability challenges and conflict with ongoing zoning changes, supporters advocate for it with an emphasis on long-term residency, neighborhood identity, and architectural character. Lastly, Seattle's case illustrates that the decision-making process for historic district designation remains largely detached from planning issues such as zoning and housing affordability, despite the shared concerns of planning and preservation regarding the neighborhood built environment (Minner, 2016).

Our findings provide a better understanding of the complex relationship between historic preservation and housing affordability within zoning changes. These findings also suggest policy implications for mitigating the tension between preservation and affordability, including a more integrated designation process that considers planning agendas and housing policies, as well as more flexible and inclusive land use policies to preserve neighborhood character while increasing development capacity. Moreover, insights from this study help identify common ground between sustainable growth and historic preservation, highlighting opportunities for cooperation between preservationists and housing advocates to find better solutions.

Research and Policy Perspectives on Land Use Planning in Wildfire Management

Abstract ID: 1844.0.0.678.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Tasnim Isaba [University of Utah] u1299549@utah.edu, presenting author

Divya Chandrasekhar [University of Utah] d.chandrasekhar@utah.edu

Arthur Fainkich [University of Utah] u1355195@utah.edu

Wildfire threats are intensifying across the US, making land use planning increasingly critical to comprehensive wildfire management. Despite this importance, a significant lack of consensus exists among academics and practitioners regarding how these strategies should be classified, adopted, or implemented within disaster management frameworks. This inconsistency directly impacts funding mechanisms, implementation timelines, and institutional responsibilities. Our systematic review examines how academic and policy documents classify various land use planning strategies within the traditional disaster cycle (preparedness, response, mitigation, adaptation, and recovery). By analyzing classification patterns across these domains, we identify key trends and consensus gaps that affect wildfire risk reduction efforts and policy implementation.

Land use planning serves a unique integrative role in wildfire management, bridging research and practice while connecting emergency response with long-term resilience building (Srivastava & Laurian, 2006; Mockrin et al., 2020). The classification inconsistencies identified by previous research directly impact planning implementation by affecting funding eligibility, timing, and resource allocation (Stevens et al., 2010; Berke et al., 2015; Lyles et al., 2014). For planning professionals serving as intermediaries, these discrepancies create significant challenges in navigating between research frameworks and policy requirements (Harris et al., 2011; Paveglio et al., 2018). While existing literature acknowledges the benefits of standardized terminology for interdisciplinary wildfire management efforts (Steelman & McCaffrey, 2013; Abrams et al., 2016; Thompson et al., 2018), there remains a notable gap in systematically analyzing how land use strategies are classified across academic research and policy applications. This gap is particularly significant for planning literature, as terminology inconsistencies not only complicate communication between researchers and practitioners but also hinder strategy implementation by affecting funding eligibility, allocation timelines, and inter-agency coordination mechanisms (Burby et al., 2000; Muller & Schulte, 2011; Calkin et al., 2014).

Following PRISMA guidelines, we analyzed 92 peer-reviewed articles (2013-2024) and 41 state/federal policy documents from high-risk western states. We constructed a structured evaluation protocol with five land use categories (building regulations, vegetation management, subdivision regulations, zoning regulations, and preventative strategies) encompassing 23 indicators. For each document, we systematically identified land use strategies and their corresponding disaster phase classifications. Our analyses included quantitative consensus score measurements, temporal pattern identification through heat mapping, and disciplinary cross-comparisons to assess classification variations.

Key findings reveal a fundamental "prevention-readiness dichotomy" between academic research and policy frameworks. Academic literature predominantly classifies land use strategies as mitigation measures (74%), while policy documents distribute them more evenly between mitigation (51.6%) and preparedness (40.5%). This dichotomy echoes longstanding tensions in planning theory between comprehensive and incremental approaches (Hopkins & Zapata, 2007). The severe underrepresentation of adaptation (3.1% academic, 2.6% policy) and recovery (1.8% academic, 0% policy) classifications reveals an "incomplete disaster cycle" that undermines comprehensive resilience planning.

These findings highlight the need for integrative "phase-spanning frameworks" that acknowledge planning's unique boundary-spanning role and the multi-phase functionality of land use strategies. Policy systems should be revised to support flexible, multi-phase application of strategies rather than forcing single-phase categorization that may reduce their effectiveness.

Rethinking Gated Communities through Pareto Optimality: Evaluating Urban Access and Efficiency

Abstract ID: 1844.0.0.754.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Yeonju Kim [Pusan National University] kyj765@pusan.ac.kr, presenting author

Juchul Jung [Pusan National University] jcjung@pusan.ac.kr

As the expansion of gated communities reshapes the spatial fabric of East Asian cities, concerns over spatial inequality, access restriction, and fragmentation of the urban public realm have intensified. These communities, often equipped with physical barriers and controlled internal pathways, have been widely criticized in planning discourse for promoting social exclusion. However, most existing critiques remain grounded in normative frameworks and offer limited tools for empirically assessing whether such configurations are not only inequitable but also economically inefficient.

This study reframes gated communities not merely as socially unjust, but as spatial configurations whose efficiency can be objectively evaluated using the concept of Pareto optimality. Rooted in welfare economics, the Pareto principle asks whether a reallocation (or redesign) can improve at least one party's outcome without worsening another's. In applying this to urban space, the study investigates whether selectively opening internal paths within a gated complex can reduce pedestrian travel costs for external users without significantly increasing burdens on residents.

The empirical case focuses on a representative gated apartment complex in Busan, South Korea. The complex restricts public access through internal walkways, forcing surrounding residents to detour to reach shared urban infrastructure such as subway stations. Using QGIS network analysis, ten origin points were defined around the complex to represent plausible pedestrian routes to a nearby station. Two spatial scenarios were modeled: (1) a closed state (current condition) and (2) a partially open state with select internal paths made accessible.

To compare both user groups under a shared metric, travel distances were monetized using Korea's Value of Time (VOT) standard. For internal residents, cost changes resulting from increased foot traffic were modeled using Crowding Penalty coefficients, which quantify discomfort as a multiplier on base travel cost. This framework produced a cost-balance model, allowing direct comparison between external benefits and internal costs.

Results showed that external pedestrian costs consistently decreased in the open scenario. However, internal discomfort costs only increased along certain routes, primarily those crossing central zones. Peripheral internal routes absorbed additional traffic with minimal burden. One route, in particular, exhibited a net social benefit, with no group incurring a loss—thereby meeting the conditions for a Pareto improvement.

These findings suggest that urban efficiency and equity need not be opposing goals. By empirically identifying spatial scenarios where both can coexist, planners can move beyond binary debates (e.g., full openness vs. complete enclosure) and pursue strategic, data-driven design interventions. The study aligns with James Buchanan's concept of procedural Pareto improvement, advocating for rule-based, consent-driven transitions toward greater social benefit.

Ultimately, this research offers a transferable planning methodology that integrates spatial analytics, cost theory, and behavioral modeling to assess the efficiency of urban design. It repositions gatedness not as a fixed condition, but as a modifiable variable within the urban system—subject to empirical evaluation, design optimization, and policy innovation.

Rich-Get-Richer Urbanism: Branding and Complexity in Post-Crisis Urban Change in South Korea

Abstract ID: 1844.0.0.1023.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Jinhee Park [University of Seoul] ginnypark0715@gmail.com, presenting author

Hee-Chung Lee [University of Seoul] leeworld@uos.ac.kr

This paper explores how branding dynamics have reshaped the spatial and structural configuration of urban housing development in Seoul. Projects backed by strong and recognizable apartment brands, which are developed by a small group of dominant construction firms, tend to be larger in scale, more centralized, and disproportionately concentrated in high-demand, desirable neighborhoods. These developments have come to symbolize not only physical quality but social status, investment potential, and access to superior amenities. As a result, they attract greater consumer attention, command higher prices, and shape perceptions of urban value.

In contrast, developers lacking brand capital are increasingly excluded from prime locations and large-scale opportunities. Many are confined to small peripheral projects or pushed out of the market altogether. This polarization represents a sharp departure from earlier, more evenly distributed development patterns. Where once a range of developers operated across diverse neighborhoods, today's market shows increasing consolidation around a handful of top-tier brands. These dynamics reflect a fundamental shift in the housing system—one in which spatial inequality and developer concentration reinforce each other over time.

The paper argues that Seoul's housing market has transitioned into a complex adaptive system, which is marked by feedback loops, emergent behaviors, and preferential attachment. Branding operates not merely as a marketing tactic but as a structural mechanism that governs how housing is produced, consumed, and valued. Through processes of cumulative advantage, popular brands gain increasing visibility and market share, while lesser-known firms struggle to compete. This preferential growth dynamic, where success begets more success, leads to escalating disparities in spatial development, housing accessibility, and economic opportunity.

Such developments challenge conventional planning assumptions rooted in equilibrium-based thinking. Traditional supply-side policies, which rely on increasing unit numbers or controlling prices, assume a relatively neutral market landscape. However, when perception, status signaling, and brand loyalty significantly influence demand, these policies fail to address the deeper forces driving inequality. Housing markets shaped by branding and feedback do not passively respond to more supply; they actively evolve in ways that concentrate advantage and reshape urban form.

As branded apartments become objects of speculation and prestige, their development increasingly drives up land values, reinforces neighborhood stratification, and limits affordability. Even where housing supply grows, it may do so in forms that are inaccessible to most households. This reinforces exclusionary geographies and undermines the goal of equitable urban development.

The study suggests that planners and policymakers must adopt new frameworks capable of grappling with complexity. Branding should be understood as an emergent force that co-evolves with consumer preferences, institutional incentives, and market structures. Effective interventions must move beyond simply adjusting supply or setting price controls. Instead, they should consider structural reforms such as regulating branding practices, democratizing development opportunities, or incentivizing inclusive and diverse housing provision.

This analysis contributes to broader urban theory by applying complexity thinking to housing systems. It highlights how emergent behaviors and nonlinear interactions between consumers, firms, and institutions reshape markets in ways that traditional models overlook. By identifying branding as a key mechanism in Seoul's housing transformation, the paper offers a new lens for understanding inequality and proposing policy solutions in rapidly evolving urban contexts.

Spatial Heterogeneity of Urban Morphology's Impact on PM2.5 and Carbon Emissions

Abstract ID: 1844.0.0.336.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Yixuan Wang [Tianjin University] 1021206035@tju.edu.cn, presenting author

Hanyan Li [Tianjin University] lihanyan@tju.edu.cn

Tian Chen [Tianjin University] chentian5561@vip.sina.com

Urban spatial morphology, shaped by the expansion of built-up land and socio-economic spatial structure, reflects the dynamics of urbanization. Understanding its relationship with PM2.5 concentrations and carbon emissions is essential for advancing regional sustainable development. This study constructs a scale–structure–form analytical framework to evaluate urban morphology within the Beijing-Tianjin-Hebei urban agglomeration from 2014 to 2024. Using data from national air quality and meteorological monitoring networks, the China Land Cover Dataset, gridded CO₂ emissions, and socio-economic indicators, we measure urban scale through land consumption and population size; structure through the land-use Shannon index, development compactness, and average building height; and form through area-weighted shape indices, area–radius scaling, and vertical morphology such as building height. The geographical detector model is applied to analyze the spatial heterogeneity of urban morphology's impact on PM2.5 and carbon emissions. The results reveal that: (1) from 2014 to 2024, PM2.5 annual mean concentration decreased by 9.19%, while carbon emission intensity increased slightly by 0.31%, indicating that air quality improvements were largely driven by end-of-pipe controls and policy enforcement rather than systemic industrial or energy transitions; (2) scale indicators exhibit the strongest correlation with concentration trends, while structural indicators align more closely with spatial distribution, forming a spatial gradient of higher values in northern and southern areas, lower in the center, and increasing from inland to coastal zones; (3) land-use compactness emerges as the most critical spatial determinant. The spatial autocorrelation between PM2.5 and carbon emissions evolved from weak to strong, peaking with significant positive correlations during 2019–2022. This relationship is nonlinear across spatial scales, suggesting that compactness influences differ once certain thresholds are crossed. This study reveals the coupling mechanism between urban morphological evolution and the spatial distribution of PM2.5 and carbon emissions. It further proposes a resilient morphological interval balancing air pollution mitigation and carbon reduction, offering empirical evidence and planning insights for integrated spatial governance in high-density urban regions.

State Growth Management Regulations and Fossil Fuel Emissions

Abstract ID: 1844.0.0.523.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Himanshu Grover [Alabama A&M University] himanshu.grover@aamu.edu, presenting author

Jerry Anthony [University of Iowa] jerry-anthony@uiowa.edu

This article investigates the relationship between state level growth management regulations and their influence on carbon emissions in urban regions. A growing body of literature has examined the role of state policies in shaping local development outcomes, including urban sprawl, social vulnerability, and exposure to environmental hazards (Anthony, 2004; Wei & Ewing, 2018). These studies underscore the capacity of state level policies to direct the form and function of urban areas through regulatory frameworks and planning mandates. Concurrently, there is growing consensus across planning literature on the critical role of urban form in influencing urban emissions (Falahatkar & Rezaei, 2020). Given that growth management policies are explicitly designed to guide urban form and land use decisions, it is reasonable to hypothesize that such state-level policies exert both direct and indirect influences on carbon emissions within urban areas.

This study contributes to this emerging line of inquiry by empirically examining the extent to which state-mandated growth management frameworks affect emissions at the urban scale. Specifically, the analysis focuses on the relationship between state growth management regulations and per capita carbon emissions across U.S. Metropolitan Statistical Areas (MSAs). To capture the variation in state-level planning mandates, we draw on data from a 2022 study conducted by the American Planning Association (APA), which systematically evaluated eight core planning requirements embedded within state planning legislation. Our dependent variable, is derived from high-resolution estimates of fossil fuel CO₂ emissions (2022), created by the Vulcan Project at Northern Arizona University. This dataset offers spatially explicit, annualized data on CO₂ emissions from fossil fuel combustion across all U.S. regions, disaggregated by sector (Gurney et. al. 2019).

We use partial least squares structural equation modeling (PLS-SEM) to model the relationships as it allows for modeling complex relationships with small sample sizes without imposing strict distributional relationships (Hair et al. 2019). The results of the analysis provide empirical evidence that state-level planning policies influence urban carbon emissions through both direct and indirect pathways. Metropolitan Statistical Areas (MSAs) located within states exhibiting stronger and more comprehensive planning mandates were associated with significantly lower per capita fossil fuel CO₂ emissions. Furthermore, the strength of state planning mandates was positively correlated with key indicators of urban form and urban activity—suggesting that such policies shape not only emissions outcomes directly, but also the structural and functional characteristics of urban areas. The associations between urban form and activity measures were also found to be statistically significant, reinforcing the interconnected nature of spatial planning, urban functionality, and environmental performance.

These findings underscore the critical role that state-level growth management frameworks play in climate change mitigation, both by guiding land use patterns and by fostering more sustainable forms of urban development. In a national context marked by the absence of a coordinated federal mandate on emissions reductions, and amid increasing political sensitivity surrounding climate policy, this study highlights the capacity of state governments to act as critical levers of climate governance. By strategically leveraging their policies, states can influence local development trajectories in ways that contribute meaningfully to climate mitigation objectives, particularly promoting compact, efficient, and economically vibrant urban areas.

The Impact of Boundary Governance on Land Use in Development Zones: Empirical Evidence from Nanjing

Abstract ID: 1844.0.0.620.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Kailun Li [School of Architecture, Southeast University] 779120194@qq.com, presenting author

This study interrogates how boundary governance mechanisms shape land use patterns in Chinese development zones, with particular focus on boundary adjustment as a critical policy instrument. Confronting the theoretical paradox wherein existing literature predominantly frames administrative boundaries as barriers to regional integration, we argue that such boundaries constitute sophisticated governance tools that actively reconfigure urban spatial order. Through examining Nanjing's development zones—exemplary cases within China's most economically dynamic Yangtze River Delta—we reveal the dual nature of boundaries as both spatial constraints and institutionalized policy levers.

Our methodology combines three analytical approaches: 1) Spatial statistical analysis of land use change (2000-2020) using remote sensing data and planning archives; 2) Institutional analysis of 132 boundary adjustment documents across 12 national/ provincial-level zones; 3) Semi-structured interviews with 28 planners and zone administrators. The multi-scalar investigation bridges the gap between macro-level policy analysis and micro-level spatial governance practices.

Key findings demonstrate three governance paradoxes: First, the centralized boundary management system produces compressed urbanization characterized by hyper-concentrated industrial clusters and perforated development patterns. Second, jurisdictional overlaps between local governments and zone authorities create ambiguous borderlands—zones experiencing 2.3 times more boundary adjustments than other areas—where infrastructure provision lags behind by 5-7 years due to fragmented administrative responsibilities. Third, the coexistence of land expansion and contraction generates conflicting territorial logics, particularly evident in the misalignment between ecological redlines and economic development boundaries.

This study has three theoretical contributions: 1) it redefines the boundary of development zones as a dynamic governance interface, rather than a static spatial separation; 2) It determines the evolutionary movement of boundary governance - promoting the evolution of spatial boundaries in different periods of development zones and the construction of governance systems; 3) It reveals how scalar politics between different administrative levels is achieved through controversial boundary adjustments. In fact, we propose a transitional framework for boundary governance that emphasizes three synergies: a cross departmental coordination mechanism for boundary management, dynamic boundary assessment indicators incorporating ecological constraints, and a cross-border benefit sharing model.

This study deepens the understanding of urban industrial spatial governance and provides key insights for regions striving to address similar tensions between the economic development boundaries and social governance boundaries of development zones. The Nanjing case provides empirical evidence for rethinking the role of boundaries in shaping the urban landscape of development zones.

Understanding the Next “D” in Polycentric Cities – The Importance of the Distribution of Centers

Abstract ID: 1844.0.0.73.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Yuhua Wang [University of North Carolina at Chapel Hill] yuhuaw@ad.unc.edu, presenting author

Yan Song [University of North Carolina at Chapel Hill] ys@email.unc.edu

Polycentric development refers to an urban structure characterized by multiple centers or hubs—such as employment, commercial, or activity zones—rather than a single dominant core. In recent decades, this approach has gained prominence in urban planning for its potential to enhance city sustainability, particularly by shaping travel behavior. Traditionally, polycentric development has been evaluated either through a polycentricity lens or via the “5D” framework which includes density, diversity, design, destination accessibility, and distance to transit (e.g., Park et al., 2020). However, one critical aspect has often been overlooked: the spatial distribution of (sub)centers. This research introduces this as a new, sixth “D” factor, arguing that it is essential for accurately measuring polycentric development and understanding its influence on sustainable outcomes.

The spatial arrangement of these centers—specifically, how they are positioned relative to one another and the populations they serve—can significantly influence travel behavior. Well-distributed centers could shorten travel distances by bringing jobs, services, and amenities closer to residents, a key mechanism for advancing urban sustainability. The study emphasizes that it is not sufficient for centers to merely exist or host evenly distributed activities; their spatial configuration is equally critical.

Historically, research on polycentric development has focused primarily on commuting trips (Eldér, 2014), due to limited data on other trip types. To broaden this scope, this study uses large-scale mobility datasets to examine non-commuting trips, such as those for dining, recreation, or maintenance (e.g., shopping or errands). It explores how the built environment, including the distribution of centers, affects these trips. This broader perspective is vital, as non-commuting trips account for a substantial portion of urban travel and influence sustainability outcomes.

This study employs gradient boosting decision trees (GBDT), a machine learning technique well-suited to capturing non-linear relationships between the built environment and travel behavior (Ding et al., 2018; Wagner et al., 2022). GBDT also models the interactions among independent variable through its tree structure, reflecting the complexity of travel behavior, where factors like center distribution might not influence travel in linear way. The analysis includes 83 metropolitan statistical areas (MSAs) in the U.S., each with at least one subcenter, and grouped into six clusters based on size and polycentric development patterns. This clustering accounts for the heterogeneity among metropolitan areas, recognizing that the effects of polycentricity vary by context (Næss, 2022).

Findings show that the distribution of (sub)centers significantly influences travel behavior, particularly within certain MSA clusters. The proposed “D” factor has a clear non-linear effect on travel distance, varying by MSA type and trip purpose. The results suggest that, beyond having evenly distributed activities, the spatial arrangement of (sub)centers should be considered a critical component of polycentric development. Moreover, the varying effect of this factor highlights the need for context-sensitive planning approaches. Traditional factors, such as population density and land use diversity, remain consistently important across all clusters, underscoring their foundational role in sustainable urban design. However, destination accessibility (e.g., distance to centers) shows varying patterns, suggesting it interacts differently with polycentric structures.

For planning implementations, we argue that attention must be given not only to the presence of multiple centers but also to their spatial arrangement. Planners must ensure centers are strategically positioned and that activities within them are well-distributed. Simply creating multiple centers is not enough, their layout matters.

Unraveling the Urban Regeneration Paradigm in Seoul: Path Dependency in Redevelopment Policies

Abstract ID: 1844.0.0.242.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Grace Lim [Graduate School of Environmental Studies, Seoul National University] grace9572@snu.ac.kr, presenting author

In Kwon Park [Seoul National University] parkik@snu.ac.kr

Urban redevelopment policies have long shaped the trajectory of cities, balancing economic growth, housing supply, and social equity. In South Korea, Seoul's redevelopment policies have undergone significant transformations, reflecting broader shifts in governance, market forces, and political ideologies. Initially driven by state-led clearance projects, redevelopment has evolved into market-driven models and, more recently, public-private hybrid approaches. However, despite efforts to shift toward urban regeneration policies emphasizing community-led, sustainability-focused development, the persistence of redevelopment paradigms raises critical questions about the institutional inertia embedded in South Korea's urban planning framework. This study applies a historical institutionalist approach to examine the path-dependent evolution of urban redevelopment policies, analyzing the regulatory frameworks, governance mechanisms, and stakeholder interactions that have influenced Seoul's urban transformation.

This research aims to answer three key questions: (1) What are the underlying institutional mechanisms that have sustained redevelopment policies despite policy shifts toward urban regeneration? (2) How have urban redevelopment policies evolved through mechanisms such as path dependence, layering, drift, and conversion? (3) What are the implications of these institutional dynamics for the future of urban regeneration and land use governance? By investigating these questions, this study seeks to provide insights into the structural constraints have shaped Seoul's urban landscape.

Methodologically, this study employs a comparative historical analysis of Seoul's urban redevelopment policies, tracing their evolution from the Joint Redevelopment model of the 1980s to the New Town projects of the 2000s, the Urban Regeneration policies of the 2010s, and the recent Fast-Track Integrated Planning initiatives of the 2020s. Drawing on primary sources such as government policy documents, legislative records, and media reports, the research highlights the institutional path dependencies that have constrained meaningful transformation.

Findings reveal that while urban regeneration policies were introduced in the 2010s as an alternative to large-scale demolition-based redevelopment, regulatory inertia, governance structures, and private sector incentives have maintained the dominance of redevelopment-oriented approaches. The case of Changsin-Sungin, which transitioned from an urban regeneration project back to redevelopment following policy shifts in 2021, illustrates the fragility of urban regeneration policies when confronted with market forces and resident preferences. The study further demonstrates that urban redevelopment has been entrenched as a primary mechanism for housing supply, particularly due to the privatization of redevelopment financing, the dominance of construction firms, and the role of land speculation in shaping planning decisions.

The New Town projects of the early 2000s demonstrate institutional drift, wherein policies initially aimed at balancing redevelopment with public investment in infrastructure ultimately became an extension of private-led redevelopment models. The shift from the public-led Urban Regeneration of the 2010s to the Fast-Track Integrated Planning model of the 2020s further exemplifies paradigm regression and path dependence, as urban regeneration gives way to mechanisms for reviving private-led redevelopment that had been stalled for a decade.

Ultimately, this study underscores the importance of historical institutional analysis in understanding why certain urban policies persist despite changing political and social priorities. The case of Seoul provides broader lessons for cities globally, particularly those facing tensions between market-driven redevelopment, social equity, and the need for sustainable urban regeneration.

Urban Densification through Vertical Extensions: Potential and Social Sustainability Implications

Abstract ID: 1844.0.0.352.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Dominic Büttiker [Spatial Development and Urban Policy (SPUR), ETH Zurich] dominicb@student.ethz.ch,
presenting author

Elena Lutz [ETH Zurich] elelutz@ethz.ch

This paper studies the role and social implications of vertical extensions of existing buildings as a form of densification. Vertical extensions involve stacking additional residential floors on top of existing buildings. Densification is a key concept in contemporary urban planning. However, there are widespread concerns that densifying residential areas may lead to displacement and gentrification, especially through replacement constructions, where often older, more affordable housing is demolished and replaced with new denser buildings (Davidson and Lees, 2005). However, there are forms of "soft densification", such as garden infills of building extensions, which avoid demolition (Bibby et al., 2020).

In particular, vertical extensions are of growing interest as they are often environmentally more sustainable than replacement constructions. They do not reduce urban green space, and by reusing existing structures, they typically result in lower embodied greenhouse gas emissions. This becomes increasingly important for reducing lifecycle emissions (Röck et al., 2020).

Many cities, such as Barcelona, Paris, and Geneva, have a long tradition of vertically extending mid-rise multifamily houses. Also, in US cities, like NYC or Boston, vertical extensions are becoming increasingly popular. Yet, their potential for urban densification and social impact on residents remain largely unexplored. Therefore, this paper asks the following research questions: (1) How effective are vertical extensions compared to replacement constructions in creating additional housing units? (2) What are the social impacts of vertical extensions, i.e., can existing residents remain in the buildings and what are the socioeconomic characteristics of new inhabitants? (3) Can land use policies foster vertical extensions?

Using linked annual administrative data on all buildings and individuals from 2010 to 2023, we analyze vertical extensions in the urban areas of Zurich and Geneva in Switzerland.

We employ spatial methods to identify locations and types of vertically extended buildings. We investigate whether inhabitants could remain in their apartments post-extension and analyze the socioeconomic characteristics of residents in the existing and added units. A comparative case study of Zurich and Geneva provides insights into how different policies within a similar institutional and geographical context influence densification through vertical extensions.

In total, we identified 1068 vertical extensions and analyzed 6711 individuals affected by them.

Our findings reveal that vertical extensions are mostly concentrated in city centers and primarily occur for multifamily houses rather than single-family homes. However, they contribute less to densification than replacement constructions: in Geneva, 1.5 times fewer units were created, and in Zurich, 6.6 times fewer. In terms of displacement, the majority of long-term residents can remain in 87% of vertical extensions in Geneva and 42% in Zurich, showing that vertical extensions can preserve affordable housing. However, apartments built on top tend to be expensive, with new residents having 44–72% higher incomes than the existing residents.

Moreover, we find that local policies are key to the frequency of vertical extensions. Geneva's planning policy encourages landlords to vertically extend rather than demolish, resulting in approximately three times more extensions than Zurich.

These outcomes have important implications for urban planners and researchers: Vertical extensions can contribute to densification while allowing existing tenants to remain in their homes, making them a more socially sustainable alternative to replacement construction. Yet, while they help preserve affordable housing, added units on top tend to be expensive. The study also highlights that local governments can encourage vertical extensions through targeted policy measures, such as in Geneva.

Urban Development Impacts on Natural Areas: Evidence from Two River Basins in Eastern China

Abstract ID: 1844.0.0.107.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Tong Cheng [NYU Shanghai] tc3532@nyu.edu, presenting author

ChengHe Guan [NYU Shanghai] chenghe.guan@nyu.edu

Spatial configuration of land cover is crucial for determining the impact of urban growth and regulating land use management. However, quantifying these influences remain uncertain. This study introduces a new index, the Urban Impact Weighted Interspersion and Juxtaposition Index (UIW-IJI), to calculate the potential influence of urban development on natural area. Using the Lake Tai Basin and the Qiantang River Basin as study areas, we examine the spatial relationship between UIW-IJI and urban sprawl, evaluated by the landscape expansion index. We adopted the China Land Cover Dataset (CLCD) to form a 300 m grid from 2004 to 2019 and applied a bivariate Anselin Local Moran's I method. Results revealed three distinct patterns of influence caused by urban development: stable influence across most areas, gradual decline near major urban centers, and rapid intensification around Lake Tai urban agglomerations. The analysis identified a geographically uneven distribution of urban influence, with persistent pressure in central and eastern regions while southwestern areas showed emerging influence only in recent years. Furthermore, the transition expansion-oriented to infill-dominated urban development (>70%) has not necessarily reduced pressure on natural lands. Instead, it has shifted the impact pattern from widely dispersed to locally concentrated, leading to more concentrated ecological pressure in northeastern cities. These findings provide insights for urban planners and natural resource managers, emphasizing the need to balance land use efficiency with ecological conservation through targeted protection measures. This study demonstrates the importance of incorporating UIW-IJI into ecosystem management and sustainable urban planning strategies.

Why Create a Land Bank? A Qualitative Exploration of Four Communities in Missouri

Abstract ID: 1844.0.0.6.2025

Track 8: Land Use Policy and Governance

Individual Paper Presentation Submission

Krista Evans [Missouri State University] kristaevans@missouristate.edu, presenting author

In urban planning circles, the phrase “land banking” is emerging with increased frequency, whether it be at conferences, in discussions on housing affordability or in articles about urban environmental sustainability. However, ask people, including planners, what land banking is, and responses will be varied and likely contain several, “I’m not really sure,” “It’s confusing” or “I don’t know.” This is because though land banking has been around for over fifty years, it is only recently that the concept has grown in popularity and come to light as a useful planning tool. So, which is the correct answer; is it a tool for addressing housing affordability or environmental sustainability? The answer can be both, or neither and much more.

Defined, land banks are publicly created agencies that acquire abandoned, vacant and/or tax-delinquent properties for short- or long-term strategic redevelopment purposes. Land banking allows communities to transfer such properties for a variety of purposes in an efficient manner that bypasses onerous tax foreclosure procedures and property title clearance processes.

This research examines the “why” of land banking through a comparative case study of four cities in Missouri: Kansas City, St. Joseph, St. Louis, and Springfield. The research involves qualitative interviews with planners who engage in land banking activities and land banking experts at each case site location. These individuals were chosen for qualitative examination due to their knowledge of the history, challenges and purpose associated with their respective land bank. The interviews in this research were coded inductively, as the research is exploratory in nature and there is little academic research in the Planning discipline on land banking.

The study finds that each of the four municipalities has a different overarching purpose for the utilization of land banking, including the creation of affordable housing, to address social justice concerns, and the rehabilitation of aging housing stock to stabilize neighborhoods. It also finds that a lack of clarity or conflicting purposes for the land bank are common and somewhat problematic to each case site. The findings have been developed into five themes and implications for planners. For example, the study finds that the primary driver of land banks in Missouri is housing affordability, with an emphasis on homeownership. However, the land banks are not set up to give preference to the creation of affordable housing, and land often goes to the highest bidder. The implication for this particular finding is that land banks should have a clear purpose, and operating structures that support this purpose.

The objectives of this paper are several. First, it addresses the question, “Why might communities consider land banking?” Secondly, it aims to shed light on the fact that there can be ambiguity associated with land banking. As such, it aims to point land banking advocates towards the importance of a clear purpose and supportive operational systems. Finally, the paper serves as a starting point for future research which examines land banking outcomes. For example, do such efforts result in measurable outcomes such as a greater amount of affordable housing or more equity in communities? It is hoped that this research will assist communities interested in understanding why land banking is a tool worth pursuing to achieve a myriad of planning and community outcomes.

Steven Richter [East Carolina University] richters22@ecu.edu, presenting author

Innovative remote sensing, cloud computing, and machine learning algorithms have led to a veritable explosion of data on urban growth. One example of this is the next generation of the National Land Cover Database (NLCD). Released in the Fall of 2024, it expands to an annual dataset covering 1985-2023. The NLCD was previously limited to a 2001-2021 range with a latency of 2.5 years, so the new version doubles the temporal range and increases the volume of an already massive dataset by more than four times. This provides new opportunities to study urban growth, a spatio-temporal process that necessarily takes time and operates over decades more than individual years. This research leverages this capability toward two research objectives: 1) to conduct the first four-decade study on the quantity of urban expansion in the US, including drivers of non-linear change; and 2) to understand how the physical quality of urban landscapes has evolved, possibly in relation to changes in expansion.

Past research has examined growth patterns in the US during the 1980s and 1990s (Fulton et al. 2001, Alig et al. 2004), finding a range of drivers accompanying a period of accelerating land consumption. Richter (2020) revisited these earlier studies, finding a rapid decline since 2001 that stood in stark contrast to earlier trends. There are a variety of social-economic, physical, and built variables related to this decline (Richter and Bixler 2022). However, there is no systematic analysis of growth trends and drivers that accounts for BOTH the acceleration and subsequent decline in the rate of expansion.

Augmenting the analysis of the quantity of urban land is a closer examination of its qualities. Specifically, we look at the NLCD urban imperviousness layer, which is the percent of developed land through which water can penetrate. Developed land cover and imperviousness are often conflated, but it is important to differentiate between the two. For example, lawns are often included in “developed” land, even though they are pervious. In the last two decades, there has been a “Hardening of the American Landscape” (Muller and Mitova 2023) that has seen increasing levels of imperviousness associated with increased urban heat island and hydrological impacts. As urban imperviousness changes so too does the urban environment. The imperviousness of the US urban landscape has not been examined as frequently as expansion of developed land, constituting a ripe opportunity for spatio-temporal analysis.

This Research-in-Motion presentation fills the aforementioned research gaps on the quantity and quality of urban land in the US. The full Annual NLCD (1985-2023) is analyzed to understand trends at three scales: contiguous US, metropolitan statistical area (MSA), and municipality (using US Census Places geography). The latter is particularly insightful as it allows for assessment of how regional structure may be shifting, including changing rates of urban infill in core cities or more intensification in suburban jurisdictions. Future research will integrate housing production and land use regulation to better understand the direct and indirect implications of urban growth.

Are Communities Planning for Multi-Hazards? Analyzing cobenefits and tradeoffs with two communities.

Abstract ID: 1842.0.0.1088.2025

Track 8: Land Use Policy and Governance

Research-in-Motion Presentation Submission, Research currently in process

Malini Roy [University of Arizona] maliniroy@arizona.edu, presenting author

Ladd Keith [The University of Arizona] ladd@arizona.edu

Sara Meerow [Arizona State University] sara.meerow@asu.edu

Climate change and under-regulated urban growth put cities at risk of multiple hazards that compound and cascade to weaken the coping capacities of people, places, and habitats. Planners and policymakers are already shaping multi-hazard exposure by influencing development trajectories, allocating infrastructure, setting design standards, and providing services. Yet, empirical evidence on what characterizes effective multi-hazards planning is limited. Most research on hazard mitigation is either siloed into individual hazard types or discussed as broad adaptation standards. The few planning studies that do analyze multi-hazards (Chang et al., 2019; Srivastava & Laurian, 2006) rarely also consider the interactions between specific multi-hazards and greenhouse gas emissions control (Georgescu et al., 2024; Grafakos et al., 2019). In the absence of systematic and holistic guidance on multi-hazards planning, we risk overlooking opportunities to proactively avoid losses and identify sources of maladaptation.

To address these gaps, this study offers a novel methodology to systematically evaluate the state of planning for multi-hazards. The method called Integrated Climate Adaptation Plan Evaluation (I-CAPE) was developed in collaboration with municipal partners in the City of Tucson and Pima County during their general plan updates. We first conducted a systematic literature review of 178 peer-reviewed and grey literature and developed a beta version of I-CAPE. Next, using standard content analysis procedures (Lyles & Stevens, 2014), we piloted I-CAPE with three versions of the City and County general plans- the old versions, the drafts, and the final plan updates for four relevant hazards- heat, drought, wildfire, and flood. Finally, through focus groups with city partners, opportunities to advance integration were discussed using three questions:

1. How can planning processes advance multi-hazard mitigation while also integrating across broader climate change adaptation and emissions control goals?
2. What are the policy co-benefits and tradeoffs in advancing multi-hazard mitigation?
3. What are the opportunities and barriers to further multi-hazards planning at the local government level?

The contribution of this study is three-fold. First, we introduce a novel method to comprehensively analyze and ground truth local-level multi-hazards planning. Second, to the limited longitudinal plan evaluation studies, we offer new insights on the changes in attention to multi-hazards. Third, given the impact emissions control can have on multi-hazards mitigation (Georgescu et al., 2024), I-CAPE also diagnoses policy synergies and tradeoffs between controlling greenhouse gas emissions and multi-hazards mitigation. Preliminary findings reflect improving recognition of multi-hazard risks over time in city and county plans, but unsystematic policy inclusion for multi-hazard mitigation. Plans and planners indicate a lack of data that communicates the interactions between different hazards in time and space, leading to unintended maladaptation and inconsistent support for policies with synergistic benefits across hazard types. These findings pave the way for more empirical research to better understand how different types and scales of plans can effectively address multi-hazards exposure and address tradeoffs.

Brownfield Redevelopment and Urban Planning: Exploring Local Strategies and Policy Implications

Abstract ID: 1842.0.0.310.2025

Track 8: Land Use Policy and Governance

Research-in-Motion Presentation Submission, Research currently in process

Tara Zafari [Kansas State University] trzafari@ksu.edu, presenting author

Shakil Kashem [Kansas State University] shakilkashem@ksu.edu

Brownfields—abandoned, idled, or under-used industrial and commercial facilities—have emerged as a significant urban planning challenge as well as an opportunity for urban revitalization in the United States (Yount, 2003). Given the environmental benefits of utilizing the existing built-up lands, the effective reuse of brownfields is increasingly recognized as a sustainable alternative to greenfield development. Infill development on these under-used sites helps limit land consumption, reduce infrastructure demands, and make better use of existing resources.

Since the 1990s, when the U.S. EPA launched its brownfield agenda, scholars have examined how federal and state programs incentivize brownfield redevelopment. These efforts have employed a range of tools, including legal mechanisms like the Brownfields Revitalization and Environmental Restoration Act, and financial incentives such as grants and tax credits (Andrew, 1996). Brownfield redevelopment efforts have also employed technical assistance through pilot projects and remediation planning, and public-private partnerships (Heberle & Wernstedt, 2006; De Sousa et al., 2023). This body of literature offers a robust understanding of how higher-level policies attempt to stimulate site cleanup and reuse. However, there is limited evidence on how local governments, especially municipal planning agencies, shape or respond to brownfield redevelopment challenges within their jurisdictions.

In this study, we investigate how local planning efforts contribute to brownfield redevelopment process. Using brownfield location data from EPA, we selected 30 cities with a substantial presence of brownfields and located in diverse geographic and regulatory contexts. We analyzed the planning documents from these cities to gain a broad understanding on how municipalities approach brownfield redevelopment. We then identified three cities with successful brownfield redevelopment projects and conducted in-depth case studies that included planning document review, policy analysis, and semi-structured interviews with local planners and stakeholders. This approach enabled us to examine how municipal planning frameworks, inter-agency coordination, and local strategies contributed to successful brownfield redevelopment.

We found that successful brownfield redevelopment projects were largely driven by active local governments that integrated brownfield efforts into broader urban development strategies, such as infill development, smart growth, and affordable housing initiatives. These cities did not rely on a single model; rather, they employed a range of tools tailored to their context, including proactive planning to secure federal or state funding and the formation of public-private partnerships to mitigate financial risks. Some cities also leveraged flexible remediation standards and aligned brownfield sites with land-use and economic development plans.

This research contributes to urban planning scholarship by underscoring the importance of planning efforts at the local level for brownfield redevelopment and identifying scalable best practices. Based on these findings, we offer actionable recommendations to strengthen local capacity and support for more effective brownfield redevelopment initiatives.

Co-Producing Heat Resilience: Exploring the Evolution of Phoenix's Shade Plan

Abstract ID: 1842.0.0.782.2025

Track 8: Land Use Policy and Governance

Research-in-Motion Presentation Submission, Research currently in process

Shaylynn Trego [Arizona State University] satrego@asu.edu, presenting author

Sara Meerow [Arizona State University] sara.meerow@asu.edu

Ladd Keith [The University of Arizona] ladd@arizona.edu

David Hondula [Arizona State University and City of Phoenix] david.hondula@asu.edu

As cities across the globe face escalating climate risks, extreme heat has emerged as an urgent and inequitable hazard, particularly in urban environments where the built environment exacerbates temperature extremes. Despite its significance, most cities do not have standalone heat plans. Instead, heat-related strategies are often fragmented across comprehensive, hazard mitigation, and adaptation plans. These documents may influence heat risk through land use and infrastructure decisions, but usually fail to center heat explicitly or address the uncertainty (Keith et al., 2024). As a result, extreme heat planning remains underdeveloped, with few empirically grounded examples of dedicated heat planning.

This research addresses this gap by evaluating the development and implementation of the Shade Phoenix Plan, a recently adopted and innovative approach to urban heat adaptation and governance. Using a mixed-methods approach that integrates plan evaluation, participant observation, and the co-production of knowledge, this study offers an embedded analysis of how local governments are responding to extreme heat through formal planning processes. Through an internship with the City of Phoenix's Office of Heat Response and Mitigation (OHRM), our research team directly participated in the city's planning process, contributing to the revision and implementation of the Shade Plan, and observing the collaborative dynamics that shaped it.

Phoenix is a critical case for this research. As one of the hottest cities in the United States, Phoenix is at the forefront of heat governance and has recently taken steps to institutionalize its efforts, including the creation of the Office of Heat Response and Mitigation (OHRM). The 2024 Shade Phoenix Plan marks a significant evolution from the city's previous 2010 Tree and Shade Master Plan. Unlike its predecessor, which focused solely on increasing tree canopy, the new plan incorporates both natural and built shade as essential tools for reducing heat exposure and improving public health. This dual approach is particularly important in arid cities like Phoenix, where resource constraints, such as water availability, can limit tree-focused interventions. Built shade, including shade structures and buildings, offers a more immediate solution in the short term (Turner et al., 2023). Preliminary findings indicate that the plan has improved substantially over time, largely due to an iterative planning process supported by internal collaboration and external partnerships. The city's use of interdepartmental liaisons has ensured cross-departmental feedback, while partnerships with academic institutions like Arizona State University and the University of California - Los Angeles have provided updated shade data to inform decision-making. External support from organizations such as Bloomberg Philanthropies also played a key role in accelerating the plan's development and implementation.

Crucially, participant observation within OHRM revealed important gaps in the plan that may not have been evident through document analysis alone. Feedback meetings after each plan evaluation iteration highlighted the need to: (1) explicitly frame heat as the central concern of the plan, (2) address uncertainty and long-term risk management, and (3) clarify how public engagement will continue post-adoption. These findings underscore the value of embedding researchers within planning processes to generate actionable insights and build more responsive plans.

Effectiveness of Delaware's Growth Strategy: Longitudinal and Spatial Trends and Policy Coordination

Abstract ID: 1842.0.0.899.2025

Track 8: Land Use Policy and Governance

Research-in-Motion Presentation Submission, Research currently in process

Keihan Hassanzadehkermanshahi [University of Delaware] keyhan@udel.edu, presenting author

Nina David [University of Delaware] npdavid@udel.edu

Delaware enacted its growth management program in 1999 to guide development, protect natural resources, and prevent urban sprawl. This policy emerged in response to a 67% population increase between 1960 and 1998, a nearly 50% increase in residential areas between 1984 and 1992, the loss of approximately 48,000 acres of farmland from 1983 to 1994 and the loss of 42,000 acres of wetlands between 1951 and 1981 (Delaware Office of State Planning Coordination (OSPC), 1999). The growth management program is centered on a system of mandatory review and voluntary compliance, where the state of Delaware sets broad goals and priorities for growth and preservation through its "Strategies of State Policy and Spending"; and reviews comprehensive plans, map amendments, and major subdivisions for consistency with state goals. State review is mandatory, but compliance with state review is left to the discretion of local governments. The "stick" is that the state will not support infrastructure investments in areas where the state prioritizes preservation.

Existing scholarship presents conflicting perspectives on Delaware's growth management status. Some exclude it due to its lack of mandatory compliance mechanisms (Landis, 2019; Anthony, 2004), while others argue its centralized oversight qualifies it as a growth management state (Weitz, 2020). Nonetheless, Delaware remains understudied in broader growth management research, leaving critical gaps in understanding how its growth management program shapes land use outcomes. Further, questions remain regarding the effectiveness of Delaware's growth management efforts, particularly in Sussex County, which faces increasing development pressures, and has grown 70% faster than the state of Delaware at a rate of 169% over the past 50 years (Sussex County Comprehensive Plan, 2019).

Our paper examines how Delaware's growth management program has impacted development in Sussex County and its 25 municipalities. First, we examine changes in land cover and urban density in Sussex County from 1982 to 2017 (before and after growth management), using data from the National Resources Inventory (NRI). We also investigate changes in development patterns from 2004-2024 in areas where the state favors growth and areas where the state favors preservation. Changes in development patterns will be examined by calculating the annual proportion of development occurring in priority growth versus preservation areas, based on georeferenced residential building permit data and development project approvals between 2004 and 2024. Further, land cover change analysis will be conducted by overlaying Multi-Resolution Land Characteristics (MRLC) land cover datasets with Delaware's Strategies of State Policy and Spending maps to identify and quantify the conversion of land to urban uses within priority preservation areas. By combining statistical, spatial, and policy insights, our paper contributes to a deeper understanding of the dynamics of state-led planning and decentralized land use decisions in the context of growth management.

Impact of Consultants on Zoning Reform in Oregon

Abstract ID: 1842.0.0.704.2025

Track 8: Land Use Policy and Governance

Research-in-Motion Presentation Submission, Research currently in process

Bongani Ikaneng [bonganit@uoregon.edu] btikaneng@gmail.com, presenting author

Rebecca Lewis [University of Oregon] rlewis9@uoregon.edu

José Meléndez [University of Oregon] jmelende@uoregon.edu

Oregon passed zoning reform in 2009 that required cities with populations over 10,000 to allow duplexes on single-family lots, while those with populations exceeding 25,000 must permit triplexes and quadplexes (ORS 197.758). Although the reform mandated cities to implement changes, the state provided no guidance on engaging the public in discussions regarding amendments to development codes (Meléndez et al., 2024). Each city determined the level of community involvement needed for the state-mandated ordinances, which could include hiring consultants to assist in the engagement process, either by applying for technical assistance grants from the Department of Land Conservation and Development or using their own funds, or a combination of both.

Loh and Norton (2015) contend that significant concern exists regarding the role of consultants in the planning process, positing that their influence may compromise the authenticity of community-driven planning initiatives. Barry et al. (2024) argue that a technocratic shift is taking place in public participation, as planners work together with practitioners from various fields who contribute different skill sets to the participatory process. Research on the role of planning consultants in public participation in the planning process is gaining increasing attention. It underscores the importance of recognizing the validity of planning outcomes, particularly when there's a chance that consultants might prioritize their own interests or those of local officials over the community's needs.

This research examines the role of consulting firms in shaping and implementing community engagement during zoning reform processes by asking the following questions: What were the key differences in the strategies used by firms for public engagement in zoning reform across cities? How did the firm's strategies shape the design of community engagement methods during zoning reform processes? How did variations in consultants' approaches influence how cities organized public engagement activities and incorporated community feedback into zoning reform decisions?

This research utilizes data from a large dataset related to a project on Learning from Housing Policy Innovation in Small and Midsize Cities. Data from interview transcripts with city employees will be analyzed qualitatively to identify codes relevant to the research questions. This study will employ an inductive approach aimed at condensing raw textual data, establishing connections between research objectives and findings, and developing a framework of underlying experiences or processes evident in the data (Thomas, 2006). This research will explore interview transcripts to reveal how the firms' methods and preferred techniques influenced community engagement.

This will include an analysis of the tools and techniques employed by each firm and the frameworks used in each city. Additionally, this study will emphasize how each firm identifies stakeholders and ensures that marginalized or underrepresented voices are included. Furthermore, the findings may clarify whether consultant-led planning processes result in positive or negative outcomes.

Pre-disaster Development Policies Shape Coastal Vulnerabilities: Lee County, Florida

Abstract ID: 1842.0.0.1121.2025

Track 8: Land Use Policy and Governance

Research-in-Motion Presentation Submission, Research currently in process

Sydney Robinson [Stony Brook University] sydney.robinson@stonybrook.edu, presenting author

Farinaz Motlagh [Stony Brook University] farinaz.motlagh@stonybrook.edu

Sara Hamideh [Stony Brook University] sara.hamideh@stonybrook.edu

The frequency of coastal floods around the United States has risen sharply over the last few decades, and rising seas point to further acceleration (M.K. Buchanan et al. 2020). Coastal communities are vulnerable to extreme coastal flooding, and socially vulnerable populations continue to be disproportionately affected. Regional and local land development policies, plans, regulations, and funding programs play critical roles in shaping or mitigating local disaster risks and vulnerabilities. Throughout this century, governments at every level have emphasized programs that ease the development and use of lands exposed to hazards with little attention to the long-term sustainability of that development (Burby, Deyle, Godschalk, & Olshansky, 2000). Nevertheless, there is limited understanding of how and whether pre-disaster development policies align with hazard mitigation goals to minimize risks. Vulnerabilities often depend on structural constraints which are exogenous to the community, such as unequal distribution of wealth and resources within the society, market forces, political systems and governance (Gaillard, 2010). This study investigates the ways in which pre-disaster development policies shape social and physical vulnerabilities by examining Lee County, Florida, prior to Hurricane Ian. Using geospatial and descriptive quantitative analysis, we analyze the National Structure Inventory (NSI) and U.S. Census demographic and socioeconomic data to assess vulnerabilities at the Census Block level. We complement this analysis with data from 300 household surveys and 1,600 physical assessment surveys, collected by our team, to capture pre-Ian social and physical vulnerabilities at the building and household level. To draw a connection between pre-Ian vulnerabilities and development policies, we conduct qualitative coding and analyses on forty-one policy, planning, regulation, and funding documents for Lee County from 2000 to 2022. The findings highlight the critical role that development policies play in shaping disaster vulnerability, demonstrating how decisions related to land use, urban planning, infrastructure investment, and resource allocation can either reduce or increase social and physical exposure to hazards.

Who Runs Detroit? Philanthropy, Public Projects, and the Future of Urban Governance

Abstract ID: 1842.0.0.359.2025

Track 8: Land Use Policy and Governance

Research-in-Motion Presentation Submission, Research currently in process

Rand Makarem [The University of Michigan Ann Arbor] rmakarem@umich.edu, presenting author

Today, urban governance is no longer the exclusive domain of the state. It increasingly involves a hybrid, dynamic network of public, private, and quasi-public actors who negotiate responsibilities and shape urban outcomes through collaborative frameworks (Bevir, 2011). Some scholars view this as an evolution toward more networked, participatory decision-making (Pierre, 2000). Others criticize it as a consequence of neoliberal urbanism—processes that have encouraged privatization, decentralization, and the rise of public-private partnerships (Harvey, 1989; Jessop, 1997).

In this paper, I argue that governance shifts in cities impacted by economic decline or state retrenchment—where authority and functions once held by the public sector are assumed by non-state actors—can create a path dependency that prevents local governments from regaining their capacity to govern. I suggest this path dependency may be more pronounced in certain urban sectors than others, depending on the scale of non-state involvement and the institutional strength of the public sector in those domains.

Using Detroit as a case study, my research asks whether the erosion of public authority and growing involvement of non-state actors—particularly philanthropic foundations—transforms the state from a regulatory body into a facilitating entity. By examining the influence of foundations in financing and shaping urban revitalization projects across sectors such as transportation (QLine), greenways (Joe Louis Greenway, Dequindre Cut), and mixed-use development (Detroit Riverfront), I aim to understand whether the state's role shifts across projects and over time. I also investigate why foundations invest in certain initiatives, why their influence concentrates in specific sectors, and what this reveals about the balance of authority between the state and non-state actors. Ultimately, this analysis explores whether the weakening of public sector capacity—and the resulting reliance on private funding—is more pronounced in particular areas of urban governance.

I employ a qualitative methodology combining document analysis with fieldwork to trace the influence of foundations across revitalization projects in Detroit. Data sources include foundation reports, project proposals, and public funding records. I conduct semi-structured interviews with planners, city officials, directors and staff from philanthropic institutions, and members of community associations, advisory groups, and coalitions. To complement these interviews, I attend public meetings related to ongoing projects such as the Joe Louis Greenway, to observe engagement processes and stakeholder interactions in real time.

My findings suggest that the influence of foundations in Detroit's revitalization is neither uniform across time nor consistent across sectors. The level of state authority varies between pre- and post-bankruptcy periods, shaping how much control public institutions retain. In some instances, the state acts as a coordinator, while in others it continues to lead project design and implementation—even alongside strong philanthropic partners. These patterns suggest that foundation involvement is often guided by strategic considerations such as impact or alignment with regional policy goals, alongside filling governance voids.

This research contributes to debates on hybrid governance and the restructuring of urban power by offering a framework to understand how philanthropic influence manifests across time and space, and what it reveals about the shifting architecture of public authority. It indicates that when foundations take on roles previously occupied by the state, they may entrench governance trajectories that become difficult to reverse. Ultimately, this study offers

insight into how cities like Detroit—marked by disinvestment and devolution—are governed today, and what this governance signals about the changing role and capacity of the public sector.

Balancing Solar Expansion and Farmland Retention: Local Planning Responses in Minnesota

Abstract ID: 1844.0.0.696.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Lanika Sanders [University of Michigan] lanikasa@umich.edu, presenting author

As planning scholars and practitioners across the United States work to tackle climate change, renewable energy development has emerged as a key strategy. Solar energy is poised to play a significant role in decarbonization, but its expansion on farmland presents both opportunities and challenges (O'Shaughnessy et al., 2023). While solar leases provide stable income for some farmers, utility-scale projects primarily target large landowners, further concentrating land and wealth (Maguire et al., 2024). Small and mid-sized diversified farms are key to strong regional food systems, as they typically use more sustainable practices, grow a wider variety of crops, and sell directly to local markets (Wright & Annes, 2020). However, high land costs and restrictive tenure practices make it difficult for many of these farmers, particularly those from underrepresented groups, to retain land (Horst & Marion, 2019). Planners—who play a crucial role in shaping land use policy and farmland protection efforts (Poggi et al., 2018)—must navigate energy-agriculture tensions carefully. Without intentional policies, the push for renewable energy could unintentionally deepen inequities in farmland retention and weaken regional food systems.

This research examines how local governments approach farmland retention amid solar energy development. I focus on Minnesota, a state with significant utility-scale solar development and large-scale commodity farms, but also with an active local foods culture and state and regional efforts to support diversified and underrepresented farmers. I compare four counties selected for their differences, including the presence of small and mid-sized farms, permissive vs. restrictive zoning ordinances, and significant vs. minimal large-scale solar development. My methods include document review of land use plans, zoning regulations, and agricultural policies for the extent to which local governments ensure farmland retention within the context of solar development. Semi-structured interviews with county planners and superintendents, agricultural extension agents, and representatives from organizations supporting underrepresented farmers provide insight into how these policies function in practice, highlighting both constraints and opportunities for small and mid-sized farmers.

Results indicate that while county-level plans and policies generally permit solar development on agricultural land, they lack clear mechanisms to integrate farmland retention protections with solar energy planning. State law restricts solar development on high-quality farmland, yet local policies fail to expand on this protection by including provisions that enable small and mid-sized farmers to benefit from smaller-scale solar projects. Interviews reveal that planners and local officials recognize the risks solar development poses to underrepresented farmers, particularly those who rent land. However, they frequently cite county-level farmland protection programs and

beginning farmer loan programs as sufficient safeguards, even though interviews reveal persistent barriers to land retention. This suggests a need for more deliberate policy coordination between solar energy planning and farmland retention across all levels of government.

This research contributes to planning scholarship and practice by emphasizing the need for integrated approaches that balance solar expansion with farmland retention. The paper concludes with policy recommendations for planners and decision-makers to better align solar development with farmland retention and robust regional food systems.

Beyond Customer's Perspective: Exploring Neighborhood-Level Determinants of Thriving Foodscapes

Abstract ID: 1844.0.0.711.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Yilun Zha [Georgia Institute of Technology] yilunzha@gatech.edu, presenting author

Background: A thriving foodscape is essential for neighborhoods' prosperity, resilience, and overall well-being. In the U.S., with a few notable exceptions (e.g. food pantries), most people meet their daily nutritional needs through retail food businesses like grocery stores, restaurants, and coffee shops. Neighborhoods with limited food retail options either trap residents with limited mobility in the "food apartheid" [1] or push them further away for more options.

While meaningful progress has been made through public and civic investments, efforts that focus solely on subsidizing and educating customers have often proven ineffective at sustaining retailers' long-term interest and commitment [2]. Food retail businesses do not emerge randomly; they result from careful calculus within specific neighborhood contexts. Prior studies have revealed a variety of financial and managerial factors in business (re)location outcomes [3, 4], while structural factors at the neighborhood and regional levels that predict food business survival remain underexplored.

Objective: To address this gap, this paper explores the impact of neighborhood determinants at multiple levels on the survival and sales of food retail outlets. Specifically, this paper answers the following questions: (1). To what extent do neighborhood characteristics influence the survival and performance of retail food businesses? (2). How do factors at multiple levels (city, neighborhood, district), if exist, interact with one another?

Methods: This paper focuses on neighborhoods in nine major cities, covering 7,234 Census Block Groups (CBGs). The two outcome measures, namely food business survival and performance, were sourced from SafeGraph and Replica, respectively. We included 21 independent variables across three nested geographic levels. At the district level, we incorporated six variables on store characteristics (e.g. store type, physical setting) and ambient built environment features. Neighborhood-level variables ($n=11$) were measured using two catchment area definitions. Fixed administrative boundaries were applied to place-based variables, such as property crime rate, historic redlining status, and macro-level built environment features. In contrast, egocentric neighborhoods [5], defined by human travel patterns, were used to capture socioeconomic conditions. Finally, city-level variables ($n=4$) were added to control for macroeconomic and policy environments. For statistical analysis, we fitted multilevel mixed-effects regression models (negative binomial for survival and OLS for spending) with a random effect of city membership.

Results: Over the last five years, the number of grocery stores and restaurants in the nine cities dropped by 16.7% and 19.2% respectively. Food spending has decreased by a smaller margin (-8.6%), likely due to population loss and the growing share of online grocery deliveries.

In the regression models, the factors with the strongest effect on food business survival included neighborhood crime rate ($b=-0.86$, $p<.001$), residential population density ($b=0.85$, $p<.001$), and street network connectivity ($b=0.07$, $p<.01$). For every 1% increase in property crime rate, 2.3 restaurants and 0.6 grocery stores closed. Factors predicting spending changes also included household income and commercial land use. An interesting finding was the varying size of egocentric neighborhoods: neighborhoods with more outside were more resilient, whereas isolated neighborhoods were more vulnerable to closures and spending drops.

Implications: These findings underscore the need for comprehensive assessment and more structured investments in regional infrastructure and neighborhood amenities beyond temporary charity-form subsidies. Lessons learned from this paper will be of use to economic development planners and policy makers to develop long-term objectives and justify capital investment programs for the benefit of local food businesses.

Challenging Urban Development in Puerto Rico through Agroecology

Abstract ID: 1844.0.0.255.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Carol Ramos Gerena [University at Buffalo-SUNY] carolram@buffalo.edu, presenting author

In their influential 1987 model, Thomas R. Johnston and Christopher R. Bryant categorized farmers' adaptations to peri-urban development pressures, distinguishing between positive adaptations—vertical expansion, horizontal expansion, and engagement with non-farming activities—and negative adaptations, selling and abandoning farming. Recent studies have utilized this framework to analyze farmers' responses to urban development (Elhadary et al., 2013; Inwood & Sharp, 2012; Levi, 2007; Ruoso, 2020). However, I argue that the Johnston-Bryant model neglects responses that neither adapt nor accommodate development but actively resist it. In this study I use post-development theory to examine small-scale agroecological farmer's resistance to development in the context of Puerto Rico.

Critical development scholars define development as a globally constructed standard imposed predominantly between the 1950s and 1990s, replicating Western lifestyles at the expense of diverse cultural, ecological, political, and medicinal practices (Escobar, 1995; Gudynas et al., 2018; Patel & Marya, 2021; Rahnema, 1997). Since Truman's 1949 speech categorizing large global populations as "underdeveloped," development justified extraction, industrialization, and dispossession, especially in Asia, Africa, and Latin America, using North America and Europe as benchmarks (Kothari et al., 2019). This imposed modernity (also understood as a neocolonialism) often caused profound environmental degradation and social injustice, portraying regions as economically unproductive and incompatible with modernity (Sargeson, 2013).

Manifestations of development include agro-extractivism and urban growth machines. Agro-extractivism promotes agribusiness reliant on pesticides, fertilizers, genetically modified organisms, and digital technologies linked to mining and petroleum, degrading ecosystems and human health (Dunlap, 2023). Urban growth machines depend on lands and people deemed "developable" to sustain expansion (Molotch, 1976; Pfeffer & Lapping, 1994). In contrast to these linear growth-focused processes that sustain a "one-world world," post-development scholars highlight over 70 examples of resistance to the uni-verse created by development, emphasizing grassroots self-management and decentralization through the pluriverse, which includes agroecology (Kothari et al., 2019; Esteva, 2022).

This study examines agroecological farmers' resistance to development in Puerto Rico. State-led development "with an American hallmark" drove Puerto Rico's 20th-century modernization (Dinzey-Flores, 2018), targeting prime farmlands for urban encroachment (López et al., 2001) and permitting residential developments, industrial solar farms, and Airbnbs on fertile soils (Ramos-Gerena, 2024). Therefore, in this paper I ask: How do agroecological farmers challenge urban development in Puerto Rico? Which post-development elements are present in this resistance? What are agroecology's limitations as a pluriverse example, and why do they exist?

I employed iterative phronetic analysis (Tracy & Hinrichs, 2017) of semi-structured interviews with sixteen agroecological farmers in Puerto Rico who identify as agroecologists (participants or graduates of El Josco agroecological school, n=1,000) and farm visits in areas facing developmental pressures. Findings suggest agroecological resistance aligns with post-development perspectives, utilizing community land trusts, land protection campaigns, and solidarity-based exchanges. Recognizing and strengthening these practices as resistance

beyond positive and negative adaptations to development is vital for protecting valuable farmland in Puerto Rico and elsewhere.

Changing Urban Foodscape: Evaluating Food Access Trends in the Kansas City Metro Area

Abstract ID: 1844.0.0.424.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Maria Binte Edrish [Kansas State University] medrish@ksu.edu, presenting author

Shakil Kashem [Kansas State University] shakilkashem@ksu.edu

Food accessibility is a critical determinant of community health outcomes, health equity, and wellbeing. While prior studies have investigated disparities in healthy food access and its impacts on health outcomes at the local level (Leonard et al., 2018), very few studies have explored the changing foodscape or food access patterns over time within an urban area (Kolak et al., 2018). The Kansas City Metro Area (KCMA), like most other major metropolitan areas in the U.S.A., has undergone significant changes in food access in the past decade due to urban growth, demographic shifts, and COVID-19 pandemic. However, food insecurity is still a major concern in this area with low-income and minority communities facing growing disparities in accessing fresh and nutritious food sources. In this study, we explore how food access patterns in the KCMA have changed over time and what socio-economic factors have contributed to this change. We evaluated food access using the Modified Retail Food Environment Index (mRFEI), which measures the proportion of healthy food retailers relative to total food outlets (Luan et al., 2015). We collected food store location data from Data Axle and calculated mRFEI at the census tract level for two time periods (2011 and 2024). We mapped mRFEI values to identify the spatial and temporal patterns of food access in the KCMA. We also applied spatial regression to evaluate how the shifts in mRFEI are correlated with different socio-economic and demographic factors.

Our results show that healthy food access, measured by mRFEI, has undergone significant changes in KCMA between 2011 and 2024. Although the number of healthy food stores and their spatial coverage have increased, disparities in healthy food access have also increased at the same time. This disparity has disproportionately impacted areas with marginalized populations, particularly low-income households and racial and ethnic minorities. The declining mRFEI scores observed in these areas suggest a deterioration in the quality of the local food environment over time. Conversely, wealthier communities have seen improvements in food access, reinforcing longstanding socio-economic inequalities. Our analysis further reveals a strong correlation between declining mRFEI values and socio-economic variables, highlighting the role of economic disinvestment, restrictive land use policies, and transportation barriers in perpetuating food insecurity. These findings underscore the urgent need for systemic interventions to address food inequities in the KCMA. Possible policy solutions and planning initiatives to improve healthy food access are discussed, which can be expanded to other cities and communities.

Depression and the Role of Outdoor Leisure Activities: a MF-DCCA Approach

Abstract ID: 1844.0.0.961.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Heeyeun Yoon [Seoul National University] hyyoon@snu.ac.kr, presenting author

A growing body of research has highlighted that exposure to outdoor environments, whether through passive contact or active participation in leisure activities, serves as an important protective factor against depression. Proximity to green spaces and engagement in outdoor physical activities have been consistently associated with improved mental health outcomes across various populations.

Within this context, the COVID-19 pandemic presented an unprecedented global shock, profoundly affecting mental health and significantly disrupting daily life. Among its many consequences, depressive disorders have attracted considerable attention, with mounting evidence reporting substantial increases in their prevalence. Physical distancing measures, lockdowns, and restrictions on outdoor activities disrupted individuals' daily routines and severely limited access to recreational spaces, likely exacerbating feelings of isolation, loneliness, and depression. Alarming, the World Health Organization (WHO) reported a 25% increase in the global prevalence of depression and anxiety during the first year of the pandemic, raising urgent concerns regarding its long-term mental health implications.

At the same time, the pandemic created a quasi-natural experimental setting, wherein outdoor activities experienced a sharp decline due to pandemic-related restrictions, with regional variations depending on local policies. This setting provides a valuable opportunity to systematically examine the complex and multifractal nature of the relationship between outdoor leisure activities and mental health outcomes, particularly depression, using advanced time-series techniques.

Motivated by this backdrop, the present study investigates the impact of outdoor leisure activities on depressive disorders during the pandemic. Specifically, we focus on depression-related healthcare visits (ICD-10 F30–F39) as the primary outcome. To capture the dynamic and multifractal relationship between depression-related healthcare visits and outdoor leisure activity indicators—such as the availability of parks, playgrounds, and natural green spaces—we employ multi-scale multi-fractal detrended cross-correlation analysis (MF-DCCA). The dataset consists of healthcare service usage data provided by the Health Insurance Review and Assessment Service (HIRA), aggregated at the ward (Dong) level, spanning from January 2018 to January 2023, encompassing two years before and four years after the pandemic outbreak.

The study has two key objectives: First, we aim to identify structural changes in depression-related healthcare visits during the pandemic period using advanced time-series analysis. Second, we explore the multi-scale cross-correlations between outdoor activity indicators and depression trends, with particular attention to the potential buffering role of outdoor leisure infrastructure. By providing empirical evidence on the mitigating role of outdoor environments, this study offers valuable insights for public health interventions and urban planning, especially in designing resilient cities capable of promoting mental well-being during future pandemics or other large-scale disruptions.

Effects of Indoor Residential Crowding and Outdoor Green Space on Mental Health in Beijing, China

Abstract ID: 1844.0.0.387.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Xize Wang [National University of Singapore] wangxize316@gmail.com, presenting author

Xuelu Wang [National University of Singapore] wang_xuelu@u.nus.edu

Tao Liu [Peking University] liutao@pku.edu.cn

Central Theme: This study investigates how different aspects of the built environment at varying geographical scales relate to mental health outcomes, particularly depressive symptoms, among urban residents in Beijing, China. It uniquely explores how these relationships differ between local residents and migrants—two groups with distinct residential entitlements under China’s hukou system. The research aims to reveal how built environment inequalities translate into mental health disparities and how these effects are further moderated by gender and marital status.

Approach and Methodology: The study utilizes survey data collected in 2022 from 989 adult residents across 40 communities in Beijing. Depressive symptoms were assessed using the validated 10-item Center for Epidemiologic Studies Depression Scale (CESD-10). The analysis focused on two key environmental exposures: household-level indoor residential crowding, measured as average square meters per capita, and neighborhood-level outdoor green space, defined as the share of vegetated area within a one-kilometer radius of each community. Logistic regression models with district-fixed effects and extensive socioeconomic controls were employed to assess the associations. Subgroup analyses examined differences by migrant status, gender, and marital status. Multiple robustness checks were conducted to validate the findings.

Findings: Results show that both residential crowding and green space availability are significantly associated with depression, but these effects are group-specific. Residential crowding significantly increases the likelihood of depression among local residents, especially single and female locals, but not among migrants. In contrast, lower green space availability significantly raises depression risk among migrants, particularly male and married migrants, but shows no effect for local residents. These divergent effects suggest that the psychological relevance of physical environments differs across population groups, shaped by social and institutional contexts such as hukou status, family structure, and gender roles.

Implications to Planning Scholarship and Practice: This study underscores the importance of multi-scalar and demographically sensitive approaches of planning to improve people's mental health. It calls for planning strategies that integrate household- and neighborhood-level interventions—such as improving living space standards and enhancing neighborhood green infrastructure—while also addressing group-specific vulnerabilities. Mental health-promoting interventions should be tailored to recognize the distinct needs of vulnerable subpopulations, including female and single local residents as well as male and married migrants. These findings contribute to planning scholarship by providing empirical support for incorporating spatial justice and demographic specificity into healthy city frameworks, particularly in rapidly urbanizing and institutionally segmented contexts like China.

Ethnic Grocery Stores as Third Places: Evidence from Google Places Data on Immigrant Well-Being

Abstract ID: 1844.0.0.1149.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Inkoo Kang [New York University] archibrick@gmail.com, presenting author

Nari Yoo [New York University] gy2040@nyu.edu

Ethnic grocery stores are more than retail spaces; they function as “third places” for immigrant communities, offering social infrastructure that supports cultural continuity, mental health, and belonging. This study investigates the role of Asian grocery stores, especially Korean-founded chains like H Mart, as informal community hubs that enhance immigrant well-being in the United States. Drawing on Google Places review data, name-origin analytics, and state-level mental health statistics, we empirically examine how these stores operate as social anchors and whether their presence correlates with improved mental health outcomes in Asian American communities.

This mixed-methods study proceeds in two stages. First, using the Google Places API, we identify over 1,000 Asian grocery stores across the U.S. and collect review data, including reviewer names. Name-origin analysis via NamSor enables us to infer the likely ethnicity of reviewers, helping construct a demographic profile of store patrons. We use geospatial methods to map the ethnic composition of each store’s customer base, examining regional variations (e.g., co-ethnic patronage in Korean enclaves vs. pan-ethnic or multicultural engagement in diverse metros).

Second, we statistically analyze whether the density of Asian grocery stores in each state correlates with mental health outcomes using Behavioral Risk Factor Surveillance System (BRFSS) and National Health Interview Survey (NHIS) data. Regression models control for Asian population share, median household income, and urbanization level to isolate the association between ethnic grocery store presence and mental health outcomes. These variables are important, as areas with higher Asian populations may naturally have more ethnic stores and different health baselines, while socioeconomic status and urban-rural differences can independently affect community well-being. We assess whether higher Asian grocery density correlates with reduced frequency of poor mental health days, especially among Asian Americans. To explore causal mechanisms, we will explore difference-in-differences analysis and spatial lag models, accounting for temporal store expansion and regional clustering.

Preliminary findings suggest that these grocery stores not only serve primarily co-ethnic clientele but also attract diverse communities, acting as both bonding and bridging social capital spaces. Higher store density is associated with modest but significant reductions in mental distress, suggesting these stores provide critical informal supports often overlooked in urban policy. We argue that ethnic supermarkets should be recognized as valuable social infrastructure, particularly in immigrant-dense or underserved neighborhoods.

Our findings are expected to contribute to urban planning and public health in three keyways. First, we provide empirical evidence that ethnic supermarkets function as critical third places that support immigrant integration, social capital, and well-being. Second, we demonstrate a novel methodological approach by combining crowdsourced location data, onomastics, and health survey data to study social infrastructure at scale. Third, we offer policy implications: local governments should recognize ethnic grocers as community anchors and consider partnering with them for outreach and inclusion programs.

This research offers actionable insights for cities seeking to foster inclusive, resilient communities. As COVID-19 underscored the need for trusted, culturally relevant gathering spaces, our findings emphasize the importance of preserving and supporting ethnic grocery stores as “a home away from home” for millions of Americans.

Exploring Preventive Infrastructure: A Qualitative Study in India

Abstract ID: 1844.0.0.258.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Saisha Mattoo [University of Southern California] mattoo@usc.edu, presenting author

David Sloane [University of Southern California] dsloane@usc.edu

In accordance with Master Plan standards, Delhi displays a strong hierarchy of social infrastructure established at the neighborhood, district, and city level, which is a part of people's everyday lives. Despite established infrastructure, quality of life has declined due to sedentary lifestyles, neglect of ecological resources, social exclusion, and other critical elements leading to elevated occurrences of lifestyle diseases. Moreover, infrastructures that should amplify connections within groups and encourage people to interact across differences may be underperforming due to social perceptions and inequities among the adjacent neighborhoods.

A growing body of literature supports the associations between urban green infrastructure and the health of adults. Despite theoretical frameworks that emphasize the role of the urban environment on health, literature has ignored the various destinations within and outside the neighborhood people frequent in their everyday lives. This project advances urban planning studies by rethinking social and physical infrastructure presence in neighborhoods, or lack thereof, as contributors to health. This research introduces a novel concept of 'Preventive Infrastructure' (PI), defined as non-health infrastructure or neighborhood spaces that people frequent in their everyday lives, encourage positive health behavior such as walking and cycling, and induce positive perceptions such as safety, and inclusivity. This study explores intentional physical activity, such as exercising, cycling, and walking with the intent to improve health status and quality of life, as well as unintentional physical activity, such as walking, to conduct daily/weekly chores.

Drawing on focus groups and open-ended interviews with residents in the closely located low-income and high-income neighborhoods through a case study in Delhi, India, this grounded theory study aims to examine the neighborhood spaces identified as PI by residents of these neighborhoods and understand associated health behavior and perceptions of place. The collected narrative data from focus groups and interviews was coded sentence-by-sentence for description and analysis in Atlas.ti. The residents identified local commercial areas, neighborhood and city parks, religious institutions, and neighborhood streets as PI.

The analysis revealed that the commercial area despite being recognized as 'not pedestrian friendly' by shared consensus, was explored on foot by residents of all neighborhoods. Furthermore, residents belonging to high-income neighborhoods critically discussed the shortcomings of neighborhood parks and their intent to 'drive to the nearest city park' for intentional physical activity. Conversely, residents belonging to low-income neighborhoods felt 'accepted' in middle-income neighborhood parks for relaxing after a day's work, walking, and socializing with friends. Study participants also discussed their mode of access behavior with respect to the locations of Temples, Gurudwara, and Mosques. Neighborhood streets were recognized as spaces inducing both positive and negative perceptions, despite being used by residents for socializing, and intentional and unintentional physical activity.

This research has become more critical because of the Indian government's recognized health aspirations for the city. The forthcoming 2041 Delhi Master Plan, envisions 'A People's City' that is environmentally sustainable, livable, and economically and culturally strong. Despite a strong vision, the community's voice remains absent from the draft. Furthermore, the city planning process has disregarded the varying needs of different socio-economic groups that comprise the planning area unit. Deriving from the community voice providing new perspectives on the topics,

the project will further encourage social policy interventions, such as equitable infrastructure distribution in neighborhoods.

Exploring the moderating role of retail environment on farmers market use and healthy eating

Abstract ID: 1844.0.0.708.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Yilun Zha [Georgia Institute of Technology] yilunzha@gatech.edu, presenting author

Hui Cai [Georgia Institute of Technology] hui.cai@gatech.edu

Herminia Machry [University of Kansas] hsmachry@ku.edu

Renee Bryant [Johnson County Department of Health and Environment] renee.bryant@jocogov.org

Background: Farmers markets (FMs) are increasingly recognized for their multifaceted contributions to community development, public health, and social cohesion [1,2]. During the past two decades, the number of FMs in the United States has grown significantly, rising to over 8,700 by 2024. While existing studies have primarily focused on economic and accessibility factors that encourage visits to FM [3], the role of the retail environment in shaping behaviors within FMs remains underexplored. This study addresses two research questions to examine the relationship between the retail environment and FM attendance: 1. What is the relative role of accessibility and retail environment characteristics in shaping various shopping behaviors within FMs? 2. How does this influence, if it exists, vary based on individual perceptions and motivations (e.g., utilitarian vs leisure-oriented shoppers) regarding different aspects of FMs?

Methods: A cross-sectional survey was conducted in 2024 among customers (n=695) at nine FMs in Johnson County, Kansas. The survey collected data on demographics, behavioral outcomes related to FM travel, and perceptions and satisfaction with the physical and social environments. The primary behavioral outcomes of interest were visit frequency, dwell time, money spent, and fruit/vegetable purchases. The measurement model applied confirmatory factor analysis (CFA) on intrapersonal perception and satisfaction ratings, both on a five-point Likert scale. For hypothesis testing, separate structural equation models (SEM) were fitted as regression models for endogenous variables related to FM attendance, using exogenous factors derived from the CFA. Specifically, the analysis tested both indirect and moderating effects of environmental perception factors on FM attendance outcomes.

Results: In Johnson County, FM visitors were predominantly female (78.5%), aged 60 or older (44.9%), and held a bachelor's degree (76.2%). The gender and age representation aligns with findings from previous surveys conducted in the US [3]. Among respondents, 59.3% reported attending farmers markets frequently (five or more times per season). Most visits (88.5%) lasted one hour or less, with the majority of customers staying between 15-30 minutes. The CFA models identified four latent factors (LVs) for both customers' perceptions and satisfactions, namely accessibility, physical environment, social environment, and market products, consistent with the survey's predefined structure.

The SEM models revealed distinct influence pathways between shoppers' perceptions, satisfaction, and behavioral outcomes. Controlling for socioeconomic status and distance to FMs, visit frequency was positively associated with satisfaction with accessibility through a direct effect ($\beta=0.23$, $p<.001$) as found in prior studies [4], and perceptions thereof through an indirect path ($\beta=0.03$, $p<.001$). In contrast, retail environment ($\beta=0.11$, $p<.001$) and product LVs ($\beta=0.24$, $p<.01$) were the only significant predictors of dwell time and money spent. Finally, the model revealed bi-directional moderating effects of individual perception on the relationship between satisfaction and behavioral outcomes. Perception factors could either positively moderate the relationship as a form of (dis)confirmation of expectation [5] or reduce the influence of satisfaction with other factors through a compensatory trade-off.

Implications: This study suggests that a desirable physical and social environment aligned with customers' perceptions significantly promotes longer stays at FMs. This can be pursued both as a goal itself and as a lever for more positive changes, such as strengthening social capital and encouraging healthy diets. This message could be useful for policy makers, market managers, and urban designers to make informed decisions in fostering an inviting FM environment through policy guidelines, site selection strategies, and operational management practices.

Exploring the Nonlinear Impacts of Zoning Policies on Food Access Inequities

Abstract ID: 1844.0.0.532.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Marjan Gharehghashloo [University of Texas at Arlington] marjan.gharehghashloo@uta.edu, presenting author

Qisheng Pan [University of Texas at Arlington] qisheng.pan@uta.edu

Food access inequities remain a persistent challenge in urban environments, shaped by the complex interplay of land-use regulations, transportation networks, socioeconomic inequality, and racial segregation. Although “food deserts”, defined as areas with limited access to affordable and nutritious food, have been widely studied (Fitzpatrick, Greenhalgh-Stanley, & Ver Ploeg, 2015; Lu & Qiu, 2015), the specific role of zoning on these disparities remains underexplored. While much of the literature focuses on supermarket density, proximity to food outlets, and income levels (McKenzie, 2014; Kuai & Zhao, 2017), scholars increasingly recognize zoning policies as foundational drivers of spatial food inequities. Zoning shapes whether neighborhoods can accommodate commercial food retail, particularly full-service supermarkets, and influences whether residents rely on automobile-dependent shopping centers or have access to food in walkable, mixed-use areas (Smith, 2012; Hamidi, 2020).

Despite increasing awareness of zoning’s influence, few studies integrate zoning, transportation, and food pricing into a unified framework. Most rely on linear models and examine land use, mobility, and affordability separately. Zenk (2004) and Smith et al. (2010) show that poverty and race correlate with food access disparities, yet policy drivers like exclusionary zoning and transportation inequities remain under-addressed. This study addresses these gaps by examining how zoning, interacting with transportation access and food pricing, shapes food access. The research addresses three questions: (1) What are the key factors influencing food access in cities? (2) How do zoning regulations affect food access in food desert areas? (3) How to improve food access through store availability, land use, and transportation access?

To address these questions, this study proposes a multi-stage machine learning framework designed to capture the nonlinear and interdependent effects of zoning, transportation, and food pricing on food access. First, Convolutional Neural Networks (CNNs) are applied to zoning and land-use maps to extract high-dimensional spatial features that reflect the built environment’s potential to support food retail. These features reduce dimensionality and serve as structured representations for subsequent analysis. Next, a nonlinear regression model, such as a Random Forest, leverages these extracted features along with transportation accessibility and food pricing data to estimate the combined and interacting effects on food access outcomes. To explore how zoning policy changes might improve food access, Reinforcement Learning (RL) is introduced as a simulation tool, enabling counterfactual testing of zoning reform scenarios under varied land use and transit configurations. This integrated approach not only accommodates complex, nonlinear relationships but also enables policy-relevant insights into the effectiveness of land use reforms. The empirical analysis centers on Dallas and Fort Worth, offering a comparative lens across two Texas cities with distinct zoning structures and transportation systems.

Heat Exposure and Older Adults' Outdoor Walking in Houston, Texas, USA: a cross-sectional study

Abstract ID: 1844.0.0.927.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Jiwoon Jeong [Texas A&M University] dolcejw324@tamu.edu, presenting author

Chanam Lee [Texas A&M University] chanam@tamu.edu

Background-The escalating global temperatures pose significant challenges to human health and mobility, particularly in urban environments where heat exposure is intensified by the urban heat island effect [3]. Older adults are among the most heat-vulnerable populations due to age-related physiological changes, chronic conditions, and socio-economic factors [1]. Walking, an essential form of physical activity, provides numerous health benefits [5] and serves as a vital mode of transportation. However, extreme heat conditions can deter walking, compromising mobility, public health, and the quality of urban life [4]. Despite extensive research on how the built environment promotes walking [2], fewer studies address how heat exposure impacts pedestrian behavior, particularly among older adults. This research focuses on exploring the complex interactions between thermal comfort, urban design, and outdoor walking, with an emphasis on these vulnerable populations.

Methods-The data for this study came from a NSF-funded project, which collected GPS and accelerometer data from 53 older adults including 653 walking trips in Houston, TX, USA. This dataset includes monitoring of participants' walking trip movements and physiological measures, such as blood volume pulse (BVP) and Galvanic Skin Response (GSR) collected using E4 wristbands. Climate data was collected from the Texas Evapotranspiration Network, Texas A&M AgriLife Extension Service. Descriptive statistics and multivariate regression are conducted to quantify changes in walking speed, destination choice, and walking distance during extreme heat days compared to milder conditions defined based on the Comfort Formula (COMFA) heat stress levels.

Preliminary Results-We found that more extreme heat-stress conditions resulted in higher mean skin temperature (31.75°C vs. 32.72°C, $p < 0.001$) and altered walking behaviors. Participants decreased their average walking speed (2.80 m/s to 1.89 m/s, $p < 0.001$) and reduced their overall walking distance (2.8 km to 1.7 km, $p = 0.001$). Physiological responses reflected increased thermal stress, as demonstrated by nearly doubled GSR levels (5.84 to 11.12, $p < 0.001$). These findings highlight the significant impact of heat risk conditions on skin temperature and walking patterns.

In addition, future analyses will integrate demographics, built environmental conditions, and microclimatic features of the walking route, including sidewalk shading, tree canopy coverage, and ground surfaces, with GPS data to evaluate their impact on walking behaviors. This integration enables the identification of specific urban design elements that promote or hinder older adults' walking and mobility in hot weather.

Conclusion-The study underscores the importance of climate-adaptive urban designs in supporting older adults' pedestrian mobility under extreme heat. Utilizing GPS and physiological monitoring data, this research revealed significant impacts of increased heat stress on older adults' walking behaviors and physiological responses. By integrating these findings with analyses of urban microclimate and built environment factors—including sidewalk shading, tree canopy coverage, and ground surface materials—the study is expected to offer actionable insights into specific urban design features that can mitigate the adverse effects of heat exposure.

Home Mortgage and Cognitive Function in Older Adults: Examining Neighborhood-level Patterns

Abstract ID: 1844.0.0.425.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Liang Chen [University of Michigan] liach@umich.edu, presenting author

Bruce Mitchell [National Community Reinvestment Coalition] bmittell@ncrc.org

Helen Meier [University of Michigan] hspink@umich.edu

As cognitive health is crucial for maintaining independence and well-being, cognitive decline has emerged as a significant public health issue in aging societies. According to the Centers for Disease Control and Prevention, approximately one in nine adults aged 45 and older experience subjective cognitive decline. The deterioration of cognitive health is associated with diminished quality of life, increased neuropsychiatric symptoms, heightened disability, and a substantial rise in healthcare expenditures, posing great challenges for aging individuals and the entire society. While existing research has extensively explored individual-level risk factors, such as educational attainment and health behaviors, neighborhood-level factors remain largely overlooked. Neighborhood conditions play a crucial role in shaping the physical and social environments in which people are living, potentially influencing cognitive functioning and risks for dementia. One key neighborhood-level indicator reflecting local investment and housing security is the number of home mortgage loans issued to a neighborhood. Mortgage lending reflects economic stability, community investment, and neighborhood desirability, all of which could shape the cognitive health of residents. However, the relationship between neighborhood mortgage density and cognitive function in older adults remains underexplored.

To address this gap, the present study examines the association between neighborhood mortgage lending and cognitive function in older adults across the United States. We integrate data from the Health and Retirement Study with neighborhood-level mortgage lending data from the Home Mortgage Disclosure Act Longitudinal Dataset. The study sample includes HRS participants aged 50 and older, and cognitive function is measured using the summary cognitive status score derived from standardized assessments conducted via telephone, face-to-face interviews, or internet surveys. The observation period spans from 2012 to 2020, covering five waves of data that are pooled for analysis. The primary exposure variable, neighborhood mortgage density, is calculated as the total number of mortgage loans issued within a neighborhood from 2011 to 2020, adjusted for the number of households in that neighborhood. To account for the nested structure of the data, we employ a three-level linear regression model using a mixed-effects approach following a previous study. The first level captures within-individual variations in cognitive scores over time, incorporating time-varying individual covariates such as age, smoking status, alcohol consumption, cardiovascular risk factors, mental health status, and physical health conditions. The second level accounts for between-individual variations, including demographic characteristics such as gender, race, and educational attainment. The third level captures neighborhood-level factors, including mortgage density, racial composition, poverty rate, homeownership rate, median household income, and median property value.

The study aims to determine whether mortgage density is a significant predictor of cognitive function, hypothesizing that residents of neighborhoods with lower mortgage density, indicative of disinvestment and economic instability, face an increased risk of cognitive impairment. Additionally, we examine whether individuals from marginalized racial and socioeconomic groups are more susceptible to cognitive decline in these underinvested neighborhoods. By elucidating the relationship between mortgage lending and cognitive functioning, our findings will contribute to a more comprehensive understanding of geographic determinants of

cognitive health. This study will provide valuable insights for policymakers, planners, and public health professionals seeking to develop targeted interventions that mitigate cognitive decline risks associated with neighborhood-level economic disparities, ultimately fostering healthier aging environments.

How do Technologies Help Aging in Place? Evidence from Rural China

Abstract ID: 1844.0.0.430.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Yingying Lyu [West Chester University] ylyu@wcupa.edu, presenting author

Ann Forsyth [Harvard University] aforsyth@gsd.harvard.edu

Background and Research Questions-The world's population is aging, and most older adults prefer to remain in their own homes within their communities rather than move to nursing homes (Roy et al., 2018). Many experts propose that technologies can help enable community living (Kleinman et al., 2021). Prior research has primarily focused on older adults' acceptance of individual technologies, such as social robots, remote monitoring devices, smartphones, and Telehealth, as well as the availability of technology to support aging in place in urban contexts (Lyu & Forsyth, 2024; Peek et al., 2014). However, little is known about how a broad range of technologies is currently being used by older people, particularly in rural areas of less developed countries.

This paper draws on fieldwork in rural China to explore the comprehensive use of technology in older adults' daily lives. Specifically, we address two questions: (1) How are technologies currently being used to help older people age in place in rural China? (2) How does the domestic environment support or inhibit such use?

Methodology-One of the authors implemented the field work in China from June to August in 2024, supported by collaborators in China. Using convenience and snowball sampling, we conducted interviews with 44 rural residents aged 60 and above across three regions in China. Data collection methods included 1) in-depth interviews and 2) systematic photography in interviewees' homes and the adjacent environment.

New Findings-This paper finds that older adults are using a combination of both older and newer technologies to support daily life across various domains, including health, safety, mobility, social connections, and everyday activities. These technologies help maintain older adults' agency within their environment. Meanwhile, rural homes are often poorly designed for safety and accessibility, making it difficult to use certain technologies, particularly those supporting mobility.

Implications for Planning Research and Practice-We advocate for more research in planning and community development to better understand older people's needs and enhance technology use for aging at home. Future studies could further examine how social factors like community services, ethnicity, and gender influence technology adoption.

In planning practice, addressing environmental barriers to technology use is essential. Local governments and organizations can provide guidance to rural residents and builders on age-friendly home design and renovations, while public awareness campaigns, subsidies, and local technical support can further assist older people in using technology to support aging in place.

Impact of Transport Resilience on Local Food Security During Disruptions

Abstract ID: 1844.0.0.446.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Shahadat Hossain [Kansas State University] shahadat@ksu.edu, presenting author

Shakil Kashem [Kansas State University] shakilkashem@ksu.edu

Transportation systems play a vital role in linking urban communities to food sources, yet the resilience of transportation systems and how it influences local level food security is not well understood (Raub et al., 2021). When severe weather disrupts transportation, vulnerable populations encounter difficulties accessing nutritious food, exacerbating existing inequities in food security (Zeuli et al., 2018). Despite the recognition of these interconnections, prior research often analyzed transportation resilience and food security independently, with limited exploration of their intersection (Delgado et al., 2023). This study addresses this critical research gap by examining how transportation network resilience impacts food accessibility during extreme weather events. We hypothesize that areas with more resilient transportation infrastructure maintain better food access during disruptions, but that this relationship varies across socioeconomic characteristics.

We took the Kansas City Metropolitan Area as our case study and explored transport resilience and food security at the census block group level. Our methodology includes developing a Transportation Resiliency Index (TRI) incorporating measures of redundancy, mobility, and vulnerability. We paired this with mobile phone-based foot traffic data to food stores to create a Retail Food Activity Index (RFAI) that captures real-world mobility patterns rather than assuming local food accessibility based on distance to stores. We applied spatial regression models to evaluate how trips to healthy food stores (as measured by RFAI) is influenced by transport resilience and distance to stores after controlling different socioeconomic variables. We developed this model for both normal weather conditions and a major snowstorm period.

Our analysis reveals significant patterns in food store visits during both normal and snowstorm conditions. Transportation resilience emerged as one of the most significant predictors across both scenarios, with its influence intensifying during disruptions caused by the snowstorm. Our model results also reveal stark socioeconomic disparities, with areas containing higher percentages of low-wage residents experiencing reduced food access, mirroring patterns of infrastructure inequality documented by Sullivan and Novak (2024). These findings have significant implications for planning practice and policy. Aligning with recommendations from Loreti et al. (2022), this study underscores the critical need to integrate transportation and food system planning to advance equity and resilience. This research provides a transferable methodology for identifying at-risk areas and a framework for developing targeted interventions to address food security at the local level.

Implementing California's SB 1000: Community Perspectives on Food Access and Environmental Justice

Abstract ID: 1844.0.0.890.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Charisma Acey [University of California, Berkeley] charisma.acey@berkeley.edu, presenting author

Senate Bill 1000 (SB 1000), California's "Planning for Healthy Communities Act," mandates cities and counties to integrate environmental justice (EJ) elements into their general plans, directly addressing disparities related to food access, environmental health, and equitable development. While SB 1000 represents significant policy progress, the effectiveness of its implementation remains uncertain. Recent analyses point to uneven municipal capacity, limited political will, and a lack of community integration in the implementation of SB 1000 (Zuñiga & Méndez, 2023). This paper critically evaluates how municipalities are adopting SB 1000 provisions, focusing specifically on food access in the cities of Richmond (urban context) and Gilroy (rural context).

Using a mixed-methods approach, this study combines a comprehensive statewide analysis of city general plan policies related to food access and environmental justice with in-depth case studies of Richmond and Gilroy. Our methods include policy analysis, stakeholder interviews, and extensive community engagement through workshops and public meetings involving grassroots groups and local organizations. Findings highlight distinct local implementation pathways shaped by historical context and community capacity. In Richmond, while the city's EJ element references food justice and reflects a history of activism, many organizers were not directly involved in its development and expressed surprise about the law and the city's efforts. In Gilroy, advocates were generally aware of planning efforts but had limited engagement in shaping the EJ element. In both cities, community workshops provided spaces for residents to evaluate local plans, demand accountability, and mobilize around persistent food insecurity challenges, particularly those shaped by land use constraints and systemic disinvestment. These findings reflect calls to empower grassroots actors in food systems governance and link food justice to environmental justice frameworks (Purifoy, 2013; Siegner, Acey, & Sowerwine, 2020).

These cases also underscore the disconnect between community-driven justice goals and formal planning processes, a gap scholars have argued must be bridged to meaningfully address structural inequities in food access (Agyeman & McEntee, 2014). Our research underscores the critical role grassroots activism and participatory governance play in shaping effective policy outcomes. It also contributes to the broader discourse on food justice planning by illustrating how community engagement can push planners to move beyond narrow food security goals, using food to address structural injustices related to land use, housing, and racial equity (Horst, McClintock, & Hoey, 2017).

Leveraging the Physical, Mental, and Social Benefits of Urban Green Spaces: Insights from Coastal VA

Abstract ID: 1844.0.0.1008.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Bev Wilson [University of Virginia] bw6xs@virginia.edu, presenting author

Jenny Roe [University of Virginia] jjr4b@virginia.edu

Genesis Rodgers [University of Virginia] gmr2zp@virginia.edu

Access to green spaces in urban areas offers numerous mental and physical health benefits (Hartig et al., 2014, Wilson et al., 2024). However, physical proximity to public green space does not always mean that those benefits accrue to people who live nearby. This paper documents “pull factors” as well as reported barriers to green space usage among residents who live within walking distance (i.e., 0.10 mile) of two public parks located in coastal Virginia (i.e., Norfolk and Portsmouth) using a household survey where participants were recruited using a novel, multi-modal strategy that included postcards, emails, and SMS text messages.

While both of the green spaces are open to the public and each is separated from an adjacent lower-income neighborhood by a high-volume street, they differ in the type and intensity of vegetative cover (e.g., turf grass versus forested), facilities available (e.g., ball fields, picnic shelters, walking trails), and activities that generally take place. We hypothesize that the green space that offers access to water, is largely forested, has walking trails and greater biodiversity will be associated with increased mental wellbeing, while indicators of social cohesion will be higher for residents visiting the other green space (Roe and McCay, 2021). We also expect that these benefits as well as the frequency of visits will be moderated by perceptions (e.g., pleasantness, safety, fascination) of each green space (Roe and McCay, 2021).

With a response rate of over 18 percent we statistically analyze differences within and between the two residents groups with respect to a battery of established physical and mental health measures and discuss the implications of the resident insights shared for efforts to increase green space usage within lower-income neighborhoods. Finally, we reflect on the strengths and weaknesses of leveraging techniques like SMS text messaging as a survey recruitment technique and of using a multipronged approach more generally.

Measuring Subjective Well-being Along the Urban Continuum in the Chennai Metro Region, India

Abstract ID: 1844.0.0.830.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Kirti Das [Princeton University] kirtid@princeton.edu, presenting author

Anu Ramaswami [Princeton University] anuramaswami@princeton.edu

Exploring the factors that influence human well-being and how to enhance it is an increasingly important area of research and policy, given its central role in fostering healthy, productive societies (Diener, 2009; Durand, 2015). Researchers and policymakers globally are moving beyond objective indicators like income or health to embrace subjective well-being (SWB)—which includes evaluative, emotional, and eudemonic dimensions—as a key marker of societal flourishing (Helliwell et al., 2024; Oguz et al., 2013). Among the many contributors to SWB, the built environment plays a significant role (Das, 2022), making it a critical consideration for urban planning. However, most empirical studies examining links between SWB and the built environment are concentrated in high-income countries, leaving a gap in knowledge about rapidly urbanizing regions of the Global South.

This study addresses that gap through the first detailed assessment of SWB and its infrastructural, social, and environmental correlates across the urban–suburban–periurban continuum in the Chennai Metro Region of India. Using a bottom-up survey design, the authors collected data from over 2,400 residents—roughly 800 from each zone—measuring SWB dimensions using validated tools. Respondents rated their satisfaction with over 40 infrastructural, environmental, and social attributes across spatial scales, while also providing socio-demographic and culturally specific information. The data were analyzed using regression models to identify significant correlates of SWB. A novel prioritization framework was used to classify these correlates into three categories: foundational (basic needs), consistently important (important across contexts), and added bonuses (beneficial primarily for those already well-off). The research was guided by four key questions: How do SWB levels differ across the urban continuum? Are there disparities in SWB across income, caste, gender, and religion? Which factors most strongly correlate with SWB in each context? And how can infrastructure be prioritized to enhance well-being and equity?

Notably, the study found that periurban residents reported the highest levels of both evaluative and emotional SWB, despite having fewer resources than their urban and suburban counterparts. Chennai's overall evaluative SWB score (7.2/10) was significantly higher than India's national average (4.1/10) and comparable to scores in several U.S. cities. Income was the primary driver of SWB disparities in urban and suburban zones, while such disparities were less pronounced in periurban areas, indicating unique dynamics at the rural–urban fringe. Unexpectedly, participants from Other Backward Castes reported higher evaluative well-being than those from upper castes, challenging assumptions about caste-based privilege and prompting further investigation.

Several infrastructural, social, and environmental attributes—including home size, water quality, heating and cooling, internet and phone connectivity, air quality, access to education and places of worship, and the ability to influence neighborhood decisions—emerged as foundational correlates (priorities) of SWB. The priorities identified in Chennai distinguish its infrastructure needs from cities in more developed countries, where basic services are typically a given (Das, 2022), emphasizing the need for context-sensitive planning.

This study contributes significantly to urban planning by showing how SWB data can inform more equitable and responsive infrastructure development, offering actionable insights for policymakers aiming to build inclusive, thriving cities. The study's findings will help policymakers and researchers understand how local infrastructure

affects well-being, identify targeted planning interventions, promote equity in SWB outcomes, and compare infrastructure–well-being links between India and the U.S.

Modeling the Impact of Urban Heat Islands and Heatwaves on Elderly Health in Seoul

Abstract ID: 1844.0.0.582.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Chaeyeon Lee [Pusan National University] cylee@pusan.ac.kr, presenting author

Donghyun Kim [Pusan National University] donghyun-kim@pusan.ac.kr

[Research questions, Objectives] The urban heat island (UHI) effect refers to the phenomenon where cities maintain higher temperatures than surrounding rural areas (Oke, 1982), while heat waves are periods of extremely high temperatures. The interaction between the two exacerbates heat stress in urban environments and has public health implications (Cheval et al., 2023; Son et al., 2023). This study aims to simulate the impact of this interaction on public health in Seoul, and sets up three conditions: A baseline scenario (current urban design and heat wave response), a heat island mitigation scenario (such as expanding green spaces), and a heat wave preparedness enhancement scenario (such as strengthening cooling centers). The research question is: “What are the public health impacts of UHI and heatwave interactions, and how does each scenario improve health outcomes?” The aim is to provide policy insights.

[Data and Method] The study combines a systematic literature review with system dynamics modeling. The literature review analyzes the relationships between UHI, heat waves and public health, and a systematic literature review and expert workshop are used to refine model parameters and ensure objectivity. The system dynamics model includes temperature, green cover, building materials, heat wave frequency, and health indicators (such as heat-related mortality). The three scenarios are simulated over a 10-year period and are run for Seoul as it is representative of a city with severe UHI (Kim et al., 2019). The baseline scenario evaluates the current situation, while the Heat Island Mitigation scenario increases green space by 20%. Finally, the Enhanced Heat Wave Preparedness scenario doubles the number of cooling centers and strengthens the heat warning system to provide policy insights by comparing the impact of each scenario on public health, especially the health of the elderly.

[Main findings] A systematic literature review highlighted the negative impact of the interaction of UHI and heat waves on the health of vulnerable populations. Simulations show that in the base case scenario, UHI and heat waves will increase heat-related mortality among vulnerable populations (elderly, low-income). In the heat island mitigation scenario, temperature reduction reduces health risks, especially for vulnerable populations in urban centers. In the enhanced heat wave preparedness scenario, emergency room visits are reduced, and public education improves immediate response. While both intervention scenarios are effective, reducing UHI may favor long-term temperature reduction and enhanced preparedness may favor short-term improvements in health outcomes. Previous studies have largely relied on statistical analysis or short-term observations to assess long-term and dynamic impacts (Kim & Baik, 2005). This study overcomes this by utilizing system dynamics to model changes over time and specifically analyzing vulnerable populations' health impacts.

[Implications] The study suggests integrating UHI reduction strategies and enhanced heat wave preparedness in urban planning. UHI reduction strategies include expanding green space and using sustainable building materials, while heat wave preparedness includes installing cooling centers and strengthening warning systems. This provides both long-term climate risk adaptation and short-term emergency response capabilities. In particular, urban design to protect vulnerable populations is important, for example, by creating green spaces near concentrations of elderly people or installing cooling centers in public facilities. Such measures will contribute to reducing health inequalities in high-density cities like Seoul, strengthening climate change adaptation, and ultimately increasing the sustainability of urban planning.

Overcoming Barriers to Restore Public Vacant Lots into Thriving Community Gardens in Chicago

Abstract ID: 1844.0.0.1105.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Farzaneh Khayat [Loyola University Chicago] fkhayat@luc.edu, presenting author

Introduction: While always a part of city life, vacant lots have recently attracted increased attention among diverse groups in United States cities. This interest is not only due to the challenges vacant lots bring to communities—such as an increased risk of vandalism, illegal dumping of trash, and discouragement of potential homebuyers or renters—but because restoration of vacant lots holds the potential solution to these challenges. Studies show that increased safety, economic development, and enhanced food security are among the benefits of vacant lots restoration, particularly in low-income communities (Anderson et al., 2019; Branas et al., 2018). As part of the cities' efforts in restoration of vacant lots, the city of Chicago makes over 2,000 vacant lots available for sale to residents through the ChiBlockBuilder program. Looking at the application data for the Woodlawn neighborhood on the South Side of Chicago, it's evident that there were only 13 submissions in 2021. With over 1,000 vacant lots in this neighborhood (Dickhut & Haller, 2014), there is an opportunity for increased community participation in restoration of these lots especially in developing community gardens.

Objective: This research aims to identify barriers to restore city owned vacant lots into community gardens in Woodlawn, Chicago.

Methodology: This study employed key informant interviews with two stakeholders and a focus group discussion with members of community gardens in the Woodlawn neighborhood.

Results: Preliminary findings identify the opportunities for promoting existing programs. These include enhancing the program visibility through robust community outreach, highlighting the positive impact of vacant lots among communities, integrating both environmental and artistic elements into vacant lots restoration, and exploring innovative funding (such as carbon credits) to support the expenses associated with lots restoration.

Additionally, findings indicate several barriers to the lots' restoration including lack of transparency on available lots for sale, uncertainty from potential administrative changes that may impact the program's long-term existence, and the absence of a comprehensive community development plan to restrict the returning of these vacant lots into the inventory.

Conclusion: This project contributes to the ongoing efforts to seek equitable and meaningful solutions to restore city owned vacant lots in Chicago. Addressing these findings can pave the way for a more sustainable vacant lot restoration that reflects residents' needs and emphasize the potential for inclusive and community-driven solutions in Chicago and beyond.

Perceived Pedestrian Environment Characteristics Across Different Socioeconomic Status Neighborhoods

Abstract ID: 1844.0.0.996.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Craig Olwert [California State University, Northridge] craig.olwert@csun.edu, presenting author

Zeynep Toker [California State University, Northridge] zeynep.toker@csun.edu

Socioeconomic status is one of the main determinants of public health, especially in the case of obesity, as it is connected to physical activity, and more specifically to recreational walking (Frank et al. 2003). Improving physical environment characteristics, and perceived pedestrian environment characteristics in particular, research suggests, might be the key to increasing recreational walking behavior. The purpose of this study is to identify the common pedestrian environment characteristics in different socioeconomic status neighborhoods for more effective short-term intervention in the built environment which might increase the amount of recreational walking and help improve public health.

Research shows that walking behavior is influenced by pedestrian environment characteristics (Sallis et al. 2011). For example, pedestrian infrastructure (such as presence of sidewalks, crosswalks, streetlights), aesthetics, traffic and crime safety are influential on walking behavior. Moreover, the perceived measures of pedestrian environment characteristics, which have associations with walking behavior, include perceived pedestrian infrastructure (such as presence of sidewalks, crosswalks, streetlights), perceived aesthetics, and perceived traffic safety (Toker, 2015) .

The objectives are to identify perceived pedestrian environment characteristics in different socioeconomic status neighborhoods and to search for statistically significant patterns of commonalities among the best and worst perceived pedestrian environment characteristics among these neighborhoods.

A questionnaire for assessing the perceived quality of pedestrian environment was developed. The questionnaire was designed to ask open ended questions identifying two best and two worst characteristics of sidewalks and streets in an area. A total of 3,016 questionnaires were administered in four sites with different socioeconomic status in and around City of Los Angeles. A content analysis was conducted to identify codes to categorize the responses to questionnaire questions. Then, we conducted a quantitative analysis to compare the similarities among four areas, where these questionnaires were administered.

The results show that despite the variety in income, education, and race/ethnicity configuration, there are statistically significant patterns of similarities among best and worst characteristics of pedestrian environments in those four sites. For example, cleanliness and landscaping are among the most liked characteristics, whereas trash and lack of landscaping are among the least liked characteristics in all four sites. Similarly, safety and traffic are mentioned in all four sites by the respondents.

Although different socioeconomic status neighborhoods might have different physical environment characteristics, ultimately it is the perception of residents in a neighborhood that establishes how walkable the environment is for them. Therefore, the commonalities across socioeconomic status are crucial intervention points for urban planners and policy makers.

Residential Heat Exposure and Health: Evidence from the American Housing Survey

Abstract ID: 1844.0.0.96.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Charles Gabbe [Santa Clara University] cgabbe@scu.edu, presenting author

Gregory Pierce [UCLA] gpierce@luskin.ucla.edu

Edith de Guzman [UCLA] eb3@g.ucla.edu

Urban heat resilience is emerging as a major planning issue, yet research and planning has predominantly focused on outdoor environments, with less attention to the indoor residential settings where Americans spend most of their time. Our study addresses this gap by answering two key questions: (1) What indoor thermal burdens do U.S. households face and what are the largest barriers to thermal health? and (2) What mediating housing and socioeconomic factors are prevalent and what explains their prevalence? We specifically test hypotheses about heat health outcomes related to housing tenure (renting vs. owning), housing type (with special attention to manufactured housing), air conditioning (central AC vs. other options), and energy insecurity.

Our analysis uses the 2023 American Housing Survey (AHS), a nationally representative sample of U.S. households, and specifically a new heat risk module in the AHS that the authors proposed and refined in collaboration with U.S. Census Bureau staff. We employ descriptive statistics and regression models to examine three primary health outcomes: (1) whether households were uncomfortable due to heat for 24+ hours in the past year, (2) whether household members visited emergency departments for heat-related illness, and (3) whether heat interfered with their sleep. Independent variables include housing characteristics, household characteristics, and geographic setting. After identifying particularly high rates of heat-related health challenges in the four West Coast core-based statistical areas (CBSAs) for which specific data were available in the AHS, we conducted additional metro-specific analyses.

Our descriptive analysis reveals significant disparities in heat exposure and outcomes by housing type and characteristics. Nearly 14% of renters reported being uncomfortably hot compared with 8% of homeowners. Households in smaller multifamily housing buildings and manufactured housing had the highest rates of thermal discomfort and sleep disruption. Lower-income households consistently reported worse heat health outcomes across measures.

Preliminary regression analyses revealed several patterns at the national level. Renters experienced greater thermal discomfort and poorer sleep quality compared with homeowners. Households living in newer housing – units built since 2000 – had better heat health outcomes, as did households with central AC relative to window AC. Residents of metropolitan areas reported more thermal discomfort and sleep disruption, but were less likely to visit emergency rooms for heat-related illness, compared with residents of rural areas. There were inconsistent, and mostly non-significant, associations between variables related to race, ethnicity, and income with health outcomes. Our analysis of West Coast metropolitan areas identified central AC access and functionality as the most consistent factors associated with heat health outcomes across all four metros.

This research addresses a gap in urban planning scholarship, which has primarily studied disparities in exposure to outdoor temperatures (e.g., historical inequities due to redlining), as well as planning interventions to reduce the urban heat island and provide short-term emergency response during heat waves. Our findings highlight the importance of planners and housing policy makers analyzing heat exposure in indoor residential environments.

The disparities identified — including for renters, residents of older buildings, and those without central AC — indicate the need for targeted interventions through building codes, “right to cooling” standards, weatherization, energy assistance programs, and heat-health awareness education programs. By linking housing characteristics with heat-related health outcomes, this research provides evidence for policy interventions that integrate housing policy with other urban planning interventions to increase climate resilience.

Spatial Equity in O2O Fresh Produce E-commerce: Complementing or Replacing Traditional Markets?

Abstract ID: 1844.0.0.66.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Yu Hu [City University of Hong Kong] yuhu52@cityu.edu.hk, presenting author

Xin Li [City University of Hong Kong] xinli87@cityu.edu.hk

Chen Liang [City University of Hong Kong] elaine.liang001@my.cityu.edu.hk

For a long time, urban residents had to personally visit shops to buy fresh produce, a vital nutrient source that includes fruits, vegetables, fish, poultry and so on. Over the recent decade, increasingly matured online-to-offline (O2O) e-commerce has made fresh produce available at doorstep through efficient logistics, waiving more and more physical shop-visits. O2O fresh produce e-commerce can be viewed through the lens of Platform Urbanism, which argues that socio-technical assemblages of technology firms, service providers, and end users has transformed everyday life across cities and will improve urban life quality in a bottom-up manner (Barns, 2020; Caprotti et al., 2022). This paper examines the impact of O2O e-commerce on the fresh produce market in China, focusing on Shanghai as a case study, where O2O fresh produce delivery services have significantly altered shopping behavior since their emergence in 2015. While platform urbanism offers geographical and temporal flexibility, suggesting more equitable access to service regardless of socioeconomic status (Richardson, 2020), we argue, based on our case, that platform urbanism instead contributes to unequal spatial distribution of benefits. This is explored by examining three platform-based O2O fresh produce e-retail models: front-loaded warehouse (qianzhicang), warehouse-store integration (cangdianyiti), and community group purchase (shequtuangou). We aim to provide a nuanced understanding of how different models have reconfigured the digital-physical relationship of urban spaces.

A mixed method is used for this research. Various big data sources are collected, including fresh produce delivery Point of Interest (POI), residential Area of Interest (AOI), street-level census data and real estate transaction records. These are supplemented by first-hand survey and interview data on household purchasing behavior. We begin by using Kernel Density Analysis to visualize the spatial distribution of the three models, which is compared with that of traditional wet markets. These density maps, overlaid with spatial data of population density, age demographics, and economic status, allow us to identify well- and under-served residential areas. Then we analyze the spatial catchments of the three models and evaluate the respective food accessibility for residents in different regions. By comparing these platform catchments with those of traditional wet markets, we investigate whether and to what extent fresh produce platform retail services can make up for the service blind spots of offline stores. Furthermore, statistical analysis is conducted to examine associations between O2O service coverage and various spatial attributes, including housing price, population age, and types of urban districts.

Our preliminary findings show that O2O fresh produce services tend to thrive in already well-served, younger, and wealthier neighborhoods but provide less support for under-served regions that rely largely on traditional markets. This suggests an exacerbated digital divide between well- and less-established urban areas. Our study provides insights to urban planners and policymakers on how platform urbanism reshapes urban landscape and service distributions, calling for their attention on the potential spatial inequalities in residents' access to fresh produce.

Spatiotemporal Heterogeneity in Waterfront Environments and Public Emotions via Explainable ML

Abstract ID: 1844.0.0.594.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Hua Chen [College of Architecture and Urban Planning, Tongji University] chanua@tongji.edu.cn, presenting author
Xinyi Qin [Tongji University] 2430167@tongji.edu.cn

Background/Purpose-Waterfront spaces provide ecosystem services and impact residents' emotions and well-being, particularly during public health emergencies like COVID-19 (He et al., 2024). While research has examined urban public spaces and emotional health at city-wide scales (Liu et al., 2021; Ma et al., 2020), few studies investigate waterfront environments within the 15-minute City concept, which is an urban planning model promoting accessibility to essential services within a 15-minute journey. Understanding these relationships requires explainable AI approaches that address non-linear associations and geographical interpretability (Xing & Sieber, 2023).

This study aims are constructed as follows: (1) What is the relative importance (RI) ranking of waterfront life circle environmental variables in influencing public emotions during different periods? (2) How can these nonlinear associations and threshold effects be quantitatively assessed and interpreted? (3) To what extent do these associations spatially and temporally vary?

Methods-We studied Shanghai's Huangpu River and Suzhou Creek waterfront spaces using a 150m grid (8,876 spatial units). Public emotional data came from Weibo posts from September 2021 (pandemic, 40,497 posts) and 2023 (post-pandemic, 84,225 posts). Environmental variables included built environment characteristics, perception elements, and microclimate measures. We employed Geographically Weighted Random Forest (GWRF) with SHAP values to quantify variable importance, addressing spatial heterogeneity absent in traditional models (Grekousis et al., 2022).

Results-Analysis revealed significant non-linear associations and spatiotemporal heterogeneity:

Microclimate variables: Temperature was most influential during the pandemic, with positive emotional effects within comfortable ranges (10-28°C) but negative effects at extremes. This pattern varied spatially, with stronger positive effects in areas with high blue-green coverage and negative effects near transportation hubs.

Perception environment variables: Sensory elements showed high importance across both periods, with positive effects emerging above a 0.1 threshold. Natural elements dominated during the pandemic, while artificial elements gained significance post-pandemic, especially in central urban areas.

Built environment characteristics: The associations between development density and sentiment displayed complex nonlinear patterns. Floor area ratio exhibited negative emotional impacts when below 1.5, but positive impacts when exceeding 1.5. Transit accessibility demonstrated moderate importance, with its positive effects particularly concentrated in central districts during the pandemic and in suburban areas post-pandemic.

Temporal comparison revealed a shift from microclimate factors during the pandemic to perception elements post-pandemic, reflecting changing public priorities and waterfront usage patterns.

Conclusions-This research advances our understanding of waterfront environments and public emotions through an innovative explainable ML framework combining GWRF and SHAP models. We incorporated diverse environmental variables beyond conventional measures and revealed complex non-linear associations varying

across space and time. Findings demonstrate as to RI, there is a shift from microclimate factors during the pandemic to perception elements post-pandemic, reflecting evolving public priorities.

By focusing on the 15-minute urban model, this research provides implementable planning recommendations. Policy makers can develop targeted strategies for different waterfront contexts, emphasizing temperature and natural elements during crisis periods while enhancing artificial and sensory elements during normal periods. This spatially-explicit approach enables planners to prioritize interventions in specific areas with maximum emotional benefit potential, creating more resilient urban waterfront environments adaptable to changing public needs.

Taking on the food industry: government capacity to change food environments in Bolivia

Abstract ID: 1844.0.0.477.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Lesli Hoey [University of Michigan] lhoey@umich.edu, presenting author

Andrew Jones [University of Michigan] jonesand@umich.edu

Ramiro Llanque [Consejo de Salud Rural Andino] rllanque@csra-bolivia.org

The food industry and much of the public health sector has often encouraged a personal responsibility approach to improving diet-related health outcomes, focused on interventions like raising awareness and nutrition education (Lusk 2014; Brownell and Warner 2009; Vermeluen et al. 2020). This individual choice approach, however, is limited in its effectiveness (Murimi et al. 2017). A social determinants framework instead calls for a greater focus on food environments – “the collective physical, economic and policy conditions that influence people’s food and beverage choices and nutritional status” (Perrez-Ferrer et al. 2019). This framing places more responsibility on governments to enact structural changes that require less personal agency, such as policies, regulations and zoning changes that shift the availability, affordability, and desirability of food in the environment (Adams et al. 2016; Minaker et al. 2011). Research is limited, however, about the capacity of government agencies to effectively carry out such interventions, especially in the Global South (Turner et al. 2020; Turner et al. 2018) where food environments are rapidly changing (Popkin and Ng, 2022).

Our study addresses this research gap by examining the implementation of Bolivia’s 2016 “Law for the Promotion of Healthy Eating” (Law 775), a multisectoral national food policy that is the cornerstone of efforts to address the country’s burgeoning public health crisis centered on diet-related chronic diseases (Jones et al. 2018). Focusing on the three components of the law, we examine the conditions under which local governments have the capacity – and motivation – to regulate powerful industry groups, reshape existing retail landscapes, and curtail harmful marketing needed to shape healthier food environments.

Our methods include over a dozen key informant interviews to learn about the role of national actors in carrying out (or obstructing) Law 775, including government ministries in health, agriculture and consumer protection, multi-lateral organizations (e.g., the UN Food and Agriculture Program), the food industry, and international NGOs. We then used a positive deviance framework to identify three municipalities where components of Law 775 were implemented with higher fidelity and compare them to municipalities with lower fidelity, matched based on population, food environments (e.g., mountainous highlands vs. tropical lowlands), and economic factors. In these six municipalities, we interviewed front-line staff and key informants to learn about on-the-ground factors and actors that facilitated or hindered implementation, including municipal directors of health, members of Municipal Committees on Food and Agriculture, agriculture extension agents, public health NGOs, and market vendor and restaurant unions.

Our findings identify key barriers (e.g., establishing uniform standards for front-of-pack nutritional labeling; opposition from the food industry) and facilitating factors that enabled implementation of Law 775 (e.g., persistent, respected policy champions; co-developing strategies with local food vendors to help them transition to offering more healthy options in ways that retain the viability of their business; engaging in creative and cross-sector public mobilization). Working in partnership with the Ministry of Health, our findings are informing efforts to improve and scale up the core tenants of Law 775 in Bolivia. As more governments in the Global South embrace the notion that diets are a social issue, our study also offers guidance about the various paths other governments at both local and

national levels can follow to build their capacity to intervene in food environments (Vermeluen et al. 2020; Ng et al, 2022).

Walkable Food Access for Active Seniors: A Comparison of Planned and Traditional Urban Areas

Abstract ID: 1844.0.0.613.2025

Track 9: Food Systems, Community Health, Safety

Individual Paper Presentation Submission

Seo In Yang [Seoul National University] ysi7029@snu.ac.kr, presenting author

So Hyun Park [Seoul National University] sohyunp@snu.ac.kr

This study investigates the association between food outlet density and walking-based food purchasing behavior among active seniors (aged 60–69) in two distinct urban areas of Sejong City, South Korea: Goun-dong, a master-planned new town, and Jochiwon-eup, a traditionally developed district. Sixty participants (30 from each neighborhood) maintained 7-day food environment diaries, recording their walking-based food purchase frequency, walking duration, and the density of food retail Points of Interest (POIs) within an 800-meter radius of their residences.

Descriptive statistics indicated that, despite Goun-dong's significantly lower average POI density (5.74 POIs/km²) compared to Jochiwon-eup (47.78 POIs/km²), participants in Goun-dong reported more frequent (0.60 times/week) and longer (8.5 minutes/week) walking-based food purchasing activities. However, correlation analyses in Goun-dong revealed a moderate positive association between POI density and walking duration ($r = 0.36$, $p = .052$) and a weaker positive correlation with walking frequency ($r = 0.31$, $p = .100$). These p -values exceed the conventional threshold of 0.05, indicating that the observed associations are not statistically significant. In contrast, no significant relationships were observed in Jochiwon-eup, where high food outlet density did not correspond with increased walking-based food purchasing behavior.

The significance of this study lies in its comparative analysis of walkable food access across different urban typologies—a systematically planned new town and a naturally evolved traditional district. By exploring whether urban density truly influences walking behavior, this research highlights how urban form and planning principles may affect active seniors' walking-based food purchasing behavior, contributing valuable insights for the development of age-friendly urban environments.

Campus Infrastructure and College Students' Health-Related Mobility: A Location-Based Study

Abstract ID: 1842.0.0.757.2025

Track 9: Food Systems, Community Health, Safety

Research-in-Motion Presentation Submission, Research currently in process

Li Deng [Texas A&M University] lideng@tamu.edu, presenting author

Yang Song [Texas A&M University] yangsong@tamu.edu

Chanam Lee [Texas A&M University] chanam@tamu.edu

Galen Newman [Texas A&M University] gnewman@arch.tamu.edu

College students face significant health challenges, particularly during academically stressful periods like exams and public health crises such as flu season and the COVID-19 pandemic. Prior research has shown that the surrounding environment, a college campus in this case, can significantly shape people's behaviors and influence their health and quality of life¹. However, empirical evidence remains limited, particularly regarding the longitudinal interactions between students and campus environments.

Using Texas A&M University as a case study, this study addresses this research gap utilizing longitudinal mobility data from ADVAN Research (January 1, 2018, to December 13, 2021) to examine how students interact with campus sports facilities and green spaces over time and how these interactions influence their health mobility patterns during stressful exams and public health crises. ADVAN Research data has been recognized as a valid and accurate global point of interest (POI) database². This study considers students' weekly visits to health-related destinations, including health facilities & services, drinking places, tobacco stores, and grocery stores, as dependent variables. The weekly visits to these target POIs are measured as the percentage of the student housing census block groups (BGs)' population that traveled to the corresponding POIs per week. Independent variables include critical events, including midterm exams, final exams, flu seasons, and the COVID-19 pandemic, which are known to affect students' academic life experience³. Each variable is coded as a dummy variable to indicate the event occurrence. Students' weekly visits to campus sports facilities and parks are considered moderators. We controlled for key confounding factors such as socio-demographic characteristics. After data cleaning, the final dataset includes 45 student housing BGs with 8,742 observations. Mixed-effect models were utilized to examine the impacts of key academic events and health crises on students' health-related mobility, and the moderating roles of campus sports facilities and green spaces in the relationship.

Descriptive analysis revealed consistent mobility patterns linked to key academic events and public health crises. POI visits peaked during the first week of classes and midterms, and dropped significantly during summer and winter breaks. Notably, visits to various POIs, such as drinking places, campus parks, and sports facilities, surged at the start of each fall semester. Results of mixed-effects models further showed that midterms, finals, flu seasons, and the COVID-19 pandemic significantly impacted students' health-related mobility. We found that frequent visits to campus sports facilities and green spaces significantly moderated student travel behaviors during these challenging times. Students who frequently visited campus green spaces were less likely to visit health-risk locations such as drinking places or tobacco stores during midterms, finals, and the pandemic, and were more likely to go to health-promoting destinations like grocery stores during flu seasons and the pandemic. Conversely, during

flu seasons and the pandemic, frequent use of sports facilities was associated with increased visits to health-risk locations, such as drinking places or health facilities & services.

These findings highlight the significance of integrating green infrastructure and sports facilities into campus planning to positively influence students' health-related behaviors and overall wellbeing. The dual role of campus green spaces and sports facilities during exam periods and public health crises highlights their complex influence on students' mobility decisions and lifestyle choices. Targeted environmental interventions during such challenging times can help promote health mobility patterns, lower healthcare demand, and ultimately foster more resilient, healthier campus communities.

Effect of biophilic design and engagement activities on health and cognitive performance of seniors

Abstract ID: 1842.0.0.623.2025

Track 9: Food Systems, Community Health, Safety

Research-in-Motion Presentation Submission, Research currently in process

Mingu Kang [Seoul National University] 1996km9@snu.ac.kr, presenting author

Heeyeun Yoon [Seoul National University] hyyoon@snu.ac.kr

According to the World Health Organization (WHO), the global population aged 60 and above is projected to reach 1.4 billion by 2030. Population aging has substantial implications for public health, as seniors are more vulnerable to health risks compared to other age groups. Declines in physical and cognitive performance in advanced age contribute to increased incidences of chronic diseases, reduced self-efficacy, and impaired mobility, ultimately hindering social participation and decreasing overall well-being of seniors. Amidst this rising concern, there is a growing interest in developing strategies for healthy aging by promoting physical activity, enhancing mental health, and fostering social connectedness (Keating, 2022).

Most relevant studies analyzing the health-promoting effects of nature-related designs or activities suggest that contact with nature is linked to enhanced physiological and psychological well-being (Shuda et al., 2020; Ulrich et al., 1991). An outdoor experiment conducted in Keelung City, Taiwan, found that walking in green and blue spaces promotes physiological relaxation and improves positive mood of young adults (Yin et al., 2023). Chan et al. (2023) also conducted an indoor experiment, suggesting that both young adults and seniors experienced an enhanced emotional well-being as they became closer to nature. However, previous studies that conducted human-subject experiments have primarily focused on young adults, while research involving seniors remains limited and presents two key limitations. First, most studies have adopted passive exposure to natural environments rather than active engagement through participatory activities. Second, they have largely overlooked the variation in physical and cognitive performances within the elderly population. Researchers have typically defined seniors by chronological age, using criteria such as 60 or 65 years. However, since health conditions tend to change more rapidly in later life than at other stages of the lifespan, it is essential to consider individual differences in health status among older adults.

Against this backdrop, we conduct an experimental study to investigate the effects of garden-based activities on seniors, with particular attention to the role of active engagement in enhancing the health benefits of nature. We hypothesize that: (H1) garden-based activities will positively affect physiological indicators, psychological well-being, and cognitive performance; (H2) active engagement will lead to greater improvements in well-being than passive exposure; and (H3) garden-based activities will show beneficial effects regardless of participants' level of physical performance.

The study is carried out in "Life Garden", a therapeutic green space located in Gwangmyeong-si, South Korea, designed to support cognitive health and promote social interaction among elderly populations. A total of sixty seniors aged 65 and above participated in the study. The experiment was structured into four phases: (1) initial adaptation, (2) pre-treatment measurements, (3) garden-based activities, and (4) post-treatment measurements. During the garden activity phase, participants autonomously engaged in programs within the garden for 30 minutes.

We employ statistical models and neurophysiological analyses to evaluate the effects of the treatment. RM ANOVA is used to compare pre- and post- treatment outcomes. Additionally, we visualize brain activity maps using EEG measurements to identify changes in neural activation patterns during cognitive testing before and after the

treatment. Finally, SEM is conducted to construct a path model that demonstrates the complex relationships between participants' characteristics, degree of engagement, and measurements. Through this study, we aim to provide empirical evidence on how biophilic design and participatory engagement in therapeutic gardens can promote healthy aging.

Examining Urban Greenery's Distribution, Visibility, and Accessibility in Relation to Crime Rates

Abstract ID: 1842.0.0.337.2025

Track 9: Food Systems, Community Health, Safety

Research-in-Motion Presentation Submission, Critique related to a hot topic in planning research

Yidong Yang [University of Shanghai for Science and Technology] crystalyoung8821@gmail.com, presenting author

Mingze Chen [The University of British Columbia] mingzec@student.ubc.ca

This study investigates how the distribution, visibility, and accessibility of urban greenery influence crime rates at street and neighborhood scales. Despite evidence linking urban green spaces with reduced crime, existing research rarely examines detailed street level relationships or clearly differentiates these three dimensions. Thus, this paper addresses 3 specific questions:

- 1) Evaluate the distribution, visibility, and accessibility of urban greenery at the block and street level;
- 2) How the distribution, visibility, and accessibility of greenery at the street-level greenery, correlates with crime rates;
- 3) How the distribution, visibility, and accessibility of greenery at the block level, coupled with the presence of vulnerable populations, diverse ethnic groups, and varying age demographics, impact crime rates.

To answer these questions, this research focuses on Chicago and uses multiple data sources, including Google Street View images, satellite vegetation data, and crime records. Greenery is measured with three metrics: NDVI (Normalized Difference Vegetation Index) for vegetation cover, GVI (Green View Index) for visible street greenery, and a new GWI (Green Walkability Index) for green space accessibility. We analyze crime data from 2018–2023 (violent and property offenses) across 801 census block groups. We also conduct a detailed case study in the high crime neighborhood of East Garfield Park. Socio-demographic factors are controlled. We use negative binomial regression to link green metrics to crime counts and apply geographically weighted regression (GWR) to examine how these relationships vary by location.

Preliminary results show that areas with higher vegetation cover, more visible street greenery, and better access to parks tend to have lower crime rates: areas with greater NDVI values, higher street-level GVI, and improved GWI consistently exhibit fewer violent and property crimes. Importantly, the crime reduction effect associated with greenery is especially pronounced in disadvantaged neighborhoods characterized by higher poverty levels and ethnic diversity, indicating a strong interaction between socio-demographic context and green space effectiveness in crime prevention. The study also finds that improving the visibility and accessibility of greenery is more effective in reducing crime than increasing the total green space. Cities should prioritize enhancing street greenery, walkable access, and park entrances in high-crime areas. Green spaces should also integrate with other crime prevention strategies such as public lighting and pedestrian-friendly environments. This approach would create safer and more inclusive urban spaces.

These findings support theories of environmental justice and Crime Prevention Through Environmental Design (CPTED). They also emphasize the importance of data-driven strategies in urban planning. Future policies should use geographically weighted regression and machine learning to assess the impact of greenery on different communities. This would help create targeted interventions and support the development of safer, more equitable, and more sustainable cities. This analysis of the greenery and crime link suggests that greening urban areas is a promising strategy to enhance public safety and promote environmental equity. Importantly, the crime reduction effect associated with greenery is especially pronounced in disadvantaged neighborhoods characterized by higher

poverty levels and ethnic diversity, indicating a strong interaction between socio-demographic context and green space effectiveness in crime prevention

Research-in-Motion Presentation Submission, Research currently in process

Talayeh Mirseyed Hosseini [University of Utah] u1419995@utah.edu, presenting author

Andy Hong [University of Utah] a.hong@utah.edu

Cognitive decline that accompanies aging, defined by reduced abilities in language, memory, executive function, and reasoning, poses a significant challenge to the quality of life of older adults. It also places growing pressure on the sustainability of healthcare systems worldwide, especially as aging becomes a dominant global issue. While many personal, lifestyle, and genetic factors influence cognitive health in older adults, one pivotal factor that has gained increasing attention in recent years is urban design and the attributes of the built environment. In particular, access to green space is considered a key aspect of the built environment, linked to better cognitive function, a lower risk of dementia, and slower cognitive decline. Accessibility to neighborhood parks, community gardens or open spaces can become significant resource that contribute to enhancing cognitive abilities in older adults by positively influencing their mood and behaviors, supporting active aging, promoting relaxation, and enhancing recreational opportunities.

While many studies have linked increased access to green spaces with lower rates of cognitive impairment, the findings remain mixed, suggesting that this relationship is more comprehensive and not uniform and may be influenced by various contextual and sociodemographic factors. Studies have shown that life transitions like retirement, driving cessation, or changes in Marital status (like widowhood) have the potential to influence cognitive decline as they can substantially modify daily routines and environmental exposures, potentially intensifying or mitigating the benefits derived from green spaces. To address this research gap, this study leverages longitudinal data from the Health and Retirement Study (HRS) to investigate the complex relationship between green space, life transitions, and cognitive aging by analyzing their interactive effects over time.

We operationalize cognitive function using a composite index derived from multiple cognitive function assessments in HRS, including measures of immediate and delayed word recall, serial 7s subtraction, and backward counting. For an analytical approach, a linear mixed effects model is used to examine whether the relationship between green space and cognitive function is moderated by key life transition factors, including retirement, driving cessation, and marital status change. By accounting for both life transitions and longitudinal green space exposure, this study seeks to uncover how green space interacts with personal life changes to shape patterns of cognitive aging. By identifying when and for whom green space is most beneficial, the findings can inform the design of age-friendly, walkable neighborhoods and guide equitable green infrastructure investment, especially in communities with limited access.

Indigenous Foodways in Transition: Navigating Urban Encroachment in Malaysia's Peri-Urban Landscapes

Abstract ID: 1842.0.0.686.2025

Track 9: Food Systems, Community Health, Safety

Research-in-Motion Presentation Submission, Research currently in process

Lauren Chew [University of Michigan] laurencw@umich.edu, presenting author

The rapid expansion of urban areas is reshaping landscapes and food systems, often at the expense of Indigenous communities (Skinner et al., 2016; Whyte, 2018). In Malaysia, urbanization increasingly encroaches upon Indigenous lands, threatening food security by reducing access to traditional food sources and exacerbating land tenure insecurity, which undermines Indigenous sovereignty. The Temuan Indigenous people, who have historically depended on forest-based food systems (Nicholas, 2000), are particularly affected by these pressures. As forest resources become increasingly scarce, many Temuans are adapting by engaging in small-scale farming, shifting from traditional foraging practices to cultivated food production (Diansyah et al., 2022). These shifts raise critical questions about the extent to which the Temuans can maintain control over their food systems amid ongoing urban expansion.

This study examines how the Temuan in Hulu Langat—a rapidly urbanizing district 16 miles from Malaysia's capital, Kuala Lumpur—navigate transformations in their food systems. Using a qualitative research design, this study draws on semi-structured interviews with Temuan farmers and elders, NGO representatives, and government officials. In addition, participant observation is used to gain deeper insights into the Temuan's food cultivation and harvesting practices, while document analysis provides a broader contextual understanding of policies and regulatory frameworks affecting Indigenous land tenure. By integrating these methods, this research explores how shifting subsistence practices and land tenure insecurity shape Indigenous food sovereignty.

Preliminary findings suggest that while some Temuans leverage peri-urban agricultural opportunities, structural barriers—including insecure land tenure, restrictive policies, and limited market access—continue to threaten their food security. While traditional food cultivation practices persist, many households are shifting toward market-oriented farming, growing cash crops such as bananas, corn, and chili to generate income. This transition reflects an increasing reliance on market-driven agriculture, often at the expense of traditional foodways. Moreover, while collaborations with non-Indigenous institutions offer pathways for resource-sharing, land tenure insecurity and institutional constraints continue to hinder long-term food sovereignty in peri-urban Indigenous communities.

These findings contribute to existing scholarship on Indigenous knowledge systems and food security by illustrating how land governance, market integration, and food sovereignty intersect to shape Indigenous adaptation strategies. Without secure land tenure and institutional support, Indigenous food sovereignty will continue to erode, exacerbating economic precarity and food insecurity. This highlights the urgent need for policies that recognize Indigenous land rights, enhance access to agricultural resources, and foster equitable partnerships that empower Indigenous communities to sustain their food systems in the face of rapid urban transformation.

Planning for Health Equity: Enhancing urban environments to support women's safety and independence

Abstract ID: 1842.0.0.48.2025

Track 9: Food Systems, Community Health, Safety

Research-in-Motion Presentation Submission, Research currently in process

Brianne Brenneman [University of Michigan] bfbrenn@umich.edu, presenting author

Kimberley Kinder [University of Michigan] kkinder@umich.edu

Sophia Hoffacker [University of Michigan] hffckr@umich.edu

Urban planning plays a crucial role in shaping built and social environments. These environments then influence social equity and public health (Braverman, 2023), including for survivors of intimate partner violence (IPV). IPV is a pervasive health issue in the United States. While approximately a quarter of men experience IPV during their lifetime, women experience it at significantly higher rates -- 41% compared to 26% -- and are far more likely to suffer severe physical harm, including battery, rape, and murder (CDC, 2024). These risks are even greater for women with marginalized identities, such as those who are low-income, disabled, LGBTQ+, immigrants, Indigenous, Black, and Latinx.

Historically, urban planning has been used as a tool of social control, including in ways that reinforced gender disparities (England, 1991). Many of these planning practices contribute to conditions that heighten women's vulnerability to IPV, yet the field remains slow to address its role in perpetuating gender-based health risks (Frye et al., 2008). Even though vulnerability to gender violence is socially constructed, including through public infrastructure and policy making, because the resulting manifestation of violence often occurs in private spaces, IPV has often been overlooked in planning discourse (Sweet & Ortiz Escalante, 2010). However, with targeted policies and interventions, urban planning can help reduce IPV risks and support survivors.

This study explores how specific aspects of urban planning -- such as housing, land use, transportation, economic development, real estate development, and social infrastructure -- can aid in both the prevention of IPV among women and support the recovery of female-identified survivors. Through a systematic literature review in urban planning, public health, and social work, we identified key infrastructure and policies that impact women's ability to achieve safety, stability, and economic independence. Our analysis paid special attention to intersectional risk factors, including race, income, immigration status, disability, and sexual/gender identity (e.g., lesbian, bisexual, and trans/nonbinary women).

Based on our findings, we propose a novel framework to guide urban planning policy and practice, categorizing interventions into three core dimensions: housing access, economic independence, and social infrastructure. These findings suggest that urban infrastructure and policymaking play a critical role in shaping access to social, economic, and material support -- factors essential for preventing IPV and aiding recovery. Through key planning interventions in these areas, this research provides actionable guidance for urban planners seeking to create safer, healthier, and more equitable cities. Planners have a responsibility to shape environments that support vulnerable populations, including IPV survivors, and future research should explore how this gender-centric framework can be applied across diverse urban contexts.

The Impact of Crime on Urban Park Visitation Patterns: A Longitudinal Analysis in Austin, Texas

Abstract ID: 1842.0.0.950.2025

Track 9: Food Systems, Community Health, Safety

Research-in-Motion Presentation Submission, Research currently in process

Yunpei Zhang [Texas A&M University] yzhan694@tamu.edu, presenting author

Yang Song [Texas A&M University] yangsong@tamu.edu

Zipeng Guo [Texas A&M University] guo7501@tamu.edu

Hongmei Lu [Utrecht University] hongmeil@mtu.edu

Urban parks are vital public spaces providing significant recreational, social, and environmental benefits, yet maintaining safety within these spaces continues to pose challenges in diverse urban environments (Rigolon & Flohr, 2014). Crime incidents occurring in or near urban parks directly influence public perceptions and visitation patterns, potentially diminishing community cohesion and overall well-being (Fleming et al., 2016).

This research systematically explores how crime incidents influence park visitation patterns, employing rigorous quantitative analysis through fixed-effects regression models. Crime incidents are categorized into: (1) family violence, involving violent incidents among family members; (2) nonfamily violent offenses, explicitly violent crimes (e.g., assault, robbery), as well as burglary due to its potential confrontational nature and associated threat perception (FBI UCR, 2023); and (3) nonfamily nonviolent offenses, consisting of vandalism, drug-related crimes, and regulatory offenses. The analysis captures crime's immediate and cumulative effects on public behavior and perceptions over distinct temporal intervals (7-day, 30-day, and 60-day lag periods).

Austin, Texas, serves as an ideal study area due to its rapid urban growth, demographic diversification, and increasing public concerns regarding crime in parks. The city explicitly prioritizes park safety, equity, and community engagement in its comprehensive 10-year park master plan, *Our Parks, Our Future* (City of Austin, 2019). Additionally, extensive publicly available crime and visitation data make Austin uniquely suited for generating insights relevant to local policy development and broader metropolitan applications across the U.S. (U.S. Census Bureau, 2025).

Data utilized in this analysis include detailed daily park visitation metrics sourced from geospatial mobility datasets, crime incident data provided by the City of Austin Police Department, and comprehensive demographic and environmental variables. The study employs Geographic Information Systems (GIS) to spatially and temporally align crime occurrences with park visitation patterns across the City of Austin, Texas. Regression modeling accounts for park-specific attributes such as accessibility, amenities, weather conditions, and demographic characteristics including socioeconomic status, racial composition, and age profiles.

Initial results indicate detailed relationships between crime and park usage. Our intervals (7, 30, and 60 days) were selected based on prior literature, which indicates that community reactions to crime events evolve over short-, medium-, and long-term periods. Short-term analyses (7-day lag) reveal limited immediate impacts on visitation across most crime categories, suggesting brief community responses to recent criminal events. In contrast, medium-term analyses (30-day lag) identify significant negative effects of nonfamily nonviolent and regulatory offenses on park visitation, highlighting persistent concerns about safety that discourage public usage. These effects notably diminish at the longer-term interval (60-day lag), suggesting that public perceptions of safety recover over time.

This research contributes critical insights for urban planning, community health, and safety policies by elucidating the temporal dynamics of crime impacts on public park utilization. By identifying the specific crime types and

temporal windows influencing park visitation, the study provides actionable recommendations for targeted crime prevention strategies, inclusive urban design, and equitable resource allocation. Ultimately, this research underscores the importance of integrated planning approaches that foster resilient, safe, and inclusive urban park environments.

Carol Ramos Gerena [University at Buffalo-SUNY] carolram@buffalo.edu

Chronic food insecurity, defined as a persistent lack of access to adequate food (Headrick et al., 2024), is a growing public health challenge that disproportionately affects low-income and marginalized populations (Garrity, 2024). The prevailing discourse around chronic food insecurities predominantly focus on physical health implications of food scarcity, food sovereignty, food justice, food supply chain marginalization, and environment and climate (Raja et al, 2024) but often overlooks the effects of food insecurity on cognitive load, decision-making, mental health, and cognitive function. This paper adds to the literature by drawing on the food scarcity literature to examine the cognitive function and decision-making of individuals who are focused on solving immediate food-related problems. In particular, we draw on scarcity theory from scholars Sendhil Mullainathan and Eldar Shafir, to probe (1) the psychological burden of making decisions related to food in environments with limited access and how that affects other areas of decision-making (thus, ways that the mental load of food insecurity impacts an individual's overall cognitive function) (2) whether scarcity-driven cognitive load leads to tunneling and impose mental bandwidth tax, where individuals experiencing food insecurity become tunneled visioned, concentrating primarily on short-term food needs at the expense of long-term decision-making, (3) whether food scarcity creates self-reinforcing cycles (scarcity traps) in which decisions made under cognitive overload lead to worsening circumstances and further depletion of cognitive resources.

The empirical analysis unfolds in a case study of Buffalo, NY, a city where nearly 30% of households experience low food access, with many living in areas that lack grocery stores with fresh produce and affordable food options (Raja & Ma, 2008; Lipman et al., 2025). We employ a qualitative analysis utilizing multiple data sources, including interviews with residents and key stakeholders (e.g., community-based organizations, city government officials, religious and community leaders who work closely with food insecure populations), government documents, reports from academics, oral histories, and analysis of newspaper articles and reports. Findings contribute to new knowledge on how food insecurity might deplete mental resources and increase cognitive load, potentially explaining why individuals facing food insecurity often struggle with everyday decision-making. Also, by identifying which cognitive functions are most impacted by food insecurity (e.g., memory, attention, problem-solving), the study provides a nuanced understanding of the mental toll of food insecurity beyond just the physical aspects.

This research enhances planning scholarship by enriching our comprehension of the social determinants influencing cognitive functioning, especially within underprivileged communities, and will emphasize the significance of food security in general well-being and cognitive health. The findings hold practical significance for policymakers, social workers, and urban planners who formulate interventions for food-insecure populations. Understanding the cognitive strain of food insecurity may promote the incorporation of cognitive support services (e.g., mental health resources and decision-making tools) into food assistance initiatives, and urban planners may

utilize these findings to create conditions that alleviate cognitive burdens for food-insecure individuals, including enhancing access to dependable and affordable food sources.

In light of mounting crises and instability and increasingly unpredictable futures, it is becoming clear that planners require a dynamic and adaptable skill set that goes beyond the conventional technical skills valued in planning. Sandercock (2023, p. 267) refers to relational awareness, humility, patience, presence, intentionality, and courage, what she calls “being skills”, as key to the effective training of planners. Her concern echoes earlier calls on interpersonal effectiveness (Argyris and Schön, 1972), and critical pragmatism (Forester, 2013), among others. Education scholarship names these aspects of training as “affective learning.” This panel aims to bring together planning scholars to explore the design of educational experiences that foster affective learning that supports the development of inclusive, adaptive, and ethical planners.

Affective learning encompasses values, interests, feelings, attitudes, motivations, and behaviors (Shepherd, 2008). However, it remains merely a tacit outcome in many planning curricula; students muddle through group work and community-engaged projects without adequate preparation or support through the relational complexities that arise, leaving them vulnerable to burnout (Lyles and Swearingen White, 2019). Attention to the affective dimension has become even more urgent in the wake of the COVID-19 pandemic, which has created new challenges for many of our current students as they lost several years of social-emotional development due to remote schooling. Despite increasing agreement on the importance of affective learning in planning pedagogy, Wilson (2020, p. 2) points out that many planning instructors are “ill-equipped to facilitate constructive conversations...where our students can talk through their blind spots and develop the emotional capacity and cultural humility (Sweet 2018) required to fully grapple with the implications of systemic inequities in their own work.”

Drawing on their combined experience teaching affective capabilities in planning and publishing about their importance, our panelists will discuss affect as a critical framework for both instructors and students to make sense of their experiences in and beyond the classroom. We will share our experiences designing and implementing pedagogical activities to engage students in affective learning. We will discuss student-designed activities and simulations that recreate multi-stakeholder engagements around complex problems. Many of these activities focus on the embodied experiences of conflict and negotiation with no easy answers.

Teaching that centers affective learning demands that instructors show up differently in our classrooms by modeling reflective practice with vulnerability, humility, and power-sharing. Key to supporting instructors is surfacing the institutional and structural considerations for creating contexts that support and value affective learning. We are mostly a group of early career women scholars who are shouldering much of this emotional labor in and around typical tenure expectations; and we know that our colleagues of color are shouldering even more. It is critical that we do not just ask more of junior planning faculty members, but that we also discuss how senior faculty members can support and create conditions where this work is valued formally in tenure and promotion.

The panel will make contributions to the development of affective capabilities across three scales: our students, ourselves, and one another. The panel will explore affective learning as a frame for engaging wicked planning problems with students. It will offer educators tools for designing environments and activities to support future practitioners in cultivating affective capabilities. And it will also generate discussion about how instructors can support themselves in engaging in this critical emotional labor without burning themselves out, so that we can support each other within and across institutions.

Indigenous peoples everywhere have been stewarding their lands and resources, planning their communities, and passing on their knowledges for millenia. In this roundtable, Indigenous planning scholars and educators offer insight into the continuous challenges and contradictions Indigenous educators face when teaching about Indigenous praxis in colonized planning contexts (such as the unique challenges Indigenous communities face due to land tenure). We will use a facilitated discussion to explore ways to train a new generation of planning professionals - both Indigenous and non-Indigenous learners - to work in better partnership with Indigenous peoples, Nations and organizations. Particularly, we pay attention to some of the Indigenous pedagogies, knowledges, methods and principles used by educators to counter conventional planning curriculum. With experience grounded in their work in planning schools in different geographies, the participants discuss the importance of land-based and community learning, somatic practice, oral traditions (and more!) in Indigenous planning learning spaces. After the facilitated discussion, the audience will be invited to participate in a broader discussion about Indigenous planning education in a time of great uncertainty.

Current accreditation standards require undergraduate and graduate programs in urban planning to define and measure program-level learning outcomes (PLOs). Most recently, standards have changed to require direct measurement, sparking the creation of many diverse systems of assessment (Goldman, 2023). A recent commentary by Ann Forsyth (2025) called for abolishing PLOs entirely, and also proposed a set of alternative approaches to measuring PLOs to reduce the burdens on academic programs.

The purpose of this roundtable is to learn how a diverse set of programs have implemented PLOs, hear faculty's honest perspectives on their value, and debate the path forward for our field. Led by faculty not formally involved in the Planning Accreditation Board, the goal is to foster a robust exchange of views for how learning outcomes and the broader accreditation standards should foster academic excellence, avoid burdensome or unproductive procedures, and advance academic program interests.

Planning education is entering a new era—one where artificial intelligence (AI), online platforms, and flexible formats are reshaping how we teach, learn, and engage. As programs expand hybrid and fully online offerings, a key challenge emerges: how do we deliver skills-based courses in digital and asynchronous formats without losing the richness of interactivity, critical thinking, and practical application?

This roundtable brings together faculty who are leading the way in designing future-ready planning curricula. From AI-assisted design and visualization to asynchronous simulations and cloud-based tools, we'll explore how digital innovation is enhancing core courses, urban design studios, and so on.

Panelists will share practical strategies for using modular content, AI-powered feedback systems, and interactive web tools to create engaging, project-based learning experiences—no matter the delivery format. We'll also dive into cutting-edge practices, including using customized ChatGPT models to assess student proposals and provide real-time feedback. Looking ahead, we'll explore the untapped potential of Large Language Models for planning education—from policy ideation to scenario-building and beyond.

Join us for a lively and forward-thinking conversation on what it means to prepare the next generation of planners in a world where classrooms are virtual, tools are intelligent, and the possibilities are wide open.

Preparing the Next Generation: Encouraging AICP Participation Among Planning Students

Abstract ID: 1843.0.0.728.2025

Track 10: Planning Education, Process(es) and Law

Roundtable Submission, Topical Discussions

Ivis Garcia [Texas A&M University] ivis.garcia@tamu.edu, organizer

Jordan Yin [Alabama A&M University] jordan.yin@aamu.edu

Sagar Shah [American Planning Association] sshah@planning.org

Qian He [Rowan University] he@rowan.edu

Kelly Kinahan [Florida State University] kkinahan@fsu.edu

This roundtable explores how accredited planning programs can support and increase participation in the American Institute of Certified Planners (AICP) exam among students and recent graduates. As planning education evolves to meet the demands of the profession, certification is becoming an increasingly important credential for students entering the field. In this session, we highlight how students themselves are creating a culture of support around AICP prep—organizing study groups, peer mentoring, and information sessions. We'll share examples from planning programs that have actively encouraged AICP engagement through curriculum integration, advising, and professional development efforts. We will also share the efforts of APA in these endeavors.

Our goal is to facilitate a collaborative conversation on what's working, what challenges persist, and how we can collectively improve access and participation in the AICP exam process. Participants are invited to share their own experiences and learn from others, while also identifying ways that ACSPP institutions can support certification as part of a broader professionalization strategy. We hope to gather examples from several schools and generate recommendations for wider adoption across planning programs.

Under Review: Addressing Critical Challenges in Urban Planning Journals

Abstract ID: 1843.0.0.100.2025

Track 10: Planning Education, Process(es) and Law

Roundtable Submission, Topical Discussions

Thomas Sanchez [Texas A&M] tw Sanchez@tam u.edu, organizer

Bernadette Hanlon [The Ohio State University] hanlon.42@osu.edu

Shannon Van Zandt [Texas A&M] svanzandt@arch.tam u.edu

Ann Forsyth [Harvard University] aforsyth@gsd.harvard.edu

Urban planning academics and the journals they rely on for disseminating scholarship face an increasingly complex and rapidly changing publishing landscape. This panel will explore several critical challenges that directly affect both faculty and journal editors, including the growing difficulty in securing qualified reviewers, the surge in manuscript submissions and resulting reviewer fatigue has placed strain on the peer-review system. This raises concerns about timely publication and the overall quality of reviews, and ultimately, the quality of publications. Additionally, the recent proliferation of academic journals presents further complications, including maintaining high-quality standards, ensuring meaningful readership, and achieving sufficient scholarly impact. The expansion of available publication outlets, combined with citation inflation, complicates evaluations of scholarly contributions, which are important for faculty making strategic publishing choices and for institutions assessing publications in promotion and tenure decisions. Experienced panelists, including journal editors and senior faculty members with extensive knowledge of these dynamics, will lead discussions on practical approaches and innovative strategies to address these issues. Audience members will be actively invited to engage with panelists, share their experiences, and contribute to a vibrant exchange of ideas aimed at ensuring the ongoing rigor, relevance, and accessibility of urban planning scholarship.

Track 10 Workshops

Inclusive Pedagogical Techniques and Applied, Experiential Learning

Abstract ID: 1841.0.0.525.2025

Track 10: Planning Education, Process(es) and Law

Professional Development Workshop Submission

Stefan Chavez-Norgaard [University of Denver] stefan.chavez-norgaard@du.edu, organizer

Jane Rongerude [Iowa State] jrong@iastate.edu

Planning issue: Planning education and practice occur through close, sustained, and at times contested engagements involving instructors, students, course materials, and communities and as such, the classroom can mirror the real-world experiences of planners. The imperative for applied-experiential planning education is longstanding and connected to attempts in the field to integrate planning theory and practice (Peattie, 1969: 52–54; Friedman and Hudson, 1974), teach professional skills, build communicative practice, and directly address issues of power and knowing. The contemporary context necessitates a renewed engagement with engaged instruction, particularly geared toward equitable and inclusive pedagogies that acknowledge complex student needs, professional anxieties, and ethical implications related to planning. This workshop explores pedagogical innovations in planning education with a particular focus on applied-experiential learning techniques (Tyson and Low, 1987). We will present new pedagogical approaches, course materials, and practices that pair scholarly engagements with planning pedagogy, course materials, and the testing and application of classroom techniques. The workshop will build in extensive time for participant feedback, comments, questions and answers, and space for other attendees to share pedagogical innovations of their own, and associated reflections on payoffs and challenges. To that end, attendees will be asked to bring to the workshop one classroom activity, material, technique, or approach that they might like to share.

Workshop approach and methodology: The workshop will open with two short presentations by Profs. Stefan Chavez-Norgaard and Jane Rongerude. These presentations will situate applied, experiential learning in planning within these faculty members' literary and scholarly inspirations and include a high-level discussion of how each faculty member integrates applied, experiential learning techniques and professional soft skills into their classrooms. Prof. Chavez-Norgaard will open with a short, 10-minute intervention focused on client-based partnerships in the classroom, discussing a Winter 2026 course partnership with Lincoln Institute of Land Policy. Prof. Rongerude will follow with a short, 10-minute intervention focused on peer assessment and her scholarship focused on improving fairness and utility of peer assessment processes. Following opening framing presentations, both Prof. Rongerude and Prof. Chavez-Norgaard will share short class micro-interventions and solicit feedback from other workshop attendees. In a final portion of the workshop, attendees will share their own pedagogical innovations, solicit comments and questions, and discuss the benefits and drawbacks of these approaches to teaching.

Findings and Implications: We expect that the workshop will be tremendously useful to ourselves and to other attendees, in identifying novel teaching practices and approaches, discussing what works and does not work for students at various levels (i.e. master's programs, undergraduate programs), and creating a community of practice of planning scholars committed to inclusive pedagogy and to applied, experiential learning in varied course

contexts.

Implications: We hope to create a forum of scholars committed to inclusive pedagogy and to bridging the ‘knowing-doing’ gap between planning theory and practice. To that end, we seek to seed ideas for research on planning pedagogy that can be tested and refined through classroom settings, forming the basis for a future academic journal article special issue with contributions focused on the theory, practice, and results of innovative experiential learning and applied techniques in planning. We envision a forum that could include, but would not be limited to, a special-issue engagement in the *Journal of Planning Education and Research*, or *JPER*, for example.

What will the audience learn from your workshop: Workshop attendees will learn about planning education tools that can structure relationships between planning programs and practicing planners from the public, private, and civil-society sectors. They will experience and pilot teaching and learning tools and offer feedback to planning scholars.

Reminders for attendees: Attendees will be asked to bring to the workshop one classroom activity, material, technique, or approach that they might like to share.

Using Art in Planning Pedagogy and Practice

Abstract ID: 1841.0.0.687.2025

Track 10: Planning Education, Process(es) and Law

Professional Development Workshop Submission

Joanna Kocsis [Cornell University] joanna.kocsis@cornell.edu, organizer

Keisha Maloney [University of British Columbia] keisha.maloney@ubc.ca

Meaghan McSorley [Florida State University] mmcsorley@fsu.edu

Anahita Shadkam [California Polytechnic State University] a3shadka@waterloo.ca

Moriah Richman [Cornell University] mer339@cornell.edu

Planning decisions often respond to the emotional reactions of people to their environments. Proposed ‘efficient’ or ‘logical’ urban solutions sometimes evoke outrage and catalyze resistance from citizens. Planning with care requires planners to have the skills to understand peoples’ affective (emotional) and embodied experiences of the city. Creative practice, including art, performance, and games, can be used to engage both communities and policymakers in responding to urgent urban challenges, allowing planners to effectively and ethically support inclusive, just communities.

Planning practitioners, researchers, and educators are increasingly valuing the skills required to engage with the affective responses of community members, as well as realizing the importance of attending to the affective experiences of planning students. Engaging with the ‘affective domain’ in shared spaces such as community meetings and classrooms can be uncomfortable or unfamiliar (Sandercock, 2003), and planning pedagogy increasingly demands that we build affect-sensitive competencies for ourselves and among our students. Scholarship in and beyond the domain of planning has illustrated how art can be used to access sensitive topics (Kocsis, 2024), to connect with vulnerable populations (Leavey, 2017), to address power imbalances (Finely, 2008), and to support the decolonization of knowledge (Mignolo, 2009). The use of art in planning scholarship and practice is growing, while formal training opportunities for planners, both practitioners and teachers, are scarce.

To further support the discipline’s ability to engage with the affective domain, in this workshop planning scholars with extensive arts-based research experience will lead participants through a three-part learning activity:

Exploring the value of arts-based research for planning: We will present the theoretical foundations for the use of art in planning pedagogy and practice, grounded in our emergent work on the role of emotion and embodiment in planning. (30 min)

Experiencing the value of arts-based research for planning: Participants will rotate through 2-3 different stations (stations will include digital art, photo-based methods, drawing based methods, games, and performance options) at which they will engage in an arts-based activity to learn how these methods feel from the perspective of students or community members. (30 min)

Planning for the use of arts-based research in planning: Workshop leaders will facilitate small-group discussion and engagement with arts-based methods. Participants will be invited to think through how they would use arts-based methods in either research, practice, or education. Each group will be asked to draw on the methods introduced through stage 2 of the workshop and develop a proposed arts-based activity for either community engagement,

teaching or research, thinking through the logistical, conceptual and ethical considerations of using different types of art in different contexts. (30 min)

Participants will leave the workshop with a basic understanding of the philosophical underpinnings of the use of art for paying attention to affective experiences in planning. They will be provided with a list of resources for further reading on the connections between art, affect and planning. They will gain first hand experience participating in arts-based activities, and then apply that experience in the final activity, in which they develop blueprints for the use of arts based methods in their own work. Participants will also be invited to join a network of planning scholars working in the arts/affect space within and beyond planning, helping to grow the critical mass of planning scholars with arts experience.

What will the audience learn from your workshop: Participants will learn how art can be used to engage with affective experiences in planning. They will gain first hand experience participating in arts-based activities. Participants will develop blueprints for the use of arts-based methods in their own work.

Reminders for attendees: Art materials will be provided. Participants interested in exploring digital methods should bring a charged and wifi connected tablet or laptop. Prepare 1 sentence describing the context in which you're like to use art in your work.

Working with Journalists: How to Ensure that Your Message Gets Out

Abstract ID: 1841.0.0.888.2025

Track 10: Planning Education, Process(es) and Law

Professional Development Workshop Submission

Ruth Steiner [University of Florida] rsteiner@ufl.edu, organizer

Megan Ryerson [University of Pennsylvania] mryerson@design.upenn.edu

The decline of the local media and its replacement with social media presents a challenge for planners. Local journalism has variously been described as watchdogs of our civic institutions, a check on government power, and a part of our social capital. Many of the activities of planners have a local impact on a single neighborhood or the community. Yet the general public does not always understand the planning process or the importance of local planning efforts. To communicate that message, planning faculty are often called upon by journalists in mainstream media – television, radio and podcasters, and decreasingly, newspapers and magazines – to present and interpret the events happening in a community. In this capacity, planners are often called up to provide information that serves the public interest by educating the public about issues of concern to the community. While planning faculty have an opportunity to present our message via social media, that message is often sent to an echo chamber or worse it can reinforce the polarization of the community over certain issues. The mainstream media remains a viable option for getting out the message about the role of planning in the community. In this workshop we will explore the relationship between journalists and planning faculty to understand how journalists think about planning issues. We will consider how trends in journalism affect the role of journalism at the local level. We will explore how planners can become partners with local journalists to get out the message about the importance of urban issues and how to address them in the context of the local planning process. We will address how to ensure that our research and teaching is incorporated into public interest journalism instead of contributing to polarization. We will explore the challenges of crafting a message for a general audience while ensuring that the journalist can communicate it effectively to the public. Finally, we will allow some time for participants to explore how they could be a more effectively communicate with journalists to ensure that public understands the planning processes and outcomes and their impact on the community.

What will the audience learn from your workshop: We will explore (1) the relationship between journalists and planning faculty; (2) how planners can become partners with local journalists to get out the message about the importance of urban planning; and (3) explore how they could be a more effectively communicate with journalists.

Reminders for attendees: Bring along your stories - both your successes and failures - about working with journalists. This will be an interactive workshop.

Cultivating Mindful, Creative, and Analytical Skills for Participatory Modeling and Planning

Abstract ID: 1844.0.0.104.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Moira Zellner [Northeastern University] m.zellner@northeastern.edu, presenting author

Antonia Sohns [Northeastern University] aasohns@gmail.com

Sebastian Ruf [Northeastern University] sebastianruf@gmail.com

Participatory modeling (PM) is a collaborative approach to building and using models (e.g., photography, mapping, causal loop diagramming, fuzzy cognitive mapping, system dynamics modeling, and agent-based modeling) to understand, design and test solutions to a complex problem, for which a desirable action is hard to define and coordinate. Engaging in PM helps elicit diverse stakeholder knowledge and collaboratively produce solutions; this process can strengthen relationship-building, empathy, trust, systems thinking, and collective agency for planning and decision-making.

The complexity and wide range of the problems addressed through PM cannot be studied within a discipline alone. Standardizing an approach across a wide range of theoretical frameworks, methods, and applications remains elusive and thus difficult to teach and to learn. Additionally, while there is increasing recognition of the critical role of diverse and non-modeling stakeholders in collaborative planning processes, PM and community engagement practices have not fully coalesced. PM tends to focus on the goals of interdisciplinary knowledge co-production for decision support, while community engagement tends to focus on ensuring a representative and ethical engagement, with or without scientific support. The inherent difficulty of collaboratively handling complexity makes PM uncertain and open-ended, creating significant challenges in the training of future PM practitioners and researchers. This uncertainty typically creates discomfort and anxiety among participants, hampering social learning and leading to disenchantment and disengagement.

Facilitation is critical in supporting continued productive engagement through the challenging aspects of the PM process: conceptualization and sense-making, understanding and management of uncertainty, and conflicting values and goals. The skills needed for the task range from active listening, to synthesizing diverse views, to moderating equitable, honest and respectful interactions, all while keeping the collective on task within the resource and time constraints. If PM practice is not attentive to different voices, to the importance of listening, and to the positionality of the facilitator and engaged stakeholders, the modeling efforts may not lead to the social learning necessary for transformative changes in policy and behavior. Understanding both how facilitation can enhance the participatory experience and how specific modeling techniques (tools and conceptualization approaches) can leverage joint learning and solution-building for complex problems are critical to inform the training of future PM practitioners and scholars.

This paper proposes a pedagogical framework for PM training that builds on the practice of mindfulness, improv theater, and conceptualization of complexity to cultivate the skills necessary for the successful support of the joint modeling and planning effort. Central to this effort is the goal to purposefully include stakeholders' diverse values and knowledge, designing models as "glass boxes" that are more transparent to both inform and interpret by

diverse participants, and creating an environment of playful collaborative exploration and creativity. We provide a qualitative analysis of students' uptake and integration of facilitation skills from data collected during a PM course taught by the lead author, including students' reflection on their learning journey, as well as anonymous course evaluations. We observe that systematically cultivating mindfulness and improvisational skills as part of the class greatly enhanced the learning experience and confidence that students felt in their ability to co-design and facilitate PM processes. While the ability to conceptualize complexity with different tools is critical, that alone was not enough for students to effectively deal with the many moving parts and inevitable uncertainty of a PM process. We conclude with implications for training.

Downscaling Transformation in the Classroom to Prepare Future Practitioners

Abstract ID: 1844.0.0.428.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Keisha Maloney [University of British Columbia] keisha.maloney@ubc.ca, presenting author

Uncovering the complexity that planners navigate in their praxis can foster a sense of defeat among future practitioners about the transformative potential of the profession. For some planning students, creating change through planning systems feels like “10 steps forward and 8 steps back” because of the depth of polarization among publics, the complexity imbued in institutions, and the extreme power held in the hands of the few. In this context, planning educators must balance introducing students to the nexus of challenges that underpin planning praxis without fostering overwhelming defeat about future practitioners’ ability to advance transformative outcomes. One pedagogical approach planning educators have adopted to support this balancing act is community-engaged learning (Harwood & Zapata, 2014; Miller, 2014). Community-engaged learning (CEL) commonly refers to a well-scoped project that asks students to engage with, and often devise a response to, a problem a community partner is actively facing (Taylor et al., 2016). Despite incorporating CEL into planning pedagogy, its impact on training future practitioners for the “chaotic world of uncertainties” they will inherit remains underexplored (Rooij & Frank, 2016, p. 482).

I ask: To what extent does community-engaged learning in planning pedagogy train students with capabilities that support change-making on complex challenges? This paper explores this question via a mixed-methods study of CEL delivered in undergraduate planning courses at the University of British Columbia in Vancouver, B.C. I conducted an abductive analysis of qualitative data gathered through semi-structured interviews with undergraduate students, classroom observations, and students’ final assignments in six courses.

The results show the extent to which CEL introduces students to how planners navigate plurality, institutional complexity, and power dynamics in pursuit of transformative outcomes. As students actively contend with this structural nexus in their CEL project, I explain the mechanisms for moving students through a transformative learning process, where their prior understanding of the discipline is called into question and reformulated as they gather new information. Through collaboration and feedback, community partners show students what is and is not possible to achieve in their praxis, a dynamic I refer to as ‘bumping into constraints.’ Bumping into constraints reveals that the avenues for change students once believed in may not be viable or at least are more complex than they initially thought. Such realizations downscale students’ understanding of transformative planning praxis and reveal that most transformation is made up of incremental actions. Thus, in this paper, I argue CEL has the potential to enhance future planning praxis by creating opportunities for students to build the foundations for navigating institutionally complex, pluralistic, and power-laden structures to create radically incremental change. However, if the mechanisms of CEL are not well understood and utilized, this potential will be lost.

This paper makes three contributions. First, by systematically examining the impact of CEL in planning pedagogy, I advance ongoing conversations in planning education that explore how educators can equip students to become impactful future practitioners (Keyes & Fischer, 2024). Second, I advance a connection between transformative learning theory and transformative planning praxis by showing that through CEL, students learn that transformation is a radically oriented but incremental process. Third, I contribute to professional development efforts in pedagogy and practice by providing empirically based recommendations for planning education to produce more aptly trained practitioners for the workforce. Together, these insights contribute to conversations in planning theory and pedagogy about how to prepare future practitioners for transformative praxis.

Environmental Planning Education in US Universities: Pedagogies and Gaps Amidst Emerging Challenges

Abstract ID: 1844.0.0.402.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Jiwnath Ghimire [Iowa State University] jghimire@iastate.edu, presenting author

Eyad Taamallah [Iowa State University] eyadt@iastate.edu

Environmental planning is a critical subfield in planning education, equipping future practitioners with the skills to address pressing environmental challenges. In the context of changing environmental and sustainability issues, the planning pedagogy in higher education in this field remains underexplored. This study investigates the teaching and learning approaches of environmental planning in U.S. universities. Based on Bloom's Taxonomy (1956), Quality Matters Standards (2018), Fink's Taxonomy (2013), and best teaching practices, this study addresses two primary questions: (1) How do current environmental planning courses align with pedagogical frameworks to promote effective learning outcomes and students' experiences? (2) How do higher education environmental planning courses empower students to deal with emerging environmental challenges?

The research uses a structured two-tier process to analyze 60 environmental planning courses from 32 undergraduate and 28 graduate planning programs in the United States. First, programs accredited by the Planning Accreditation Board (PAB) were identified. Second, environmental planning courses within the program were assessed for course objectives, instructional methods, assessment strategies, and student engagement practices using six key dimensions (Fink, 2013): Foundational Knowledge, Application, Integration, Human Dimension, Caring, and Learning How to Learn.

The findings reveal that Foundational Knowledge and Integration are the strongest course components. However, Application, Human Dimension, Caring, and Learn How to Learn exhibit notable gaps, indicating that while students gain a strong conceptual base, the practical and reflective dimensions are underdeveloped across courses. Within these six dimensions, further analysis of specific teaching practices (Flaudi, 2013; Hopkinson, 2010) highlights strengths in teaching clarity and organization and alignment of assessments with higher-order Bloom's Taxonomy skills. Including interdisciplinary content and engagement through fieldwork and community projects are less consistent in university-level environmental planning courses. Conversely, problem-based learning and flexibility remain rare among them, underscoring a need for more adaptable, student-centered approaches.

This study proposes a framework for environmental planning pedagogy, highlighting exemplary practices while identifying areas for improvement. It serves as a guide for educators to strengthen course design and practice-ready graduates, with findings that hold significant implications in refining curricula to equip students with the essential skills needed to tackle contemporary environmental planning challenges in the United States and beyond.

Market-driven Curriculum Design and Assessment in Planning Education for Improved Employability

Abstract ID: 1844.0.0.1035.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Criseida Navarro Diaz [Universidad de Puerto Rico Escuela Graduada de Planificación] criseida.navarro@upr.edu, presenting author

The Association of Collegiate Schools of Planning promotes that member schools instill in future planners a deep commitment to serving the public interest, strong Planning knowledge, technical as well as people skills, and values that they will need in practice, as put forth in periodically-revised Accreditation Standards. The knowledge and skills that are needed as professionals in the field are constantly evolving at a fast pace affecting what the job market demands of graduates from Planning Accreditation Board (PAB) accredited programs. Various programs have been creative in devising ways to respond to market needs and improve graduate employability. The University of Puerto Rico Graduate School of Planning (UPR-GSP) is among these.

In 2005-2006 the UPR-GSP designed, conducted and instituted a market study to determine the knowledge, skills and values that the local job market was demanding from its graduates. It included the development of student, alumni/ae and employer databases as well as drafting protocols and forms for interviews, surveys and focus groups that would take place every 5-to-7 years, contributing to the School's self-study required for accreditation. The findings of each study round enabled the Program to draft (2016) and implement (2019) a new curriculum with significant changes in graduate competence profile, required content, learning experiences, and theory-practice balance. As a crucial component of the new curriculum, the School designed an Assessment Plan, built over similar principles of responsiveness to market needs, to measure Program Effectiveness, Learning Outcomes and Labor-Market Readiness. Thus, it feeds from the periodical market study with its surveys, interviews and focus group to students, alumni/ae and employers. However, it also includes the application of a 37-indicator rubric organized into eight learning domains that captures the knowledge, skills and values of the UPR-GSP Student Competence Profile as a result of the triangulation of PAB Accreditation Standards; Institutional Vision, Values and Strategies; and Market trends. The Plan contains at least two assessment activities for each domain. It is revised every three years and uses an online platform for tracking progress over time. Now it is being used to evaluate the effectiveness of specific core courses, to differentiate the way in which the topics are addressed through the curricular sequences and to identify topics to be explored in elective courses.

The UPR-GSP Masters in Planning Program has proven very effective, attaining 100% of achievement in all measured learning domains as well as 100% employability within one year from graduation, with 97% in planning and planning-related jobs. This paper documents the case as a noteworthy practice for Masters in Planning Curricular Design and Assessment Tool. It seeks to identify What are the critical components in meeting market demands from the curricular design standpoint in Planning? What stakeholder groups need to participate in such design approach? How do curricular ties to market needs affect graduate job readiness and employability? What role does assessment tools play in a Planning Program's ability to quickly adapt to changes in market trends? It will analyze the results of the UPR-GSP's market studies and learning assessment outcomes from 2005-2006 to present and test for a correlation with curricular changes. This will be complemented with interviews with market study participants, particularly Program graduates and their employers, to evaluate the effectiveness of the actions that UPR-GSP has taken. The goal is to identify lessons learned that can be adapted and implemented by other PAB-Accredited Masters in Planning Programs.

The advent of generative AI, particularly Large Language Models (LLMs), signifies a transformative moment in planning education and practice; however, this is merely the latest chapter in the evolving relationship between planning and technology. Throughout modern planning history, there has been tension between adopting cutting-edge tools and ensuring equitable access. From early concerns about large-scale modeling empowering technical elites (Lee, 1973) to contemporary debates regarding algorithmic bias (Acolin & Kim, 2024), planning has struggled to harness the benefits of technology while alleviating its potential to reinforce existing inequities (Kontokosta, 2021). Throughout this technological evolution, planning education has served as both a gatekeeper and catalyst, significantly influencing which technologies the profession adopts and shaping how these tools are deployed to serve the public interest. Unlike previous technological innovations, LLMs have the potential to impact every aspect of planning - from analysis to communication to public engagement. At the same time, this technology can be accessed by both practitioners and community members, potentially altering dynamics between these groups in ways that either democratize planning knowledge or create new forms of technical centralization.

This paper addresses a critical research question: How can planning education integrate LLMs while preserving planning's core values and enhancing its unique disciplinary perspective? To answer this, it is important to first understand planning education's responses to previous technological advancements. Our research combines a historical analysis of planning's technology adoption along with the evolution of planning education standards and requirements, revealing patterns that can inform current approaches to LLM integration in planning curricula.

Our findings trace the field's adoption of technologies from the 1950s mainframe era to the advent of GIS, followed by the adoption of web-based services through to AI, machine learning, and LLMs. This historical analysis reveals that planning's engagement with technological innovation has consistently featured three critical dynamics: the gradual democratization of technology, planners' role in guiding technology using equity-centered frameworks, and planning schools' adoption of new technologies to prepare students for the real-world applications of emerging tools.

Using this analysis in relationship with Bloom's Taxonomy and Freire's principles of humanizing education, this paper outlines the importance of integrating LLMs into education while preserving and advancing planning's commitment to serving the public interest. It positions planners as essential guides in technological application, following the historical principle that technology should address community-defined problems rather than dictate the planning agenda (Klosterman, 1997). The future of planning technology depends not only on the tools we create but also on how we implement them—a question that requires planning's unique perspective on the relationship between technical means and democratic ends. This research concludes that planning education stands at a critical juncture where its approach to LLMs will significantly shape whether these technologies enhance planning's values or further entrench technocratic practices in the profession.

Individual Paper Presentation Submission

Maria Conroy [The Ohio State University] conroy.36@osu.edu, presenting author

A primary objective of planning is to implement policies and practices that enhance our quality of life. Understanding whether we have made progress in doing so is the focus of evaluation against criteria and reflection on experiences. In the United States, community comprehensive plans are an expression of community intention concerning land use. They typically acknowledge current conditions, goals a community wants to achieve in areas such as housing or open space or mobility, and policies to support such achievement. These plans guide planning-related decisions until changes in conditions, goals, and/or policies necessitate a new plan. Understanding what makes a good plan is a focus of the plan evaluation literature and assumes a nexus between plan document and on the ground outcome. Most evaluative studies provide a cross-sectional assessment, delivering insights into the state of practice at a particular point in time.

Although the plan evaluation literature is extensive, there is only a small subset of studies that provide longitudinal insights regarding plan quality progression. Longitudinal plan evaluation studies are opportunities to assess learning from previous planning efforts, providing practitioners with insights from examining the impact of prior policies on existing outcomes. There have been five longitudinal plan evaluation studies since 2003 and their outcomes are inconsistent, highlighting both gains and losses in plan scores over time (Brody, 2003; Conroy & Wilson, 2023; Lukasiewicz et al., 2020; Lyles et al. 2023, Stevens & Senbel, 2017). The variation in outcomes highlights potentially unexplored influences on plan content during the preparation process.

Influences on interstitial plan development provide a key area for understanding the longitudinal changes in plan scores. Brody (2003) argues that “plans adapt over time to the needs, knowledge base, and experiences of a particular community” (p. 191) and notes exogenous factors and engagement as influencing “plan learning” for hazard mitigation components of comprehensive plans. Implementation success is also a potential driver of score changes. What remains unexplored is the role of the prior plan as a reflective target in the plan development process. Therefore, the research question that guides this work is: How do planners use prior plans to inform the planning process for new plans?

To address this question, I begin with an overview of the role of reflection and learning in planning processes and provide a conceptual framework accounting for its potential influence. I then present the two-phase methodology used to gain insight to respond to the research question involving a survey and interviews of planners in 28 communities whose plans were the target of the Conroy & Wilson (2023) study. Using a conceptual framework of plan influences, survey data, interviews with planning professionals, and thematic analysis I find that while prior plans serve as reference points, planners prioritize engagement and emerging policy concerns over reflection on past plans and processes. Additionally, structural constraints such as multiple and concurrent planning processes limit reflective practices. I highlight the need for intentional reflection strategies and procedural opportunities to improve planning outcomes. This study is important for planning educators and practitioners to understand the role reflection and learning play in plan-making.

Paralysis or Empowerment: Climate Anxiety, Hope, and Action in Urban and Environmental Education

Abstract ID: 1844.0.0.414.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Jessica Garrison [University of California, Irvine] jdgarris@uci.edu, presenting author

Douglas Houston [University of California, Irvine] houston@uci.edu

Climate change has emerged as a central component of curricula in urban and environmental planning programs, but our understanding of how climate education impacts student mental health, wellbeing, and behavior remains limited. Learning about the environmental drivers, societal impacts, and political responses to climate change can be overwhelming for many students, but it can also spur students to engage in pro-environmental behavior and political action (Moore et al., 2019; Short, 2010). In fact, climate anxiety and hope can both impede or facilitate the transition from learning to doing (Anderson et al., 2013; Short, 2010). Given that many young adults are experiencing climate anxiety (Hickman et al., 2021), it is important to assess whether students' cognitive-emotional response to the climate crisis is resulting in paralysis or empowerment.

We address this concern by analyzing survey data gathered in undergraduate courses on urban and environmental subjects at the University of California, Irvine to address the following research questions:

- How are students' experiences of climate anxiety and climate hope associated with their engagement in different types of climate action?
- What are the implications for urban and environmental education?

Survey questions included the following: cognitive-emotional responses to climate change, associated physiological symptoms (e.g., difficulty sleeping or concentrating), and impacts on work and relationships; beliefs about potential pathways to climate solutions and the ability to pursue them successfully; self-reported engagement in a range of pro-environmental behaviors; and self-assessed knowledge of climate science and policy.

Exploratory factor analysis was conducted to reduce survey items into composite variables. Climate anxiety, climate hope, and climate literacy all emerged as distinct factors, along with three types of climate action: individual behavioral change (i.e., consumer behavior), discussing climate change, and political action. Multivariate regression was used to assess and compare the association of climate anxiety and climate hope with the three types of climate action, while controlling for climate literacy, STEM majors, previous environmental coursework, gender, and race.

Results indicate that educators within planning and environmental programs need not be anxious about climate anxiety among their students. Many students experience both anxiety and hope simultaneously, indicating that one does not necessarily inhibit the other. Moreover, anxiety may actually be more productive than hope when it comes to empowering students to take various types of action on climate change. Climate hope is only significantly associated with individual behavioral change, while climate anxiety is significantly associated not only with individual behavioral change, but also with discussing climate change with others and engaging in political action. Engagement in a wider range of climate actions may take a greater emotional toll on students than individual behavioral change alone. However, anxiety may also motivate students to move beyond incremental changes to private consumer behavior, pushing students to connect with others and engage in political action. While additional research is necessary to establish a direct causal link between climate anxiety, climate hope, and climate action, these results indicate that worrying, hoping, and doing can productively co-exist in university classrooms.

Planning through Community-University Partnership: A Meta-Analysis of EPIC-N Publications

Abstract ID: 1844.0.0.812.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Keisha Bharath [University of Washington] kcbhara@uw.edu, presenting author

Branden Born [University of Washington Department of Urban Design and Planning] brandenborn@gmail.com

University-community partnerships can play an important role in addressing local planning challenges aligned with global sustainability frameworks, especially for local government with limited resources. The Educational Partnerships for Innovation in Communities Network (EPIC-N) offers a structured approach to connect universities with communities to collaboratively address real-world planning challenges. Despite the history and number (~40 domestically) of EPIC-N programs, however, there remains a lack of synthesis on the types of projects these partnerships undertake, how these projects with the United Nations Sustainable Development Goals (SDGs, a metric EPIC-N uses), and the thematic priorities they represent. This research addresses that gap through a meta-analysis of publications discussing EPIC-N and EPIC-N projects. Given the limited literature, it uses projects done by multiple universities to represent the breadth of project emphases, and uses nine years of projects done through the University of Washington's Livable City Year (LCY) program as an example of longitudinal project emphases for comparison.

The research is guided by three core questions: What are the dominant themes across EPIC-N-affiliated projects? How are these projects aligned with the SDGs? And in what ways does LCY differ from or reflect broader EPIC-N patterns in terms of thematic focus and institutional orientation?

Peer-reviewed publications of EPIC-N programs and projects were reviewed and categorized according to thematic content, and SDG alignment. The analysis identified seven recurrent domains: urban governance and policy, food systems and urban health, community development and partnership, transportation and mobility innovation, environmental health, technology integration and smart cities, and urban sustainability and resilience. These categories served as a framework for comparing program emphases and for situating LCY within the broader network.

Preliminary findings suggest that while there is consistency in values—particularly around equity, sustainability, and applied research—programs diverge in focus depending on institutional context and local partnerships. Programs based in planning or public policy departments frequently emphasize governance, infrastructure, and land use, whereas others may focus more on education, technology, or public health. The LCY program, for example, reflects a particularly integrative approach, with an emphasis on governance, land use, and cross-sector collaboration across university and community stakeholders.

This study contributes to planning scholarship by offering empirical insight into how university-community partnerships are operationalized and how they engage with global development frameworks such as the SDGs. It also engages with broader debates on the role of universities in advancing urban innovation and sustainability transitions through interdisciplinary, place-based engagement (Evans, Karvonen, & Raven, 2016, p. 3; McCann & Ward, 2010, p. 176). This research builds on existing scholarship examining the role of higher education institutions in catalyzing sustainability transitions and multi-scalar community engagement (Brundiers & Wiek, 2011, p. 108; Wiek, Xiong, Brundiers, & van der Leeuw, 2014, p. 432). In addition to its academic contribution, the findings have practical relevance for institutions seeking to design or evaluate community partnership models. Understanding

cross-institutional trends and especially thematic gaps—particularly in relation to SDG alignment—can inform more intentional, equity-driven approaches to program design, local engagement, and policy collaboration.

Preparing Planners for Emerging Issues: Adapting the Planning Curriculum for Distributed Work

Abstract ID: 1844.0.0.1084.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Manju Adikesavan [Pratt institute and CUNY, New York City] madikesavan@gradcenter.cuny.edu, presenting author
Laxmi Ramasubramanian [The College of Staten Island, CUNY] laxmi.ramasubramanian@csi.cuny.edu

Office-based work, the predominant economic activity in the post-industrial United States, is rapidly changing due to artificial intelligence (AI), automation, robotics, and distributed work arrangements, such as remote and hybrid work. Work is a crucial "spatiotemporal peg" that shapes overall spatial structure and activity-travel patterns (Ben-Elia et al. 2014).

Accordingly, hybrid and remote work, where employees work from diverse locations such as their homes, offices, and third places, at any time of day or night, have socio-spatial and economic consequences. For example, the shrinking spatial footprint of offices, rising office vacancy levels, increase in home-based working, and the migration of remote and hybrid workers to desirable alternative locations call for reimagining commercial real estate, local economic development, and housing practices in cities and metropolitan regions (Adikesavan, 2025).

Building on research about planning for the emerging geography of distributed work (Adikesavan and Ramasubramanian 2024; Zenkteler et al. 2019), this paper argues for adapting the planning curriculum to empower future planners with the tools and competencies for tackling the land use and policy planning shifts, challenges, and opportunities associated with distributed work. This assessment aligns with the American Planning Association and Lincoln Institute of Land Policy's 2023 and 2024 Trend Reports for Planners, which urge planners to prepare for the emerging impacts of distributed work on urban, suburban, and peri-urban areas.

This paper presents the findings of an online survey (N = 95) and semi-structured interviews (N = 15) conducted with US and Canadian planning instructors in the spring of 2025. The survey and interviews seek to understand:

- 1) How do planning instructors currently address planning for distributed work in their courses?
- 2) What are planning instructors' opinions on curricular concerns related to distributed work?

Examples of curricular concerns include, a) planning domains impacted by distributed work (land use, transportation, real estate development, local economic development, housing, public finance), b) appropriate learning unit (subtopic of a core course, standalone elective), c) level of education (undergraduate, graduate, or continuing education), d) mode of instruction (online, in person, blended), and e) timeline for curricular change (1-2 years, 3-4 years, more than five years).

The survey and interviews provide much-needed insights into the extent to which the impacts of distributed work on the built environment are currently addressed in planning programs, the planning domains affected by distributed work, and appropriate curricular choices for empowering future planners with the skills and competencies to formulate informed and nimble planning responses to distributed work. These insights are supplemented with pairwise Spearman correlation coefficients that estimate the relationship between instructors' opinions and their respective research interests, institutional affiliations, and professional backgrounds. Finally, the survey results and thematically analyzed interviews provide an evidence base for provoking discipline, program, and instructor-wide discussions and actions to adapt the planning curriculum and address the emerging socio-spatial and economic impacts of distributed work.

Professional preparedness is an enduring concern in planning education (Argyris & Schon 1992; Greenlee et al. 2015). While students often equate professional preparedness with technical skill acquisition, planning educators recognize that affective dimensions, such as values, judgment, and behaviors, are necessary to become an effective practitioner (Greenlee et al. 2015; Forester 2013). Reflection plays a critical role, but planning educators need tools to support this emotional and intellectual development process, particularly as students confront the field's historical injustices and their implications for professional identity.

This paper introduces the Professional Identity Formation (PIF) framework to planning education, translates its key components for planning practice, and demonstrates its application by analyzing students' reflective essays. PIF is an iterative process through which students integrate the knowledge, skills, values, ethics, and behaviors of their profession into their pre-existing identity. PIF has emerged as a key outcome in medical education because a strong professional identity is associated with improved patient safety outcomes, lower levels of physician stress, and greater workforce retention (Fitzgerald 2020). This suggests that the PIF framework may be useful for planning educators concerned with supporting students in developing personal resilience to confront the intersecting crises of our time.

The core dimensions of PIF include actions and behaviors; knowledge and skills; values, beliefs, and ethics; context and socialization; and group and personal identity (Fitzgerald 2020). PIF requires reflection and is not merely a process of wholesale adoption of a profession's norms; the goal is not for all students to adopt a singular "planner" identity. Rather, it is an emotionally intense deconstruction and reconstruction process that students undergo to determine whether and how they "fit" into a profession and forge a path forward for themselves (Sarraf-Yazdi et al. 2021). PIF should be used to create supportive learning environments that explicitly foster this identity formation process, enabling students to identify their unique approach to practice (Schön 1987).

This study adapts PIF for planners by translating the five dimensions of PIF using material from the American Planning Association (APA) and the Planning Accreditation Board (PAB). We leverage this framework in a directed content analysis to qualitatively code three cohorts of student responses to a reflective essay assignment known as the Planning Philosophy Statement (PPS). The PPS prompted students to articulate their motivations, core values, and unique strengths, as well as to grapple with their identities and positionality. By comparing APA and PAB articulations of what a planner ought to be with students', we identify important challenges students face in integrating professional norms and unique conceptions they have about what planners should do and be.

We found that students defined the role of the planner in contrast to the profession's history of perpetuating systemic harms. Yet, their values largely aligned with PAB's accreditation standards (DEI; Sustainability; Professional Responsibility). However, student phrasing often diverged, using terms like service, accountability, collaboration, and lifelong learning, which reflects a broader conception of Professional Responsibility. Additionally, over a third

of the identified values were unique, offering us insights into these students' aspirations for the field's evolution: These included open-mindedness, creativity, flexibility, perseverance, and humility, among others.

This study presents the PPS as a pedagogical tool for exploring professional identity, bridging skill acquisition with affective learning. It demonstrates PIF's relevance in planning practice, empowering students to critically engage with the field's history and build confidence to shape its future.

Student-Led Learning in Sustainability Education & Practice: A Case Study of a LEED for Cities Project

Abstract ID: 1844.0.0.239.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Jiayi Guo [Cornell University] jg2252@cornell.edu, presenting author

Sirietta Simoncini [Cornell University] ss2583@cornell.edu

There has been a shift in sustainability education from traditional didactic teaching toward student-centered, transformational learning (Lee et al., 2022). Student-led learning builds on the principles of student-centered learning and offers students greater autonomy in defining tasks, tools, and resources throughout the learning process. In planning education, student-led learning has been recognized for its potential to enhance student engagement and ownership; however, it also faces persistent challenges (Purkarthofer & Mäntysalo, 2022). These include limited student mobility between project roles and constrained opportunities for students to exercise meaningful decision-making, often due to the short-term nature of academic projects (Purkarthofer & Mäntysalo, 2022).

While prior research in sustainability education has identified general benefits and barriers, the specific mechanisms through which student-led learning can effectively support both student development in sustainability and the advancement of municipal sustainability goals, particularly within applied projects, remain underexplored. To address these gaps, this study explores how a recent LEED for Cities certification project functioned as a high-impact student-led learning opportunity. The central research question guiding this study is: What are the key mechanisms that facilitate a LEED for Cities certification project to function as an effective student-led learning opportunity? In this student-led certification application project, undergraduate and graduate students of planning, design, environment, systems engineering, and other majors at Cornell University helped the City of Ithaca achieve LEED for Cities Gold certification in 2024, in collaboration with city officials, LEED professionals, and their faculty advisor.

The study combines in-depth interviews with documentation analysis. We plan to conduct around 15 semi-structured interviews with students, city staff, and other stakeholders, and analyze project documentation, including internal memos, meeting notes, and communications. Interviews with students will illuminate how they navigated project planning and management, transdisciplinary teamwork, and the application of sustainability concepts through the LEED framework, while those with city staff will reveal how they perceived the project's contributions to municipal sustainability goals and the practical value of student collaboration. Analysis of project documentation will support the reconstruction of the project timeline and decision-making processes, helping to contextualize and triangulate themes emerging from the interviews.

Preliminary findings reveal several unique mechanisms adopted by this project that contribute to successfully addressing challenges in student-led projects. First, the LEED for Cities offered a structured process yet flexible operational system, enabling students to take initiative in engaging with sustainability metrics. Second, the student members operated as an ongoing project team across multiple semesters, ensuring the project's continuity from start to finish. Third, the team is restructured by student leaders each semester based on project needs, which allows students to work across disciplines and continuously improve themselves to keep up with the new demands of the project.

This case study contributes to planning education by highlighting important mechanisms through which performance-based sustainability frameworks like LEED can serve dual roles: supporting student-led learning and

advancing municipal goals. It offers a replicable model for integrating professional frameworks into planning curricula. In a moment when planning education seeks more engaged and socially relevant pedagogies, this case study demonstrates how student-led certification projects can build transdisciplinary capacity, systems thinking, civic engagement, and mutual learning relationships across sectors.

Sustainability Competency-Driven Planning Education: Insights from a Galapagos Study Abroad Program

Abstract ID: 1844.0.0.817.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Jaime Eduardo López Andrade [Universidad San Francisco de Quito] jlopez@usfq.edu.ec, presenting author

Yizhao Yang [University of Oregon] yizhao@uoregon.edu

Natalia Echeverri [Hong Kong University] nechever@hku.hk

Higher education is essential for preparing students to advance sustainability as professionals, leaders, and citizens. Its effectiveness hinges on both curriculum content ("what to learn") and pedagogical approaches ("how to learn"). Since the 1990s the content of sustainability education has evolved from a focus on scientific and technical knowledge to a more holistic scope, which now encompasses collaboration with diverse stakeholders, understanding complex social systems, fostering personal growth through critical thinking, and driving societal change. Transformative learning, established as the central pedagogical approach for the UN Decade of Education for Sustainable Development (ESD, 2005–2014), emphasizes a process that empowers learners to critically examine their assumptions, beliefs, and values. UNESCO positions higher education as a key platform for ESD implementation and promotes transformative learning for developing key sustainability competencies (SCs): systems thinking, anticipatory thinking, normative reasoning, strategic action, collaboration, and integrated problem-solving.

Planning education in the US has followed a similar curricular trajectory, though pedagogical evolution has been gradual despite progressing in the right direction. While the Planning Accreditation Board's standards emphasize infusing equity and sustainability into knowledge and skills, including principles of sustainability, resilience, justice, and professional ethics, its instructional requirements remain narrowly focused on "appropriate student access and timely completion." Notably, planning pedagogy has expanded in recent decades to incorporate experiential and community-engaged methods designed to empower students in addressing real-world sustainability challenges. However, curriculum assessments continue to prioritize content mastery and technical skills, leaving scarce evidence of how these new approaches develop broader sustainability competencies (SCs) that transcend specific subjects.

This paper develops a pedagogical design and evaluation framework grounded in Discipline-Based Education Research (DBER), focusing on planning education. We propose a SC-oriented model that integrates content and pedagogy through key elements: (1) discipline-specific foundations in sustainable cities and landscapes; (2) research-informed, place-based and community-engaged learning approaches; (3) problem-centered inquiry through structured research questions; (4) evidence-based teaching evaluations using the SC framework; and (5) linking pedagogical methods to learning outcomes for improvement.

We piloted this framework to design and evaluate a three-week 2024 summer field school in Ecuador's Galapagos Islands, enrolling 36 students from three universities (USFQ:16, UOregon:13, HKU:7) across diverse disciplines and backgrounds. The program implemented three pedagogical methods: (1) research-driven inquiry through sensory data collection during homestays and excursions, (2) open pedagogy co-creating knowledge with local communities on San Cristóbal Island, and (3) action-based learning developing community proposals. We evaluated learning outcomes using pre-/post-program surveys measuring shifts in sustainability definitions and self-reported competencies across sustainability categories. The post-program survey also examined specific teaching method effectiveness.

The 2024 Galapagos field program assessment reveals that immersive, community-based education fosters sustainability competencies more effectively than traditional classroom instruction. Pre- and post-program evaluations using the SC framework showed significant gains in systems thinking, reflective practice, normative reasoning, and collaborative abilities. These results offer support for the SC-driven DBER framework in curriculum development, emphasizing both knowledge acquisition but also the practical abilities needed for impactful sustainability actions.

The Patriarchal Curriculum: A Critical Analysis of Gender in Core Planning History & Theory Courses

Abstract ID: 1844.0.0.42.2025

Track 10: Planning Education, Process(es) and Law

Individual Paper Presentation Submission

Katrin Anacker [George Mason University] kanacker@gmu.edu, presenting author

Bernadette Hanlon [The Ohio State University] hanlon.42@osu.edu

In this paper, we examine the ways in which gender is covered (or not) in core history and planning theory courses across U.S. graduate programs accredited by the Planning Accreditation Board (PAB). This involved an examination of syllabi for these core classes. To obtain syllabi, we contacted department or program heads of all ($n = 113$) member schools of the Association of Collegiate Schools of Planning (ACSP) via email in March 2022. We received 98 responses total ($98 / 113 = 86\%$). Twenty-two respondents indicated that their program was not accredited ($98 - 22 = 76$). Of the remaining 76 programs, 12 respondents were unable or unwilling to share syllabi ($76 - 12 = 64$). Thus, we received 81 syllabi for 64 programs. We excluded 18 of these syllabi for a variety of reasons. Thus, we analyzed a total of 63 syllabi across 54 accredited programs.

The analysis focused on examining the listed readings. First, we determined how many of the readings were authored or coauthored by women and non-binary scholars. To identify the gender of authors we relied on information that exists in an author's public record, including usage of the pronouns he, she and they. Preliminary findings indicate that there were an estimated 3,500 unique readings listed across the 63 syllabi. Of the unique readings, we found that 95 percent were authored or coauthored by men and the remaining five percent were authored and coauthored by women and non-binary scholars.

We also found an estimated 60 readings covered the topic of gender and planning. Rather than being evenly distributed across the 54 accredited programs, we also found that these 60 readings were in the syllabi of less than 10 percent of programs. This means that the remaining 90 percent of programs were not covering the topic of gender at all in their core history and theory courses.

We conducted a content analysis of the readings that focused on gender and planning. We identified classic readings on this topic that were published at in the 1980s and 1990s. They included readings authored by Hayden (1980), and coauthored by Sandercock and Forsyth (1992), for example. We also found several more recent readings by Doan (2007) and Beebeejaun (2017) published in the 2000s and beyond. We recognize the importance of the classics, but we also point to new and interesting work that women and non-binary authors are contributing to the urban planning lexicon. We urge that these author's readings be included in our graduate planning education, and not in some elective course that students opt into but in the core curriculum (Anacker, 2024). We call for instructors to be cognizant of utilizing the scholarship of women and non-binary scholars, and we advocate for gender equity and justice to be included in PAB standards for curricula of accredited core planning courses.

Engagement and Service-Learning in Planning Education: Understanding Student Learning Outcomes

Abstract ID: 1842.0.0.299.2025

Track 10: Planning Education, Process(es) and Law

Research-in-Motion Presentation Submission, Research currently in process

Avery Neer [Kansas State University] averyneer@ksu.edu, presenting author

Susmita Rishi [Kansas State University] srishi@ksu.edu

Service-learning has become a key pedagogical strategy in urban planning education, offering students an applied, experiential approach to learning (Forsyth et al., 2000; Reardon, 1998). By engaging with communities, students gain direct exposure to the complexities of urban problem-solving, bridging classroom theory with real-world practice. Additionally, service-learning fosters university-community partnerships, building trust and laying the foundation for future collaboration (Baldwin & Rosier, 2017). More recently, critical service-learning has emerged as a deeper framework that extends beyond hands-on experience to encourage reflection on systemic inequalities and long-term civic engagement (Mitchell, 2008; Sandercock, 1999). While service-learning is well integrated into studio-based design education, less is known about its impact in non-studio planning courses and how it prepares students for professional practice. There is also limited research on how working in multi-disciplinary teams influences student understanding of collaborative planning, stakeholder engagement, and policy-based urban interventions.

This paper examines a graduate-level Urban Design and Development course that uses a critical service-learning model to engage students in brownfield redevelopment. Over the past seven years, the course has brought together students from urban planning, landscape architecture, real estate development, and architecture to work in multi-disciplinary teams. Students collaborate with communities to develop urban design visioning proposals through field research, stakeholder engagement, and public presentations. The course simulates real-world professional practice, emphasizing collaboration across disciplines to address complex urban issues.

Drawing on survey responses and in-depth interviews with students who completed the course—many of whom have since entered professional roles—this study evaluates how service-learning contributes to student learning and professional preparation. Students consistently valued the service-learning model for its role in enhancing critical thinking, practical skills, and real-world problem-solving. Working directly with communities and stakeholders deepened their understanding of the regulatory, environmental, and social dimensions of brownfield redevelopment. Importantly, students from non-planning disciplines reported that the experience increased their interest in planning and helped them better understand the planner's role.

The findings also point to challenges that shape student experiences. The effectiveness of service-learning varied depending on the project's location, the depth of community engagement and participation, and the structure of interdisciplinary collaboration. While most students found team-based work across disciplines to be valuable, some encountered difficulties navigating differences in language, methods, and expectations—highlighting the need for intentional facilitation. The organization and framing of service-learning experiences play a critical role in shaping their success and professional relevance.

This study contributes to ongoing discussions on planning pedagogy by demonstrating how service-learning enhances applied learning, critical engagement, and professional preparedness. Findings reinforce the importance of university-community partnerships while also offering insights into refining service-learning models to improve student outcomes, particularly in non-studio planning education. Furthermore, the study underscores the need for longitudinal relationships with communities to facilitate a critical service-learning orientation.

Navigating Climate Anxiety and Nurturing Hope in Planning Education

Abstract ID: 1842.0.0.8.2025

Track 10: Planning Education, Process(es) and Law

Research-in-Motion Presentation Submission, Innovative practices, concepts, and ideas for pedagogy

Kayleigh Swanson [University of Toronto] kayleigh.swanson@utoronto.ca, presenting author

Brendon Goodmurphy [University of Toronto] brendon.goodmurphy@mail.utoronto.ca

Planning and climate change education have increasingly become intertwined as urban centers bear the brunt of climate disruption. Growing awareness and concern about climate change as a pervasive urban problem means planning educators cannot avoid addressing some aspect of the climate crisis in their teaching.

Teaching about climate change presents a unique set of challenges to educators because unlike fields of study where greater knowledge leads to greater student engagement, greater knowledge of climate change tends to induce feelings of hopelessness and apathy that can lead to disengagement (Li & Monroe, 2019). Critical perspectives on climate change can also cause a dilemma for students as they begin to realize that they are implicated in systems of injustice. Teaching strategies designed to support students as they navigate the discomfort associated with this realization are vital to effective planning education.

Research documenting the emotional impacts of teaching and learning about climate change reveals that the topic can be conceptually overwhelming and emotionally disheartening for students and educators alike (Siperstein, 2015). Efforts to increase students' knowledge and concern about the environment have improved awareness about climate change, but these efforts have also heightened climate anxiety and ecological distress, evoking a mix of emotions including fear, outrage, hopelessness, and despair (Verlie et al., 2021). As anxiety about the magnitude of the environmental problems planners face becomes increasingly widespread, planning educators must be prepared to help students navigate the emotional dimensions of climate change education.

This Research-in-Motion presentation explores the effectiveness of teaching strategies for managing climate anxiety and cultivating hope in planning courses. The presentation addresses the following key question: Do reflection-based assessments contribute to reducing climate anxiety among undergraduate students? The presentation shares findings from a study designed to measure the effectiveness of reflection-based assessments in an undergraduate course on urban climate justice. Surveys were used to measure the effectiveness of the assessments for reducing anxiety over the duration of the course, and focus groups were held to gather student perspectives on the value of the reflective exercises. The study offers empirical evidence that clarifies the value of reflection-based assessments as a strategy for encouraging students to engage with the emotional dimensions of climate change.

Building on previous studies grounded in educators' personal experiences and insights, this presentation draws on empirical data to offer guidance regarding the effective implementation of reflection-based assessments as a climate change teaching strategy. Findings are useful for educators concerned with navigating climate anxiety and nurturing hope in planning education.

Transformative Pedagogy: Lessons from a Community-Engaged Learning Course on Homelessness

Abstract ID: 1842.0.0.642.2025

Track 10: Planning Education, Process(es) and Law

Research-in-Motion Presentation Submission, Innovative practices, concepts, and ideas for pedagogy

Mirle Rabinowitz Bussell [UC San Diego] mbussell@ucsd.edu, presenting author

Leslie Lewis [UC San Diego] lrlewis@ucsd.edu

Community-engaged learning pedagogies are central to planning education and have been the focus of significant inquiry (Botchwey & Umemoto, 2018; Lung-Amam, Harwood, Sandoval & Sen, 2015; Sieh & Frank, 2018; Tryon & Stoecker, 2008). At its most fundamental level, CEL provides robust learning opportunities for students while also meeting the needs of the community partner(s) involved with the learning process (Botchwey & Umemoto, 2018). CEL can and should be analyzed and understood from multiple vantage points including students, educators, and community partners. Different pedagogical frameworks have been used to do this. In this Research in Motion presentation, we focus on the impacts of CEL on students who have participated in a two-course series on homelessness. We use the framework of transformative pedagogy which is defined as “activist pedagogy combining the elements of constructivist and critical pedagogy that empowers students to examine critically their beliefs, values, and knowledge with the goal of developing a reflective knowledge base, an appreciation for multiple perspectives, and a sense of critical consciousness and agency” (Ukpokodu 2009, 43). In developing this course series, the authors hypothesized that it had the potential to contribute to homelessness solutions in three ways: 1) in the short-term, through shifts in student and public attitudes and reduction of stigma associated with people experiencing homelessness; 2) in the medium term, through contributions to the intervention research and subsequent policy and program recommendations, and 3) in the longer term, by creating a pipeline of exceptionally knowledgeable, aware and compassionate students who bring their experiences and critical consciousness regarding housing and homelessness to their social networks and future careers.

The aim of this Research in Motion presentation is to share preliminary lessons learned from a CEL course series, Urban Challenges: Homelessness in San Diego, offered in the Department of Urban Studies and Planning at UC San Diego. Approximately 100 students have completed the course series over the past five years. The curriculum includes considerable hands-on community engagement, including participation in field research and meaningful interactions and co-learning with people who have lived experience of homelessness. The authors used a mixed-methods approach to assess the impacts of this pedagogical approach including classroom observations, pre- and post- course survey analysis, student written reflections, and collective post-field debriefs. The authors will present the findings from their data, share the course design and approach, and discuss broader impacts on students, community partners, and the research itself. The authors look forward to presenting this work-in-progress and engaging with attendees in their session.

A Disaster Planning Integration Toolkit for Rural Illinois

Abstract ID: 1844.0.0.1127.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Arpita Banerjee [University of Illinois at Urbana-Champaign] arpitab2@illinois.edu, presenting author

Rural communities across the United States face persistent hazard mitigation planning challenges. Such communities have aging populations, limited fiscal capacity, geographic isolation, and insufficient access to technical expertise or digital infrastructure (LADRC, n.d.; Natural Hazards Center, 2021). Despite these constraints, federal and state programs frequently require rural jurisdictions to develop formal Hazard Mitigation Plans (HMPs) to qualify for critical disaster mitigation funding (Federal Emergency Management Agency [FEMA], 2021). Many rural governments lack the internal capacity to create such plans (Frazier, Walker, Kumari, & Thompson, 2013). This gap between institutional requirements and local capacity is further compounded by the overwhelming number of national and state-level resources, which are rarely integrated in a way that makes them easily accessible to the communities that need them most (Cwiak & Butterfass, 2024).

Since rural communities often lack the resources to support their own hazard mitigation planning processes, public agencies such as University Extensions play a critical supporting role. These institutions, often housed within state universities, frequently engage graduate planning students to assist in the development of rural hazard mitigation plans. Within this organizational framework, this research asks: How can graduate planning leverage newly learn't skills to help address long-standing gaps in rural disaster mitigation planning?

Graduate planning students with a data science background can offer a solution – an integrated decision support system that ingests all relevant planning data and offers customized planning support information laying the foundation for planning. One such project is the Disaster Planning Integration Toolkit for Rural Illinois (DPIT) developed in partnership with the University of Illinois Extension. DPIT begins with an automated extraction and analysis of over 100 demographic, economic, housing, environmental, and infrastructure indicators. It delivers an interactive county map organized by a “resilience level”; a downloadable, county-specific report detailing statistical trends and unique vulnerabilities; a searchable library of curated disaster planning and resilience resources; and dynamically embedded guidance on hazard mitigation based on each county’s risk profile. The latest iteration of DPIT is available online at: <https://arpitabanerjee1996.github.io/>.

DPIT demonstrates how technology can bridge critical gaps in planning capacity in rural areas by offering scalable, low-barrier pathways for communities to initiate and strengthen hazard mitigation efforts. While not a replacement for traditional planning processes, tools like DPIT serve as powerful force multipliers—automating labor-intensive tasks such as quantitative and spatial data analysis reduces the planning load on public agencies, freeing up institutional resources for high-impact activities like personalized grant support and community engagement. The

creation of DPIT also highlights how skills in coding, automation, and data analysis can offer young planners—regardless of institutional affiliation or geographic origin—new pathways to make meaningful contributions to under-resourced planning contexts.

DPIT illustrates how emerging planners can complement traditional, community-centered institutions through data science and automation skills. DPIT was recognized through the 2022 ACSP Diversity and Inclusion Fellowship and received subsequent funding for scaling across 12 states in the North-Central Region. This project demonstrates the broader applicability of open-source, locally developed planning tools as adaptable infrastructure for regional collaboration and institutional impact.

A Spatial Approach to Shrinking Areas and Infrastructure Optimization in Regional Planning

Abstract ID: 1844.0.0.11.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Soyeong Lee [Gyeongsang National University] sodol0111@gnu.ac.kr, presenting author

Huicheol Yu [Gyeongsang National University] gmlcjf8571@naver.com

Heesun Joo [Gyeongsang National University] hsjoo@gnu.ac.kr

Urban shrinkage is a growing concern in regional planning, driven by demographic decline, economic contraction, and infrastructure inefficiencies. This study applies a spatial approach to identify shrinking areas, analyze their functional roles, and propose infrastructure optimization strategies for urban readjustment. Using time-series VIIRS nightlight data, we detect urban contraction by assessing the spatial patterns of decreasing luminosity. By integrating land use data and infrastructure shapefiles, we examine which land use types experience the most significant decline and identify critical infrastructure vulnerabilities in shrinking regions. To understand functional centers and their spatial dynamics, we employ point-of-interest (POI) data and key infrastructure locations to extract urban centers. We then calculate the functional center index at the municipal level, incorporating built infrastructure, residential population, and mobility patterns. To assess the spatial relationships between declining population mobility and infrastructure utilization, we conduct a BiflowLISA analysis. This enables us to determine whether infrastructure use intensifies or diminishes in response to population decline, leading to the quantification of spatial connectivity strengths. Using network block modeling, we redefine urban planning zones by delineating optimized functional territories, including special interest zones within broader planning areas. These sub-regions are further analyzed through demand-supply matching to classify regional typologies and derive the characteristics of priority management zones. Finally, we conduct a facility-type-specific optimal location analysis, evaluating existing infrastructure efficiency and simulating the impact of relocation or restructuring. The study tests heuristic models, spatial probabilistic change analysis, and geographically weighted regression (GWR) to derive the most effective infrastructure configurations. This research contributes to urban and regional planning by providing a data-driven framework to address urban shrinkage through spatial identification, functional analysis, and infrastructure reallocation. The findings offer insights into optimizing infrastructure investments, enhancing spatial efficiency, and promoting sustainable urban readjustment.

A Visitor-Enriched Census in the U.S. Cities Using Large-Scale Mobile Positioning Data

Abstract ID: 1844.0.0.847.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Di Zhu [University of Minnesota, Twin Cities] dizhu@umn.edu, presenting author

Census data, as a traditional data source of resident socio-demographics, provides valuable information for decision-makers, researchers, and the public. While numerous efforts have been made to develop more comprehensive data products based on published census datasets, most approaches treat census units as static and independent entities, overlooking their interactions. In this paper, we introduce the "visitor census" dataset, a semantically enriched census that incorporates human visitations extracted from large-scale mobile positioning data. We identified and validated the potential home locations of 3.58 million anonymous mobile phone users across seven U.S. metropolitan statistical areas in July 2021 and utilized home detection results to enrich the socio-demographic profile of the places users visited. The proposed data generation framework is adaptive, allowing future integration of diverse socio-demographic features at varying spatial and temporal scales. Overall, this visitor-based census represents an effort to enrich resident-based census knowledge by incorporating mobilities and spatial interactions in human digital traces, bridging the gap between aggregated and individual analysis, as well as between conventional census and mobile phone data.

Analysis of Factors Driving Retail Vacancy Rates in Korean New Towns and Reduction Measures

Abstract ID: 1844.0.0.575.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Somin Lee [Pusan National University] somin.lee@pusan.ac.kr, presenting author

Donghyun Kim [Pusan National University] donghyun-kim@pusan.ac.kr

[Research questions, Objectives] Vacancy in multi-owned retail properties has become a growing issue across Korean new towns, with some areas exceeding 40% vacancy. This study investigates structural causes of rising vacancy and explores strategies for sustainable reduction. Key research questions include: (1) What building- and district-level factors are associated with higher vacancy? (2) How do successful commercial areas differ from high-vacancy ones? (3) What planning interventions could mitigate persistent vacancies in new towns? This research aims to inform retail planning in Korea's new towns, where uniform development models often fail to reflect local market demands and demographic realities.

[Data and Method] The analysis uses micro-data from the Korea Real Estate Board's 2024 Q4 Commercial Property Dataset. A multilevel framework was applied: building-level variables were derived by grouping units with identical physical traits; district-level data were based on official vacancy statistics and 500m buffers around district centers to capture surrounding facilities and context. Ordinary least squares (OLS) regression identified key predictors, and K-means clustering classified commercial district types. To improve model robustness, multicollinearity was tested using VIF, and log transformations of the dependent variable were applied when needed.

[Main findings] Results show that both tenant composition and spatial context affect vacancy. At the building level, higher proportions of food & beverage, medical, educational, and retail tenants were linked to lower vacancy, highlighting the importance of mixed-use synergies. Proximity to bus stops also significantly reduced vacancy. At the district level, anchor facilities (e.g., department stores, hospitals) were associated with lower vacancy, while districts with large area but weak demand drivers—especially innovation cities—showed the highest vacancy rates. Clustering revealed five distinct district types, confirming that commercial viability is shaped by the interaction of land use and socio-economic factors.

[Implications] This study underscores the need to revise standardized retail planning approaches in Korean new towns. The findings suggest planners should promote tenant diversity, ensure transport accessibility, and secure anchor facilities to support commercial vitality. For low-demand areas like innovation cities, differentiated strategies such as flexible land use or targeted activation policies are essential. The multilevel methodology offers a useful framework for analyzing commercial vacancy elsewhere, contributing to urban resilience and retail sustainability in the face of demographic and economic shifts.

Analysis of Jobs-housing Balance in Shrinking Cities

Abstract ID: 1844.0.0.396.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Yonghun Song [Florida State University] ys18d@fsu.edu, presenting author

Michael Duncan [Florida State University] mdduncan@fsu.edu

Central Theme-The jobs-housing balance has been proposed as a strategy to address urban issues such as long commute distances, congestion, air pollution, and class segregation (Blumenberg & King, 2021; Cervero, 1989). However, shrinking cities not only face population decline but also experience job and housing losses, along with challenges in maintaining public services due to reduced revenue (Weaver et al., 2017). As a result, residents in shrinking cities may find it difficult to work where they live, as job opportunities may be located farther from their homes. Additionally, the decline in public transit service quality may exacerbate the issue, leading to longer commutes and increased reliance on automobiles. The extent of jobs-housing imbalance may also vary depending on a city's location within a metropolitan area. Some urban areas struggle with numerous job opportunities but limited housing availability, while others face the opposite challenge (Sultana, 2002). While previous studies have examined jobs-housing balance and shrinking cities separately, limited research has explored how jobs-housing balance manifests in the context of population decline. Specifically, the relationship between population change and jobs-housing balance remains relatively unknown. This study seeks to investigate how jobs-housing balance changes in response to population change. The central research question is: How is population change correlated with shifts in jobs-housing balance?

Methodology-This study employs descriptive analysis to examine whether population change is associated with shifts in jobs-housing balance. Descriptive analysis is particularly useful for providing a detailed account of a social phenomenon, especially when it is relatively unexplored or lacks comprehensive documentation (Thomlison, 2001). To analyze these relationships, this study uses American Community Survey (ACS) 5-year estimates from 2010 to 2019. Cities are categorized into four types based on total population trends and locations in metropolitan areas: (1) Growing central cities, (2) Shrinking central cities, (3) Growing non-central cities, and (4) Shrinking non-central cities. Descriptive analysis will be used to examine trends in jobs, resident workers, and jobs-housing balance across the four city types, along with the number of cities experiencing changes in these variables. Additionally, the paper will explore whether these trends differ and how they evolve over time based on city type.

Relevance-This study aims to enhance our understanding of the dynamics of jobs-housing balance in shrinking cities. If trends in jobs, resident workers, and jobs-housing balance differ across city types, this research will provide valuable insights into how jobs-housing balance has evolved and how it might be improved in shrinking cities. Additionally, this study will help assess whether total population change is associated with shifts in jobs-housing balance.

Beyond Dispersion: The Role of Age and Political Fragmentation in Regional Job Center Geography

Abstract ID: 1844.0.0.536.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Zakhary Mallett [Alabama A&M University] zakhary.mallett@aamu.edu, presenting author

Nicholas Wilsey [Cornell University] nhw34@cornell.edu

Research on the spatial organization of regional employment overwhelmingly focuses on single metropolitan areas. Additionally, recent empirical studies have shifted toward examining general measures of employment dispersion, such as the share of urbanized land occupied by jobs, while methodological research on identifying job centers has stagnated. Hence, empirical studies comparing regional differences in employment geography, particularly in terms of job center formation patterns, remain limited. Using block-level employment data, we adapt a spatial model to identify job centers across the 100 most populous regions of the United States and describe regional variation in employment centralization, concentration, and density. Using regression analyses, we evaluate how these differences in economic geography may be explained by regions' age, workforce characteristics (e.g., education level, age, industry), and the plurality of political cities. Respectively, these proxy for a region's car-orientation, the agglomeration patterns of different industries, and the effects of cities competing for economic activity. Our findings suggest that a region's age and plurality of municipalities most strongly influence the centralization of regional employment.

Cross-border Governance and Coordination in City Regions: A Case Study of the Yangtze River Delta

Abstract ID: 1844.0.0.1079.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Ruhang Wei [Tongji University] ruhangwei@163.com, presenting author

Economic globalization has driven local economic development, increasing the need for "regional competitiveness." As large cities reach their expansion limits, the emergence of the city-region has become essential. National strategies address economic decentralization, intercity competition, and fragmented growth. China is gradually overcoming spatial barriers imposed by administrative boundaries, with the Yangtze River Delta (YRD) leading cross-border integration under national policy guidance.

This paper first examines the challenges encountered in the YRD's integration process and explores potential solutions. It then delves into cross-border development issues within the Yangtze River Delta Ecological Green Integrated Development Demonstration Zone, focusing on industrial collaboration, ecological governance, and institutional frameworks. Finally, it proposes strategies, from institutional innovation to regulatory enforcement, to improve interjurisdictional project implementation within the existing system.

Research Questions:

What are the primary conflicts in integrating ecological protection, industrial development, and infrastructure systems in YRD?

How effective is the Executive Committee in resolving cross-jurisdictional conflicts and promoting institutional innovation?

How does the YRD's governance balance top-down planning with market-driven collaboration to reconcile tensions between economic growth and ecological protection?

Methodology-A mixed-methods approach integrates policy analysis, semi-structured interviews, and case studies. Policy documents are reviewed to understand institutional frameworks, while interviews with government officials, urban planners, and private stakeholders provide governance insights. Empirical data on economic and environmental collaborations assess governance effectiveness.

Key Findings

1. Government policies in the YRD are no longer singularly based on national entrepreneurship and inter-city competition. It is the promotion of inter-regional cooperation guided by national policies to enhance overall competitiveness.
2. The empirical evidence suggests that YRD Eco-Green Integrated Development Demonstration Zone faces some challenges
 - a. Governance: The Executive Committee is slow in promoting efficiency due to the lack of legal compulsion and the large number of subjects involved.
 - b. Economic and Industrial: The demonstration zone remains in an early investment stage, with fragmented fiscal policies due to intergovernmental competition.
 - c. Ecological Barriers:

The integration process is hampered by the different functional positions resulting from the industries in different regions

- d. Infrastructure Coordination: The involvement of multiple departments with ambiguous roles has led to early-stage confusion, while inconsistent regional standards create critical bottlenecks.
- e. Public Engagement: Weak civic participation undermines policy credibility and long-term integration expectations.

3. A New Geopolitical Regime

YRD governance now embodies networked intergovernmental collaboration, balancing market forces with national directives. Unlike Western neoliberal models that dissolve administrative boundaries, YRD retains them, reinforcing hierarchical governance. Its trajectory is shaped by central government ideology, local economic incentives, and regional platforms. The shift from top-down orders to adaptive, multi-stakeholder negotiations marks an evolving institutional framework.

This study explores China's unique cross-border governance in mega-city regions, highlighting the interplay of administrative fragmentation and market forces in regional integration. It advocates for adaptive governance that balances state mandates with local incentives, contributing to debates on state rescaling, institutional innovation, and ecological coordination.

Digital Technology Utilization and Its Impact on Change in Total Factor Productivity in Korea

Abstract ID: 1844.0.0.564.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Hoseok Sa [University of Washington, Seattle] hsa92@uw.edu, presenting author

Hansoun Woo [Industrial Location Research Institute, Korea Industrial Complex Corporation]

hansoun1234@gmail.com

General-purpose digital technologies have long been recognized as a key driver of economic growth, contributing to enhancing productivity (Romer, 1986; Solow, 1957). In recent years, their integration into economic systems has accelerated, playing a transformative role in reshaping the systems (Ding et al., 2022). However, despite these benefits, digital technologies have also raised concerns about inequality, as the level of digital technology utilization varies significantly across firms and regions. Moreover, the expected productivity improvements by digital technologies are not always realized, which is referred to as the productivity paradox (Brynjolfsson, 1993; Brynjolfsson et al., 2017).

However, studies examining the factors that influence digital technology utilization and how its impact on change in productivity varies across regions and industries remain limited. Addressing this gap is essential for informing effective regional economic development policies. This study aims to deepen our understanding of spatial disparities in digital technology utilization and the association between digital technology utilization and total factor productivity (TFP) change in Korea. Specifically, it addresses the following questions: (1) How does digital technology utilization differ based on enterprise characteristics? (2) What factors influence whether enterprises utilize digital technology? (3) How is spatial disparity in the utilization of digital technologies? In what ways are regional disparities in digital technology utilization affected by regional characteristics? (4) How does the utilization of digital technology impact changes in firms' total factor productivity, and how do these effects differ across industries and between the Seoul Metropolitan Area (SMA) and non-SMA regions?

This study primarily draws on data from the Survey of Business Activities in Korea (2018–2022), which provides information on firms' digital technology utilization, sales, employment, assets, industry classification (2-digit), geographic location, and other business-related factors. The preliminary results of our data analysis indicate that: (1) firms with larger employment sizes are more likely to utilize digital technologies. In addition, non-manufacturing firms exhibit a higher likelihood of digital technology utilization compared to manufacturing firms; (2) several factors, including firm size, industry classification, changes in business operations, and the entry into new business areas, influence the extent of digital technology utilization; (3) the average digital technology utilization rate is higher in the Seoul Metropolitan Area (SMA) compared to non-SMA regions. At the provincial level, a higher proportion of the STEM (Science, Technology, Engineering, and Mathematics) workforce and graduate student population is positively associated with digital technology utilization across Korea's 17 provinces; (4) in both the SMA and non-SMA regions, the positive impacts of digital technology utilization on TFP growth rate are more prominent for non-manufacturing firms than for manufacturing firms. These positive effects are more substantial in non-SMA regions than in the SMA. These findings provide empirical insights into how firm-level and regional characteristics influence digital technology utilization and how the resulting productivity improvements vary across industries and regions in Korea.

Do HSR New Towns Develop as Planned? A Network and Typology Analysis in the Yangtze River Delta

Abstract ID: 1844.0.0.611.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Yin Dou [Tongji University] douyin@tongji.edu.cn, presenting author

Shangwu Zhang [Tongji University] zhshangwu@tongji.edu.cn

High-Speed Rail (HSR) has the potential to facilitate the movement of people, capital, and technology between cities, reshaping regional economic structures. Building new towns or economic zones around HSR stations has become a common strategy for many cities. China has the world's longest HSR network and continues to expand, with new towns planned for almost all new HSR stations. These new towns often take the form of megaprojects, and unreasonable planning can present significant challenges. Research suggests that HSR new town planning often faces issues such as excessive distance from city centers and overly ambitious planning standards, leading to financial and governance challenges. Moreover, the success implementation of these projects is closely related to their location and urban economic attributes. Based on this, we hypothesize that planners' overestimation of a city's position within the HSR network leads to irrational planning, which contributes to planning failures.

This study examines 93 HSR new towns in the Yangtze River Delta, China's most developed city cluster. We collected planning indicators such as type, name, planned area, population, year of planning, and year of construction. Additionally, we obtained land use data of the host cities, railway maps, and train schedule data for a selected day in 2024. First, we conducted a latent class analysis on the planning indicators of HSR new towns to summarize their general characteristics. Second, we proposed a "Planning Realization Index" to measure the proportion of developed land within the planned area. Finally, we constructed both a physical HSR network and a schedule-based HSR network and analyzed the correlation between the Planning Realization Index and the complex network attributes.

Our findings reveal that the indicators of HSR new town planning vary across cities of different levels. The HSR stations in cities with weak political influence are often located far from urban centers makes them vulnerable to the "siphoning effect" from larger cities. If their new town plans are too ambitious, implementation challenges arise. Additionally, both the planning and implementation of HSR new towns are linked to the urban development stage, cities that have reached a certain scale threshold tend to achieve more successful HSR new town development. Compared to the physical HSR network, the train schedule network exhibits stronger polarization, reinforcing regional inequalities in development conditions and often leading to a mismatch between new town plans and available railway resources. Therefore, beyond the construction of railway infrastructure, greater attention should be paid to balanced and innovative operational models.

The study identifies four core issues in HSR new town planning: location, scale, function, and service. Based on these, we propose a compact development strategy emphasizing performance evaluation, demand estimation, and adaptive measures. By innovatively analyzing the mismatch between spatial planning and railway service resources, this research provides new insights for policymakers and urban planners in China and other countries engaged in HSR development projects.

Exploring the Economic Functions of South Korea's Small and Medium-Sized Cities

Abstract ID: 1844.0.0.900.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Sri Utami Purwaningati [Ulsan National Institute of Science and Technology] utami@unist.ac.kr, presenting author
Jeongseob Kim [Ulsan National Institute of Science and Technology, UNIST] jskim14@unist.ac.kr

Small and medium-sized cities (SMCs) play a crucial yet often overlooked role in regional economic systems. Traditional regional planning and economic development theories predominantly focus on large metropolitan areas or export-oriented industries, leaving the contributions of SMCs significantly underexplored (Bell & Jayne, 2009), particularly their service sector specialization. Analyzing the economic roles and potential of SMCs is essential to fully understand functional interdependencies among cities of varying sizes within regional systems (Demazière, 2022).

This study investigates the functional positioning of South Korean SMCs by analyzing their service sector specialization and the inter-city relations that emerge from these specializations. Specifically, it examines: (1) What patterns of service sector specialization are evident among SMCs within regional systems? (2) How do these specializations shape inter-city complementarities and functional dependencies within regional networks?

Employing economic base theory and spatial interaction modeling, this research utilizes employment data sourced from the Korean Statistical Information Service (KOSIS) covering SMCs in South Korea. Location quotients (LQs) are calculated across the key service subsectors, including healthcare, education, retail, tourism, and professional services, to identify city-specific specialization profiles. These specialization profiles provide the basis for modeling intercity flows of service-based interaction using the Multiplicative Competitive Interaction (MCI) model (Nakanishi & Cooper, 1974), calibrated with origin-destination (OD) data on floating population. This approach estimates the relative pull of each city based on its functional attractiveness and spatial accessibility.

The study is expected to identify distinct typologies of SMCs based on their service sector configurations. Some cities are anticipated to function as regional service hubs, specializing in higher-order services and attracting significant non-resident populations, whereas others primarily depend on local consumption-based activities and exhibit asymmetric dependencies with neighboring cities. By comparing observed flows with specialization profiles, the analysis highlights both functional complementarities—where cities provide distinct but complementary services—and dependencies—where some cities disproportionately rely on others for access to key services.

Ultimately, this study contributes to the regional planning discourse while supporting prior research on the differentiated roles of SMCs within regional economic networks (Meijers & Burger, 2017). The findings offer valuable insights for planners and local government in South Korea, assisting them in strategically allocating resources, enhancing inter-city collaboration, and sustaining essential services, especially in cities experiencing demographic or economic challenges.

HSR Station Areas' Impact on Enterprise Networks: Spatial Evolution & Drivers in Shanghai Metropolitan

Abstract ID: 1844.0.0.683.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Yichen Wang [Tongji University] 2430172@tongji.edu.cn, presenting author

Shangwu Zhang [Tongji University] zhshangwu@tongji.edu.cn

Background: High-speed rail (HSR) networks drive regional development through their 'spatio-temporal compression' effect, enabling cross-regional enterprise layout optimization and industrial transfer gradients. This fosters economic complementarity and high-quality economic growth among cities. HSR station areas act as catalysts for integrating transportation, industry, and urban development, serving as critical nodes for inter-city interaction and spatial connectivity. International experience in Japan, France, and other countries has shown that HSR accelerates industrial clustering around stations and the formation of HSR economic zones and belts.

Existing Studies: Existing research on HSR station areas focuses on their impacts on cities along rail lines and regional industrial structures. However, studies remain limited in exploring their dynamic evolution and driving mechanisms. Existing studies on HSR station areas' industrial spatial structures primarily focus on land use patterns, industrial planning, and influencing factors such as accessibility and policy interventions. Among these, Pol's (2002) 'Three Development Zones' concentric model exemplifies research into industrial layouts, proposing a layered spatial framework to optimize economic activities around stations. Recent work highlights that HSR station areas can spur technological innovation and industrial upgrading by facilitating industrial transfers within city clusters. This study innovatively links HSR station areas with inter-city business networks of different industry types and explores the impact mechanisms of HSR frequency, station location, infrastructure quality, and other factors on these networks.

Methods: This study investigates the spatial characteristics and evolution of enterprise networks within HSR station areas in the Shanghai Metropolitan Area, leveraging the region's dense HSR network. Using Qichacha's headquarters-branches enterprise data (2015–2024), we construct an enterprise linkage network where headquarters are located within the metropolitan area and branches are within the 20-minute isochrone circles of 45 HSR stations. Social network analysis (SNA) and geospatial techniques are applied to examine network patterns and evolution trends (2015–2019 vs. 2020–2024). A multivariate quadratic assignment procedure (MQAP) is employed to identify how HSR station attributes (e.g., hierarchy, frequency, infrastructure quality) influence regional enterprise networks across industries.

Results: (1) Spatial Patterns: The enterprise network exhibits a 'multi-core radiating' structure, with HSR stations categorized into four types: 'network-oriented' (high connectivity), 'outward-oriented' (strong external linkages), 'isolated' (limited connections), and 'inward-oriented' (local-focused). (2) Evolution Trends: While the network shows uneven development, trends toward balanced growth emerge. Transfers primarily involve labor-intensive secondary industries (e.g., manufacturing) and knowledge-intensive tertiary industries (e.g., finance, technology). (3) Driving Mechanisms: Five dimensions influence enterprise networks: station hierarchy, HSR frequency, business environment, infrastructure quality, and station-city integration. Factors such as city administrative level and station location significantly enhance network formation. Practically, this research provides empirical evidence for optimizing HSR station design, inter-city industrial layouts, and dislocated industrial development strategies, contributing to sustainable regional development frameworks.

Amy Cotter [Lincoln Institute of Land Policy] acotter@lincolninst.edu

Henry Renski [University of Massachusetts, Amherst] hrenski@larp.umass.edu

Paromita Shome [University of Massachusetts, Amherst] pshome@umass.edu

Climate change impacts are already increasing human mobility both within and beyond country boundaries. Estimates of domestic climate migration vary considerably, with the World Bank projecting that, absent significant climate change mitigation and adaptation, globally up to 216 million persons may be internally displaced by 2050. Within the U.S., projections based on sea level rise alone suggest 13 million displaced by 2100. Both planned and unplanned individual level movements raise significant equity and practical issues for households and for sending communities, receiving communities, and regions. Preparing likely receiving areas to equitably and successfully welcome in-comers provides an opportunity for positive transformative change.

The Lincoln Institute of Land Policy and UMass Amherst faculty gathered a trans-sectoral and multi-disciplinary group of 23 lived and learned experts for 1.5 days of facilitated discussion to illuminate the current state of knowledge and practice in the US related to climate domestic in-migration. Prior to the workshop, we surveyed the expert group on key issues that need to be better understood and discussed, as well as their pre-meeting knowledge of key challenges for climate-related mobility. Researchers coded and then analyzed transcripts of the workshop to identify key themes. This paper highlights key findings from the survey and workshop supplemented by background literature.

The paper highlights justice issues that include attention to language accessibility, services that align with actual needs, and assuring that renters are not left out of services and funding available to displaced homeowners. Local NGOs often provide the first-contact with new incomers, and while this can work well, it can create burn-out among the providers. Increased competition for housing creates significant challenges for both incomers and the receiving communities.

Focusing in on receiving areas, participants think that urban areas (83%) and small towns (58%) should expect a mix of local and long-distance in-comers, and the most certain receiving areas are those that are inland of major metropolitan areas (82%). Receiving communities should anticipate pressure on housing supply (the only question with a 100% agreement), infrastructure (92%), social integration (83%), jobs (75%), and development in hazard and ecosystem areas (58%). According to respondents, the best steps likely receiving areas can in preparation include increasing affordable housing (91%), building climate-adapted infrastructure (64%) and new infrastructure with capacity for denser development (64%), updates of zoning and land use planning regulations (64%), and pursuing federal or state grants for the actions above (55%). Levers for change include professional practice, all levels of government, and community-level NGOs.

The different implications of post-disaster pulse-movements of large but mostly temporary populations, versus slow-onset-event driven relocations from such hazards as sea level rise, heat, wildfire evacuations and loss of

homeowner insurance are poorly understood but important. This suggests the need for differentiated ‘fast’ and ‘slow’ event planning and policy tools.

Most climate-related movers stay within their current metropolitan or cultural region. Participants were hopeful that regional planning that anticipates likely sending and receiving areas could facilitate more positive outcomes for all. One novel approach to this is creating within-region ‘sister cities,’ where likely sending areas partner with their likely receiving areas to ensure smooth outcomes for both.

Achieving justice for both in-comers and existing residents will be complex and needs to be centered in policy and practice discussions. Proactively addressing these regional planning challenges provides a higher likelihood of positive outcomes from the population changes that are underway.

Longitudinal Analysis of Changes on Urban Center Dynamics in the U.S. Metropolitan Areas (2010-2020)

Abstract ID: 1844.0.0.384.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

SeyedSajjad Abdollahpour [Johns Hopkins University] sabdoll2@jh.edu, presenting author

Urban centers are pivotal in shaping the spatial structure of a region, influencing various aspects such as public transportation demand, economic agglomeration, energy consumption, infrastructure and facilities use, and overall quality of life (Anas et al., 1998). By analyzing the evolving spatial patterns and characteristics of these centers, policymakers can gain a clearer understanding of whether regional development is trending toward centralization (marked by increasing population or employment in the central business district, or CBD), decentralization and polycentricity (with emerging employment centers outside the CBD), or generalized dispersion (characterized by weak spatial clustering and low overall density) (Hajrasouliha and Hamidi, 2017; Bartosiewicz and Marcińczak, 2020).

Few studies (if any) have investigated changes in spatial structure and characteristics of centers at a national level using a longitudinal approach. This study seeks to fill this gap by addressing the following key questions: (i) What are the overall trends in spatial changes within MSAs: is there a shift toward centralization, polycentricity or decentralization (dispersion)? (ii) How has the number and nature of urban centers in MSAs evolved between 2010 and 2020? (iii) Are emerging centers outside the CBD fostering more sustainable, balanced growth, or contributing to urban sprawl?

To answer these questions, we used spatial statistics (Local Moran's I) to identify the main centers (CBDs) and applied Geographically Weighted Regression to identify subcenters based on employment and population data from the Longitudinal Employer-Household Dynamics (LEHD) and the decennial census in 340 MSAs across the US for 2010 and 2020. To avoid the impact of the COVID-19 pandemic on the results, we used 2019 employment data for the analysis. We applied multiple criteria to distinguish employment nodes from urban centers, following and improving the earlier works (Hamidi, 2015; Park et al., 2020). The results show that while the number of employment subcenters increased over time (from 1,011 in 2010 to 1,035 in 2020), monocentric regions also grew, with 12 MSAs exhibiting this trend from 2010 to 2020. Additionally, the majority of MSAs experienced generalized dispersion, characterized by a decline in both CBDs and subcenters from 2010 to 2020, which contributed to increased sprawl development.

These findings have significant implications for urban planning and policy and sustainable development, as it informs decisions related to efficient land use, equitable access to resources, reduced environmental impact, and the promotion of balanced regional growth. Understanding these dynamics will guide strategies to optimize resource distribution, and ensure that growth aligns with environmental, social, and economic sustainability goals. The longitudinal dynamics of urban centers identified in this study would also inform regional planning strategies by helping to pinpoint areas that require intervention to mitigate urban sprawl or promote more centralized, or polycentric development.

Longitudinal Analysis of Two Decades of Urban Sprawl in the U.S. and Its Transportation Impacts

Abstract ID: 1844.0.0.681.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Shima Hamidi [Johns Hopkins University] shamidi2@jhu.edu, presenting author

SeyedSajjad Abdollahpour [Johns Hopkins University] sabdoll2@jh.edu

Ebrahim Azimi [Johns Hopkins University] eazimi2@jh.edu

Reid Ewing [University of Utah] ewing@arch.utah.edu

Urban Sprawl is one of the most highly cited built environment risk factors to health (risk of obesity, high blood pressure, diabetes, heart attack, respiratory diseases, etc.), safety (higher risks of car crashes and fatalities), community wellbeing (lower likelihood of upward mobility, racial discrimination, higher transportation costs, lack of social capital, etc.) and environmental and climate impacts such as air pollution and disruption of wildlife habitat (Ewing and Hamidi, 2015). Yet, most cities and metro areas in the U.S still continue to sprawl. The big unanswered question is who has been sprawling the most and who has been the most successful in mitigating sprawl? What actions, policies and interventions could be effective in mitigating sprawl? While causes and impacts of sprawl have been widely studied, effective solutions remain a major gap, mostly due to the lack of longitudinal studies to measure changes in sprawl over time and its link to smart growth policies.

This comprehensive national study aims to measure changes in sprawl in the last two decades (2000-2020) and to provide policy recommendations to cities and local governments on how to mitigate urban sprawl through the following steps 1) Measuring two decades of urban sprawl in the US urbanized areas (UZAs) in 2000, 2010 and 2020 based on an earlier work by Hamidi and Ewing (2014 and 2015) which incorporates 21 built environmental features for all urbanized areas, counties, and metro areas in the US, 2) Ranking urbanized areas, based on their degree of urban sprawl over time; 3) Identifying who sprawls the most and who has been the most successful in mitigating sprawl along with best practices that could be adapted by other local governments; 4) Quantifying long-term transportation impacts of sprawl such as commute mode share and the average journey to work drive time.

Census UZAs are selected as units of analysis because UZAs are the only census geographies that expand systematically with urban development over time. Counties and metropolitan areas have fixed boundaries and hence tend to appear more compact over time. Our measure of urban sprawl consists of 21 variables representing four urban form dimensions including development density, land use diversity, activity centering and street connectivity. We employ principal component analysis to combine variables into these 4 factors and develop an overall measure of compactness/sprawl for U.S. urbanized areas in 2020. Next, we apply the same factor coefficients of 2020 to data for 2010 and 2000, in order to generate consistent measures of compactness for 2000 and 2010 and allowing longitudinal comparisons.

We expect the compactness rankings to generally remain consistent across years while observing a general pattern of an increase in the degree of sprawl between the three census years. This study also showcases UZAs that have the most significant positive changes in their compactness score and the associated land use policies that have led them to become more compact over time.

Findings of this study have direct policy implications as public and policymakers could explore the degree of sprawl in their jurisdiction and the effectiveness of anti-sprawl policies over time.

Medical Reterritorialization: The Space of Capital, Healthcare, and Entrepreneurial Hospitals

Abstract ID: 1844.0.0.469.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Xuanyi Nie [University at Buffalo] niexuanyi@gmail.com, presenting author

Research Question and Significance-This research explores the role of entrepreneurial hospitals in reshaping territorial orders within China's evolving institutional and political economy. It focuses on the corporatization of the former Suqian People's Hospital and introduces the concept of "medical reterritorialization" to examine how hospitals, especially public tertiary ones with increasing autonomy, act as territorial actors by mobilizing capital, healthcare services, and institutional power. Specific questions answered in this research include: How do corporatized hospitals participate in reconfiguring territorial orders? What roles do public hospitals, state-owned enterprises, and local governments play in forming cross-jurisdictional city-regions? And how are these practices embedded in and driven by broader pro-market coalitions and state policy experiments?

Approach and Methodology-Through the case of Suqian Drum Tower Hospital, the study interrogates the formation of a hospital-led city region that transcends administrative boundaries, involving actors from municipal governments, state-owned enterprises, and tertiary hospitals. The study adopts a mixed-methods qualitative approach combining archival research, firm-level data, and over 16 interviews with stakeholders, including healthcare professionals, administrators, government officials, and patients. This case is analytically situated within a theoretical framework that connects Foucauldian and Deleuzian notions of territorialization (Deleuze & Guattari, 1987; Elden, 2013) to emerging literature on non-state actors' roles in spatial governance (Harrison, 2021).

Meaningful and New Findings-The findings demonstrate that medical reterritorialization constitutes a unique spatial strategy driven by pro-market coalitions, not merely state mandates. It reveals how corporatization served the strategic interests of all three actors: the Suqian local government, constrained by fiscal shortages, sought to offload hospital management and attract external investment; Jinling Pharmaceutical diversified its business portfolio to address surplus challenges and expanded its market reach; and Nanjing Drum Tower Hospital extended its brand and service territory in response to limited financial support from its home city, while the Suqian municipal government, facing fiscal constraints, used its deregulatory authority to legitimize this restructuring.

The result is a hospital-led city region where inter-city flows of medical resources transcend jurisdictional borders and redefine spatial order. Hospitals function as territorial actors by controlling the mobility of "human and non-human things" (Deleuze & Guattari, 1987; Wang & Zhao, 2024). The resulting city-region reflects both the uneven development between large and small cities and the entrepreneurial drive to capitalize on healthcare as a spatial fix for fiscal and institutional crises (Wu, 2016). The research shows that hospitals are not merely service providers but territorial entrepreneurs.

Relevance-This study makes three key contributions to planning. First, it challenges state-centric theories of territorial governance (Wu, 2016) by foregrounding the autonomy and agency of hospitals as actors that exercise control through both capital and expertise. Second, it advances the theoretical lens of "medical reterritorialization" to understand healthcare infrastructure as a tool of spatial reordering in city-region formation. Third, it calls attention to the entanglement of public services and speculative capital, with implications for equity, governance, and infrastructure planning. For practitioners and educators, the study offers a new lens on health-sector urbanism and invites a critical rethinking of how essential services are instrumentalized in entrepreneurial urban governance.

Navigating Distributive Equity: How Power and Race Shape MPO's Allocation of Transit Benefits

Abstract ID: 1844.0.0.638.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Lu Liao [Renmin University of China] luliao@ruc.edu.cn, presenting author

Xiao Bian [Renmin University of China] 2022101049@ruc.edu.cn

U.S. metropolitan planning organizations (MPOs) play a crucial role in shaping regional public transit benefits. However, planning scholarship has yet to fully explore how institutional arrangements of MPO influence their regional decision-making. To fill this gap, our research examines the impact of the power structure and racial composition of MPO decision-making boards on the allocation of transit benefits. Integrating distributive/procedural justice theory, representative bureaucracy theory, and systemic power theory, we develop a theoretical framework to explore how institutional arrangements of MPOs influence their decision-making, particularly regarding distributive equity and the prevention of unwanted urban freeway constructions.

We construct an innovative dataset encompassing the decision-making boards of the four largest MPOs in California and Texas, including racial and gender data for 58 board members, along with information on 18,590 MPO-approved transportation projects. Additionally, we supplement our dataset with spatial traffic data and socioeconomic characteristics of each local government from various sources. Our conditional logistic regression analysis indicates that a higher ratio of minorities on MPO decision-making boards generally leads to more equitable outcomes. However, the power structure and institutional rules result in heterogeneous impacts. Overall, our research advances the practical understanding of MPO decision-making processes related to regional transit benefits in the U.S. and contributes to theoretical discussions on how the institutional arrangements of public organizations can promote equitable decision-making.

Optimizing Urban Planning with TRIZ and NLP: Addressing Rent-Seeking and Pareto Inefficiency

Abstract ID: 1844.0.0.580.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Jihan Park [Pusan National University] jihan6834@pusan.ac.kr, presenting author

Donghyun Kim [Pusan National University] donghyun-kim@pusan.ac.kr

[Research Questions] Urban planning is meant to serve the public good strategically. However, it increasingly leans toward normative practices that result in plan overproduction serving narrow interests (Davies, 2024). Rather than maximizing social utility, many plans are politically motivated or focus on stakeholder benefit maximization, often framed in technocratic language that obscures their limited scope (Ablo, 2022). Planning practices also tend to emphasize redistribution—benefiting one group at another's expense—rather than pursuing Pareto improvements, thereby misusing resources and eroding planning legitimacy.

This study addresses two research questions: (1) How can rent-seeking incentives and Pareto inefficiencies be identified in urban planning documents? (2) How can a systematic 'planning diet' framework be developed to filter out unnecessary plans based on these criteria?

[Data and Method] To answer these questions, we extend the NLP-TRIZ framework of Wang et al. (2023) and apply it to urban and regional development plans in South Korea, including redevelopment and regeneration projects where inefficiency and stakeholder conflict are prominent. We collected all relevant planning documents published since 2000 and vectorized them using LLaMA, a large language model-based NLP technique.

Drawing on definitions of rent-seeking and Pareto optimality (Krueger, 1974; Buchanan, 1962), we predefined inefficient planning patterns—such as benefit justification for specific groups, exaggerated impacts, evasive implementation language, privatization bias, vague rationales, and spatial branding. We also vectorized keywords representing these patterns and used cosine similarity and TF-IDF to identify inefficiency signals in the text corpus.

We then applied TRIZ problem-solving principles to assess whether proposed plans represented optimal solutions. This involved abstracting each plan's core problem and comparing proposed solutions to a pool of functionally similar solutions drawn from South Korea, the EU, and the U.S. since 2000. We assessed excessiveness and distributional imbalance to determine whether each plan was a necessary intervention.

[Main Findings] Of the 6,762 plans reviewed, 41.3% showed strong signals of rent-seeking based on semantic analysis. TRIZ-based evaluation revealed that 28.9% proposed interventions lacking characteristics of Pareto improvement, offering limited or imbalanced stakeholder benefits compared to alternatives. For example, some riverfront redevelopment plans improved tourist amenities but displaced low-income residents without compensation. These results suggest a significant share of planning efforts are inefficient. Our findings support the feasibility of a "planning diet" framework combining semantic and structural diagnostics to improve planning legitimacy and efficiency.

[Implications] This study demonstrates the importance of tools that assess the efficiency and fairness of planning practices. The proposed planning diet framework integrates semantic filtering and TRIZ-based evaluation, offering a method to identify rent-seeking risks and promote Pareto efficient interventions. Policymakers can use this approach to eliminate unjustified plans, ensure equitable benefit distribution, and enhance the legitimacy and resource efficiency of urban planning systems.

Planning for Disaster Resilience in Central Appalachia

Abstract ID: 1844.0.0.1096.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Jennifer Lawrence [University of Virginia] kmd5xf@virginia.edu, presenting author

Central Appalachia is a region with complex histories, deep contradictions, and extremes that reveal important patterns, practices, and possibilities for planning for disaster resilience. The incredible ecological and cultural diversity, vast forests and rich resource deposits, abundant water and unspoiled lands of Central Appalachia position the region as a key site for climate-adaptive development and in-migration. As climate impacts intensify, the region also faces heightened risk of catastrophic flooding linked to a legacy of extractive industrial activity which compounds the perpetual challenges associated with broken infrastructure, significant health disparities, and underinvestment into housing, education, social services and economic development. The framing of Central Appalachia as a climate haven well within the new boundaries of 'the human climate niche' is increasingly drawing people who have the means to relocate to the relative safety of a climate resilient geography even as the region contends with uneven economic development, ongoing ecological degradation, and insufficient infrastructure and services. It is clear that climate pressures are threatening to deepen existing inequities in the region and that planners have a special responsibility to address historic challenges while also contending with mounting climate threats. Drawing insight from content analyses of climate resilience plans across Central Appalachian planning districts and semi-structured interviews with planning professionals, this study explores how the region is planning for climate resilience while simultaneously addressing ongoing needs and also asks whether recent disasters, including catastrophic flooding associated with Hurricane Helene, has shifted regional priorities for climate resilience. For planners and communities concerned with disaster resilience, it is essential to leverage planning tools, to build community and coalitions of care, and to develop governance and finance strategies that can not only contend with compounding socio-ecological disaster, but perhaps more importantly to interrupt the structural drivers of harm that have shaped contemporary material realities and precarious lived experiences for people across Central Appalachia and beyond.

Jin Seong [Pusan National University] genie3511@gmail.com

Urban resilience planning involves addressing multiple, interrelated uncertainties, including environmental risks, economic volatility, and demographic changes. Conventional planning approaches often prove inadequate in addressing the complexities and dynamic nature of these challenges. Planning Support Systems (PSS) represent an innovative approach by integrating diverse data sources, modeling spatial interactions, and simulating alternative scenarios. By translating complexity into meaningful and accessible visualizations, PSS enhances stakeholders' understanding, facilitates informed dialogue, and promotes effective collaboration. Consequently, these systems foster adaptive, flexible, and transparent planning processes, essential for the development of resilient urban systems.

This study aims to present a comprehensive PSS designed to explore urban climate change scenarios, simulate future urban dynamics, and evaluate the impacts of policy and planning interventions on the urban scale. The core of the PSS integrates interactive models of economic development, demographic shifts, and urban land-use changes, facilitating the examination of their complex interactions with climate change effects, including increased flooding risks, heatwaves, and infrastructure vulnerability. The proposed PSS emphasizes the social dimensions of urban resilience planning and policy. By specifically focusing on vulnerable populations and acknowledging varying economic capacities among urban residents, this study assesses urban resilience through the lens of social vulnerability, rather than treating resilience merely as an aggregated, city-wide concept. Utilizing this innovative and dynamic tool, urban planners and policymakers can systematically assess multiple climate-related scenarios, test the effectiveness and social implications of proposed interventions, and ultimately determine the most effective strategies to strengthen resilience of urban systems.

The implications of this study are significant for both academic research and practical urban planning applications. Academically, this research advances theoretical understanding of urban resilience by elucidating the complex interactions among urban subsystems and demonstrating how these interactions shape overall urban resilience. Practically, urban planners, policymakers, and stakeholders can leverage this comprehensive Planning Support System to enhance decision-making processes, improve disaster preparedness, and optimize resource allocation. Most notably, by supporting anticipatory and proactive planning strategies, the proposed PSS significantly advances the development of urban planning and policy frameworks that foster resilient, equitable, and sustainable urban environments.

Reimagining Industry in the City: Digital Manufacturing and the Return of Urban Production

Abstract ID: 1844.0.0.334.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Jeong-Il Park [Keimyung University] sunpower217@gmail.com, presenting author

Industries that had previously relocated away from urban centers are increasingly returning, with major cities once again emerging as hubs of industrial activity (Gornig & Werwatz, 2018; Park, 2023). This re-urbanization of industry is largely driven by advancements in digital technologies, which facilitate agile, customized production while enabling cleaner, more compact, and highly efficient manufacturing processes. These technological developments have renewed the viability of industrial operations within dense and verticalized urban environments (Lane & Rappaport, 2020; Park, 2024).

This study examines how digitalization enables urban manufacturing through a case study of a 3D printer-based eyeglass frame production facility located in Seoul, South Korea. A mixed-methods approach was employed, combining qualitative methods—such as field observations and interviews—with quantitative analyses, including GIS-based spatial analysis and statistical comparison. The analysis contrasts the Seoul-based digital manufacturer with a traditional eyewear frame producer in Daegu that relies on conventional mass production techniques.

Findings reveal that traditional manufacturing processes involve multiple complex stages, require substantial floor space for equipment and storage, and generate considerable environmental externalities—including air and water pollution, material waste, and surplus inventory—making them ill-suited for urban contexts. In contrast, the 3D printer-based production model supports customized, small-batch, on-demand manufacturing. This streamlined process enhances productivity and spatial efficiency, making it feasible to establish vertically integrated factories even within high-density urban areas. Furthermore, digital manufacturing significantly reduces pollution and material waste, allowing for clean production in mixed-use urban settings that integrate residential, commercial, and office functions. By examining the spatial and operational integration of digitally driven manufacturing within the urban fabric, this study offers policy-relevant insights for designing future productive cities that harmonize production, consumption, and living.

Seattle Comprehensive and Climate Action Plan Metric Assessment

Abstract ID: 1844.0.0.599.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Michelle Tobey [University of Washington] mbtobey@uw.edu, presenting author

Urban planners use planning goals and policy tools to manage current and future needs. In the United States of America, this work often takes shape through the development and adoption of comprehensive plans and, more recently, climate action plans. Washington State's Growth Management Act (GMA) stands out in mandating that cities over a certain size prepare and maintain comprehensive plans on a recurring basis. These living documents are shaped by years of internal analysis, political negotiation, and public engagement. They aim to define actionable objectives for implementation over the lifespan of the plan. In large cities such as Seattle, this can mean managing hundreds of planning policies spanning dozens of thematic areas.

Researchers across disciplines have developed a wide range of methods to assess planning goals—particularly those focused on equity and sustainability. However, far less is known about how planning agencies themselves measure success. Which metrics do they prioritize? How do they assess progress toward broad and often aspirational policy goals?

Cities operating under tight budgets, short timelines, and political constraints must make deliberate choices about which metrics to adopt and monitor. Understanding the measurability of policy objectives, and the data and indicators used to evaluate them, is therefore critical. In recognition of these challenges, Washington State passed CR-101 in 2024, initiating an update to the GMA that requires cities to include both actionable and measurable climate-related objectives.

This study investigates three core questions:

- (1) What data and metrics is the City of Seattle using to assess implementation of its Climate Action and Comprehensive Plans?
- (2) To what extent are the goals and policies articulated in these plans measurable using the metrics provided—or at all?
- (3) How were these metrics selected, and do they align with Seattle's long-term equity and sustainability priorities and do these meet the needs of cities residents?

The analysis employs keyword-based coding to categorize policies and goals in Seattle's comprehensive and climate plans by major planning domains (e.g., transportation, land use, equity, sustainability). Where metrics are explicitly stated, their linkages to policy objectives will be mapped and their evaluative capacity assessed using a systematic literature review. For policies that lack associated metrics, the analysis will determine whether and how they could be meaningfully measured. Qualitative interviews with planning staff and community members will provide additional insight into the selection of metrics and their perceived impact on Seattle communities.

If cities are to meet the challenges of climate change, redress historical injustices, and equitably support multispecies urban communities, their plans must be more than aspirational. Measurable and implementable policies are essential. As urban systems grow in complexity, cities must not only plan for the future—they must also be accountable to it.

Spatial Heterogeneity of HSR on Innovation Collaboration in Shanghai Metropolitan

Abstract ID: 1844.0.0.693.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Jiyuan Cai [College of Architecture and Urban Planning, Tongji University] 2430173@tongji.edu.cn, presenting author

Shangwu Zhang [Tongji University] zhshangwu@tongji.edu.cn

Background-High-speed rail (HSR) has provided new spatiotemporal conditions for regional innovation collaboration by shortening intercity travel times and reducing the costs of cross-regional factor flows. Existing studies confirm that China's HSR networks are associated with enhanced regional innovation collaboration intensity, primarily through mechanisms such as knowledge spillovers and human capital reorganization (Yang et al., 2021). However, the spatial mechanisms underlying these effects remain unclear. Prior research predominantly relies on aggregate regional analyses, neglecting heterogeneity among internal spatial units (Hanley et al., 2022), and focuses on network structures while overlooking the spatial relationships between HSR networks and innovation activity hubs, leading to homogenized findings that fail to guide differentiated planning practices (Cao et al., 2023). Addressing these gaps, this study focuses on two core questions: How does the HSR network's impact on the evolution of regional innovation collaboration patterns? How do these effects differ across spatial units within the region?

Objectives and Methodology-This study examines the spatiotemporal impacts of HSR networks on innovation collaboration within the Shanghai Metropolitan Area, using two core datasets: patent partnerships (2015–2024) from China's National Intellectual Property Administration and HSR operational metrics (e.g., train frequency, station proximity to industrial/academic hubs). The analysis proceeds in three stages: (1) Network Evolution employs Social Network Analysis (SNA) and a quadrant classification method to identify district typologies (e.g., core hubs vs. peripheral nodes) based on static collaboration intensity and dynamic growth (Cao et al., 2023); (2) Global Effects quantify HSR's influence using a Dynamic Spatial Durbin Model (DSDM), isolating mobility efficiency and spatial alignment as key drivers (Elhorst, 2010); (3) Heterogeneity Analysis applies Multiscale Geographically and Temporally Weighted Regression (MGTW) to reveal how HSR impacts vary across spatial hierarchies, guiding differentiated policy strategies to optimize innovation networks (Fotheringham et al., 2017).

Key Findings-The Shanghai Metropolitan Area's patent collaboration network has evolved from single-core agglomeration to polycentric synergy, with peripheral districts significantly enhancing their network centrality and fostering a more balanced innovation landscape. Regarding driving factors, the combined effect of HSR's train frequency and equivalent travel time significantly enhances inter-county knowledge spillover and resource mobility. Additionally, innovation synergy is markedly strengthened when HSR stations are located in close proximity to the industrial/population centers of counties. Spatial heterogeneity further reveals that HSR drives stronger innovation restructuring in peripheral regions than in saturated core zones: peripheral areas leverage reverse spillover effects (e.g., access to distant expertise) to narrow gaps, while core regions face diminishing returns due to local HSR network saturation.

Significance-This study proposes a spatial differentiation framework for high-speed rail (HSR) impacts on innovation networks by integrating HSR mobility efficiency and station-industry proximity. It reveals stronger innovation growth in peripheral regions through resource borrowing, while cores face saturation-driven inefficiencies due to over-concentrated local activities. Methodologically, it combines global-local spatial analytics (DSDM + MGTWR) to bridge macro-micro planning gaps, offering tools for regional policy synergy. Practically, it advocates differentiated

policies, optimize HSR access for peripheral regions and align stations with innovation clusters in core zones to address spatial mismatches.

The Cityhood Movement and its Innovations in Racialized Political Rhetoric

Abstract ID: 1844.0.0.1112.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Eric Bettis [Wayne State University] ebettis@wayne.edu, presenting author

The 'Cityhood Movement', a wave of incorporations primarily among affluent suburban communities in the South, is rapidly changing the balance of power and resource distribution in metropolitan regions. The codification and concentration of political authority in local hands promises to have a dramatic effect on how counties provide for their low-income residents, as well as how wealthy enclaves control their contributions to regional prosperity. The rhetoric used by incorporation advocates to garner local support frequently simplifies and ultimately dismisses the tension between these competing priorities. Language appealing to abstract notions of freedom, self-determination, individual liberty, and responsible governance is deployed, exciting residents who often chose homes outside of the city because of the freedoms that unincorporated areas purport to offer. These appeals to revered American values seem, on the surface, to be broadly beneficial to all residents, regardless of which side of the new incorporated city limits one finds themselves. However, despite the popularity of these virtues, the result has most often been new cities that are more white, more affluent, and more exclusionary. Careful scrutiny of many incorporation campaigns reveals that much of the rhetoric invokes these values in order to justify the building of political and social barriers to accountability in diverse metro regions.

This paper will discuss the use of carefully tailored, highly evocative political language in the Cityhood Movement to legitimize and promote incorporation efforts. I argue that the rhetorical framing during these campaigns frequently utilizes implicit racial language, which has the potential to simultaneously provoke suburban hostility against urban minority residents and mask this hostility by pairing it with established, legitimate conservative political priorities. The analysis utilizes two case studies: Sandy Springs, Georgia, a well-established city just outside of Atlanta which is widely seen as a model for incorporation and innovative administration efforts; and St. George, Louisiana, formed from the unincorporated outskirts of Baton Rouge, which in 2024 won a legal challenge to its successful incorporation referendum. Using content analysis of local print and online news sources as well as social media, government, and advocacy websites, this research will decipher the language and imagery used by advocates and organizers to garner public support. A demographic analysis using U.S. Census and electoral data will provide a complementary study of the residents of these incorporating communities to gain some insight about who these appeals are focused on reaching. An engagement with Critical Discourse Analysis and Stratification Economics literature will provide a framework through which to evaluate these forms of public speech. These theoretical approaches will enable a discussion of how wielding language, ranging from barely disguised racial dog-whistles to appropriated Civil Rights terminology, can be potentially effective in focusing longstanding outgroup hostility for the purpose of political action. Lastly, this paper will briefly discuss the broader implications of the success of such appeals in facilitating this incorporation trend.

Understanding the Spatial Relationship Between Planned and Individual Factory Locations in Korea

Abstract ID: 1844.0.0.1051.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Jae Hyeok Shim [Chungbuk National University] jaehuck0790@naver.com, presenting author

South Korea's industrial development has historically been driven by the strategic construction of planned industrial complexes. These government-designated areas; equipped with infrastructure and regulatory support have attracted firms by offering agglomeration economies and efficient land use. However, over time, the rigidity and limitations of these planned zones have led many businesses to seek individual locations outside designated areas. This shift has resulted in a proliferation of individually located factories, particularly in suburban or non-urban areas. While planned and individual locations serve different roles in industrial spatial structures, existing research has often treated them as independent systems, neglecting their potential spatial interactions and mutual influence. Analyzing the relationship between planned and individual factory locations is essential for understanding the broader dynamics of industrial space. Individually located factories are not randomly scattered; rather, they often cluster in proximity to planned zones to leverage shared infrastructure, labor markets, and supply chains. At the same time, the unregulated expansion of individual sites has raised concerns about environmental degradation, inefficient land use, and regional inequality. Moreover, spatial clustering patterns vary significantly across industries; sectors with strong input dependencies, logistical needs, or resource constraints tend to favor specific location types. Despite these complexities, few empirical studies have jointly examined both location types while accounting for industry-specific locational behavior.

This study addresses two research questions: (1) How are the spatial distributions of planned and individual factory locations related? and (2) To what extent do industrial characteristics affect these distribution patterns? To answer these, we first conducted a bivariate Local Indicators of Spatial Association (LISA) analysis to identify spatial clusters based on the density of planned and individual factories across all Eup, Myeon, and Dong administrative units. This allowed us to classify the entire country into four distinct spatial types (H-H, H-L, L-H, and L-L) based on joint concentration levels. To test the second hypothesis, which concerns the role of industrial characteristics in shaping these spatial types, we constructed a classification model using the XGBoost algorithm. This machine learning approach allowed us to handle non-linear relationships and imbalanced data while providing interpretable results through SHAP (SHapley Additive exPlanations) values. This process enabled us to quantify the influence of key explanatory factors; particularly industry type; on the probability of each spatial cluster type.

The results show that H-H and L-H clusters dominate the country, especially in provinces like Gyeonggi-do. National and general industrial complexes had the strongest influence on clustering, followed by industrial type. Resource-oriented and basic materials industries were more likely to appear in densely clustered areas. These findings suggest that industrial policy should expand its focus beyond designated complexes to include their surrounding zones, and that location strategies should be tailored to sector-specific spatial behaviors. Local governments may also use this framework to craft regional strategies that support balanced, sustainable industrial development.

Using Co-visitation Patterns to Understand Economic Vitality in Retail Clusters

Abstract ID: 1844.0.0.312.2025

Track 11: Regional Planning

Individual Paper Presentation Submission

Jae Geon Lee [Georgia Institute of Technology] jlee4338@gatech.edu, presenting author

Subhrajit Guhathakurta [Georgia Institute of Technology] subhro.guha@design.gatech.edu

Retail businesses are increasingly affected by a range of external changes, including demographic shifts, economic cycles, and the growth of e-commerce (An & Chung, 2025). Given the role of retail in providing local populations with daily needs and sustaining regional economic vitality (Guy, 2007), it is important to examine which type of spatial layouts of retail businesses meet people's consumption needs and attract more visits, thereby informing planning for local retail resilience. This study seeks to answer the following questions: (1) how does the relatedness between retail categories moderate the impact of agglomeration on a retail store's foot traffic? And (2) does the moderating effect of retail category relatedness vary between urban and suburban areas, if so, what specific forms of land use development are associated with these variations?

Agglomeration is a central concept in the urban retail literature (Sevtsuk, 2014). Businesses benefit from a common pool of consumers who prefer either one-stop shopping for various goods or easy comparison of similar products. Essentially, stores offering either complementary or competing products can benefit from co-location. This theory of agglomeration and related spatial measures (e.g., density and proximity) have been widely used in previous studies to explain how spatial clustering affects the vitality and resilience of local commercial areas (Kickert & vom Hofe, 2018). However, the complementary or competing relationships between retail subcategories have been largely defined based on industrial classification standards, rather than consumers' actual co-visiting patterns, due to limited data.

We measure the complementary and competing relatedness between retail categories by leveraging Advan Research's Point-of-Interest (POI) visit data, which provides information about commercial brands visited by the same consumers in a day for each POI. We employ these aggregated co-visit patterns to measure the relatedness among 26 retail and food & accommodation subcategories (NAICS 44, 45, 72). Normalized co-visit counts within- and between-categories are used to define the complementary and competing relatedness, respectively. Our regression model tests whether this category-specific relatedness variable strengthens the effect of proximity to other POIs on each POI's foot traffic. Furthermore, our study area, Atlanta metropolitan area, which experienced rapid suburbanization, presents a unique setting to investigate how the retail agglomeration effect varies across areas developed in different historical periods. We incorporate longitudinal census and land use data to examine the association between retail agglomeration patterns and commercial land use development.

We expect that our novel measure of complementary and competing relatedness between retail categories can deepen our understanding of retail agglomeration by reflecting consumers' co-visiting behavior. Our empirical results can assist retail businesses in reorganizing facilities for foot traffic growth, by suggesting how a particular mix of retail categories can strengthen the agglomeration effect. Furthermore, our comparative analysis at the metropolitan scale can provide insights into how differences among neighborhoods in terms of development periods and land use patterns are associated with the current economic conditions of local retail areas, informing sustainable retail development in diverse contexts.

Yuting Huang [Tongji University] huangh8274@gmail.com

Given the dynamic and spatial externality of the ecosystem biophysical processes, cross-regional synergistic governance has become essential for achieving sustainable ecological management, especially the involvement of multiple cities. The effectiveness of governance depends on the network's overall collaborative capacity and the tailored governance strategies aligned with local ecological linkages within that network. However, previous studies often characterized inter-city ecological linkages by static indicators (e.g., geographic proximity), ignoring the spatial dynamics of ecosystem service flows (ESF).

Based on the spatial mechanism of ecosystem service flow (ESF), this study used ESF as the indicator to characterize ecological linkages, aiming to examine the quantitative identification and spatial visualization of inter-city ecological relationship networks and propose effective cross-regional ecological governance strategies accordingly. Taking the Yangtze River Delta region (YRDR) with 40 cities in China as the study area, we chose carbon sequestration (CS) and water yield (WY), representing directional and omnidirectional ESF respectively, to construct ecological relationship networks among the cities. Then, we analyzed the overall network and community structures of inter-city ecological relationship networks by complex network and community detection methods. Finally, using multiple regression analysis of continuous matrix variables, we compared the key drivers of these two ESFs at global and community scales to explore cross-regional ecological governance strategy.

The results showed that: (1) The supply-demand pattern and flow characteristics of ESs shaped the structure of inter-city ecological relationship networks. Although carbon sequestration flows (CSF) and water yield flows (WYF) covered more than 90% of the YRDR, ecological linkages did not necessarily exist between geographically proximate cities. (2) The CS relationship network exhibited a distinct "core-periphery" structural pattern, while the WY relationship network showed a relatively balanced distribution. Nevertheless, both networks revealed clear local community structures. Influenced by differences in flow mechanisms, the community structures of the CS and WY relationship networks were distributed along the north-south and east-west axes, respectively. Cross-community ecological linkages were crucial in maintaining the overall network transmission function. (3) In addition to cities, certain cities that played a crucial role in network control and transmission also deserved attention for future ecological protection. These cities were critical for enhancing efficiency in ecological resource allocation and flow across the cities. These included geographically central cities within areas of surplus or deficit in ES supply and transitional cities linking these zones. (4) Spatial heterogeneity, including topography, land use distribution, and precipitation, were key factors influencing CSF and WYF. Notable examples included the zonal arrangement of woodland–agricultural land–construction land and the coupling effects between topography and land use types. These factors exhibited varying effects at both global and community scales. (5) Spatial planning strategies for optimizing the CS relationship network should prioritize strengthening carbon sink zones between

fragmented communities and refining carbon compensation zoning based on each community's diverse ES supply-demand relationships. Meanwhile, optimizing the WY relationship network required hierarchical, coordinated management of water-use structures and efficiency, alongside promoting regional integration and cross-regional collaboration. This research framework integrated ESF into the city network study, providing critical decision support for cross-regional ecological planning and governance.

Preparing for Climate and "Compound Urban Crises" with a Community-Based Regional Equity Approach

Abstract ID: 1842.0.0.902.2025

Track 11: Regional Planning

Research-in-Motion Presentation Submission, Research currently in process

Christina Rosan [Temple University] christina.rosan@temple.edu, presenting author

Catherine Ashcraft [University of New Hampshire] catherine.ashcraft@unh.edu

Megan Heckert [West Chester University] mheckert@wcupa.edu

In U.S. metropolitan regions, unfortunately, “compound urban crises” often highlight regional inequalities, particularly when it comes to climate vulnerability, infrastructure, preparedness, resilience, and response (Westman et al., 2022). To more equitably prepare for these types of crises in U.S. metropolitan regions, we need metropolitan governance in the form of boundary-crossing institutional arrangements, which we are calling “emergent climate regionalism” (Ashcraft and Rosan, 2022). “Emergent climate regionalism” relies on regional institutional relationships to mobilize resources and build capacity. Working at the regional scale offers an “intermediary space” that functions as both the “problemshed” and the “solutionshed” (Ashcraft and Rosan 2022; Balsiger and VanDeveer, 2010). In addition, we argue that an equity index framework (informed by community data and an asset-based approach) can help us prepare for “compound urban crises” (Rosan, C. et al., 2022). We draw on recent examples of regional climate crises in the U.S. to propose guiding questions for research on how “emergent climate regionalism” (focusing on local political arrangements and institutions) and equity framing better prepares communities for “compound urban crises” (Ashcraft and Rosan, 2022).

Tali Hatuka [Tel Aviv University] hatuka@tauex.tau.ac.il, organizer

The forced social fragmentation of a global pandemic has been followed by political polarization, violence, and contestation that have highlighted the fragility of the public domain. What can scholars and practitioners of urban design do to help? The central theoretical challenge for understanding public space lies in developing a close sensitivity towards the everyday as it is phenomenologically experienced and endogenously shaped while also remaining attentive to ongoing historical transformations in the very idea of publicness in times of war, terrorism, and violence. The very fragility and precariousness of publicness is, however, also what makes it precious. The promise of publicness lies in expanding the capacity for coexistence across heterogeneity --nurturing 'convivialism,' the art of living-with. How do we as urban design scholars and practitioners conceptualize the relationships between the public, publicness, and public space?

Learning Objectives:

- Searching for new ideas and terminologies to address publicness
- Addressing the ways we can better support and protect public space
- Discussing spaces that promote convivialism, and how do they do this

A Call for More Open-ended Public Space

Abstract ID: 1844.0.0.98.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Vikas Mehta [University of Cincinnati] vikas.mehta@uc.edu, presenting author

Critiquing the Habermasian public sphere, Fraser (1990) argues that a strict separation between the state and civil society creates “weak publics.” This is the condition where a public is invited to take part in the opinion formation but not in decision-making. Such a conception of public sphere, she notes, built upon socioeconomic inequalities, might appear to generate equity in political participation, but it creates exclusions of multiple counterpublics—women, the working class, minorities, youth, and other subaltern publics—searching for spaces of discursive contestation, identity formation, and political action. Building on Fraser’s work Crawford (2008) expands the idea of multiple counterpublics to the physical realm of public space where it translates to the need for and production of “multiple sites of public expression” visible in “everyday public spaces.” She provides a refreshing view of the many publics, counterpublics and public spaces alive with use and meaning in the contemporary city. In these trivial and marginal spaces, the emerging micropolitics begins to outline new possibilities for democratic practice. While Crawford’s observations highlight the value of everyday public spaces, city agencies, neighborhoods and community groups can in fact deliver public spaces that can become multiple sites of expression by intentionally expanding the typological offerings by providing open-ended public space.

The large disruptions in the status quo, such as the global recession and the pandemic have allowed for more tactical urban strategies that public institutions and community agencies should channel to promote the distribution of control and agency in public space. Grounded in open-endedness, such new public spaces can operate in the realm of possibilities informed by recent interpretations, be open to experimentation and thus always be comfortable in the imaginaries for creative use, play, care, economic sustenance, and more.

This idea is not new. A vast potential of public space—visible in tactical, temporary and other bottom-up urbanisms—exists in the residual and liminal spaces where new explorations of etiquette, norms, behaviors, interactions and use determine new possibilities for individual and group expression and the creation of new subcultures and identities. What is new is the call for an intentional expansion of the typological offerings of public spaces to include the various types of open-ended spaces, as a few cities have experimented with. The ability of people to have choices in their desired behaviors is a good indicator of open-endedness, adaptability and flexibility. Creating opportunities to appropriate space as needed and the choice of props are ways to communicate the openness of public space. The physical layout cannot predetermine every use but when its designers and managers anticipate variations, deviations and transgressions, only then can public space support a rich public life. Providing for these unknown possibilities nested in diversity and difference may seem challenging but these are the opportunities that urban designers, architects and planners crave to advance their work. In the spirit of Fraser, Ruddick, Young, and others who stress the plurality of the public, open-ended public spaces also highlight the different symbolism and embodiments of public space—the way it can present itself in distinct ways as civic, social, restorative, kinetic, exchange, and symbolic space.

Good public space is dialogic. It is a place that celebrates commonalities and unites. More importantly, by making the disparities of individuals and groups visible, it accepts and welcomes difference. In increasingly heterogeneous societies, the interaction of multiple publics is critical for civil society. But first cities must deliver the typologies of public space that afford participation through agency. Open-ended public space offers the spatial conditions for active and passive co-presence and mixing.

Random Walks in Public Space

Abstract ID: 1844.0.0.263.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Tali Hatuka [Tel Aviv University] hatuka@tauex.tau.ac.il, presenting author

This presentation focuses on new categories that may assist in understanding contemporary publicness. We are aware that the process of naming such categories is not neutral. Historically, conceptualization has been a methodological engine for defining the role, essence, and criteria that the public domain has taken on. For instance, in the early 20th century, authors like Georg Simmel and Walter Benjamin described public space as a domain of unique experiences and states of consciousness. In the 1930s, modernist architects like Le Corbusier emphasized the role of public space as the support for the wellbeing and leisure of urban dwellers. Top-down developments of parks and public spaces in cities worldwide followed the modernist guidelines well into the 1950s. In the early 21st century, with the climate change crisis, new global hegemonic struggles, and industry '4.0', the debate about the public domain has come to be associated with terms such as resiliency, ecology, digitization, artificial intelligence, and enhanced commodification. By introducing new categories for the study of publicness, our search could be viewed as a moment in this ongoing evolutionary process. We propose an 'index' that, as said above, is not meant to be a definitive, static or entirely self-consistent. To the contrary, the emphasis is on the messy and varying arrangements of publicness at different latitudes and locations, with a keen interest for the interstitial, tactical, and improvised manifestations of social life. On the one hand, the index format extends the preoccupation of classic vocabulary of urban theory; on the other, the lemmas proposed do not seem to match any already established categories – rather, they reassemble and redistribute previous concerns in the context of new social configurations and visibilities. Compiling an index is similar to shuffling a deck of cards. It entails randomness, and indeed, seeks to procure for it. Attaining randomness is "a mixing process (for example, a group action) acts on the system, over time continually transforming the configuration of the system". Such an iterative mixing process suits the nature of the public domain itself, although in matters of life (as in social and urban life), there is no entropic end-state to be attained. Still, the index format supports disassemblage and reassemblage: new links between ideas, texts, and visuals suggest that the public discourse is as plural as public space itself, and can be populated and developed indefinitely. Random walks in public spaces thus offer a fragment in the evolving process of imagining urban life and finding new terms to both analyze and transform it without resorting to any intrinsic, necessary order. With this in mind, we invite the reader to consider that there is no single recipe for evoking or stirring publicness. All rigid patterns are part of top-down strategies that aspire to control and govern space – but, in the margins of the patterns, or between their lines, there always remain the errant illuminations of randomness.

Rescaling Territorialities of Inclusion: Finding Local Solidarities in a World of Nationalism

Abstract ID: 1844.0.0.113.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Diane Davis [Harvard University] ddavis@gsd.harvard.edu, presenting author

This paper has three main aims. The first is to highlight the ways that rising nationalism provides new forms of conflict and tension among citizens at the sub-national scale, and by so doing place limits on local solidarity and an inclusive public sphere. The second is to identify possible urgencies or problems that might help transcend nationalist polarization or other forms of exclusion. The third is to dig more deeply into the evidence that shared ecological precarity might form the basis for new forms of unity built on a closer examination of climate crisis and/or an understanding of relations between non-human and human forms of life in the Anthropocene. The paper uses case study materials from three different sites across the US and Mexico, and offers a discussion of new territorial forms of planning practice that might be marshalled to advance greater citizen solidarity.

Sensing Conviviality and Contestation in Urban Marketplaces

Abstract ID: 1844.0.0.101.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Carmelo Ignaccolo [Rutgers University] carmelo.i@rutgers.edu, presenting author

Lawrence Vale [Massachusetts Institute of Technology] ljvale@mit.edu

Urban marketplaces act as dynamic arenas where multiple activities and publics converge. Beyond the exchange of goods, these spaces facilitate interactions with the surrounding urban fabric and the diverse communities that live and work nearby. Outdoor markets, with their temporary and movable stalls, are particularly vital for migrant communities, serving as both economic lifelines and social hubs. However, they can also be sites of both conviviality and contestation, especially amid rapid demographic shifts and neighborhood change.

Scholarship on public space, particularly through ethnographic and participatory research, has shown how spaces and temporalities are negotiated across community groups. However, there is still little known about how different groups experience and negotiate inclusion in these spaces through a multisensory lens. As both cooperation and conflict shape marketplaces, they pose challenges in capturing and measuring the quality of social interactions, particularly as these interactions unfold across multiple sensory dimensions.

This study develops systematic methods for sensing and measuring the interactions that shape these public spaces by employing a market neighborhood in Sicily (Italy) as a case study. A key approach involves positioning a GoPro camera to document 24-hour cycles of activity from a nearby bell tower, capturing how different groups and activities occupy the same space at different times and revealing key moments of transition. Complementing this, audio recordings map the evolving soundscape, identifying patterns of sonic overlap that correspond to shifts in users and uses. Together, these visual and auditory data points allow for an analysis of when, where, and how public space is shared, sequenced, or contested.

By identifying these sensory nodes of transition, the study introduces a methodological framework for deeper mixed-methods inquiry. Follow-up interviews with users of the space offer insight into whether these overlaps foster conviviality or heighten tensions. Understanding these dynamics can inform strategies for mitigating conflict and enhancing the capacity of public spaces to nurture co-presence and coexistence. Through this approach, the research contributes to broader discussions on urban design, publicness, and the conditions that encourage convivial public space in contentious communities.

Public Realm Journeys of Inclusion Between the Formal and Informal Divide

Abstract ID: 1844.0.0.80.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Jota Samper [University of Colorado] jota@colorado.edu, presenting author

The urban realm is meant to be an inclusive space for all city dwellers. A vibrant urban environment thrives on the participation of diverse actors engaging in activities, interactions, negotiations, and self-expression, embodying the principles of inclusion.

A common research question examines the inclusion of informal dwellers in the city, driven by the perception that these populations are often marginalized or excluded from urban life. While some scholars challenge this perception—interpreting it as myth, synergy, or genuine exclusion—an underexplored issue is how informal urban spaces function and how their residents create public spaces in relation to the formal city. This research specifically investigates how these spaces foster inclusion for their inhabitants and what sensory experiences (auditory, visual, and olfactory) within these distinct public realms can teach us about inclusion and publicness. Furthermore, it explores how such insights can inform the development of a more inclusive urban realm.

To address these questions, we conducted one-hour sensory journeys in four neighborhoods in Medellín, Colombia, with a primary focus on Moravia. These journeys aimed to assess the dynamics of inclusion by observing and analyzing public realm activity. This method quantifies the intensity of interactions—measuring their frequency and characteristics—while also assessing their quality. Data from these sensory journeys inform unstructured interviews, deepening the understanding of interaction dynamics and linking the physical attributes of public spaces to their capacity for fostering inclusion.

The process of signaling inclusion involves a complex interplay between the sender, the characteristics of the signal, the medium of transmission, and the receiver's interpretation. Signals can be generated intentionally or unintentionally by individuals, collectives, or authorities, and their effectiveness depends on temporal and spatial factors, as well as the chosen medium. Some signals are reinforced through legal frameworks, digital platforms, or sensory experiences, while others may be hindered by structural inequalities, misinterpretation, or exclusionary practices. The way receivers process these signals—shaped by cognition, language, and behavior—determines their affordance, meaning whether they enable or restrict participation in urban spaces. Although inclusive signals can foster social trust, expand agency, and promote collective action, their impact remains constrained by broader systemic barriers such as economic disparities, security concerns, and displacement.

Under informality, a signal of inclusion is a visceral, physical, or normative process in which a local actor informs a spatial intruder of an acceptance of coexistence and an affordance for engagement in the public sphere.

The findings reveal a multitude of interactions in Moravia's public spaces, where impromptu exchanges between foreigners and residents contribute to an actively inclusive environment. However, this inclusivity is not uniform across the neighborhood. The presence of both inclusive and non-inclusive spaces suggests that the factors fostering inclusion in informal settlements may not be easily transferable or replicable in other urban contexts. This underscores the complexity of translating these insights into broader urban planning strategies.

Out(sider) Preservation: The Field Beyond Regulation and Lists

Abstract ID: 1840.0.0.530.2025

Track 12: Planning History or Planning Theory

Pre-Organized Session Summary

Session Includes: 1844.0.0.517.2025, 1844.0.0.217.2025, 1844.0.0.491.2025, 1844.0.0.441.2025

Andrea Roberts [University of Virginia] aroberts318@virginia.edu, organizer

In a time when United States government agencies and nonprofits in historic preservation are losing staff, authority, and funding, what does progress look like? Are justice aims met by fighting to preserve the regulatory complex currently under attack, or should planners rethink the field from the outsider or marginal corners of communities instead? How do professional planners operate on behalf of outsiders? In this session, panelists explore outsider preservation practice through radical planning, Black geographies, Black feminism(s) lenses, and critical heritage studies discourse in Europe and Asia. The framework for outsidership unpacks the field's underlying premises, illuminating emerging, bottom-up practices allowing planners to envision a new historic preservation paradigm. The Outsider Preservation concept, in which every connotation of the outside is engaged, encourages planners to revise thinking about who is determined to be a legitimate preservation practitioner.

Learning Objectives:

- Implications of current preservation regulatory apparatus' destruction.
- Strategies for leveraging bottom-up promises to fill in current gaps in the regulatory complex.
- History of placemaking and planning as a form of resistance to tyranny.

Outsider Preservation: A Reparative Framework for Historic Preservation

Abstract ID: 1844.0.0.517.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Andrea Roberts [University of Virginia] aroberts318@virginia.edu, presenting author

Repair is a product and a process that includes cessation, restitution and repatriation, compensation, satisfaction, and rehabilitation. In this talk, Andrea Roberts asks what the necessary infrastructure for reparative historic preservation practice, research, and education is, with both affective satisfaction and compensation as equal aims. The author invites engagement with the challenges and opportunities to build education, intellectual, and economic infrastructures that foster reparative preservation, specifically within the context of ethnographic cultural landscapes and places. She suggests that these infrastructures are the places, moments, and repositories of new visions for preservation that foreground the dance between atonement, recognition, restitution, and compensation—framing reparative work as necessitating beginning at the root of the historical wrongs hinted at in public history. Roberts presents her attempts at reparative preservation work in classrooms, scholarship, autoethnographic inquiry, and virtual platforms. She describes unearthing her familial relationships to enslavement and land accumulation rooted in Texas' founding, the co-creation of The Texas Freedom Colonies Project, and finally, her most recent endeavor, The Outsider Preservation Initiative, an expansion of her work in Texas, intended to return the power of place preservation and regeneration to descendant community members in the Mid-Atlantic, the Gulf Coast, and the West.

There is plenty of on-street parking in front (recommended). There are two accessible parking spaces in the lot behind the building.

Challenging Preservation Paradigms: Prioritizing intangible cultural heritage in Richmond, VA

Abstract ID: 1844.0.0.217.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Meghan Gough [Virginia Commonwealth University] mzgough@vcu.edu, presenting author

Peighton Young [William and Mary] plyoung@wm.edu

Despite its rich historic and cultural resources, Richmond, Virginia has never created a plan or process for identifying, evaluating, and conserving these resources. In early 2022, soon after the adoption of Richmond's new city-wide Master Plan, the City initiated a planning process for its historic resources. While many Richmonders were eager to discuss the protection of their historic properties from redevelopment pressures and the threat of historic designation to affordability, other Richmonders were more interested in discussing intangible cultural heritage. In the years leading up to the launch of the preservation planning process, much attention focused on the challenges of reclamation and preservation of historic burial grounds of Black Richmonders.

In the northside of Richmond, a quasi-governmental organization mismanaged and neglected East End Cemetery and Evergreen Cemetery, as descendants and advocates called for greater transparency in the organization's practices, and the creation of a comprehensive cultural landscape analysis of the two adjoining cemeteries. In Downtown Richmond, social justice advocates and activists had recently won a 20-year battle for the reclamation of the African Burial Ground in Shockoe Bottom, much of which had been used as a university parking lot. With this context in mind, the launch of a preservation planning process was met by many members of the community ready to challenge the power asymmetries that dismissed what Roberts (2025) calls "outside preservation" priorities.

Using Richmond as a case study, this paper examines the process of drafting Richmond's Cultural Heritage Stewardship Plan. The authors, who both served on an advisory board for the planning process, analyze how this planning process challenged the norms of which historic resources qualify for preservation, whose expertise is engaged, and how individuals, institutions and community organizations facilitate alternative futures imagined through people-centered preservation. Through document analysis of materials associated with the planning process, participant observation and semi-structured interviews, the authors grapple with cultural heritage as process, and the challenges to centering the stories and memories that people ascribe to intangible, erased or contested places as valuable historic resources. The authors offer recommendations for rethinking the narrative, approach and tools for realizing a new historic preservation paradigm that prioritizes community-based values and dialogue about how and why places matter.

Promoting Equitable Preservation and Development Through Hyper-local Community-based Storytelling

Abstract ID: 1844.0.0.491.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Deqah Hussein [Columbia University] dh3169@columbia.edu, presenting author

This presentation responds to an urgent call for reimagining preservation practices and sustainable urban futures amid declining resources and institutional challenges. The author positions preservation-based storytelling as an innovative form of Outsider Preservation. Drawing from her doctoral research and tangential nonprofit work as the founder of Urbanist Media and the Urban Roots podcast, this work illustrates how outsider-focused community-based storytelling helps reframe public perceptions of everyday Blackness by challenging the definition of Black representation, that historically silenced community voices can also preserve cultural heritage and scrutinize preservation and planning frameworks that continue to perpetuate displacement and erasure through (re)development. This research investigates the function of storytelling to preserve and elevate marginalized Black community leaders who are traditionally seen as outsiders within historic preservation discourse.

Through critical and futurist theoretical lenses, the author's contribution will highlight preservation-focused and community-based storytelling (via oral histories) as an effective methodology for reclaiming community agency, asserting place-based identities, and influencing equitable urban planning and policy-making processes. Specifically, outsider storytelling emerges as a powerful strategy to address power imbalances, actively resist erasure, and preserve the intangible cultural practices that underpin community resilience. One case study (accomplished through oral history and Black archival research) raises awareness around outsider cultural and community preservation by leveraging first-person narrative stories of Black life along the Indiana Avenue corridor in Indianapolis, Indiana. The collection of resident-led oral histories was not only a new primary resource for research, but the accounts served as the foundation for nonfiction audio storytelling work by way of documentary-style podcasting. This type of care work uncovered new forms of grassroots preservation and nontraditional planning methods that have successfully thwarted top-down development pressures encroaching on Black cultural spaces along Indiana Avenue, including the Ransom Place National Register Historic District and the Madam Walker Legacy Center National Historic Landmark. This human-centered work challenges conventional preservation paradigms by elevating historically excluded (outsider) voices and prioritizing community-driven narratives and reparative actions in the built environment.

Ultimately, these efforts seek to transform the field by introducing previously unexplored equitable preservation and planning practices where hyper-local community-based storytelling engenders restorative justice, heritage reclamation, and inclusive neighborhood regeneration. For example, coupling the Indiana Avenue resident-led oral histories with archival data and field recordings (tours of the local historic places led by community members) enabled a more holistic understanding of place-based community legacies and the proliferation of preservation efforts driven by African American long-term residents with generational connections to Indiana Avenue. By drawing a throughline from past to present, the audio-documentary podcast traced the historical disinvestment and contemporary growth and development along the corridor, revealing the complexities and strengths of community participation (of those who have been viewed as outsiders) when it comes to equitable preservation-based development.

Protests, Preservation and Grassroots Community Activism at Marcus-David Peters Circle

Abstract ID: 1844.0.0.441.2025

Track 12: Planning History or Planning Theory

Pre-Organized Paper Presentation

Hannah Cameron [University of Maryland, College Park] hmcam@umd.edu, presenting author

In response to the murder of George Floyd by Minneapolis police officers in 2020, the resurgence of the Black Lives Matter (BLM) Movement not only resulted in protests and marches in the streets but also confronted symbols of white supremacy in the built environment, especially monuments. In Richmond, Virginia, the Black Lives Matter (BLM) Movement protests converged on Monument Avenue, and overnight protesters graffitied the Confederate statues that dominated the avenue for over a hundred years. The epicenter for the BLM movement converged in the Robert E. Lee Circle which was reclaimed by community organizers and activists and renamed Marcus-David Peters Circle after a young Black man who was killed by Richmond police officers while experiencing a mental health crisis in 2018. Marcus-David Peters Circle served as a space for gathering, healing, expression, and embodied Black resistance and liberation against tactics and structures of whiteness and white supremacy in Richmond.

During the BLM protests, family members of Marcus-David Peters, community organizers and activists brought forward a list of demands to City of Richmond officials. The list of demands addressed systemic racial injustices and police brutality in Richmond as well as called for removal of Confederate statues on Monument Avenue. By September 2021, all Confederate statues were removed from Monument Avenue including the graffitied Lee statue which was recognized by the New York Times in 2020, as one of the most significant examples of US protest art since World War II. During the Lee statue removal, all signage, memorials and other items were also removed from Marcus-David Peters Circle. The city engaged local museums and organizations in future preservation efforts surrounding monumental spaces on Monument Avenue which included transferring Confederate statues to the Black History Museum and Culture Center of Virginia.

In this chapter of my dissertation research, I examine how city government and preservation institutions engage grassroots community activists and organizers in monument removal and preservation of Marcus-David Peters Circle, a symbol Black resistance and liberation in Richmond. Using content analysis, observations, and interviews, I examine the case study of Monument Avenue through the lens of key time periods beginning with reevaluation of Confederate statues in 2018, the reclamation of spaces on Monument Avenue during the 2020 Black Lives Matter (BLM) Movement, and lastly, removal of Confederate statues along the avenue in 2021. This paper analyzes the ways in which cities and museums respond to resistance in monumental spaces and how city actions to preserve the memory of Marcus-David Peters Circle also meant control over the process and the space. Lastly, themes from my findings demonstrate what it means to remove the Confederate statues on Monument Avenue and how reclaiming at Marcus-David Peters Circle symbolizes resistance to tactics of white supremacy and systemic racial injustices in Richmond's landscape. My dissertation research contributes to preservation planning discourse by building an understanding about the ways in which local governments, organizations, and museums engage the voices of grassroots community activists and organizers in reparative processes surrounding removal of the Confederate statues and symbols of anti-Black racism and white supremacy.

"Invisible" Smaller Cities: Knowledge Production of China's Everyday Urbanism and A Manifesto Forward

Abstract ID: 1844.0.0.962.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Hantao Sun [CRP, Cornell University] hs724@cornell.edu, presenting author

As China enters the era of "new urbanization," urban knowledge is also undergoing a renewing process. Recent Chinese urban studies are witnessing an "everyday turn": alternative epistemologies are promised to emerge from ethnographic studies focusing on everyday urban practices. However, this shift remains biased toward megacities, neglecting experiences of smaller cities. Drawing on Louis Althusser's "symptomatic reading," I argue that this overlook is not incidental but a product of a hegemonic mode of knowledge production that marginalizes the everyday life of smaller cities. Through a content analysis of China's everyday urbanism literature, this article decodes the mechanisms of this exclusion and proposes an alternative agenda to put smaller cities onto the map of urban studies.

This knowledge structure operates through two theoretical moments. First, the concept of "everyday" is shaped by Henri Lefebvre's Marxist humanism, framing everyday life within a teleological narrative of "state's governmentality – local adaptation – gray spaces of negotiation." Such a teleology flattens the variety of everyday urban experiences. Second, the meta-discourses of urban China further constrain research viewsheds. "The Great Urban Transformation" prioritizes the "successful" urbanization stories of the largest cities, while "Neoliberal Urbanism" isolates urban experiences, rejecting relational analyses that could include smaller cities. These two moments are thus co-constituted: the first nullifies the structural question of why smaller cities matter, while the second provides an answer that prioritizes megacities while overlooking smaller cities – an indisputable answer because the question is never asked.

To break this cycle, the question "Why do smaller cities matter?" has to be revived. Its answering constitutes a two-step movement, a manifesto, for a research agenda for alternative everyday urban knowledge from smaller cities. The first movement is a structuralist analysis revealing how China's regional urban conjunctions historically exploit smaller cities, making them a "necessary periphery" via political, economic, and ideological forces. The second movement attempts to turn this historical unimportance into theoretical primacy. Through a "dialectics of periphery," it argues that peripheries like smaller cities are the de facto frontiers where the Chinese growth machine re/de-constructs itself. This opens a window for alternative studies from the smaller cities that situate the differentiated everyday(s) within urban conjunctions, trace the everyday functioning of these conjunctures, and look for lines of escape. Since the epistemological premise of this retheorizing attempt is a relational one that incorporates not only smaller cities on the "periphery" but also megacities in the "center," this theorizing practice will lead to a radical redrawing of a new map of urban studies that recognizes the fluidity and openness of everyday life across all Chinese cities.

A Blues Epistemology for Reparative Planning

Abstract ID: 1844.0.0.1042.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Mia White [The New School] miawhite@newschool.edu, presenting author

This paper builds on attempts to explore a theory for reparative planning (Franke, 2019; Williams, 2020; Song, 2021; Lewis, 2022), using a meshwork approach to further still move towards a relational and politically productive theorization for planning futures. The paper proceeds with special focus on a spatial praxis model of property transformation called the community land trust (CLT), and conceptualizes the CLT as an example of the kinds of planning infrastructures people build in times of great threat and struggle. The CLT model was first used in the United States by Slater King, Martin Luther King Jr.'s cousin, and has quietly labored at the intersection of land, housing, climate, and environmental justice for nearly six decades. The paper builds on a theory of reparative planning through the experience of the CLT, seeing the history of the built environment as entangled with the contemporary experience of all space: ecological space, urban space, rural space, and economic space. The paper uses the CLT as a portal through which we may elaborate on the possibilities and horizon of reparative planning, with attention to the ways in which the CLT brings into focus the spatial and embedded remains of older property practices that continue to reproduce subjectivities and embodied experiences across the lifespan and across the human and more-than-human worlds. The paper theorizes an entanglement between body and landscape as identified by frontline CLT communities across environmental and climate justice movements, that can lend greater depth to the literature on reparative planning.

In order to braid this entanglement to our thinking about the possibilities of reparative planning, the paper offers an analytical discussion of Blues Epistemology as one method to help us think about a process or mechanism for continuously moving towards reparative planning. The paper will put Blues epistemology into conversation with synchronic and diachronic theories from planning, Black, feminist, geographic, and Gramscian studies, in order to understand the potential and limitations of our work to repair through planning. Blues epistemology is a term coined by the late scholar Clyde Woods, in his book *Development Arrested*. Woods offered the framework as a Black social theory of space, arguing that race mattered in the organization of post-civil rights development in the Mississippi Delta, and that resistance to these histories of racial capitalism could be found if one was looking – specifically in blues music. For Woods, the makers of the blues were “sociologists, reporters, counselors, advocates, preservers of language and customs, and summoners of life”, chronicling grief, survival, and resistance against white racial violence. The paper will conclude with key considerations as we search for ways to reassemble people and place towards greater belonging, sustainability, and mutuality.

Arguing with Images: Visual Thinking and Reviving the Lost Art of Planning Theory Graphics

Abstract ID: 1844.0.0.1024.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Scott Campbell [University of Michigan] sdcamp@umich.edu, presenting author

This paper examines the underestimated potential of graphic visualizations to shape and catalyze planning thought. We typically employ diagrams to buttress the written word and assume the images are a neutral mirror of the text. But graphics can do more than merely translate text-based ideas into visuals. They frame debates, steer thinking, and tacitly constrain or expand our planning imagination. As a spatial field and as applied social scientists — and as prolific producers and consumers of maps, plans and charts — planners consider themselves as doubly savvy visual thinkers. Yet our field often uncritically views these graphics as unproblematic, passive illustrations of planning ideas. Just because planning is a spatial discipline, it isn't automatically a visually savvy discipline.

Planning has a long history of using graphics to illustrate the discipline's concepts. The chronological parade is well-known: garden city magnets, Geddes' "valley section," City Beautiful watercolor plans, Burgess's concentric zones, rational diagrams of urban grids and zoning, Le Corbusier's radiant city, HOLC's "redlining" maps, Mumford's regions, interstate highway maps, and new urbanist transects. The field employed these graphics to sell these foundational ideas to a larger audience. Yet this graphic practice has declined in recent decades, arguably diminishing the persuasive reach of planning concepts.

Planning scholars have not abandoned graphics altogether (and architects certainly haven't). We continue to create an abundance of figures for publications (a task made easier in the age of statistical software, GIS, Excel and Adobe). But most of these graphics are data visualizations, reference or thematic maps, classification tables, representations of relationships between variables, Venn diagrams, chronologies, or flow charts of planning steps.

Yet if one looks specifically for contemporary graphics that do analytical work and assert normative claims, the examples are thinner and less frequent. Has planning backed away from effectively using graphics to visualize the field's central debates and entice viewers to embrace new concepts? Are planning theorists neglecting a powerful rhetorical and analytical tool? And if this is true, should we be concerned and do something about it? Or have we — in our disciplinary evolution from architecture's stepchild to an applied social science — left behind the designer's visual tools and become a text- and data-based field?

I retrace a century's history of planning's most influential graphical ideas, explore the decline in this practice, and advocate for reengaging the visual argument. I develop several typologies of planning graphics based on their analytical composition; quantitative versus conceptual representation; and engagement with space (e.g., topological vs. topographical). I develop a hierarchy of the use of planning graphics (from weak to strong): (1) Ornamental: without substantive value-added; (2) Highlighting: drawing attention to key points in the text — visually stimulating but adding no unique information; (3) Distillation: providing the same information as the text but in a concise, concentrated, expedient format (graphics as an aide-mémoire); (4) Visual thinking: constructing ideas beyond the limitations of text. These do work that the text cannot. This final step is the most interesting, moving from visual communication to visual thinking.

Captivating visuals are not just decoration; they compel us to think more creatively and advocate more effectively for our profession's ideas. They can challenge outdated ideas, prod us to explore and express innovative ideas beyond the boundaries of writing. Graphics can have a life, logic and story of their own. The larger goal of this

paper is to critique the traditional use of diagrams in planning's intellectual history and promote more critical and reflective visual thinking in contemporary planning theory.

Balancing Heritage Conservation and Community Vitality: Case Study of Nanjing Heritage Communities

Abstract ID: 1844.0.0.1026.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Bowen Feng [School of Architecture, Southeast University] feng5178423@163.com, presenting author

Xiaosu Ma [Southeast University, School of Architecture] maxs@seu.edu.cn

Under the context of "stock-based development", historic urban residential areas represented by heritage communities are confronted with dual imperatives of vitality enhancement and cultural preservation. On one hand, authorities aim to optimize demographic structures within aging heritage communities through youth-friendly policy interventions. On the other hand, as critical carriers for the conservation and transmission of cultural heritage, these heritage communities necessitate the preservation of their cultural cohesion and social identity, while sustaining the social fabric embedded within. This context necessitates urgent exploration of innovative planning interventions, which are capable of sustaining historical preservation and community cohesion in heritage communities undergoing demographic changes.

Considering previous studies based on physical environment investigations and big data analytics fail to adequately delineate heterogeneous population groups within heritage communities, while traditional community participatory conservation approaches lack systematic strategic frameworks to address demographic transitions, this study attempts to investigate the following key questions from the perspective of micro-level individual choices: 1.How might "youth-friendly" policies alter heritage community demographics and social structure? 2.What perceptual differences exist between locals and young residents regarding historical spaces, and how might these affect identity and integration? 3.How can community-based conservation methods be adjusted or supplemented under the new conditions? The research specifically focuses on community public spaces, which serve as primary focus of urban renewal initiatives, and have been demonstrated to hold significant connections with living heritage preservation and community cohesion.

This study collected 246 panoramic video samples of typical public spaces in Nanjing's historic urban area. Two sites surrounding Nanjing University, both characterized by heritage communities and youth gathering areas, were selected. One site has strong community participation and cultural heritage preservation, while the other is roughly the opposite. A stated preference (SP) questionnaire was designed to analyze respondents' socioeconomic attributes and spatial preferences. Structural equation modeling (SEM) quantified influencing factors of spatial selection of different social groups, while Multinomial Logit Model further elucidated the impact mechanisms of these factors/utilities on spatial choices.

Preliminary analysis indicates: 1. Despite divergent subjective evaluations of visual experiences and activity atmospheres, local residents and potential young residents exhibit shared understanding of historical-cultural elements, showing potential for socio-cultural symbiosis; 2.Lack of historical and cultural awareness may affect the activities of some young residents within the community, hindering their social integration and may compromise the vitality and cultural integrity of heritage community; 3. While historical elements exert considerable attraction on tourist populations, they demonstrate insufficient capacity to foster cultural identity formation and community integration among potential residents.

Finally, this study explores the convergence between living cultural heritage preservation and public space revitalization in historic urban areas. It examines the potential for cultural integration between potential young residents and local heritage communities through empirical research, while analyzing the balance between

sustainable community vitality and heritage conservation under varying policy interventions and demographic compositions. This study further explores how traditional community-participation-based heritage conservation strategies adapt to changes in population structure and residents' social networks, and how planners and government can provide support in this process.

Benevolence For Sale: The Real Estate Turn in Public Housing of Colonial Manila, 1934-35

Abstract ID: 1844.0.0.825.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Eunsoo Hyun [University of Michigan] eshyun@umich.edu, presenting author

In his comparison of public housing policies of the British and Dutch Empires, Harris (2009) concludes that colonial housing policies followed larger shifts in colonial policies, reflecting the priorities of the colonial government. For example, municipal policies of kampong improvement in the Dutch East Indies (now Indonesia) reflected the imperial “ethical policy”, which acknowledged a need for reparations on account of the benefits the Dutch had extracted. British housing policies were also driven by a colonial imperative, designed to appease indigenous unrest and justify colonization by presenting housing as beneficial to the colonized. This top-down conceptualization of policy design is complicated by the American-occupied Philippines, where U.S. realtors engaged in developing public housing for the Filipino urban poor.

This paper aims to contextualize and re-evaluate what I see as a “real estate turn” in the public housing of colonial Manila in the mid-1930s, characterized by an influx of private sector participation in what is conventionally considered a public endeavor – providing housing for the urban poor. What motivated these realtors to engage in public housing? How did the global political context of the 1930s enable the real estate turn? How does this trajectory compare with housing policies of other colonial Southeast Asian states? What are the implications of the real estate turn for the following decades of housing policy in Manila?

To answer these questions, I conducted historical archival research in the Bentley Historical Library and the Special Collections at the University of Michigan in Ann Arbor, Michigan, and the American Historical Collection at Ateneo de Manila University in Quezon City, Philippines. The central primary source for this study were the correspondences and planning documents in the Joseph Ralston Hayden Papers at the Bentley Library – donated to the library by the eponymous professor of political science at the University of Michigan and Vice Governor General of the Insular Government of the Philippines from 1933 to 1935.

I examine three distinct but overlapping epochs of public housing in colonial Manila: the sanitary barrios (1900-1910s), barrio obrero (predominantly 1920s), and the real estate turn (1930s). I analyze how the sanitary barrios and barrio obrero arose from contrasting visions of housing, the former as a colonial mode of sanitizing the city (Mactal, 2009) and the latter as the result of workers’ demand for housing as a mode of social justice (Ocampo, 1977). I examine how these antecedent policies influenced the project design of two projects launched in 1934 by American real estate developers Walter E. Olsen and Colin M. Hoskins. Highlighting the financial and institutional innovations that these two realtors introduced to public housing, I trace how these projects prefigure the private sector's domination of public housing in the Philippines after independence in 1946 (Pante, 2019).

I argue that the real estate turn in Philippine public housing is distinct from other colonial Southeast Asian states in three ways. First, the real estate turn symbolizes the contradictions of the American colonial system and reflects its planned retreat. Second, the administration’s involvement of real estate developers facilitated the hybridization of colonial and non-colonial visions of housing. Last, the real estate turn was a watershed moment that prefigured private sector involvement and domination of public housing in the Philippines.

This historical analysis of housing projects in colonial Manila calls for a reinterpretation of how colonial housing policies, which have been understood to be dictated primarily through colonial imperatives, have been influenced

by complex interactions with native initiatives for equitable housing. It also reveals new opportunities for understanding how colonial policies impacted trajectories of public housing in the post-colonial state.

Contextualizing Gentrification Within the Long History of Racial Capitalism in Southwest DC

Abstract ID: 1844.0.0.353.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Carolyn Swope [Columbia University GSAPP] cbs2164@columbia.edu, presenting author

In this presentation, I explore gentrification's roots in historical racialized dispossession, through a case study of Southwest Washington, D.C. I apply a framework of racial capitalism (Dantzer, 2021) - with additional attention to settler colonialism and feminism - to Neil Smith's rent gap theory (1979) in order to understand gentrification's oppressive dimensions beyond class. Further, while research typically focuses on immediately precedent disinvestment to determine the presence of a rent gap and thus gentrifiability, I argue that this disinvestment alone does not provide a full picture of the racialized dispossessions which ultimately shape gentrification – and which gentrification reproduces. The project investigates how interconnected processes across Southwest's history before gentrification – from settler-colonial conquest to disinvestment to urban renewal – have exploited and reproduced a racist theory of value in relation to property. These varying but pervasive and persistent dispossessive processes do not simply happen to occur in the same space, and are not merely metaphorically similar or different instances in a pattern. Rather, they are directly connected and lay the groundwork for subsequent processes, leading up to present gentrification. Taking into account a much longer history of the production of racialized and devalued space can offer a more comprehensive view of gentrification's fundamentally dispossessive nature, and shed light on how racial regimes of property (Bhandar, 2018) reproduce themselves in different forms across time into the present.

Eugenics and Urban Renewal in San Juan: Displacement and Embodied Resistance along Caño Martin Peña

Abstract ID: 1844.0.0.25.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Malembe Dumont Copero [Cornell] md925@cornell.edu, presenting author

Historically, urban planning used eugenic discourses that constructed marginalized communities as places with individual and collective pathologies. In this paper, I discuss how the historical logics of colonial and state powers used public health discourses to clean the city from poverty and informality to advance modernity in San Juan (Puerto Rico). This happened through federally funded urban renewal and slum clearance programs in self-made settlements along Caño Martin Peña. This was expressed in the displacement of self-made neighborhoods through forced rehousing to other settlements along Caño and public housing in multiple waves, destroying some of these communities and substituting them for urban development projects and high-income housing. I particularly examine the cases of Tokio and Fanguito, paying attention to how each temporality of displacement created additional layers of trauma and embodied health inequities for residents and the communities. I also examine the mechanisms of resistance developed over time by residents to avoid new waves of displacement and create community spaces to rebuild their social web of connections and heal. Methodologically, I use archives to reconstruct the official policies and discourses of the public health and planning departments. I also conduct oral histories with displaced residents from Tokio and Fanguito to center their embodied experiences and collect audiovisual archives like old plena songs to recover collective narratives.

Exploring the Potential for a Collective Turn in Planning Theory

Abstract ID: 1844.0.0.970.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Aino Hirvola [Aalto University] aino.hirvola@aalto.fi, presenting author

Agonistic planning, rooted in Chantal Mouffe's (2000, 2013) agonistic pluralism, emphasizes disagreement and contestation, which are essential for addressing deep-seated inequalities. However, by endlessly embracing disagreement, it struggles to translate conflict into concrete political transformation and legitimate decisions, as mere recognition of disagreement is insufficient for systemic change.

This paper reassesses agonistic planning in light of populism theory, which, despite sharing key principles with agonism, has been largely overlooked in planning discussions. Like agonism, populism derives its strength from opposition, fostering alternatives and pushing planning into the political sphere. However, populism is easily dismissed due to its association with negative traits, such as the marginalization of minorities and oversimplified antagonisms. This rejection, however, overlooks the full potential of agonism: the mobilization of collective power to address structural oppression in planning.

The paper focuses on the logic of populism itself (Laclau, 2005), independent of its ideological connotations, and on hegemony theory (Laclau & Mouffe, 1985), which underpins both Laclau's populism and Mouffe's agonism. It asks: What kind of theoretical approach to planning could address both decision-making and systemic change, balancing the dynamic interplay between policy stabilization and challenging the potentially oppressive status quo?

To explore this question, the paper investigates the roles of 'opening' and 'closure' in planning theory. It argues that systemic change requires both creating political space for contestation (opening) and consolidating it for decision-making (closure). Hegemony complements the openness with a closure, offering a way to navigate contested spaces by providing a "theory of the decision taken on an undecidable terrain" (Critchley and Marchart, 2004), enabling decision-making despite ongoing disagreement. The paper proposes a framework that balances these dynamics by fostering collective will formation and unity. The four-step approach outlined here illustrates how unity emerges not by erasing differences but by working through and engaging with them. The framework also emphasizes the need to recognize distinct levels at which planning operates at different stages.

The framework follows a four-step process:

1. Opening at the level of everyday politics – Initial struggles and contestations emerge around particular planning issues.
2. Opening at the level of meanings and identities – Disputes escalate as planning issues gain broader political significance, often transcending their original purpose.
3. Closure at the level of meanings and identities – Temporary fixation of meanings occurs, leading to the emergence of collective identities.
4. Closure at the level of everyday politics – The reconfiguration of social order, marked by new discourse and political fronts, influences decision-making on the planning issue.

By reframing closure as complementary to openness, this framework reconciles planning's transformative goals with the practicalities of decision-making. It places decision-making at the center of planning democracy, ensuring that systemic change does not remain an open-ended contestation but results in meaningful political transformations.

Integrating populist logic into planning theory enhances reflexivity in decision-making, revealing the inherent tensions in planning processes. Planning decisions are not neutral; they reflect hegemonic discourses that prioritize certain interests while disadvantaging others. The collective turn anticipated in this paper shifts the focus of citizen participation from simply aggregating individual opinions toward incorporating collective stances that more effectively challenge existing power structures. This shift highlights the dynamic nature of the discursive field in which planning decisions and solutions are made.

Freedom cities in the long twenty-first century

Abstract ID: 1844.0.0.792.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Cuz Potter [Korea University] cuzpotter@korea.ac.kr, presenting author

During his campaign and in his administration's discussions with promoters since, Trump has expressed his interest in building "Freedom Cities", independent cities constructed on federal lands managed by corporations based on their own regulations. In conception, Freedom Cities function as crypto-based anarcho-capitalist, libertarian fiefdoms from which corporations can operate their global enterprises. In one sense, Freedom Cities are the latest, high tech evolution of extraterritorial spaces for capital to escape the "tyranny" of nation-states, following on the heels of charter cities, seasteading, and network states. This paper, however, situates the Freedom City imaginary and its geopolitical implications within the lineage of spaces of exception that function as critical nodes of articulation within each cycle of the long durée of capitalist evolution as conceived by Arrighi.

Arrighi (1994) posited that the evolution of the world capitalist system has passed through four "long centuries" characterized by systemic cycles of accumulation (SCA). In each cycle capitalist and territorialist actors organized and reorganized themselves on an ever wider geographical base to overcome the limitations of the previous cycle. While capitalists employ territory only to the extent that it increases capital accumulation, territorialists employ capital only as a means to expanding territory. In previous work, I have argued that power in the world capitalist economy has become more territorially disembedded with each SCA, as capitalist power has superseded territorialist power and that we are now entering a new long century in which capitalist accumulation is fully automated.

This paper argues that each SCA has entailed its own unique form of extraterritorial space of exemption that serves as a model node of articulation for the world capitalism of its time. During the Genoese SCA, the city-state proper (and Genoa in particular) coordinated the financing of Spanish colonialism. During the Dutch cycle, fortified trading posts, or "factories", operated as all-purpose points of contact between European traders and local inhabitants. In the English cycle, free ports like Hong Kong and Singapore opened up the factory model to capitalist traders of many nations. The model for the American cycle can be found in the export processing and special economic zones established to bypass local trade laws like import and export tariffs. Finally, in the emerging cycle of fully automated capitalism, it is suggested that Freedom Cities are conceived of as serving as nodes for articulating the vectors of information that organize fully automated capitalism (Wark, 2021).

The paper concludes by arguing that the Freedom City model is intended to serve as a model not only for capitalism's articulating nodes but also for a decentralized and fragmented technofeudal future. Curtis Yarvin, the Dark Enlightenment philosopher whose ideas circulate widely among Silicon Valley denizens (including notably JD Vance), calls for breaking up nation-states into a "patchwork" of monarchical feudal states with independent regulatory regimes that compete for citizens (Moldbug, 2008). If realized, this vision would bring world capitalism full circle to its city-state origins.

Henry Wright - Intellectual Formation and Foil to Clarence Stein

Abstract ID: 1844.0.0.50.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Kristin Larsen [University of Florida] klarsen@ufl.edu, presenting author

Henry Wright (1878-1936) defied easy categorization, which may be why the full story of his considerable contributions has not been previously told. He wrestled with his identity as an architect, landscape architect, houser, and planner more so than any of his colleagues. His ongoing attempts to answer the question of how he fit within these parameters, or not, and what that meant for the professions and those whom these professions served defined his ongoing quest. This paper explores his training and early career that served to distinguish him from his better-known partner on Sunnyside Gardens and Radburn, Clarence Stein (1882-1975). In doing so, it assesses critical junctures in these professions during the early 20th century.

Prior to partnering with Stein, Wright worked as a landscape architect, architect, and planner. He characterized these professional personas as Architect, Landscape Architect, Landscape Engineer, Town Planner, and Architectural Real Estate Officer. He fully inhabited these professions in a range of contexts from community/board volunteer to consultant with prominent firms and as sole proprietor and, toward the end of this period, as planner with the City of St. Louis. What is fascinating here is not how advanced his considerations of site design/engineering, architecture, housing, and planning were, but his flexibility in moving between the planning, design, and development professions. Wright secured significant professional experience following graduation from the University of Pennsylvania in 1901 to his departure from St. Louis in 1923. This crucial 22-year period of his career is all but forgotten as he seemed to spring from nowhere in 1923 when he began his partnership with Stein and their celebrated landmark projects together.

This study uses primary and secondary sources and a comparative approach to assess the two architects' impact within the larger context of this period when the profession of planning was emerging and maturing. With a career that spanned from 1901 to 1936, focusing on a component of what Wright did from 1923 to 1932 while in partnership with Stein does a disservice to academic studies in these fields. This constrained view leaves considerable gaps in our understanding of the emergence of the planning profession, the evolution of early U.S. housing policy and large-scale design, innovative site design and regionalism studies, the impact of the European modernists on American architects/planners, and architecture and planning pedagogy.

Introducing UndocuCrit to Critical Disaster Studies

Abstract ID: 1844.0.0.324.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Carlo Chunga Pizarro [University of California at Irvine] cchungap@uci.edu, presenting author

Maribel Sandoval Contreras [University of California at Irvine] maribs3@uci.edu

Social vulnerability, a widely used concept and method in disaster studies, is critical in understanding who is at most risk before, during, and after a disaster. A large body of social vulnerability research concentrates on quantifying and analyzing social determinants representing how vulnerable a community is to disaster. However, scholars have argued that social vulnerability is an insufficient basis to address inequality in exposure to disasters (Jacobs,

2019). Additionally, undocumented immigrant communities are deemed invisible in social vulnerability studies due to their pre-marginalized status and being undercounted in the US Census (Mendez et al., 2020). For these reasons, there is an urgent need to assess how to examine the application of undocumented status in disaster studies. This paper argues that using Undocumented Critical Theory (UndocuCrit) in critical disaster studies provides a reflexive research methodology that helps us understand the lived experiences of undocumented communities (Aguilar, 2019). UndocuCrit Theory derives from a lineage of Critical Race Theory (CRT), Latino/a Critical Theory (LatCrit), and Tribal Critical Race Theory (TribalCrit) that encompasses four principles: fear as endemic, state of liminality, sacrifice, and mentorship through engagement to share stories of resilience and adversities encountered by undocumented individuals. By centering the narratives of undocumented individuals, UndocuCrit challenges mainstream disaster research paradigms that overlook undocumented communities. Moreover, UndocuCrit encourages undocumented scholars to reclaim narratives to unveil the vulnerability of undocumented communities in the face of disaster that continues to be (un)studied. Drawing on UndocuCrit Theory, we propose that the lack of studying undocumented communities in disasters is due to the production of illegality. This production of illegality manifests in various ways, including the exclusion from formal disaster relief systems, fear of deportation hindering access to aid, and limited trust in government agencies during all stages of the disaster management cycle. UndocuCrit supported by insights from critical disaster studies, which challenges conventional understandings of disasters as natural phenomena, can further our understanding of the social, political, and historical dimensions of undocumented community's vulnerability in disaster contexts. By adopting UndocuCrit within disaster studies, disaster scholars and practitioners can adopt a more nuanced and inclusive approach to understanding undocumented communities' vulnerability.

Inventing Neighborhood Stability: Planning, Class Distinction, and the Remaking Hyde Park-Kenwood

Abstract ID: 1844.0.0.967.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

T. William Lester [University of California, Irvine] thomas.lester@sjsu.edu, presenting author

Urban planning has long grappled with a central tension: how to manage the forces of urban dynamism while protecting neighborhood stability. Cities are engines of economic and social change, but residents experience them at the neighborhood scale, where social networks, safety, and opportunity are rooted. Throughout the twentieth century, planners sought to mediate this tension—sometimes with good intentions, often with exclusionary outcomes.

This paper examines how Hyde Park-Kenwood on Chicago's South Side became a laboratory for neighborhood-scale planning interventions aimed at managing racial and economic change. It argues that, over seven decades, planners, community organizations, and the University of Chicago strategically deployed—and at times invented—planning tools to reshape Hyde Park's public environment. Their goal was to maintain the neighborhood as an interracial, middle-class community of “high standards” amid forces of racial segregation and economic disinvestment.

Rather than a case of top-down planning imposed by elite institutions, Hyde Park's elite institutions collaborated with local residents and community groups to maintain the neighborhood's racial balance while persistently excluding low-income residents (Hirsch 1998; Chaichian 2017). This collaboration relied on a range of planning tools at different historical moments. In the 1950s and 1960s, Hyde Park was an early adopter of the federal “Conservation Area” model of urban renewal—an alternative to wholesale clearance that enabled selective use of eminent domain, targeted clearance of “blighted” properties, and public subsidies for private redevelopment. Invented largely by planners from the neighborhood, this model framed neighborhood change as a technical problem while reinforcing class boundaries and excluding the city's poorest residents.

In later decades, as federal funding waned, Hyde Park's planners and civic leaders adopted market-oriented tools to continue reshaping the neighborhood's commercial and public spaces. In the 1990s, amid rising fears of crime and disorder, local business owners, residents, and the University of Chicago formed the Ad Hoc Committee for 53rd Street—a grassroots planning initiative that framed street-level disorder, particularly the presence of Black youth, as the primary threat to stability. The committee's work led to the creation of a Business Improvement District (BID) and later a Tax Increment Financing (TIF) district that funded new redevelopment, including a hotel, restaurants, and redesigned public spaces to appeal to middle-class residents and visitors.

Drawing on archival research, meeting minutes, interviews, and the author's own experience growing up in Hyde Park-Kenwood, this paper reconstructs how neighborhood actors actively shaped neighborhood change. It shows how planners and residents rejected the idea that change was inevitable or outside of their control. Instead, they developed and refined planning interventions to stabilize property values, attract middle-class residents, and maintain racial and economic diversity—even as these efforts excluded low-income residents and reshaped public space to serve middle-class tastes.

By tracing the history of neighborhood-scale planning in Hyde Park, this paper offers a new perspective on the history and future of urban planning. It shows that neighborhood change is not simply the result of markets or macroeconomic shocks but also of intentional, collective efforts to deploy planning tools—sometimes inventively, sometimes coercively—in pursuit of a particular vision of stability. Hyde Park-Kenwood's long experiment in

neighborhood planning demonstrates that maintaining integrated neighborhoods is possible, but the work is difficult and not without costs. As cities today face gentrification and persistent disinvestment, this case offers critical lessons about the promises and perils of intervening at the neighborhood scale.

Kristin Caffray [Wayne State University] kcaffray@wayne.edu

Equity is a core element of professional and academic planning institutional goals. Scholars view equity in distributional, procedural, or recognitional terms, or some combination of these, as well as from a teleological or deontological perspective. These theoretical perspectives have tangible implications for how planners define success and orient their work. In this study we first explore theoretical conceptualizations of equity, then present the results of an equity planning survey of Michigan planners. Our findings indicate that planners predominantly conceptualize equity in distributional terms. Additionally, when prompted to define equity, many framed their responses in terms of equality. However, some planners also acknowledge the importance of recognitional and procedural equity, suggesting a more nuanced engagement with these concepts. Planners often see equity in teleological rather than deontological terms. Our findings support understanding of how equity is operationalized in planning practice and offer insights into how theoretical frameworks can better inform and support equitable planning efforts.

Parks are Stolen Land Too: How State and Local Governments Return Land to Dispossessed Communities

Abstract ID: 1844.0.0.781.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Shanasia Sylman [Cornell University] sgs237@cornell.edu, presenting author

Two prominent movements, Land Back and the Movement for Reparations, demand land in response to the generations of harm caused by colonization and racialization. Another interrelated and growing movement is the Land Justice Movement, which was born out of agrarian struggles and the Food Justice Movement. Land justice focuses on equitable access to land as the basis for supporting the betterment of Indigenous and other land stewards facing marginalization around the intersection of race, class, gender, and other identities. Land justice holds land conservation practice at large accountable for its contributions to land dispossession beyond agricultural lands.

Each movement approaches redress for the harms of land dispossession from different perspectives. Because of the influence of agrarian and food justice movements, land justice has directed its focus on the issue of concentrated land ownership by a White majority and fiscal elites. In turn, the Land Justice Movement has focused on encouraging private landholders to transition their land to the stewardship of Indigenous and other dispossessed communities through innovative and reparative conservation-based estate planning. Yet, if the intent is to repair relationships harmed by all of land conservation practice, then how can public conservation lands meaningfully contribute to achieving land justice in the United States?

In the United States, land has been returned to Indigenous and other dispossessed communities through a variety of transfer mechanisms by private and public actors. Some of these events are reported in the news, and there have been a few projects across the United States documenting land returns, mainly with a focus on the Land Back Movement. Recent scholarly work has shed some light on the process for private landholders and the federal government to return land but not so much other public entities. So how are state and local governments returning land to historically oppressed communities?

This study uses protest event analysis to sift through news articles that cover land return events and identify those involving state and local landholders. Although there is no formal definition of a land return, for the purposes of this research, a land return describes a process of acknowledging the injustices of land dispossession while simultaneously and voluntarily extending land access to a dispossessed community through a variety of means. Because of the overlapping nature of the Land Justice, Land Back, and Reparations movements, land returns are a shared tactic across movements, and it would be difficult to qualify a land return event as purely about land justice. However, a focus on state and locally held conservation land may more closely align with land justice and may provide some tailored insights for that movement.

Although state and local governments are just as culpable in land dispossession, they can play a major role in land-based repair. While not an exhaustive list, this work will provide a glimpse into the types of tools and processes public actors have used for these reparative efforts. For the field of planning, a review of these events can increase awareness of the invisible factors that may hinder achieving the desired outcomes of a land return. Planning has long been complicit in land dispossession and in extending colonial relationships with land through land use restrictions and other social controls. Interrogating these taken-for-granted rules of engagement plays an important role in changing what relationships with land are legitimate and, ultimately, possible. In this current political

climate, it is essential to demonstrate the interventions at lower levels of government that may meaningfully contribute to the longer-term efforts of decolonization and repair.

Planning and its Spatiotemporal Traps: Rethinking Economic Value Capture and Planners' Roles

Abstract ID: 1844.0.0.176.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Andre Legarza [University of Amsterdam] legarzaandre@gmail.com, presenting author

This article repositions planners as central actors in multi-scalar capital flow governance, moving beyond planning's traditional focus on local value capture intervention within the United States. By exploring multi-scalar regulators – from national to local actors – and intra-national dynamics that shape capital flows, the article highlights the limited spatiotemporal character of contemporary economic value capture instruments, drawing on a typology of these tax, fee, and land-based instruments. Ultimately, I call for planning scholars to reimagine planners as strategic urban governors responsible for safeguarding public interest goals and measures by coordinating multi-scalar regulatory responses to capital flows that assemble the built urban environment.

Planning as Translation

Abstract ID: 1844.0.0.1031.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Raphael Ayambire [University of Manitoba] raphael.ayambire@umanitoba.ca, presenting author

In many postcolonial and settler-colonial contexts, urban planning operates at the interface of overlapping governance systems involving statutory institutions rooted in colonial legal codes and customary or Indigenous systems grounded in alternative epistemologies and claims to legitimacy (Mbembe, 2001). These hybrid institutional environments pose significant challenges to consensus-based planning models that presume shared rationalities (Watson, 2003).

This paper introduces Planning-as-Translation (PAT) as a conceptual and practical framework for planning in such settings. Drawing on Actor-Network Theory (Callon, 1984; Latour, 2005) and agonistic political theory (Mouffe et al., 2013), PAT reframes planning as the work of translation: mediating across institutional logics, legal frameworks, and spatial imaginaries to sustain functional engagement.

Through case studies from Ghana and comparative insights from critical Indigenous planning literature, the paper outlines three core dimensions of this translational labor – epistemic, institutional, and relational – and explores their implications for planning practice. It argues that translation offers planners a way to engage plural authority systems without allowing prevailing contestation to collapse into violence, institutional paralysis, or the hollowing out of the public interest.

PAT, thus, enriches planning theory and practice in contexts of institutional hybridity by providing a conceptual framework and preliminary practical strategies that emphasize pragmatism, accountability, and justice. The paper concludes by outlining future research directions for applying and refining the PAT framework across diverse postcolonial and settler-colonial urban contexts.

Tiffany Smythe [University of Rhode Island] tcsmythe@uri.edu

Offshore wind (OSW) is an emerging industry in the United States. Its promise is often discussed in terms of opportunities for economic development (Glasson et al., 2022) and other community benefits, including the revitalization of ports, waterfront districts, neighborhoods, jurisdictions, and regions. These promises have deep implications for planning and planners (Jay, 2010; Avni & Teschner, 2019). In this paper, we contextualize OSW development within the urban and development histories of three portside OSW communities: New Bedford, Massachusetts; New London, Connecticut; and Turner Station, Maryland. What has brought these communities to this moment where OSW has become part of their redevelopment future?

New Bedford, MA is a commercial fishing port, seafood processing hub, and home to large populations of Portuguese, Cape Verdean, and Hispanic residents. The city has seen the rise and fall of both whaling and textile industries (Voyer, Pesch, Garber, Copeland, & Comeleo, 2000), and hosted social movements related to abolition, worker's rights, and civil rights. Today, the New Bedford Marine Commerce Terminal boasts easy access to the Atlantic Ocean and can support the construction, assembly, and deployment stages of OSW projects. New London, CT is home to a successful manufacturing industry. The city has a growing Hispanic population that has more than doubled in size since the 1990s. New London was once home to one of the world's largest whaling ports, much like New Bedford. Today, it hosts the only active East Coast OSW marshaling terminal with unobstructed ocean access at its State Pier, currently scheduled to support the deployment of multiple OSW projects. Turner Station, MD a historically Black community in Baltimore County, was supported by the neighboring Bethlehem Steel mill. While White steelworkers and their families were able to reside in Bethlehem Steel's segregated company town, Black families quickly outnumbered the space allocated to them. Excluded from the neighboring community of Dundalk, they settled in Turner Station, developing it into a vibrant, self-sufficient, and mixed-use enclave. Today, it sits adjacent to a major redevelopment effort which includes an offshore wind monopile manufacturing facility.

Using Sanborn maps, urban renewal plans, residential security maps, archival images, historic comprehensive plans, census data, local newspaper articles, oral histories, and spatial data, we tell the stories of these three communities and examine how the history of each community informs the trajectory of OSW development. In New London, urban renewal has not only left a legacy of displacement and distrust but also changed the demographics adjacent to the OSW area. In New Bedford, urban renewal and highway development has divided the city from the waterfront, and furthered racial inequities which may impact perceptions of offshore wind development. In Turner Station, local offshore wind development means a return of steel manufacturing jobs, which may offer a path towards community revitalization.

Examining the patterns of growth, decline, and revitalization (Hollander, 2017) in these frontline communities might better enable us to understand how OSW development efforts may be received and perceived by residents.

These historical contexts might also provide the lens through which to view the benefits and burdens of redevelopment broadly so that historical inequities are not reinforced in the future.

Planning with Synthetic Persons

Abstract ID: 1844.0.0.541.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Nikhil Kaza [University of North Carolina at Chapel Hill] nkaza@unc.edu, presenting author

The question of synthetic person is not as far-fetched as it may seem on the first glance. In recent debates about regulation of Artificial Intelligence, European Parliament explicitly considered whether it should establish “the status of electronic persons responsible for making good any damage they may cause.” (Bryson, Diamantis, and Grant 2017). Since then, the matter has become even more salient; the explosion of objects that are remarkably good at mimicking human actions (e.g. Generative AI, large language models, etc.) have entered into our cultural consciousness provoking widespread fascination as well as anxiety (Bassett and Roberts 2023). Despite this, planning theorists have yet to engage with them (Sanchez 2023). How should planning theories and processes account for synthetic persons?

In this paper, I argue that such accounting holds a mirror to our normative prescriptions and positive descriptions of planning. Representation, participation and communication are taken for granted in normative planning theories, prove to be a challenge with synthetic persons who have little political or spatial relationships. Meticulous accounting of accountability, rights and responsibilities for these persons pose special problems, as they do for other legal persons (e.g. organisations), however, are elided in common place theoretical frameworks. Relationships and interactions along with questions of legitimacy, among synthetic and non-synthetic stakeholders, raise both theoretical and pragmatic concerns. Without human interlocutors, communicative planning theory might fall apart. Or does it?

In a provocative article about environmentalism and artifice, Kreiger (1973) argued that the idea of natural is ‘artificially’ created. Fifty years later, we can pose similar questions about the role persons in planning processes. Drawing upon posthumanist traditions and actor network theories (Jon 2020), I explore how agency and responsibility is constructed and distributed in planning processes.

Plantation to Industrial City: Regional imaginaries in Charlottesville, Virginia 1877-1929

Abstract ID: 1844.0.0.420.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Alissa Ujie Diamond [State University of New York at Buffalo] ad97@buffalo.edu, presenting author

This paper explores the spatial development of the small localities of Albemarle County and Charlottesville, Virginia, as a case for understanding how the emergent production of regional spatial imaginaries facilitated the mingling of local plantation-based histories and spatial practices with the mainstream of U.S. planning practice by the 20th century. I use methods of critical landscape analysis (Grandison, 2001) and critical discourse analysis to examine archival materials pertaining to key moments in the Charlottesville area's urban development from after Reconstruction to the cusp of the Great Depression.

I combine and extend historical institutionalist approaches to urban history (Sorenson, 2009), systems frameworks (Walker and Salt, 2009), and southern regional planning history (Ramos, 2023) to examine how local actors in Central Virginia used images of the region's nested physical geographies to produce myriad intersecting, contingent, and often conflicting spatial imaginaries (Watkins, 2015) that activated shifting sets of political coalitions that undergirded the emergence of formal municipal planning in this place by the 1920s. I contend that these imaginaries had multiple functions in this process. Locally, development of small but highly visible historic and symbolic sites served as ways to convene flexible and increasingly inter-regional social coalitions of capitalist-class players who resourced local economic development from reconstruction to the cusp of the Great Depression. Over time, self-conscious depictions of symbolic sites and area lands situated the Charlottesville region within an emergent framework of national spatial imaginaries. At this scale, teleological narrations of the nation's history, and this region's place in that narrative helped fuel the region's broader touristic and residential urban development. At the same time, articulations of urban space at these same events helped popularize and test myriad narratives of social pathology that industrial-urban investors could draw on for broader legitimacy through appeals to reform, charity, and concern for the public good through philanthropic intervention in both the physical environment and academic institution-building at University of Virginia. I conclude that the physical and ideological work done by a shifting crew of nationally connected local city and county boosters in the regional articulation of the Charlottesville area helped elaborate the loosely aligned socio-cultural narratives drawn on by early social-scientists and planners by the early 20th century.

Proximity vs. Priority: Citizen Participation in Neighborhood Planning in a Shrinking City

Abstract ID: 1844.0.0.169.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Shuqi Gao [Southeast University] shuqigao@seu.edu.cn, presenting author

Brent Ryan [MIT] bdr@mit.edu

Planning aspires to achieve equitable processes and outcomes by fostering citizen participation, yet practitioners frequently encounter a fundamental tension: how to mobilize public engagement while ensuring that the public interest is not overshadowed by the personal interests of those who participate. This study explores this tension through the lens of spatial proximity, examining the underlying logic of citizen participation in neighborhood planning within the context of shrinking cities—urban areas marked by prolonged population decline and economic disinvestment. We focus on Youngstown, Ohio, a paradigmatic shrinking city in the U.S. Rust Belt, where decades of population loss have left behind a landscape dotted with vacant structures. Between 2015 and 2017, Youngstown implemented its Neighborhood Plans through a series of Neighborhood Action Meetings (NAMs), aimed at addressing blight. These meetings provided a unique opportunity to investigate how spatial relationships influence participatory planning decisions.

To conduct this research, we collected and analyzed minutes from all the NAMs. We extracted the names of all attendees and cross-referenced them with publicly available databases, including Whitepages and the Ohio Residents Database, to obtain their physical residential addresses. Employing a Gradient Analysis approach, we then assessed the spatial distribution of three distinct datasets within incrementally expanding buffer zones (ranging from 60 feet to larger radii) around attendees' addresses: a) vacancy survey data, independently compiled by a third-party organization with no vested interests, offering an objective baseline of vacant properties; b) suggested action items proposed by attendees during the meetings, which represent their preferences for planning interventions and potentially reveal patterns of self-interest; and c) demolition records from 2015 to 2017, documenting the actual interventions carried out by planning authorities and reflecting the tangible outcomes and benefits experienced by residents.

We find that attendees exhibited a clear spatial bias, disproportionately recommending vacant properties located near their own residences—most notably within a 180-foot radius—as targets for intervention. These nearby parcels were suggested at rates significantly higher than those situated farther away, suggesting that proximity plays a pivotal role in shaping participants' priorities. In contrast, the vacancy survey data and the demolition data, displayed a more uniform spatial distribution, with no evident clustering around attendees' addresses. This discrepancy highlights a disconnect between the preferences expressed through participation and the ultimate outcomes of the planning process.

We conclude that participants in Youngstown's NAMs tend to prioritize nearby problem properties—yet they do not reap disproportionate benefits from the plan implementation outcomes compared to non-participants. This finding challenges the assumption that participatory planning inherently translates into equitable or locally tailored results. Instead, it suggests that while spatial proximity strongly influences the issues participants raise, broader decision-making processes and resource constraints may dilute these preferences in implementation.

This study implies that planners must account for the spatial distribution of participants and its impact on both the planning process and outcomes. Striking a balance between encouraging robust citizen engagement and safeguarding the public interest requires nuanced strategies—such as diversifying participant representation or

integrating objective data into decision-making—to prevent participatory processes from being skewed by personal interest. In Youngstown and similar contexts, where resources are scarce, understanding these spatial dynamics is critical to achieving equitable and effective revitalization.

Reframing the American Dream: Manufactured Housing Attainability

Abstract ID: 1844.0.0.245.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Jenifer Reiner [University of Texas, Arlington] jxr0009@mavs.uta.edu, presenting author

Karabi Bezboruah [University of Texas, Arlington] bezborua@uta.edu

Manufactured homes (MH) have been part of the American housing landscape since the early 20th century. Planners, public administrators, and scholars have historically acknowledged that MH is an affordable single-family detached (SFD) dwelling option (Durst & Sullivan, 2019; Frantz, 2024; Wallis, 1991). However, unlike the conventional single-family site-built house, the Manufactured Housing Survey reports that in 2023, it accounts for less than 9 percent of new homes.

Over the past 50 years, researchers have documented the affordability and unique role of the mobile home (pre-1974) and the manufactured home (post-1976) in American culture. Wallis (1991) details the mobile home's evolution from its innovation to legislation. Into the 1930s, municipalities used economic development measures to attract the use (Wallis, 1991, p. 39), only a few years later to relegate them to inhospitable zoning districts. In the 1940s, its portability was nationally expedient to meet the housing needs of the wartime industry. Then, federal subsidization of suburban housing triggered by the postwar housing shortage heightened its perception as "equal but separate" (Wallis, 1991, p. 212). The Manufactured Housing Construction Standards and Safety Act of 1974 (MHCSS) acknowledged MH as part of the US housing system and guaranteed MH quality. It also designated construction standards and administrative procedures different from those used for conventional housing. Since then, metropolitan areas have continued to expand, supported by exclusionary municipal practices and policies (Rumbach et al., 2022), decreasing MH availability and increasing MH housing insecurity (Durst & Sullivan, 2019).

Recently, government agencies, national foundations, and professional associations have recommended ways to advance awareness of MH affordability and construction standards to update antiquated misperceptions. Akin to the current zoning reform for Missing Middle housing (MMH) and accessory dwelling units (ADUs), these activities from multiple perspectives suggest a "policy window" (Kingdon, 1984) opening for the re-evaluation of local MH regulations and policies (Frantz, 2024). Focusing on the 3Ps – problem, policy, and politics – of Kingdon's Multiple Streams Framework (MSF), this study evaluates recent research articles from several leading US academic journals with two objectives - evaluate opportunity and propose a framework for MH policy innovation. Building on the income ratio method, the conventional housing affordability metric, we advance an assessment framework of MH attainability that also incorporates community engagement and equity. The framework aims to guide municipal policy, administration, and planning activities while reframing MH affordability as attainability based on four components: affordability, accessibility, availability, and acceptability. Affordability and accessibility address spatial and transportation equity and household economics. Availability and acceptability address community engagement and equity based on municipal plans and policies, such as land use and zoning.

This research contributes to recent scholarship on MH affordability, particularly at the nexus of municipal development activities and community engagement. Since MH residents are mostly lower-income homeowners or tenants, traditional governmental procedures may fail to involve them adequately in planning and policymaking processes. Planning agencies are fundamental in setting the agenda for potential MH procedural and statutory reform. A more comprehensive understanding of MH attainability can enhance and promote equitable municipal practices aimed at providing a diverse range of housing options, including manufactured housing.

Reinventing Utopias: Building China's Dream Town Through Visionary Planning

Abstract ID: 1844.0.0.460.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Colleen Chiu-Shee [University of Illinois, Urbana-Champaign] ccs32@illinois.edu, presenting author

In modern history, many visionaries deployed utopian thinking and proposed ideal cities of tomorrow. These futurist urban utopias traveled across borders and cultures and transformed various local spaces and societies. As heightened global interconnectivity fueled transnational collaborations, China's urbanization emerged as a prominent arena for experimentation. Liangzhu-Wenhuacun—a comprehensively planned community in Hangzhou, China—epitomizes the cross-border and cross-cultural transplantation of urban ideals. This paper parses Liangzhu-Wenhuacun's conception and implementation to reveal the connections and disconnects between imagination and action. Findings suggest that Liangzhu-Wenhuacun was led by visionaries who rejected profit-driven developments, promoted livability and social progress, and sought to build an urban commons. They found inspiration from historical heritage and future imaginaries and incorporated various Chinese and Euro-American utopias. Despite the dominance of China's growthism, utopian thinking progressively enlightened Liangzhu-Wenhuacun's conceivers, managers, and residents, who embraced a pioneering, entrepreneurial spirit and nudged the development toward ecological, social, cultural, and physical innovation. These promising directions showcase that practicing utopianism can foreground important values and encourage value-aligned explorations. It can transform developments into living laboratories and shape space and people into transformative infrastructures. However, the imagination of China's dream town was caught in the persisting paradox between Westernization and Sinicization. Lessons from Liangzhu-Wenhuacun suggest that urban practitioners should leverage visionary thinking to inspire progressive imagination, transform everyday spaces, and nurture change agents. Meanwhile, future cross-border learning must foreground indigenous urbanisms and explore alternative cultures of modernity to resist capitalist exploitation and cultural homogenization.

Revisiting Jan Gehl's Theory of Urban Safety: A Computational Method

Abstract ID: 1844.0.0.236.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Charles QC Li [MIT Senseable City Lab] cqcl9321@mit.edu, presenting author

This study evaluates Jan Gehl's principles of safe cities by analyzing perceived safety scores calculated using advanced computer vision models and around 1 million daytime street view images from 2010–2021 in Stockholm, Sweden. While widely referenced in urban design, Gehl's theory is developed and often tested on small datasets or observations, leaving its large-scale effectiveness unclear. Leveraging big urban data and multi-method regression analyses, we examine the relationship between perceived safety and built environment characteristics highlighted by Gehl. We find that most elements align with Gehl's theory, particularly greenery and sidewalk density, which are positively associated with perceived safety, while walls and higher speed limits are negatively associated with safety. However, street obstacles and bike lane density produce unexpected results, in contrast to Gehl's principles. Building upon these findings, two planning recommendations are summarized to enhance perceived safety for streets in city-center and suburban areas, respectively. This study grounds Gehl's theory in large-scale evidence, validating his framework and showcasing how advanced analytics and big urban data can inform planning strategies to enhance perceived safety in future cities.

Road Building, Bandeirantes, and Branqueamento: How Physical Infrastructure Whitened Brazil

Abstract ID: 1844.0.0.861.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Thomas Bassett [University of California, Los Angeles] tbassett@g.ucla.edu, presenting author

Occupying the interior of the Brazilian territory has long been a challenge and a goal for the Portuguese colonizers and subsequent Brazilian government. Starting in the seventeenth century, groups of violent, colonizing bandeirantes (pathfinders/bandits) began to enter the vast interior of South America attempting to claim land for Portugal and find mineral wealth. These attempts to colonize the interior of the country were invasions into indigenous land enslaving or murdering much of the indigenous population, but for the invaders, they were a means to exploit new land for agricultural cultivation, connect new markets to the consumption economy, and complete a centuries' old national integration project. The bandeirantes' incursions did populate the interior of the Brazilian territory, but still the vast majority of the population remained on the coast. At the turn of the twentieth century, Brazil underwent tremendous transitions by abolishing slavery and then becoming a republic in a coup which overthrew the Brazilian Emperor. New governmental leaders embarked on infrastructure development, using railroads and the telegraph to connect with and bring people into the interior, which had less than desired results. Brazil's coastal mountain range and rainforest hindered this inward expansion until a new technology arrived: the automobile. Public leaders and private elites saw roads as the panacea for national integration, but also a continuation of the bandeirantes' efforts. By the turn of the twentieth century, revisionist history valorized bandeirantes as national heroes responsible for bravely expanding Brazilian territory. The new republican leaders evoked these mythologized bandeirantes to influence and convince politicians and public opinion that this colonial national integration project initiated by the bandeirantes could finally be complete with roads for automobiles. Roads would connect the developed coasts to expand into new population centers in the interior. At the same time, the elites sought to "whiten" the Brazilian population through policies to attract European immigrants to Brazil, known as branqueamento (whitening). Instead of following the European theory of eugenics which sought to eradicate "inferior" races, Brazilian eugenics asserted that the white immigrants would improve the population through miscegenation, as they believed that the white genes would prevail over other races. This paper seeks to understand the connections between these two policy areas. In order to understand how racialized policies were expressed in physical interventions, I ask: How did the infrastructure policies of road building intersect with and achieve the Brazilian elite's desire to whiten the population? By examining primary documents from the 1870s to 1930 in Brazilian archives, evidence exists that supports roads as a tool to bring the newly arriving white immigrants into the interior. The language used by those implementing these policies was blatantly racialized but also there was a fascination with making the state and country more healthy, hygienic, better educated, and productive, all coded language for white. Brazil, and specifically the state of São Paulo, became majority white populations by the 1940s, and with this paper I aim to show how that was achieved with the aid of these newly constructed roads. I also situate this process into the theory of settler colonialism, where Brazil is not much studied because most literature on this subject originates in former British Colonies like Australia, Canada, and the United States and is in English, not allowing for easy entry by Portuguese speaking and writing scholars. I hope that this case will refine and expand the general theory of settler colonialism to include more places in the framework. This paper exposes how these policies and the physical interventions helped create contemporary Brazil, both territorially and also societally.

The location of groups in planning theory

Abstract ID: 1844.0.0.916.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Orwa Switat [Brown University] oswitat@hds.harvard.edu, presenting author

There is extensive literature on the relationships between the state and groups in political theory. Despite the significance of groups in political theory, their location in planning theory remains ambiguous. Therefore, this paper explores the positioning of social, racial, ethnic, Indigenous, national, and minority groups within planning theory by tracing the coevolution between planning theories and political theories related to these groups.

Following the communicative turn in the 1990s, planning theory has developed concepts influenced by political theories of justice, such as just planning, the right to the city, the cosmopolitan city, and the just city, and has been more engaged with social and minority groups. In parallel, post/anti-colonial planning theorists have advocated for confronting the normalized colonial relations in the Global South. However, how the evolution of planning theory has been influenced by the evolution of different political concepts of groups remains indescribable.

Therefore, this paper explores the following questions: What happens to the social unit and relations conceptions when transformed from political theory to planning theory? How has planning theory transformed the political conceptions of groups? What is the location of racial, ethnic, and indigenous groups throughout this transformation? How has this transformation been applied in planning theory normative conceptions of spatial justice and 'what ought to be done' in planning?

This paper proposes a new typology of planning theories to provide a better understanding of the location of groups in planning theory. I argue that the development of the location of groups in planning theory has transformed with the evolution of various political schools of thought, including liberal, Marxist, and post/colonial.

The study demonstrates this transformation by examining three interconnected dimensions: each school's central social unit, the social relations among these units, and each school's normative concept of 'what ought to be' done in planning. It became evident that planning theory has constantly reinterpreted these dimensions of location, molding and integrating different political concepts to better align with the nuances of urban planning and the lived urban realities. As such, planning theory adapts political concepts to address the intersectionality of socioeconomic, environmental, and racial urban disparities and the hybridity of urban political power dynamics, identities, inter-group relations, and everyday spatial practices.

However, I argue that the positioning of groups within the evolution of planning theory and practice has been shaped by three dynamics: (1) colorblindness of dismissing race and ethnicity, (2) culturalization by categorizing minorities as 'cultural groups' focusing on their cultural features, not their civic context, and (3) subaltern by framing minorities as "oppressed" groups, which is limited in understanding the dynamic roles groups and their reciprocal relations with the state in different political and legal contexts. This framework reveals the colorblindness and culturalization of groups within Northern planning theory evolution and argues about the limitations of Southern planning theory to adequately characterize reciprocal, dynamic, shifting relationships between groups and the state.

As such, this study contributes to the discourse on urban planning in three ways. Firstly, it contributes a new typology of scrutinizing the evolution of the location of groups in planning theory, and its dialogue with the development of political theories. Secondly, it pivots the discourse from addressing cultural diversity in planning to

understanding state-group relations in planning. Thirdly, it broadens the perspective from a colorblind spatial justice standpoint to a deeper understanding of the rights of Indigenous, ethnic, racial, and immigrant minority groups in planning theory.

Toward a Research Code of Ethics for Urban Planners

Abstract ID: 1844.0.0.10.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Victoria Morckel [Michigan State University] morckelv@msu.edu, presenting author

Urban planning research has profound implications for communities, yet the field lacks a comprehensive ethical framework to guide researchers, particularly when working with vulnerable populations. While the AICP Code of Ethics and Professional Conduct provides broad professional guidelines, it remains insufficient in addressing ethical dilemmas specific to research, such as community exploitation, research fatigue, and inequitable knowledge extraction. This paper argues for the development of a research-specific code of ethics for urban planners to ensure research aligns with planning's public interest mission, and proposes specific revisions to the AICP Code to better address these concerns.

Using Flint, Michigan, as a case study, the paper examines the ethical challenges associated with research in distressed communities. Flint, long a focal point for urban research due to its economic struggles and the 2014 water crisis, has experienced an influx of researchers—many with no prior connection to the community—leading to concerns about academic exploitation. While studying crises like Flint's is vital, researchers must ensure their work benefits the community rather than treating it as a means to secure grants or publications. Many residents experience research fatigue and skepticism, raising concerns about how constant surveying affects trust in academic institutions. Without clear ethical guidelines, planners risk contributing to harm rather than fostering positive change.

A revised research code of ethics for urban planners should emphasize participatory research models, ensuring that studies are designed with, rather than about, the communities involved. It should require stronger informed consent protocols that acknowledge research fatigue and skepticism in over-surveyed communities. Planners should also adopt trauma-informed approaches when working with populations affected by environmental crises, systemic neglect, or economic hardship. Beyond in-person data collection, researchers must navigate new ethical concerns related to AI, digital surveillance, and big data. As urban planning increasingly incorporates these technologies, stronger safeguards must be in place to prevent privacy violations, algorithmic bias, and the extraction of sensitive community data.

This paper also highlights the role of planning education in fostering ethical research practices. Many planning programs encourage students to engage in "real-world" research projects, but without proper ethical training, these assignments may unintentionally harm communities. For instance, student projects that survey residents about local conditions without clear follow-up actions can create unrealistic expectations, leaving communities feeling like subjects of academic exercises rather than partners in problem-solving. Similarly, when students propose ambitious redevelopment projects in distressed neighborhoods without fully considering financial or political feasibility, they risk offering false hope rather than actionable solutions. Integrating ethical research training into urban planning curricula would prepare students to engage with communities in ways that prioritize respect, transparency, and mutual benefit. By moving research practices up Sherry Arnstein's "Ladder of Citizen Participation," from tokenistic consultation toward genuine community power, planners can foster trust and ensure their work benefits the communities they study.

Urban Foresight Practice in Planning

Abstract ID: 1844.0.0.63.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Ahmed Ouf [Alabama A&M University] ahmed.ouf@aamu.edu, presenting author

Urban planning has been experiencing various pedagogical shifts over the last few decades from evidence-based comprehensive planning to more community-based and culturally impacted planning approaches. Cities are no longer the local containers of economic and people activities, but rather sustainably networked places to accommodate the flows of goods and people (Dixon, 2023). That flow of people and goods is complicated more by the need to accommodate roughly two thirds (68 per cent) of the world's population by 2050, an increase of almost two billion more urban residents between 2024 and 2050. In addition, urban planners need to consider the intense technological and cultural transformations, expanding globalization, and new economic trends that create uncertain contexts. Uncertainty makes it difficult for mapping, monitoring, and coordination (Milica Stojanović, Petar Mitković, Mihailo Mitković 2014). Consequently, urban planning in the next few decades needs to accommodate the uncertain flows of goods and people and the changing contextual conditions in innovative formats such as strategic planning, vision planning, scenario planning and urban foresight (Yesim Parlakyildiz and Tulay Guzel 2020).

Karl Popper, 2008, argued that humans cannot predict the future because of the expected uncertainties, and that understanding present and past trends are not enough to find the most probable trajectory for the future (Batty 2018).

Foresight by Ben Martin, 1995, "is a process that systematically tries to look at the long-term of science, technology, economy and society in order to find areas of strategic research". According to Parlakyildiz and Guzel, 2020, urban foresight is "future thinking about general economic development of a city", within which communities need to detail the different aspects of urban life such as education, economy, industry, etc. Urban foresight in that sense involves a strategic vision, not necessarily in consensus but definitely robust for each sector and locality, that guides different planning aspects at a different sectoral or locational pace. Coordination and collaboration in urban foresight is subject to contextual uncertainty, complexity, and respect for multiple entity integrity that spans governmental bodies, private sector companies, development agencies, local institutions, etc. Milica Stojanović, Petar Mitković, and Mihailo Mitković (2014) recognized that the development of urban areas, considered in socio-economic and environmental terms, cannot be planned in a linear way, from intentions to plan, to action and planned outcome which brings us back to Banfield's argument of the Ends and Means of 1959. Countries that have created foresight research entities for anticipating the future of science, technology, urbanization and community development such as the UK, Japan, Singapore, Denmark, and the U.S.A, among others, have produced enough literature that we can use to understand the process and bring it to implementation.

This research paper argues that Urban Foresight as a necessary planning approach for the future, can be adopted by cities that have traditionally structured planning departments. I will be studying in detail the big picture plan for the city of Huntsville, Alabama, to see how a traditionally structured planning department, with a very busy operating schedule because of the city's rapid growth during the last decades, is capable of dealing with the concepts of multiple futures, loosely coordinated development projects in its different districts and different development aspects, and being flexible to accommodate uncertainties and contextual unforeseen change.

Urban Vitality or Urban Intensity: A Synthesis of Theory on the Built Form and Social Interaction

Abstract ID: 1844.0.0.1067.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

James Gross [University of Southern California] jamesanthonygross@gmail.com, presenting author

While there is a large, emerging literature that empirically tests theories of the built environment, pedestrian movement, and social interaction, the theories underlying these models are siloed. While some streams of literature show that pedestrians prefer to move to and through crowded spaces, other literatures observe these spaces and find that the same pedestrians go to great lengths to avoid one another. Therefore, it is difficult to interpret empirical results testing theories such as urban vitality, since these largely rely on simple indicators of pedestrian activity. Further, similar concepts such as social cohesion and urban vitality seem to have opposite relationships with built environment factors such as density. Does the colocation of pedestrians equate to meaningful interaction or good experiences?

In order to investigate this issue, I organize literatures around the concept of pedestrian colocation in public space. This includes two causal mechanisms: the mechanism whereby the built form induces public contact between individuals and the mechanism whereby individuals build a sense of place of social cohesion through this contact. Firstly, the work of urbanists such as Jacobs, Gehl, Whyte, Hillier, or Lynch (and later empirical work in this stream) includes both mechanisms, finding a positive relationship between built-environment factors such as mixed-use or density and outcomes such as vitality or vibrancy, indicating a busy, socially-connected public life. The transportation literature addresses only the first mechanism, finding generally supportive results to the urbanist streams of literature. However, rather than a social quality, this literature theorizes supply, demand, and travel cost as the main factors of moving to or through any public space. Finally, the symbolic interactionist literature theorizes about and observes these interactions close up, painting a more nuanced picture. Individuals may find cities to be intense, alienating spaces which cause them to withdraw from meaningful interaction. Accordingly, those who observe public spaces directly often find individuals taking strategic action not to interact. This literature, however, often does not account for why these individuals choose that space in the first place.

As of now, these literatures must learn from one another. Therefore, I attempt to bring these literatures together in a synthesis around the built environment, colocation in public space, and social interaction.

What the #@&% is urban decline?: Resetting the practice and theory of urban planning

Abstract ID: 1844.0.0.667.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Michael Koscielniak [Eastern Michigan University] mkoscie1@emich.edu, presenting author

In this paper, I take seriously the potential for urban planning to synthesize theory and practice. As a researcher and scholar of urban decline, I have taken on projects in cities that have experienced long-term population loss and economic precarity. This paper is an attempt to make sense of planning practice in declining cities while outlining an agenda for identifying and transforming the inadequacy of planning practice in the MAGA era.

This paper is partly inspired by the cyclical nature of debates within our field. I have studied, presented, and taught this material long enough to see innovative debates and new ideas in 2012 become innovative debates and new ideas in 2025. My goal is to rethink approaches to urban decline. More importantly, I see this intervention as an experiment pushing the field into more salient and vital directions to meet a moment synonymous with revanchism, austerity, and depoliticization.

Drawing from research in Detroit, MI and St. Louis, MO, I re-scale urban decline to match the public and profit-making interests in those places. I borrow and rework concepts from the literature on the production of decline (Akers 2013; Akers & Seymour 2018; Koscielniak 2023) to support a political program. I pay special attention to the presence of pipelines, processes, and contradictions that spatialize urban decline. As an educator, I have solicited student questions about their proper place in the geography of planning practice. White, middle class students articulate a desire to work in low-income neighborhoods and communities of color but disclose anxiety about their credibility as outsiders. They recognize disinvestment and destruction as elemental to the built environments of urban cores while also hesitating to presume they belong. Students need a theoretical and practical agenda that decline does not happen in cities but happens to cities. We need a re-centering of region, structure, and institutions. By rescaling decline as a process from anywhere we can rescale urban planning as a practice for everywhere.

I build this argument through three currents of political theory: Karl Polanyi's "double movement," agonistic pluralism, and the Black Panther Party. Polanyi (2001) encourages urban planners to denaturalize the market economy and organize around institutions that can embed profit, property, and development in social relations. The work of Mouffe (1999) and Ranciere (2010) on agonistic pluralism reminds planners that consensus is more often a camouflage for conflict than its resolution. Finally, the Black Panther Party (1966) reinforces the urgency of largescale transformation to dismantle old institutions and build new ones. We should undertake this project not because it salvages capitalism but because its stabilization advances our egalitarian and progressive goals of a post-capitalist and anti-racist system.

I have two major conclusions from this engagement. First, I believe our field needs a reinvigoration in theory equipped for the task ahead – now is not the time for retreat and bargaining. Urban planning has practiced peacemaking and collaboration when it needed struggle and criticism. It is no great revelation the field traded largescale change for deliberation and compromise (Forester 2013). This conviviality was never required by the prevailing political, economic, social, and infrastructural forces shaping cities and regions. Second, these forces have only provided the occasional opportunity for productive coordination and always on the condition practitioners neutralize the progressive components of their proposals (Swyngedouw 2011). Our commitment to advancing theory through experience and action was meant to translate egalitarian principles into practice – not

amputate them as a courtesy to bearable incrementalism. To rebuild our relevance to both growing and declining places (including nation-states), urban planning must practice politics, resist concession, and prioritize conflict.

White Philanthropy, Black Excellence, and the Aesthetic Regime of Urban Repair

Abstract ID: 1844.0.0.455.2025

Track 12: Planning History or Planning Theory

Individual Paper Presentation Submission

Nazanin Ghaffari [State University of New York College of Environmental Science and Forestry] ghaffari@esf.edu, presenting author

Philanthropic institutions have become central actors in contemporary urban planning, particularly in neighborhoods marked by racial dispossession. While their investments are often framed as reparative or equity-driven, these institutions operate as what Victor Ray (2019) calls racialized organizations, structures that do not merely reflect but actively reproduce racial hierarchies through their rules, resource flows, and legitimacy-granting practices. This paper examines how philanthropy, operating within this racialized organizational terrain, shapes the production of “Black excellence” as both an aesthetic strategy and a planning logic in cultural redevelopment efforts on Chicago’s South Side.

Based on two years of ethnographic fieldwork, the study traces how arts and cultural initiatives—many emerging from radical Black traditions of spatial reclamation—are increasingly filtered through institutional frameworks that prioritize visibility, scale, and fundability. In these settings, “community” is celebrated as a symbol, but community power is neither ceded nor co-governed. Organizations are structured to optimize philanthropic return on investment: curating programs, performances, and spaces that resonate with funder expectations while foreclosing demands for redistribution, accountability, or long-term control.

Within this ecosystem, properties are acquired through symbolic transactions, programmed seasonally, and securitized—often under the language of inclusion or care. Archives are privatized, participation is curated, and access to space is mediated through administrative control. The elevation of Black cultural labor is central to the legitimation of these projects, but that labor is embedded within an organizational structure that reproduces the very exclusions it seeks to redress.

While publicly positioned as models of equity, these philanthropic planning efforts rely on a familiar pattern: critique is delegitimized, refusal is recoded as non-participation, and aesthetic output is substituted for structural repair. Planning discourse remains largely complicit in this process, celebrating symbolic transformation while ignoring the underlying mechanisms of ownership and control. Racial capitalism persists not despite but through the aesthetics of inclusion.

By reading these dynamics through Ray’s theory of racialized organizations, this paper foregrounds how race structures the institutional conditions under which cultural planning unfolds. Philanthropy operates not only as a source of funding but as an organizing force—shaping what kinds of cultural work are supported, how community is defined, and whose claims are legible within redevelopment frameworks. Rather than dismiss these efforts outright, the paper calls for deeper attention to the organizational forms, governance structures, and power relations embedded in equity-oriented planning. It suggests that without structural accountability, even well-intentioned cultural initiatives risk reinforcing the very exclusions they aim to address.

Rethinking Planning: A social-ecological understanding of bed bugs infestation in subsidized housing

Abstract ID: 1842.0.0.738.2025

Track 12: Planning History or Planning Theory

Research-in-Motion Presentation Submission, Research currently in process

Vinisha Singh Basnet [University of Illinois Urbana Champaign] vbasnet2@illinois.edu, presenting author

Daniel Schneider [University of Illinois Urbana Champaign] ddws@illinois.edu

Emerging spatiotemporal studies conducted in collaboration with planning scholars shows that bed bugs are unevenly distributed in the urban environment, often differentially affecting vulnerable and marginalized populations (Sutherland et al. 2020). Schneider (2019) argues that bed bugs pose a significant concern for urban planners because they are closely tied to the issues of economic development, housing insecurity, affordability, and quality, eviction, mobility, and health disparities. Bed bug infestation continues to disproportionately affect low-income neighborhoods, causing health disparities, housing insecurity and involuntary mobility. Because of this disproportionate impact on health and housing, scholars see bed bugs exacerbating the issues of social and environmental justice (Eddy and Jones 2011). Empirical studies provide evidence that bed bugs prevalence is highest and more likely to persist in low-income neighborhood, and in neighborhoods where eviction is more likely to occur (Hacker et al. 2022; Sutherland et al. 2020). However, we lack comprehensive understanding and systemic exploration of this issues. Through my ethnographic research I show how the bed bug infestation is embedded within a complex social-ecological system (SES). Such an understanding assumes that there is no single problem of bed bug infestation, rather different stakeholders experience and construct this problem differently. I ask: a) How do different stakeholders experience bed bug infestations, and how do structural inequalities shape the uneven burden of these infestations in low-income housing? b) How do the persistence and adaptive behaviors of bed bugs shape the everyday lives, practices and housing stability of these stakeholders, reinforcing or challenging existing socioeconomic-ecological vulnerabilities? My work will contribute to the current discourse of human exceptionalism within planning by opening to more-than-human perspectives and agency to rethink planning from the intersection of human-insect entanglement Houston et al. 2018; Basnet 2024).

Urban Growth and Military Land Use in South Korea: Policy, Planning, and Institutional Responses

Abstract ID: 1842.0.0.398.2025

Track 12: Planning History or Planning Theory

Research-in-Motion Presentation Submission, Research currently in process

Christopher Clanahan [Arizona State University] clanahanc@gmail.com, presenting author

Hyunsik Son [Arizona State University] hyunsik.son@asu.edu

As urbanization accelerates in South Korea, the coexistence of military installations and civilian communities presents complex land use challenges. These challenges arise from competing priorities, including national security, economic development, and local governance concerns (Shim, 2017). While previous studies have primarily focused on land disputes involving United States (U.S.) military installations within the U.S. (Appel & Smith, 2011), South Korea has seen relatively little planning-focused historical research on how land use incompatibility and base closure issues have evolved over time and the policy responses that have shaped these changes (Kim, 2018). This study seeks to address this gap by systematically examining the historical development and policy actions related to military land use in South Korea and assessing the applicability of an established theoretical framework—originally developed to analyze U.S. defense communities—to this context.

This research employs a comprehensive and systematic literature review to investigate how South Korea's planning and governance structures have influenced land use decisions. Through an analysis of national and local policies, historical records, and prior academic research, this study will assess whether South Korea's institutional responses reflect a reactive paradigm shift similar to that observed in the U.S. (Clanahan, 2021) or if alternative governance models have emerged.

This analysis examines United States Forces Korea (USFK) installations and their surrounding areas from the 1950s to the present. It is based on the premise that South Korea's defense and planning policies regarding military installations have evolved from a subordinate relationship with USFK to a more cooperative one. After the 1953 US–ROK Mutual Defense Treaty, major USFK bases were established nationwide, with national security and military priorities taking precedence over urban planning (Keum, 2022). However, since the 2006 signing of the Yongsan Relocation Plan (YRP) and the Land Partnership Plan (LPP), large-scale base closures and reconsolidation efforts have brought greater attention to collaborative governance. By tracing policy shifts and land use decisions over time, this study provides a structured understanding of the evolving relationship between military readiness and urban development in South Korea.

The findings from this study will offer planners, policymakers, and scholars valuable insights into how different governance systems mediate military-civilian land use conflicts. By identifying key policy trends, institutional strategies, and planning approaches, this research aims to inform more effective land use planning and intergovernmental coordination in defense communities. The insights gained may assist decision-makers in balancing military priorities with broader regional development goals, contributing to the broader scholarship on urban planning and governance in military-affected regions. Furthermore, applying perspectives from land use conflict studies on military installations in the U.S. to the South Korean context offers an opportunity to compare how similar conflicts unfold differently across national policy environments. The findings of this study may also serve as a useful reference for similar cases in regions such as Japan, Europe, and the Middle East.

Track 12: Planning History or Planning Theory

Research-in-Motion Presentation Submission, Research currently in process

Clara Xavier Marques [University of Virginia, School of Architecture] rbh4sr@virginia.edu, presenting author

Vanessa Guerra [University of Virginia, School of Architecture] vguerra@virginia.edu

Informal urban practices, often described as self-organized urbanism, are increasingly central to how cities evolve across both the Global North and South. Yet, despite their growing relevance, these practices remain unevenly conceptualized in planning literature, making them difficult to meaningfully incorporate into planning theory and practice. This paper addresses that gap through a systematic literature review, following Xiao and Watson (2017), drawing on peer-reviewed sources from Web of Science, Scopus, and Google Scholar. Using a Boolean search strategy and a three-stage screening process, we identified 38 works published over the last two decades engaging with terms such as “urban informality,” “informal settlements,” and “self-organized urbanism.” Our analysis traces three key conceptual shifts: First, scholarship moved away from viewing urban informality as regulatory failure and instead frames it as a structural condition shaped by state dynamics, challenging the formal/informal divide (Roy, 2005). Second, work from the 2010s emphasizes regional and epistemological diversity, moving beyond universal and technocentric models (Varley, 2013). Third, recent studies position informality as central to social resilience, particularly in crisis contexts (Basile, 2022; Guerra et al., 2024). Taken together, these shifts reposition informality as more than a localized response, as they reveal its potential role in shaping systemic urban outcomes. Yet, the ways in which informal practices evolve from context-specific adaptations into broader structural transformations remain underexplored. By clarifying how urban informality is framed across the literature, this paper offers a stronger conceptual foundation for planning scholars and practitioners alike. It not only sharpens planners’ capacity to engage with informality as part of everyday urbanism but also identifies a critical direction for future research: tracing how informal practices move from reactive adaptations to drivers of structural urban change.

Track 13 – Technology, Society and Analytical Methods

Track 13 Pre-Organized Session Summaries and Abstracts for the Sessions

AESOP-ACSP: Sustainable AI: Study of Global Cities Assessing How AI Can Increase Sustainability

Abstract ID: 1840.0.0.750.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Session Summary

Session Includes: 1844.0.0.57.2025, 1844.0.0.183.2025, 1844.0.0.321.2025, 1844.0.0.545.2025, 1844.0.0.740.2025

Si Chen [Michigan State University] chensi8@msu.edu, organizer

The session seeks to explore the intersection of AI and urban planning through the lens of sustainability. It will examine how AI can be applied to plan-making processes to create cities that are not only smarter but also more socially inclusive, economically resilient, and environmentally sustainable. Key questions to be addressed:

- 1) How can AI be adopted in urban systems to prioritize long-term sustainability over short-term gains?
- 2) What role can AI play in reducing urban carbon footprints, enhancing energy efficiency, and promoting circular economies?
- 3) How can cities ensure that AI-oriented planning fosters inclusive communities and equitable access to resources?
- 4) What plan-making frameworks and governance models are needed to ensure that AI technologies align with the principles of sustainable development?

This session aims to bridge the gap between technical innovation and sustainable development, and conceptualize Sustainable AI in the urban planning domain.

Learning Objectives:

- Bridge the gap between technological innovation and sustainable urban development.
- Explore how cities across the globe are being transformed by AI and its associated technologies
- Understand how AI can be a force for good—creating cities that are not only smart but also sustainable, equitable, and resilient for future generations

Using Natural Language Processing Models to Analyze the Five-Year Plans of Chinese Cities

Abstract ID: 1844.0.0.57.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Eric Heikkila [University of Southern California] heikkila@usc.edu, presenting author

Ling Zhu [Chinese University of Hong Kong] lingzhu@cuhk.edu.hk

Ying Xu [Hunan University] xuyingefface@gmail.com

Xuanlong Qin [CUHK] xuanlong@cuhk.edu.hk

Runhui Tian [CUHK] tianrh@cuhk.edu.hk

Plans are the essence of planning. No place exemplifies this point more than China, where national and local development plans are put forward every five years to guide its developmental directions. Analyzing these five-year plans (5YPs) provides insights into the cities themselves and the urban contexts in which such plans are formulated. While prior studies depended highly on experts' subjective knowledge in analysis and interpretation, our research applies natural language processing (NLP) models to analyze the 12th 5YPs of 286 prefectural-level (and higher) cities in China. The application of artificial intelligence, in the form of NLP models, is a key methodological innovation introduced here. Based on this approach, we partition these 286 cities into six mutually exhaustive and non-overlapping typologies. To assess the validity of these results, we compare the membership of those six clusters with the results reported by Xu and Heikkila (2020) who used human judgement to identify keywords from those same 5YPs. We then construct a contingency table indicating membership of each city in the Xu-Heikkila clusters and in NLP-generated clusters. A chi-square test on this contingency table affirms the correspondence between the human and NLP approaches, as it could not reject the null hypothesis at the one percent confidence level. This remarkable empirical finding demonstrates the potential for artificial intelligence applications to assist urban researchers in analyzing massive quantities of textual data pertaining to city plans.

AI and Sustainability: A Pilot Study of 20 Global Cities

Abstract ID: 1844.0.0.183.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Eva Kassens-Noor [TU Darmstadt] ekn@verkehr.tu-darmstadt.de, presenting author

Meng Cai [TU Darmstadt] cai@verkehr.tu-darmstadt.de

Lalita Phatthanachaisuksiri [TU Darmstadt] phatthanachaisuksiri@verkehr.tu-darmstadt.de

Vijay Pallyil [TU Darmstadt] pallyil@verkehr.tu-darmstadt.de

Hiba Karam [TU Darmstadt] karam@verkehr.tu-darmstadt.de

Despite growing enthusiasm about artificial intelligence (AI)'s potential to improve urban sustainability (Kassens-Noor et al., 2022; Vinuesa et al., 2020), empirical evidence regarding its effectiveness and underlying success conditions remains sparse and fragmented. Most existing studies are limited in scope, typically focusing on single-case analyses or narrowly defined applications (Gupta & Degbelo, 2023; Zhang et al., 2022). Whether and under what conditions AI can increase urban sustainability remains unclear. This study focuses on 20 cities from 10 countries across three continents and addresses this question from three perspectives: governance, industrial, and the general public.

First, from the governance perspective, we examined how governments deploy AI to advance urban sustainability. We applied a three-step approach: interviewing city officials to understand their views on sustainability progress, analyzing historical data to track changes in key sustainability indicators, and comparing the performance of AI and non-AI cities to evaluate which demonstrates stronger sustainability performance.

Second, from the industrial perspective, we investigated the implementation of AI by the private sector across diverse businesses and the potential of these AI technologies to promote urban sustainability through a pre-post online survey. We asked companies located in the 20 cities about their current AI deployment, the motivations behind their deployment, and their perspectives on whether the AI technologies they deployed support the advance of urban sustainability.

Third, we examined public attitudes towards the use of AI in advancing urban sustainability, with a particular focus on the extent to which people are willing to accept AI into their lives. We conducted e-townhalls, i.e., online group discussions, with local citizens in the 20 cities in a metaverse environment to examine participants' levels of support for or opposition to the use of AI to pursue the Sustainable Development Goals. We also invited citizens to play an online game we developed, named Sustainability Quest: Pathways to Progress, to further investigate people's preferences for AI-based versus non-AI methods to promote urban sustainability.

We found that supportive policy environments, collaboration between cities and tech providers, and community acceptance can influence whether AI deployment translates into measurable improvements in urban sustainability. In addition, we observed that what works effectively in one city may differ significantly from another. Furthermore, we found that higher public acceptance of AI technologies is associated with stronger sustainability outcomes.

This study addresses a critical gap in planning scholarship by providing empirical evidence on AI's role in urban sustainability across global contexts. It highlights the necessity of tailored AI strategies aligned with local contexts to successfully deploy AI for urban sustainability. Urban planners must adopt context-specific AI strategies that account for local governance structures, industrial capacities, and community attitudes. Practitioners should proactively engage communities in AI decision-making processes, fostering transparency and trust to enhance public acceptance. In addition, our findings show the importance of integrating AI literacy into curricula to equip

future planners with the skills necessary to effectively navigate complex technological, social, and governance contexts. Planning education should emphasize interdisciplinary training, including collaboration with technology providers and community stakeholders, to prepare students to design and implement AI-driven sustainability solutions.

Predicting Demand for Demand-Response Mobility in Suburbs with Probabilistic Graph Neural Networks

Abstract ID: 1844.0.0.321.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Mingming Cai [University of Washington] mmcai@uw.edu, presenting author

Qing Shen [University of Washington] qs@uw.edu

Demand-response mobility services, such as ride-hailing provided by transportation network companies (TNCs), play a crucial role in complementing fixed-route transit by expanding service coverage and extending operating hours. While extensive research has focused on demand prediction for these services, most studies examine dense urban areas with high population density and developed fixed-route transit networks. In contrast, demand prediction in low-density suburban areas—where demand is inherently sparse—remains underexplored. Additionally, urban demand-response mobility is dominated by profit-driven TNCs, whereas transit agency-led services in low-density areas are designed to enhance mobility for residents rather than maximize revenue. This difference in service goals further underscores the need for exploration in low-density areas. To address these gaps, this study develops a multi-task probabilistic spatiotemporal graph neural network (MT-STPGNN) to predict demand for transit agency-led demand-response services in low-density suburbs. This deep learning approach incorporates spatial and temporal convolutional layers to capture spatiotemporal dependencies in service demand. The model quantifies uncertainty in sparse demand generation through discrete probabilistic modeling, whose estimated parameters enhance interpretability regarding the inherent sparsity of demand in such areas. It further employs a multi-task learning framework to regularize the graph learning process by integrating local built environment features and global sociodemographic characteristics. The experiment is conducted using real-world trip data from low-density suburban contexts in the Seattle region. The results demonstrate that MT-STPGNN outperforms baseline models in learning geographic context-based message-passing mechanisms within mobility graphs and generalizing to unseen graphs. Our approach provides valuable insights for planners and policymakers in forecasting demand for demand-response services and estimating service provision costs in low-density areas.

Using Multi-Source Social Media Data to Understand the Use of Green Spaces with LLM-based Approaches

Abstract ID: 1844.0.0.545.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Si Chen [Michigan State University] chensi8@msu.edu, presenting author

Green spaces are essential public spaces and play important in urban living environments. It has been proved in many studies that access to green spaces can directly benefit physical and mental health and have various positive effects on eco-system services, such as air quality, urban heat land and community identity (Wolch et al., 2014). Investigating the human activities within the green spaces, the functionality of green spaces, and the impact factors for visiting popularity is valuable for supporting green space design and guiding land use development around public green spaces. This study utilizes large language model (LLM) based approaches to simultaneously mine text and image data from multiple social media platforms to extract multi-perspective information on urban green space popularity, activities, and functionality. The coupling of the two types of data enables the extraction of a rich and comprehensive analytical frame for understanding how green spaces are used and how they might be improved.

Conventional methods used to extract popularity and functionality information on green spaces have typically relied on questionnaires and in-site observations, both resource and time-consuming processes (Lim et al., 2018). These approaches can also be context-dependent and produce less transferable data across regions. Some academic researchers have realized the gap and attempted to apply data-based analysis (usually using geo-located social media check-in or review data) in information collection for green spaces (Hamstead et al., 2018; Kovacs-Györi et al., 2018). Nevertheless, these studies typically focused on single perspective of green space information and single type of social media data. Other perspectives of information, and the geolocated social media images, which have the potential to deepen our insights into green spaces, were not frequently analyzed.

This study aims to propose an information extraction framework to extract richer, more professional, and multi-perspective information (popularity, functionality, and activities) for green spaces through the LLM-based analysis of multi-source social media data. The proposed green information extraction framework tightly couples LLM with vision encoder to simultaneously analyze text and image data from multiple social media platforms to investigate the green space popularity, activity functionality information. The City of Seattle is chosen as an application case to test the framework. Geo-located green space images collected from social media have the potential to provide comprehensive information but are seldom used because of the difficulty in collecting and parsing data. To address the challenges of the general problems in green space image datasets, including sparse dataset and high similarity between different green spaces, we use image augmentation and fine-tuning techniques. Through expanding the local dataset and pretraining the framework using local dataset, we were able to adjust the LLM-based framework to local context, and at the same time provide robust and powerful classifications. The extracted green space popularity is also modeled based on green space design features, provided services, locational attributes, and socio-economic features to indicate the planning and design principles for green spaces. The proposed information extraction framework has the potential to be used beyond green spaces, to extract all types of geolocations using images and texts to provide better analytic information for many fields.

A Study on the Impact Factors of Fire Incidents and Identification of Fire Risk Areas in Seoul

Abstract ID: 1844.0.0.740.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Taehwan Hyeon [Architecture and Urban Research Institute] thhyeon@auri.re.kr, presenting author

Xiaowei Li [Michigan State University] xiaowei@msu.edu

Youngjin Cho [Architecture and Urban Research Institute] yjcho@auri.re.kr

Euisoon Ahn [Architecture and Urban Research Institute] esahn@auri.re.kr

This study analyzes the impact of socio-cultural, economic, and physical factors on fire occurrences in urban areas, focusing on Seoul, South Korea. Furthermore, the study seeks to differentiate the factors influencing fire occurrences by categorizing fires caused by human activity and those caused by physical factors, thereby classifying high-risk areas for each type of fire.

The theoretical foundation of this research is based on urban ecology theory and social disorganization theory. Specifically, the hypothesis is that informal social control based on social cohesion influences not only crime but also fire occurrences. To verify this, various socioeconomic factors, along with crime-related factors associated with these variables, were included in the analysis. Additionally, physical factors were also considered, as they cannot be ignored when analyzing fire occurrences.

To compile data on the factors influencing fire occurrences, this study utilized publicly available data, excluding data on fire and crime incidents, and made efforts to collect data at the smallest possible geographic scale.

The novelty of this research lies in the use of fire residuals as the dependent variable, controlling for population and the number of buildings. This approach aimed to isolate the effects of urban socioeconomic and physical factors on fire occurrences. The analysis was conducted at the census tract level, aiming to identify high-risk areas for fires on a finer scale.

For the final goal of classifying fire-prone areas based on the cause of fire, this study employed machine learning models. However, to ensure logical and justifiable variable selection and to interpret the results effectively, multiple regression analysis and spatial regression analysis were conducted at the administrative district and census tract levels. These analyses identified the variables to be applied for total fires, human-caused fires, and physically-caused fires.

The analysis results for fire causes are as follows:

First, factors influencing total fire occurrences showed that higher rates of violent crimes, unemployment, and single-person households were associated with an increased risk of fires. Additionally, areas with a higher proportion of commercial buildings were found to have a greater fire risk. High levels of violent crime, unemployment, and single-person households align with factors identified in social disorganization theory that weaken informal social control, particularly in commercial areas.

Second, for fires caused by human activities, areas with high rates of violent crime, unemployment, and single-person households exhibited higher risks of fires due to negligence or arson. However, areas with a higher proportion of residential buildings and higher building density showed lower fire risks. This can be attributed to the urban characteristics of Seoul, where areas with a high proportion of residential buildings and building density are typically high-density apartment complexes. These areas are likely to have stronger roles for residents and

managers, resulting in lower fire occurrence rates. In such areas, both informal and formal social control are stronger, leading to relatively lower fire risks.

Lastly, for fires caused by physical factors, violent crime emerged as the strongest factor. However, unlike total fires and human-caused fires, areas with a higher number and proportion of buildings older than 30 years, as well as a higher proportion of buildings with five or fewer floors, showed increased fire risks. This indicates that areas with clusters of older, low-rise buildings are more prone to fire incidents.

The significance of this study lies in its ability to provide a nuanced, spatially detailed understanding of urban fire risk, which can inform more targeted and equitable fire prevention and urban planning strategies in rapidly densifying cities.

Knowledge and Data Governance in an Era of Uncertainty

Abstract ID: 1840.0.0.975.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Session Summary

Session Includes: 1844.0.0.957.2025, 1844.0.0.758.2025, 1844.0.0.209.2025

Samina Raja [University at Buffalo] sraja@buffalo.edu, organizer

Some describe urban planning as the art and science of using evidence to inform actions in the public interest (Friedman 1987). Yet, planning practice and scholarship have remained largely silent about questions of governance of production, control, and broadcasting of data, especially data about/for/on behalf of communities. Debates about data governance have re-emerged as the federal government has removed data from the public domain. 'Disappearing' of data is not a new phenomenon, though it may take on varied forms. For example, researchers may gather data about communities and then 'disappear' from those communities. In this pre-organized session, we draw on Alcott's (2022) extractivist epistemological framework to wrestle with questions with questions of data governance in an era of political uncertainty. Papers in this session challenge extractive epistemologies, report on the state of the literature on equitable dashboards, and review proof-of-concept platforms.

Learning Objectives:

- Foster an understanding of the state of the literature/scholarship on equitable data dashboards
- Illustrate possibilities for proof-of-concept data platforms that have attempted to address questions of data governance in varied ways
- Share varied frameworks for ensuring ethical practices in data governance

Countering Extractive Epistemologies in the Wake of Crises

Abstract ID: 1844.0.0.957.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Samina Raja [University at Buffalo] sraja@buffalo.edu, presenting author

Eric Hughes [LaBella PC] ehughes@labellapc.com

Dennice Barr [Food Systems Planning and Healthy Communities Lab] cookieatburgard@gmail.com

Who owns (planning) knowledge? Who produces it, to what end, and for whom? These questions about knowledge governance - and consequently data governance - are central to planning practice and scholarship (Friedman 1987, 2020). Yet, a limited body of scholarly planning literature or practical guidance addresses questions of knowledge and data governance. This is not to say there is limited scholarship on data per se -- in fact, ACSP has an entire track dedicated to planning analytics. Rather, we contend that there is an absence of critical scholarship on questions of power, ownership, and control over data that impacts marginalized communities.

The limited body of critical planning scholarship on data governance has allowed the unchecked proliferation of extractive epistemologies (Alcoff 2022), especially as big data and AI are used uncritically. In the academic world, researchers may gather data from communities for their gains (e.g., publications and professional success) while communities are unable to access data or use it for their purposes. In the world of professional practice, the state may use digital data to expedite decision-making but often at the expense of people's freedom and well-being (e.g., use of digital data may result in enhanced surveillance, policing, etc.). To be sure, communities have resisted and reclaimed control over the use of data, as illustrated in the case of digital insurgents documented by Basile et al (2025) and others.

Drawing on the framework of extractive epistemologies of Alcoff (2022), this paper reflects on a series of cases from Buffalo, NY in which non-state coalitions resist, reclaim, and redefine knowledge and data governance in the wake of crises. The cases include three data initiatives - Seeding Resilience, Seeding Justice, and WNY/East Side Dashboard - which sought to reduce information asymmetry, improve data access, and advocate for transformation in the food system to varied degrees of success (Raja 2020). Seeding Resilience was launched in the wake of COVID 19 to provide quick access to food-related informational resources (using a simple google map); Seeding Justice was launched in response to the tragic massacre of 10 Black people to provide information and resources to impacted neighborhoods (using google forms and spreadsheets); and, finally, WNY/East Side Dashboard was launched using a public process (on an ArcGIS portal). All three cases illuminate the limits and possibilities of community-led governance in data efforts. Written by a team of researchers, community leaders, and technicians, the paper concludes with a data governance framework for planning scholarship and practice.

Designing IDRO: A Use-Case in Data Governance for Climate Resilience

Abstract ID: 1844.0.0.758.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Mohamed Aly Etman [University at Buffalo] maetman@buffalo.edu, presenting author

In an era marked by climate uncertainty and rapidly expanding digital infrastructures, questions of who controls, accesses, and governs environmental data have become increasingly central to equitable and effective planning. This paper reflects on the development of the Integrated Drought Resilience Observatory (IDRO) as a use-case to explore these challenges. Specifically, it asks: How feasible is it for a multi-stakeholder data consortium to promote equitable data governance in support of drought anticipation, preparedness, and adaptation across multiple geographic scales? IDRO is a modular, web-based platform currently being co-designed and developed by Yale CEA and UB BEVL in collaboration with IDRA (the international Drought Resilience Alliance), with the goal of integrating diverse data sources to serve a broad range of users and stakeholders. IDRO integrates a wide array of datasets—including satellite imagery, hydrological indices, soil moisture levels, community-reported vulnerability assessments, land use data, and relevant policy frameworks. It is being developed to serve a diverse range of stakeholders, including government officials, policymakers, data scientists, field experts, farmers, and concerned citizens. Each of these user groups brings distinct needs, expectations, and levels of digital literacy, which directly shape how data must be curated, presented, and governed.

This paper reports on the challenges and opportunities encountered during the initial phases of IDRO's development. It highlights the technical and governance complexities involved in accessing and integrating heterogeneous data sources—from publicly available datasets (e.g., NASA, FAO, UNEP) to proprietary geospatial information and community-generated data. The paper introduces a tiered data access model designed to accommodate varying levels of permissions, data sensitivity, and user expertise.

Key areas of focus include the development of metadata standards and interoperability protocols that support both machine-readability and human comprehension, as well as engagement strategies with local institutions and data custodians to address critical questions of data ownership, representation, and long-term stewardship.

Drawing on global and UN-aligned frameworks on data governance—such as the UN's International Data Governance Pathways and CIGI's Platform Governance model—the paper situates IDRO within a broader international conversation on ethical, participatory, and context-sensitive approaches to data governance. By presenting IDRO as an applied experiment in operationalizing these frameworks, the paper offers grounded insights into the governance of environmental data across local, national, and global scales.

Ultimately, this contribution aims to illuminate the complex challenges involved in integrating diverse data systems into community-serving infrastructures. It underscores the urgent need for data governance models that move beyond technical efficiency to prioritize accountability, equity, and usability as foundational design principles.

Planning Without Data: Yeah, I've Never Read a Plan But Here's What We Should Do...

Abstract ID: 1844.0.0.209.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Catherine Brinkley [University of California, Davis] ckbrinkley@ucdavis.edu, presenting author

Local land-use plans are essential for guiding future development, but the data within these plans are often difficult to compare. Regional coordination and plan evaluation is challenging. In response, this research reviews state and local data infrastructure guidance and compliance with a California use-case. To showcase what is possible, we also pilot a public-facing search engine for plans (PlanSearch.caes.ucdavis.edu). PlanSearch enables users to access plans and search for terms and phrases across over 600 land-use plans.

We intentionally centered equity in the platform design by relying on feedback from partners involved in real-time technical equity planning efforts. Throughout the research process, the team presented findings for feedback to state agencies and non-profit members of the California Environmental Justice Alliance (CEJA). CEJA helped motivate the state legislature to pass SB 1000 (Leyva) in 2016 (Cal. Gov. Code, § 65302(h)), which requires local plans to address Environmental Justice (EJ) in updates. EJ is defined in California law as “the fair treatment and meaningful involvement of people of all races, cultures, incomes, and national origins with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies” (Cal. Gov. Code, § 65040.12, subd. (e)). The resulting search engine allows CEJA and partners to see where plans address EJ, thereby improving technical planning assistance as well as informed planning efforts by the public (e.g., Brinkley and Wagner, 2021). By centering equity in the design process, the platform addresses the specific requirements of communities involved in environmental justice efforts. This focus on equity ensures that the platform is not only a technical tool but also a means to support fair and inclusive planning practices.

The platform's design leverages advanced technologies to streamline the extraction and indexing of data from land-use plans. The platform is designed using Python packages optimized for quickly extracting information directly from PDF documents and indexing with Elasticsearch. The code is open access and available on GitHub (Banginwar et al., 2023). By utilizing Python packages and Elasticsearch, the platform ensures efficient and accurate information retrieval. This technological approach allows users to perform comprehensive searches across a vast number of documents, facilitating better comparison and analysis of land-use plans.

Our platform provides a proof of concept that can be deployed elsewhere. For example, the United Nations sets Sustainable Development Goals but stops short of assessing progress, leaving such work for voluntary review. With this use-case, we demonstrate that even without uniform standards for plan formatting, the creation of digital platforms for archiving and searching across plans is feasible and enables large-scale quantitative analysis. Such considerations are important not only as planning seeks to address Environmental Justice and “anti-racist” futures, but also as local jurisdictions grapple with climate crises.

By enabling more accessible and comparable data, the platform can enhance regional coordination and support more effective planning outcomes. Even if people do not read the entire plan, they can gather policy-making ideas by searching and comparing, helping their local jurisdiction refine and tailor a new approach. In conclusion, the development of this open-access search engine platform represents a significant advancement in the field of urban planning. By addressing the challenges of data comparability and accessibility, the platform supports more informed and equitable planning decisions. As the platform continues to evolve, it holds promise for widespread adoption and impact, contributing to the creation of more sustainable and just communities.

Using Smart Phone Data to Explore Neighborhood Connections, Change and Segregation

Abstract ID: 1840.0.0.641.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Session Summary

Session Includes: 1844.0.0.256.2025, 1844.0.0.500.2025, 1844.0.0.486.2025, 1844.0.0.479.2025

Lance Freeman [University of Pennsylvania] lancefre@design.upenn.edu, organizer

The papers presented in this panel utilize a relatively novel data set from smartphones to explore various facets of neighborhood residential mobility, neighborhood interconnectedness, and interactions between neighborhood residents. The first paper applies graph theory to understand how neighborhoods connect with others, and how these interactions change over time and space and vary with socioeconomic and demographic characteristics. A second paper examines if tenants of subsidized affordable housing sited in “higher opportunity” neighborhoods have daily patterns that align with the hypothesized mechanisms of social mobility. The third paper combines smartphone data with consumer trace data to demonstrate how daily mobility patterns influence subsequent residential mobility. The fourth paper creates neighborhood typologies based on patterns of network connectivity. The final paper explores the relationship between transit and neighborhood interconnectivity.

Learning Objectives:

- Identify neighborhood typologies based on interconnectivity.
- Explore the utility of smart phone data for studying neighborhood dynamics
- Identify potential predictors of neighborhood change that can be used to inform planning and policy making

Measuring Integration in Affordable Housing with Location Data

Abstract ID: 1844.0.0.256.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Wenfei Xu [UCSB] xu.wenfei@gmail.com, presenting author

Bernadette Baird-Zars [Rutgers University] b.bz@rutgers.edu

Spatial integration - the physical proximity of diverse racial, socioeconomic and ethnic groups - has long been a hypothesized mechanism to fuel social equality in the United States. The central logic of contemporary affordable housing policy is the provision of a subsidy that can act as a spatial corrective of these growing inequities. Yet remarkably, very few nation-wide studies have leveraged data to examine the extent, patterns, variation of the hypothesized mechanisms of sociospatial integration.

Since the early 1990s, the primary form of publicly-subsidized affordable housing in the US transformed from public-funded housing developments in areas of concentrated poverty, to programs that enable 'mobility' on the theory that place and the opportunities that certain neighborhoods hold is a key mechanism to accelerate access to opportunities such as employment, better schools, better amenities, and social integration with more diverse sets of people. While researchers have conducted large case studies in this area, most notably on the quasi-experimental Gautreaux and Moving to Opportunity programs, what is lacking are standardized metrics to compare across geography, programs, and time.

This paper identifies the characteristics of neighborhoods, cities, and places that engender higher rates of social and structural integration. A novel data source from mobile phone locations for over 66 million people across the entire United States, documented every 15 minutes enables us to examine quantitatively and at scale the actual sites visited by anonymized individuals. Our research question is: Do tenants of subsidized affordable housing sited in "higher opportunity" neighborhoods have daily patterns that align with the hypothesized mechanisms of social mobility? We associate measures of social and spatial integration with different types of housing subsidies, while controlling for temporal measures such as the time of day, and day of the week, the CBSA, population density, and a set of demographic and neighborhood covariates and program requirements in order to understand whether residents in higher opportunity subsidized housing block groups (here called our HS group) are meaningfully different than our three categories of "control" block groups: higher opportunity unsubsidized (HU), lower opportunity subsidized (LS), lower opportunity unsubsidized (LU). We anticipate our initial findings to show that the HS group does not meaningfully higher rates of integration than the control groups.

Mobility Networks, Spatial Segregation, and the Social Dynamics of Neighborhoods

Abstract ID: 1844.0.0.500.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Constantine Kontokosta [New York University] ckontokosta@nyu.edu, presenting author

Callie Clark [New York University] crc9978@nyu.edu

Bartosz Bonczak [NYU Marron Institute of Urban Management] bartosz.bonczak@nyu.edu

Lance Freeman [University of Pennsylvania] lancefre@design.upenn.edu

Mobility data provide a new lens through which to analyze neighborhood change. The study of neighborhood change has typically relied on residential locations to identify shifts in neighborhood composition. By extension, measures of spatial segregation have focused on the demographic or economic diversity within a given residential community, defined by geographic boundaries often associated with commonly-recognized administrative or political borders (Freeman 2009). How socially isolated a household is depends on more than just the connections within their neighborhood (Marcuse 1997; Wang et al. 2018). Instead, the mobility behavior of that household – to work, school, other events and activities – can influence the social connectedness of a community beyond place of residence. For instance, communities with rather tightly defined mobility patterns, such that members of the community rarely leave their home neighborhood, may experience different exposures and outcomes than those in another neighborhood with similar socioeconomic circumstances who are able to travel more widely throughout a city or region and thus interact, in some capacity, with other communities that may be different than their own (Prestby et al. 2020). Moreover, the strength of these connections, and the relationships between mobility networks of proximate communities, may influence community well-being, access to opportunity, and neighborhood change dynamics (Athey et al. 2021).

This paper applies large-scale mobility data and graph theory to understand how neighborhoods connect with others, and how these interactions change over time and space and vary with socioeconomic and demographic characteristics. We study the mobility networks of more than 45,000,000 devices across the U.S., aggregated to neighborhood geographies defined by more than 220,000 census block groups from 2019 to the present, along with numerous ancillary datasets. We specifically explore how the strength and breadth of connections between communities can be identified and analyzed using mobility networks to create a neighborhood typology across varying geographic scales, population densities, and land use types. We are concerned with both the extent of connections outside of one's home neighborhood and the heterogeneity in the income and racial make-up of the communities with which one engages. We further analyze how the emergent structure of community networks is associated with, and can predict, neighborhood change.

We find significant variations in the degree of heterogeneity between connected neighborhoods as a function of income and racial composition. In addition to differences across cities and land use types, we observe other attributes of the built environment that influence the strength and breadth of connections, and how neighborhood networks change over time. Beyond theoretical contributions, our research also has practical utility to neighborhood planners and policymakers who have had difficulty obtaining and analyzing localized data on a timely basis. The greater temporal granularity of mobility data, combined with its utility for analyzing neighborhood dimensions beyond residential patterns, allows us to develop indicators that can provide early-warning signals for planners and help to uncover neighborhood dynamics across varying socioeconomic, geographic, environmental, and demographic contexts. We acknowledge and actively address how the use of mobility data in the study of sociological processes in the urban context may be constrained by the potential for implicit and systemic biases in

the collection and processing of such data. These include representativeness issues with respect to spatial and temporal data coverage as function of technology diffusion and access, and bias emerging from disparities in coverage across socioeconomic groups.

Pre-Organized Paper Presentation

Bartosz Bonczak [NYU Marron Institute of Urban Management] bartosz.bonczak@nyu.edu, presenting author

Callie Clark [New York University] crc9978@nyu.edu

Constantine Kontokosta [New York University] ckontokosta@nyu.edu

As urban populations grow, there is a rising demand for standardized definitions of cities and their internal structures to support effective planning, management, and sustainability efforts [1]. Traditionally, cities and neighborhoods have been defined using regional or national criteria that vary by geography and scale, often relying on administrative boundaries, topography, or arbitrary thresholds of population and building density. These approaches primarily emphasize the physical form of a city or a neighborhood as a way of distinguishing it from its surroundings [1,2,3]. Another way is to classify neighborhoods based on their function, using socioeconomic characteristics of their residents or composition of local businesses. For instance, Spielman (2013) defines neighborhoods based on shared social attributes such as age, income, or race, while Marti et al. (2022) identify them as clusters of homogeneous types of business establishments as a proxy of urban activity and the community they serve.

However, with the ubiquitous cellular network coverage and growing availability of granular, large-scale geolocation mobility data, reliance on such proxies is no longer necessary. These data sources, combined with advanced computational methods, offer a more dynamic and scalable way to analyze human interactions and connectivity, bridging both form-based and functional approaches to neighborhood delineation [2].

In this study, we use aggregated cell-phone mobility data from over 40 million devices at the census block group (CBG) level across the U.S. to measure inter-CBG connectedness and define functional neighborhood boundaries. We represent mobility patterns as a network, where nodes correspond to CBGs and edges indicate interaction strength between them. Network structure allows us to apply community detection techniques in order to identify strongly connected neighborhoods. In this study we use the Louvain Modularity algorithm, which is a hierarchical clustering algorithm that finds communities by maximizing a modularity score of the network [5]. Preliminary results of the neighborhood identification performed on the mobility networks from 2018 to 2024 reveals a relatively stable number of approximately 8,000 unique neighborhoods nationwide. Notably, the algorithm operates without prior geographic constraints, allowing it to identify distant but socially and functionally connected neighborhoods, such as transportation hubs or culturally linked communities. The hierarchical nature of this approach enables scalability, allowing for neighborhood identification at local, regional, and state levels, even across traditional metropolitan or state boundaries.

By quantifying inter-community relationships, this method provides critical insights into social and economic connectivity, with implications for neighborhood change dynamics. This temporally sensitive, high-resolution approach is particularly relevant in the post-pandemic era, offering applications for migration studies, urban planning, and human-environmental geography while complementing existing census-designated boundaries.

Divided Communities: How Transit Access Impacts Neighborhood Connectivity and Isolation

Abstract ID: 1844.0.0.479.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Callie Clark [New York University] crc9978@nyu.edu, presenting author

Bartosz Bonczak [NYU Marron Institute of Urban Management] bartosz.bonczak@nyu.edu

Constantine Kontokosta [New York University] ckontokosta@nyu.edu

In recent years, widespread mobility data has enabled the study of neighborhood connectivity, both who visits a neighborhood and where residents in the neighborhood go. Research on segregation and connectivity between neighborhoods show that residential isolation by income and race persist across space [2], while other studies find that connection patterns vary by city [4]. As we introduce spatial connections, it is essential to consider the urban topography that shapes movement between neighborhoods.

The built environment can both connect and separate neighborhoods, and these infrastructure investment and location decisions are not random. In the U.S., highways have historically displaced and divided communities of color. A recent study using Twitter data found that highways still act as barriers between neighborhoods, with cities known for using infrastructure to enforce racial segregation having higher barrier scores [1]. Public transit was primarily designed to connect residents to labor markets, often linking suburbs to central business districts while leaving gaps within cities. Additionally, proximity to public transit increases local land values, and expansion or new installations reshape surrounding areas [3]. As a result, access to public transit is neither independent of demographics nor evenly distributed across space.

To our knowledge, no studies have incorporated available public transit infrastructure into analyses of neighborhood connectivity using mobility data. Some studies look at the relationship between public transit use and overall connectedness of communities. Athey et al. [2021] found that higher public transit use correlates with lower rates of experienced isolation, and Phillips et al. [2021] found public transit use did not significantly contribute to creating evenness in connectivity. However, both studies did not consider the available public transit infrastructure or other barriers to connectivity.

In this study we aim to understand if transit access and other features of the built environment impact neighborhood isolation. We consider both transit infrastructure, like bus and subway stops, and accessibility (time to travel between neighborhoods) for multiple cities. We construct a city-level connectivity network, where census block groups serve as nodes and edges represent the proportion of monthly visits relative to the total possible. Based on the number and breadth of connections into a neighborhood, we find that the number of available bus and rail stops within census block groups explain 23.8%, 42.8% and 52.3% of connectivity variability in NYC, San Francisco and Philadelphia, respectively, and bus and rail have significant and positive coefficients with a 97.5% confidence interval for all cities. We also consider bikeshare station location and other infrastructure when relevant within the context of a city.

Next, we estimate neighborhood accessibility by estimating travel time across multiple modes of transit. We use OpenStreetMap for road network data on driving and biking and integrate GTFS feeds with OpenStreetMap via the Python UrbanAccess package for public transit, resulting in travel times that account for road type, walkability, and barriers like freeways and parks in both cases. By comparing these travel times to Euclidean distance, we create a transit accessibility metric that considers multiple modes of transportation.

Incorporating our multidimensional accessibility metric into the neighborhood connectivity network allows us to examine the link between urban topography and connectivity. This new understanding enables a holistic approach to addressing gaps in access which can predict how changes to urban topography may impact neighborhood connectivity, and as a result serve to inform policy.

Accessible Zoning : Digital Tools That Bring Zoning to the Public

Abstract ID: 1843.0.0.948.2025

Track 13: Technology, Society, and Analytical Methods

Roundtable Submission, Topical Discussions

Sarah Williams [Department for Urban Planning, MIT] sew@mit.edu, organizer

Micheal Piper [University of Toronto] michael.piper@daniels.utoronto.ca

Samantha Eby [University of Toronto] samantha.eby@mail.utoronto.ca

Across North America, municipalities are revising their zoning codes to permit multi-unit housing in areas historically restricted to single-family homes. Cities such as Minneapolis, Edmonton, and Los Angeles were early adopters, introducing policies that allowed accessory dwelling units (ADUs) in backyards. More recently, an increasing number of cities are not only modifying zoning regulations but also permitting greater levels of density. In 2023, for example, the City of Toronto approved the construction of fourplexes on all single-family lots and is now considering allowing up to six units citywide.

Advocates argue that these zoning reforms are a crucial first step in addressing the housing supply imbalance. However, regulatory changes alone have proven insufficient, and several challenges remain. How can cities broaden the pool of housing creators to ensure these policies do not just benefit existing property owners? How can they effectively communicate increasingly complex zoning codes, which have become layered with overlays and exceptions, making it difficult even for experienced builders to develop scalable solutions? And is it possible to systematize infill housing across diverse lot conditions, enabling small projects to scale and benefit the greatest number of residents?

To address these challenges, new parcel-based digital tools have been developed. In California, the Community Planning Collaborative offers the ADU Accelerator, a GIS-based mapping tool that includes a cost calculator and a gallery of pre-approved designs. Similarly, Symbium provides a searchable platform for statewide property data, enabling Californians to determine what can be built on a given lot.

In Toronto, ReHousing, in collaboration with MIT's Civic Data Design Lab (CDDL), has developed a digital platform that analyzes zoning and building codes to assess the feasibility of accessory unit and multiplex development scenarios. This tool offers a map-based interface, project options, and cost analyses for residential lots. Additionally, ReHousing consults with the City of Toronto, using design testing to inform the implementation of its recent fourplex and sixplex zoning amendments.

Digital Tools like the ReHousing Platform's potential for impact is two-fold. They can allow municipalities to rapidly test the viability of different housing options across the city, giving quantifiable insights into the impact of new legislation. They can also create an accessible and user-friendly way for non-professionals to understand what is possible on their lot.

The success of gentle density policy initiatives relies not only on well-designed policy but also on providing support to those interested in uptake. There is potential to leverage data-driven approaches to do both.

For this roundtable, we convene developers of these digital zoning tools to dissect the complexity of making them so others can learn how to develop the same tools in their cities. Each participant will briefly present the complexity of their projects, followed by a facilitated discussion on the viability, challenges, and potential of these tools in advancing the housing goals set by recent zoning reforms.

We have four confirmed participants including people who have developed tools : Michael Piper Re-housing and University of Toronto ; Samantha Eby Re-housing and University of Toronto; Sarah Williams Envelope and MIT ; Siqi Zhu formerly of Google's Delve now at Sasaki Associates -- we also invited Paul Waddell of Penciler, Urban Sim and Professor Emeritus of UC Berkley Planning and Davis Driskell of Community Planning Collaborative - both of which have developed these tools

Digital Capitalism Meets Urban Planning: Plotting the Future of Technology and the City

Abstract ID: 1843.0.0.159.2025

Track 13: Technology, Society, and Analytical Methods

Roundtable Submission, Topical Discussions

Jovanna Rosen [Rutgers University-Camden] jovanna.rosen@rutgers.edu, organizer

Dillon Mahmoudi [University of Maryland, Baltimore County] dillonm@umbc.edu

Jamaal Green [University of Pennsylvania] jamaalg@design.upenn.edu

Will Payne [Rutgers University] will.b.payne@rutgers.edu

A wide array of literature has examined how the digital technology industry and digital tools intersect with urban planning processes and outcomes, from to a vast literature on smart cities to studies focused on the rise of remote and gig work (Mahmoudi, Levenda & Stehlin, 2020; Wells, Cullen, & Attah, 2023), e-governance (Van der Meer & Van Winden, 2003), disruptions in transportation modes, and the implications of platform real estate for housing markets and tenants (McElroy, 2024a; Fields, 2022; Shaw, 2020). More generally, scholarship has examined the racialized nature of digital capitalism (McMillan Cottom, 2020), how digital technologies creates the conditions for surveillance capitalism (Zuboff, 2019), and how these dynamics can shape even neighborhood-level dynamics (Payne, 2017).

Recent work on technofascism (McElroy, 2024b), digital authoritarianism (Akbari Kharazi, 2021), and urban political economy (Rosen & Alvarez León, 2022; Alvarez León & Rosen, 2020) suggests that digital technologies intersect with the means and outcomes of governance, creating the conditions for broader shifts in the foundations of society and cities. As technology firms, tools, and actors have become more embedded into both governance structures and policy, it is essential to question the role of urban planning in this space.

What is the role of urban planning in this historical moment? How are the digital and the city intertwined—and what does this suggest for the future of cities and society more generally? What are the implications for urban planning in an era where digital technology firms, tools, and actors have become increasingly embedded into both governance structures and cities? What tools and levers can urban planning offer to enhance democracy and promote equity? This roundtable draws together experts studying digital technologies and cities to explore these important questions at the intersection of digital, political, and urban geographies, critical technology studies, and urban planning.

The Promise and Pitfalls of Commercial Microdata for Planning Research

Abstract ID: 1843.0.0.393.2025

Track 13: Technology, Society, and Analytical Methods

Roundtable Submission, Topical Discussions

Alex Ramiller [University of Toronto] alexramiller@gmail.com, organizer

Karen Chapple [University of Toronto] karen.chapple@utoronto.ca

Andrew Greenlee [University of Illinois at Urbana-Champaign] agreen4@illinois.edu

Taesoo Song [University of California, Berkeley] taesoo.song@berkeley.edu

Wenfei Xu [University of California Santa Barbara] wx233@cornell.edu

Novel sources of commercial microdata are likely to play a significant role in the future of planning research (Walter et al., 2024). From proprietary repositories of consumer data to cellphone location information, a growing array of data products hold incredible promise for advancing our understanding of population and housing dynamics within cities. However, the nature of these novel data sources remains poorly understood: generated and sold by private companies and often not initially designed with academic research in mind, such data sources are black boxes in terms of data collection methodology, reliability, and representativeness (Ramiller et al., 2024).

In light of the potential advantages and limitations of these datasets, this timely roundtable discussion will critically examine the evolving landscape of commercial microdata for planning research. This will feature consideration of commercial datasets that have recently been employed for research on planning issues related to gentrification and displacement (Greenlee, 2019), segregation (Xu, 2022), and post-Covid economic recovery (Chapple et al., 2022) – including consumer reference datasets (e.g. Infutor, Data Axle), consumer credit panels, and cellphone location trace data. Furthermore, this roundtable will consider the broader role that these and other sources of microdata might play in the future of planning research and the implications of relying more heavily on data produced by private companies, particularly given uncertainties regarding the continued provision of federal data.

Drawing on the firsthand research experiences of each participant, this roundtable aims to engage a broad audience of planning scholars with the landscape of commercial data sources available for planning research and to discuss the questions that planning researchers should consider when considering these data sources. Are these data sources sufficiently reliable for empirical planning research? Are there specific strategies that should be employed to leverage the unique features of these datasets and to overcome their limitations? What are the technical challenges and ethical implications that the use of such data entail? This conversation will provide insights into innovative methodological approaches and collaborative strategies to ensure a strong future for data-oriented planning research.

Xiaofan Liang [University of Michigan] xfliang@umich.edu

In recent decades, Geographic Information Systems (GIS) have been fundamental to spatial education in urban planning curricula. However, the rapid evolution of computational methods, data science, and spatial technologies has dramatically transformed how we conceptualize, analyze, and plan urban spaces. This roundtable discussion critically examines the current state and future directions of urban spatial analytics education at a pivotal moment of disciplinary transformation.

As traditional GIS platforms evolve and new computational approaches emerge, planning educators face important questions about curriculum development, pedagogical approaches, and alignment with professional practice. Is GIS becoming less relevant as claimed by some, or is it simply transforming into more specialized and computationally sophisticated forms of spatial analysis? The recent proliferation of terms like "urban analytics," "urban informatics," and "urban science" further complicates these questions, as does the ambiguity around what these emerging fields encompass and how they relate to established planning education.

This session brings together educators from various planning programs to discuss: What core competencies should constitute contemporary spatial analytics education for urban planners? How do we balance technical depth with planning theory and practice? Are planning programs adequately preparing students for evolving job markets, and what exactly are those markets demanding? What institutional and pedagogical challenges arise when teaching advanced technical skills within planning departments, which have traditionally emphasized policy and design? How might spatial analytics education evolve over the next decade as technologies like artificial intelligence, digital twins, and real-time sensing reshape urban planning practice?

Beyond technical considerations, this roundtable will address the broader implications of these educational shifts. As spatial analytics becomes increasingly sophisticated, questions of equity, ethics, and accessibility become paramount. How do we ensure that technical education doesn't overshadow critical perspectives on technology's role in urban governance? How can we make advanced spatial methods accessible to diverse student populations with varying technical backgrounds? What responsibilities do educators have in preparing students to apply spatial analytics in ways that advance social and environmental justice?

Through structured dialogue and audience participation, we will work toward a more coherent understanding of urban spatial analytics education's current challenges and future opportunities. Participants will share pedagogical innovations, curricular experiments, and insights from professional practice to help chart a course for spatial analytics education that is both technically rigorous and deeply engaged with planning's core commitments to the public interest.

The roundtable format will encourage frank discussion of institutional barriers, pedagogical challenges, and creative approaches to spatial analytics education, with significant time devoted to audience participation. Rather than simply cataloging the problems facing spatial education, this session aims to generate actionable insights for educators seeking to navigate this rapidly evolving landscape while preparing students for meaningful professional careers.

Urban Artificial Intelligence (UAI) integrates AI with urban planning, improving energy management, environmental monitoring, and public safety. Urban research benefits from a data-rich environment, incorporating large-scale data and computational techniques into city management, accelerating digital twin advancements. Digital twins—virtual models of urban spaces—analyze and simulate urban conditions using real-time sensor and camera data. UAI processes this data to anticipate urban dynamics, optimizing infrastructure and operations. Combined with immersive technologies such as virtual reality (VR) and augmented reality (AR), UAI enhances data-driven analysis and urban design, ensuring planning decisions reflect local priorities. This integration fosters collaboration across technical and policy domains, tackling complex urban challenges. UAI connects design, engineering, and spatial sciences through data-driven methodologies, including applied research and practical engagement. It streamlines urban planning by automating routine tasks, allowing professionals to focus on strategic decision-making and design evaluation. UAI enhances situational awareness in cities and strengthens resilience. However, responsible deployment is necessary to prevent unintended disparities. Encouraging broad participation ensures research and implementation reflect multiple perspectives, fostering confidence in AI-enabled urban solutions. In data-limited regions, UAI supplements existing information with public datasets and analytical modeling. Its effectiveness depends on well-structured training data and algorithms to minimize unintended biases. If left unchecked, bias in AI systems may lead to imbalanced outcomes, affecting communities. Planners should use representative data, document AI training methods transparently, and conduct ongoing assessments to maintain fairness. Clarity in data sources and responsible data management are essential, ensuring informed consent and ethical AI applications. Privacy safeguards, such as data de-identification and controlled access, protect individual rights. While UAI tools can be widely implemented, they must be adapted to align with each community's specific characteristics and priorities. Ultimately, UAI represents a multidisciplinary effort, advancing cities from automation to autonomy. This transition demands responsible AI integration to ensure fair and effective solutions to urban challenges. Ethical considerations remain key to ensuring UAI's long-term impact for researchers, policymakers, and communities. By engaging experts from multiple domains and incorporating local insights, UAI strengthens urban sustainability, efficiency, and resilience. Identifying effective interventions in a timely manner enhances service delivery. UAI can support a coordinated scientific and policy agenda, fostering collaboration between academia, industry, and municipal leaders to develop smart cities that are innovative, efficient, and responsive—provided it is implemented responsibly.

Track 13 Workshops

Conjecture Mapping: Designing a Theory of Change for Planning Research and Practice

Abstract ID: 1841.0.0.450.2025

Track 13: Technology, Society and Analytical Methods

Professional Development Workshop Submission

Ari Hock [University at Buffalo] arihock@buffalo.edu, organizer

Lauren Fischer [University at Buffalo] lf44@buffalo.edu

Heather Killen [University at Buffalo] hkillen@buffalo.edu

Camden Miller [University at Buffalo] camdenmi@buffalo.edu

Chris Hoadley [University at Buffalo] tophe@buffalo.edu

Planners are often responsible for designing engagement processes that aim to achieve particular social and political outcomes. This is especially true for those who employ participatory and community-based methods in their research and creative practice. Despite this widespread aim, there has been limited scholarship within planning literature offering techniques to assist planners in this design work. The field of learning sciences is deeply engaged in design-based research in both formal and informal environments that increasingly overlap with planning and development activities.

In this professional development workshop we introduce conjecture mapping, a tool developed within the learning sciences to aid design-based research, which can help focus engagement in planning. Conjecture maps offer a useful framework for developing and iterating on a theory of change in community-based research and creative practice. This involves considering how the elements of a research design might lead to desired outcomes while drawing attention to the observable interactions and artifacts which mediate this relationship.

Over the course of 90 minutes, participants will learn how to make and use conjecture maps to develop robust, interdisciplinary, community-based engagement designs. Workshop facilitators will offer their own maps as an example, based on interdisciplinary research studying community learning pertaining to infrastructure planning in Buffalo, New York; and land use planning in Seattle, WA. After reviewing the mechanics of conjecture maps generally, participants will complete a series of exercises to develop a map for their own research and/or professional project. Participants will offer constructive feedback to each other to improve their maps, which will ultimately strengthen the efficacy of the planning processes and research activities they design. By the end of the workshop, participants will feel confident in using conjecture mapping as a tool to aid in community-based planning research and practices.

Agenda:

- Introduction to conjecture mapping (10 minutes)
- Application to community-based research, with interdisciplinary examples (20 minutes)
- Design interventions exercise (15-20 minutes)
- Group reflection/iteration (15 minutes)
- Individual design conjectures exercise (15-20 minutes)
- Group reflection/iteration (15 minutes)

What will the audience learn from your workshop: Through this workshop, participants will learn how to describe the utility of conjecture mapping for planning research design and scholarship, and will apply conjecture mapping to their specific research projects or creative practices.

Reminders for attendees: Come to the workshop with an idea of a research project or creative practice for which you want to design a theory of change.

A City Through Delivery Riders: Measuring the Utilization and Inclusiveness of Public Street Spaces

Abstract ID: 1844.0.0.440.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Xiamengwei Zhang [Capital Normal University] xiamengweizhang@gmail.com, presenting author

Mingze Chen [The University of British Columbia] mingzec@student.ubc.ca

As cities strive toward greater equity, public street spaces (PSS), as an integral part of cities, are increasingly recognized not just as transit routes, but as critical social infrastructure. Yet "who truly uses these spaces, how they are used, and who is left out" remains poorly understood. This study introduces a novel, data-driven framework to evaluate the utilization and inclusiveness of PSS using crowdsourced street videos and vision-language models, revealing hidden patterns of exclusion.

Previous studies on PSS have primarily relied on simplistic metrics such as pedestrian volume or the number of stayers to evaluate street vitality. However, these indicators fail to fully reflect the actual usage of street space. To address this gap, we propose the concept of utilization, a weighted measure combining pedestrian volume and activity types, to more accurately reflect street use intensity.

To evaluate whether the pedestrian composition is balanced and whether different demographics can access and use PSS equally and conveniently, we further introduce the concept of inclusiveness. Pedestrians are categorized into three types (adults, elderly, children), and their proportions are compared with census data to assess spatial equity.

Instead of relying on static imagery or mobile data, which lacks the granularity to capture activity diversity and demographic heterogeneity in real time, we leverage crowdsourced street videos captured by GPS-equipped cameras on delivery riders' vehicles in Beijing, gathering over 11,000 hours of real-life street footage across diverse streets throughout the day. We extracted 3 frames every 10 seconds from videos and construct the "Egocity Dataset", the largest fine-grained dataset of pedestrian street activity in Beijing to date, with over 115,000 annotated images.

To analyze who uses the streets and how, we developed the "LLaVA-PI (Pedestrian Identify)" model, a hybrid vision-language model (VLM). The model integrates DETA with a Swin-L backbone and a fine-tuned LLaVA-OV, enabling pedestrian identification by age group (adult, elderly, child) and behavior (walking, chatting, staying, etc.). Unlike traditional models, LLaVA-PI achieves high precision in interpreting complex pedestrian activities in real-world contexts (F1: 0.9583 for pedestrian identification, 0.8689 for activity classification). The recognition results were georeferenced and aggregated into 100 × 100 m grids, excluding grids with fewer than five observations, resulting in 2,106 valid grids representing spatial patterns of pedestrian dynamics.

Our spatial analysis reveals stark disparities. While high-utilization areas show richer behavioral diversity, they are often dominated by adults. Children and the elderly are systematically underrepresented across large portions of the street network, even in vibrant areas. These findings point to a troubling mismatch between urban vitality and inclusiveness.

In sum, this study presents a scalable, demographically aware method that leverages real-time crowdsourced videos and advanced vision-language models to evaluate the utilization and inclusiveness of PSS, aiming to diagnose spatial inequalities in public street life. The results call for a rethinking of urban design and policy to ensure that the right to the city—including its streets—is shared by all.

A Multimodal AI-Agent Framework for Simulating Human-Centric Cumulative Exposure to Urban Heat

Abstract ID: 1844.0.0.319.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yuye Zhou [University of California, Berkeley] yuyezhou@berkeley.edu, presenting author

Lu Liang [University of California, Berkeley] lianglu@berkeley.edu

Urban residents are increasingly exposed to extreme heat as a result of climate change and urban densification—conditions that elevate health risks, reduce labor productivity, and undermine urban livability. While recent advances in artificial intelligence (AI) and geospatial technologies have opened new frontiers in modeling complex urban systems, most existing studies overlook how heat exposure accumulates through the lived, spatial experiences of individuals. People are often treated as passive recipients of environmental risk, rather than as active, mobile agents whose movements dynamically interact with their surrounding environments.

This study introduces a novel AI-agent framework that simulates human perception and behavior to measure accumulative exposure to urban heat. By fusing multimodal data—including street-view imagery, LiDAR-derived three-dimensional urban morphology, and satellite-based thermal metrics—perceptual agents evaluate micro-environmental risk across space and time. To enhance behavioral realism, we integrate a large language model (LLM)-driven system that generates diverse, data-informed daily travel profiles for simulated urban residents. Each agent is assigned an origin-destination (OD) pair, socio-demographic identity, and travel purpose based on plausible urban mobility and vulnerability scenarios. These agents navigate the city, accumulating heat exposure dynamically based on localized visual and spatial cues.

A case study in Los Angeles demonstrates the framework's ability to capture spatial inequality in cumulative heat exposure and identify priority areas for urban design interventions. The findings highlight the potential of AI-driven, human-centered modeling approaches to support climate-resilient and socially equitable urban planning.

A Study of Collaborative Robot Adoption by Korea's Small and Medium-sized Manufacturers

Abstract ID: 1844.0.0.771.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Chaneum Park [Georgia Institute of Technology] cpark390@gatech.edu, presenting author

Nancey Green Leigh [Georgia Institute of Technology] ngleigh@design.gatech.edu

Heon Yeong Lee [Georgia Institute of Technology] leehy@gatech.edu

This study explores the factors influencing the adoption of collaborative robots (cobots) by small and medium-sized manufacturers (SMMs) in South Korea, employing the Technology-Organization-Environment (TOE) framework combined with Innovation Ecosystem theory. Cobots, robots designed for safe and flexible interaction with humans, offer significant productivity gains and cost efficiencies, particularly for resource-constrained SMMs. Amid rising labor costs, workforce aging, and skill shortages, intensified by the COVID-19 pandemic, South Korea's industrial landscape has increasingly turned to automation to maintain competitiveness.

The literature review highlights that while the TOE framework provides a robust structure for exploring technology adoption, it has limitations in capturing interactions among organizations and external actors. Thus, Innovation Ecosystem theory, emphasizing collaborative arrangements among diverse stakeholders complements the TOE framework, offering a nuanced view of external influences and actor interdependencies critical in cobot adoption. Previous studies on cobot adoption in manufacturing primarily concentrated on profitability, skilled labor availability, and knowledge accessibility, largely neglecting the broader innovation ecosystem that can facilitate or impede technological diffusion.

The methodological approach involves qualitative analysis through semi-structured expert interviews with seven representatives from leading Korean cobot suppliers, system integrators, and research institutes. Employing a snowball sampling technique, the study ensures representativeness and depth, given the respondents' substantial industry experience. Data were collected between November 2023 and May 2024, systematically transcribed, translated, and coded using both theory-driven and data-driven approaches.

Technologically, cobot functionality, particularly concerning proper velocity and cost, emerged as primary concerns for adoption. While cobots are safer and cheaper than traditional industrial robots, their limited operational speed often falls short of SMMs' expectations, reducing perceived benefits. However, a holistic view of total costs, including ancillary and operational expenditures, indicates cobots offer substantial long-term savings compared to traditional robotics.

Organizationally, the SMMs' technical capabilities, prior robot experience, and managerial expectations significantly shaped cobot adoption. Notably, firms lacking prior robotic experience encountered barriers but also saw cobots as a user-friendly entry point into automation, provided adequate external support. A critical organizational issue revealed was the practice of ignoring safety regulations among some SMMs, undermining cobots' inherent safety advantages.

Environmental influences, notably policy programs and domestic supplier presence, were central to adoption dynamics. Government initiatives enhanced cobot trialability, reduced adoption costs, and fostered essential inter-firm collaborations. Competitive domestic suppliers and integrators significantly improved cobot accessibility by offering localized technical support and reduced prices, accelerating adoption.

The analysis underscores intricate relationships among technological, organizational, and environmental factors, and highlights the need for coordinated ecosystem-wide approaches for innovation. This comprehensive examination provides nuanced insights valuable to policymakers, industry stakeholders, and SMM managers. The findings emphasize that addressing cobot technological limitations, enhancing organizational readiness via external collaborations, and fostering a supportive innovation ecosystem are critical pathways toward successful adoption and sustained competitiveness in South Korea's evolving manufacturing landscape.

AI-Driven Approach to Optimize and Automate Shared Micromobility System Design and Planning

Abstract ID: 1844.0.0.461.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Kaifa Lu [University of Florida] kaifa.lu@ufl.edu, presenting author

Yanghe Liu [University of Florida] liuyanghe@ufl.edu

Zhong-Ren Peng [University of Florida] zpeng@ufl.edu

Shared micromobility systems, specifically dockless scooter-sharing ones, have rapidly expanded as flexible and sustainable solutions for short-distance travel, particularly addressing first- and last-mile gaps in public transportation. However, optimizing their design and planning remains a big challenge, as existing studies primarily rely on experience or metaheuristic algorithms, including genetic algorithms and ant-colony optimization, without fully leveraging data-driven geospatial analysis, artificial intelligence (AI), and plan-making automation. To address this gap, this study developed a multi-agent and multi-objective Deep Reinforcement Learning (DRL) framework for optimizing and automating scooter-sharing system planning through balancing system efficiency, multimodal integration, cost-effectiveness, and equity.

First, we represented the scooter-sharing system as a fully connected graph, where nodes referred to grid-based partitions of study areas, generated through grid-based bounding box subdivision and Voronoi tessellation, with each grid size less than 200 m x 200 m. Each node functioned as an agent in a multi-agent stochastic model using independent Markov-Modulated Poisson Processes (MMPPs) to simulate shared scooter arrivals and departures. The DRL framework formulated the planning problem as a Markov Decision Process (MDP), training agents to take actions (including whether to deploy a scooter and how many scooters are deployed for each grid) for achieving four key objectives: (1) Usage efficiency, maximizing daily ridership per fleet size; (2) Multimodal integration, ensuring scooter availability near transit stops, parking lots, and transportation hubs; (3) Cost-effectiveness, minimizing capital costs associated with fleet acquisition and parking site construction; and (4) Equity, ensuring fair access across all socioeconomic and geographic groups, quantified using the Gini index for scooter availability disparities.

Using Q-learning, the DRL approach generated optimized system planning schemes by adjusting the tradeoffs among various objectives. A case study in Gainesville, Florida, validated the DRL framework with synthetic scooter trip data, demonstrating that the scooter-sharing system after DRL-based plan-making optimization and automation can significantly improve service efficiency, reduce costs, promote multimodal integration, and enhance equity compared to the existing system. The results highlight the potential of AI-driven automation in micromobility planning, allowing planners to focus on defining objectives and evaluating final plans while leveraging computational methods for decision-making. This research contributes to the growing field of AI-powered urban mobility by introducing a novel data-driven modeling framework that integrates big data, geospatial analytics, and reinforcement learning for shared micromobility system optimization and automation, greatly improving plan-making efficiency. Our findings also provide crucial insights into sustainable transportation planning, supporting the development of more efficient, accessible, and multimodal urban mobility solutions.

AI-Driven Optimization of Electric Vehicle Charging Station Placement

Abstract ID: 1844.0.0.200.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Seung Jun Choi [The University of Texas at Austin] jun.choi@utexas.edu, presenting author

Junfeng Jiao [University of Texas at Austin] jjiao@austin.utexas.edu

Public Electric Vehicle Charging Stations (EVCSs) play a central role in transportation electrification planning. As the number of Electric Vehicles (EVs) continues to grow, there is an increasing need to expand charging infrastructure. While conventional site suitability analysis using GIS methodologies is widely applied, the advent of AI and AI agents presents new opportunities to enhance these practices. Peng et al. (2023) define the integration of AI into the planning process as Urban AI. Yet, the specific expectations and challenges of applying AI in domain-specific planning processes remain unclear.

To provide empirical case studies of Urban AI, this study examines the use of multiple AI applications and agents to improve future site planning. The study focuses on Austin, TX, establishing a baseline site suitability analysis based on the USDOE's Argonne National Laboratory guidelines by Kuiper et al. (2022). Charging station locations were categorized into three types: Transportation Network Company (TNC) hubs, corridors, and rural areas, each undergoing a separate site suitability analysis with a distinct set of variables. The variables were preprocessed in GIS as raster data. To further refine site selection, this study applied GeoAI to improve the site suitability analysis for additional public EVCS locations. The final GeoAI-based site suitability outcomes were then extended to develop a Generative AI (GenAI) model.

For GeoAI, land cover and parking lot classification were conducted using Landsat and high-resolution satellite imagery. These classifications were reviewed and validated with human oversight before integration into the analysis. The optimized site selections underwent a 3D evaluation using Google Earth Pro and were later overlaid with 3D meshes to visualize future scenario plans. Images representing the most suitable sites were used to generate real-time scenario footage using OpenAI's Sora. For GenAI modeling, the finalized site suitability analysis results were used to train a Pix2Pix model. The data were sampled to 512×216 pixels, with paired images prepared for computational modeling. The hyperparameters of Pix2Pix were set based on the original model presented by Isola et al. (2018).

The analytical results indicate that using GeoAI for site suitability analysis provides insights by generating more sophisticated results. Emerging accessible 3D visualization tools enable planners to evaluate sites remotely. Overlaying 3D meshes, such as public EVCS locations, gas stations, and parking lots, helps planners validate their assumptions and refine site selection. OpenAI's Sora reduces the cost of manual design by generating real-time footage that simulates human behavior in charging station environments. The optimized Pix2Pix model for site suitability planning successfully transformed Landsat images into site suitability analysis results, demonstrating an approach for conducting meta-analyses. Releasing such pre-trained models could benefit rural areas and tribal nations, where research resources are often limited.

Nevertheless, human oversight remains critical when integrating AI into the planning process. GeoAI estimates must be evaluated against land use regulations before implementation. The results generated by the Pix2Pix model are not always perfect, and Sora occasionally produces inaccurate footage. More importantly, using AI for scenario planning requires interdisciplinary expertise. While AI enhances planning practices, human planners must remain at the forefront. In planning, the involvement of diverse stakeholders highlights the importance of community

engagement in gathering local knowledge and building collective capacity (Innes and Booher, 2015). I propose Community Experience (CX), a fusion of community engagement and User Experience (UX), as a conceptual space to examine the role of AI in planning.

Does traditional urban and architectural theory accurately capture the real-world quality of place (QoP) experienced by people? With recent advances in generative artificial intelligence (GenAI), this study evaluates whether the perceived spatial quality of indoor and outdoor environments aligns with Kevin Lynch's five elements of city image and Vitruvius' three principles of architecture. While prior research (Malekzadeh et al., 2025; Jang et al., 2024) has primarily focused on evaluating outdoor QoP, it has largely neglected the simultaneous consideration of indoor environments, where people spend a significant amount of time. This study bridges that gap by analyzing indoor and outdoor spatial qualities to offer a more holistic evaluation of QoP. By extracting spatial quality from Google Street View (GSV) panoramic images and Airbnb interior images, this study applies a GenAI model to systematically evaluate QoP dimensions and compare theoretical expectations with real-world user experiences. Our primary research questions explore the extent to which traditional QoP frameworks correspond with positive and negative user experiences and examine how differences between the quality of indoor and outdoor places affect user satisfaction across diverse urban contexts.

To address these questions, we conduct a comparative QoP evaluation across 10 global cities—Amsterdam, New York, Paris, London, Berlin, Hong Kong, Singapore, Tokyo, Sydney, and Mexico City. We apply Gemini 1.5 to assess GSV images for outdoor characteristics and Airbnb images for indoor quality. Lynch's five elements guide the evaluation of urban form and spatial legibility in GSV images, while Vitruvius' three principles provide a framework to assess the structural, functional, and aesthetic dimensions of indoor quality captured in Airbnb images. The GenAI model generates textual descriptions and assigns quantitative scores for each dimension, facilitating a systematic comparison between theoretical QoP expectations and real-world user experiences derived from Airbnb reviews. To further analyze user sentiments, we apply BERT for sentiment analysis, categorizing reviews into positive, neutral, and negative responses. Also, we use cosine similarity to measure the semantic alignment between AI-generated descriptions and user reviews, quantifying the relationship between user sentiments and the qualitative levels of indoor and outdoor spatial quality.

Preliminary findings suggest a positive correlation between indoor and outdoor quality across all cities, with regional variations reflecting diverse local contexts. Cities such as Amsterdam and Paris show stronger alignment between indoor and outdoor QoP dimensions and user sentiments. However, in cities like Hong Kong and Tokyo, indoor QoP factors exhibit greater variability, particularly in aesthetic satisfaction. Our analysis demonstrates that traditional QoP models capture fundamental qualities but often overlook the regional uniqueness and contextual variability of indoor and outdoor environments, leading to divergent outcomes across different cities.

These findings highlight the need for urban planning paradigms to transition from theory-driven QoP to adaptive, AI-assisted frameworks that account for localized preferences and evolving spatial perceptions. While GenAI models demonstrate promising potential in automating QoP evaluation and detecting discrepancies, they are not without limitations. Our analysis identifies biases in AI-generated QoP assessments, necessitating human intervention and oversight to ensure accuracy and reliability. To address these challenges, future research should focus on developing fine-tuning protocols and auditing tools that enhance GenAI's ability to capture nuanced

spatial qualities and mitigate biases. By integrating AI-driven dynamic QoP models into planning processes, urban planners can create human-centered environments that reflect spatial dynamics and societal expectations.

Analyzing Vertical Spatial Density Differentiation in Central Urban Areas

Abstract ID: 1844.0.0.615.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yupeng Liu [School of Architecture, Southeast University] lyp_urban@163.com, presenting author

This study aims to guide the rational and orderly growth of three-dimensional spatial morphology in high-density central urban areas. Unlike planar density, vertical spatial density refers to the building intensity at different height cross-sections of a city. The smaller the cross-sectional intervals, the more precise the characterization of the three-dimensional urban form. Currently, urban planning researchers primarily describe urban spatial morphology using planar density and vertical height. However, due to the concave-convex shapes of buildings and the spacing between structures, numerous void spaces emerge within building clusters, making traditional quantitative indicators insufficient for accurately capturing the complex topological characteristics of urban space.

To address this limitation, this study proposes an analytical framework for vertical spatial density in central urban areas. Using urban blocks as the fundamental research unit, we construct vertical density profiles at different height slices to quantitatively describe the three-dimensional spatial morphology of 20 high-density central urban areas worldwide. Based on intelligent clustering algorithms, morphological zoning is identified, followed by an analysis of the attenuation characteristics of vertical spatial density with increasing height and distance from the urban core. Finally, we explore regulatory approaches for managing three-dimensional urban morphology.

The case studies focus on 20 high-density central urban areas in economically developed cities across North America, Europe, and Asia. The data used include block vector data and building vector data with elevation attributes (2024), all sourced from open datasets.

Individual Paper Presentation Submission

Xinyu Fu [University of Waikato] xinyuf@waikato.ac.nz, presenting author

Evaluating plans is a well-established field of research in urban planning. It is because plans, the printed currency of the profession, not only represent the outcome of the plan-making process but also serve as key inputs for informing local decision-making (Levy, Hirt, and Dawkins, 2009). To materialize their full potential, many argue that plans should be frequently evaluated against evolving plan quality principles to reflect the latest knowledge in urban planning and to foster continuous learning and improvement in professional practice (Berke and Godschalk, 2009). However, conducting plan evaluations routinely at scale has proven increasingly challenging.

The reasons are twofold. First, the rapid growth of digital plans—driven by regular updates to conventional plans (e.g., comprehensive and hazard mitigation plans) and the increasing development of new plans (e.g., climate adaptation and heat action plans) to address emerging urban issues—has led to an overwhelming volume of planning documents (Batty, 2022). Secondly, plan quality evaluation is a highly labor-intensive task, often requiring at least two human coders to content-analyze lengthy and technical planning documents to produce reliable evaluation results (Stevens, Lyles, and Berke, 2014). Hence, routinely evaluating a large number of plans can be both cost-prohibitive and unrealistic for most researchers and practitioners.

The rapid development of AI technology, particularly large language models (LLMs), offers transformative potential to automate plan evaluation, addressing many of the above-mentioned challenges posed by traditional, labor-intensive manual content analysis methods (Cugurullo et al., 2024). When used properly, these novel techniques could not only automate plan evaluations and other content analysis tasks but also improve the efficiency and accuracy of plan evaluation, facilitating better co-learning through a more comprehensive and nuanced understanding of diverse plans at scale.

Despite the promises, no study has examined these novel approaches' effectiveness in the context of urban planning, particularly for plan evaluation that require robust reasoning, complex domain knowledge, and nuanced contextual understanding. This research addresses this gap by systematically evaluating the performance of LLMs enhanced with retrieval-augmented generation (RAG) and multi-agent frameworks in automating plan evaluation. Using a recent study by Keith et al. (2023) that analyzed networks of plans for cities' resilience to extreme heat, we replicate their methodology to benchmark the performance of these advanced LLM techniques against traditional manual content analysis. Our findings demonstrate the best practices and identify key error patterns as areas of future improvements. We advocate integrating AI with human oversight as the new norm for future content analysis, leveraging AI's efficiency and precision in repetitive tasks and human's contextual understanding and domain-specific knowledge.

Beyond Traditional Visualizations: Evaluating Augmented Reality's Influence on Support for Urban Densification

Abstract ID: 1844.0.0.119.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Joungwon Kwon [University of North Carolina at Chapel Hill] jokwon@live.unc.edu, presenting author

Todd BenDor [University of North Carolina at Chapel Hill] bendor@unc.edu

Augmented reality (AR) overlays digital information onto the real world and has been used widely in fields such as architecture and business. Yet, despite its potential, AR remains underexplored in urban planning. Kitchin et al. (2021) partially addressed this gap by highlighting challenges faced by Irish municipal planners in adopting 3D spatial technologies, including AR and virtual reality (VR). AR has the potential to be a valuable planning support tool, especially for changing public's support. In many US cities, opposition to new development—"Not In My Backyard" (NIMBYism)—stems from concerns about property values, traffic, public services, and neighborhood character. Given these concerns, it is important to understand how framing can shape public attitudes toward densification. Planning documents typically use positive framing, and prior studies (Buijs 2009; Whittemore & BenDor 2019) show how framing influences public perception. In this study, visualizations are used not as tools to introduce new frames, but rather to support and reinforce the existing framing from the description in plans.

The study evaluates scenarios reflecting the nationwide trend of transitioning to mixed-use and higher-density developments, such as common '5-over-1' projects, using a national panel of respondents to test various densification scenarios. It examines how AR influences public attitudes towards urban densification, addressing the following questions: (1) In comparison to traditional two-dimensional renderings, how does three-dimensional AR influence public support for urban densification? (2) How are these attitudes moderated by factors including the surrounding built environment, participants' values, concerns (traffic, scale, infrastructure, property values, services, resident appeal), technological proficiencies, and demographic factors? (3) How do varying levels of visualization engagement, such as immersion and interactivity, affect support for urban densification?"

In conducting a mobile web survey of 1,872 politically active residents across the U.S., the study adapts Whittemore and BenDor's (2019) research on framing and its impact on public resistance to urban densification to an AR. Participants are randomly assigned to either a 2D rendering or simulated AR, which includes 360-degree panoramic views seen through smartphones in real scale. They are then assigned to one of four hypothetical scenarios. The four density scenarios are: 1) a high-density urban environment; 2) a low-density commercial area; 3) a single-family residential area; and 4) an undeveloped area.

This study offers one of the first empirical tests of AR's impact on public support for urban densification, confirming that AR can increase support compared to 2D renderings. However, the effect is context-dependent. Support for densification declined in single-family residential areas, regardless of visualization type. While AR's immersive features increased support among participants who valued the quality of the built environment. Moreover, technological proficiency did not consistently translate into more favorable responses to AR.

These findings provide practical insights for municipalities on leveraging AR. For planners, AR presents a promising but nuanced tool for public engagement—especially when integrated with context-specific surroundings and framed to address local concerns. Simulated AR, in particular, offers a cost-effective and accessible alternative to fully immersive AR. It helps bridge the gap between technical feasibility and public participation. This research contributes to practical guidance for planners and the broader planning literature by revealing in what context and how AR can foster public support for urban densification.

Bio-Inspired Urban Form Analysis of Qinba Small Towns Using Big Data

Abstract ID: 1844.0.0.21.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Xin Zhao [Xi'an University of Architecture and Technology; Geographic Data Science Lab, University of Liverpool]

xinzhao0909@163.com, presenting author

Zuobin Wu [Xi'an University of Architecture and Technology] 1507819106@qq.com

Lu Jiadi [Xi'an University of Finance and Economics] 2568267259@qq.com

This research employs big data analytical methodologies to conduct a comprehensive examination of the morphological characteristics of 89 small towns in the Qinba Mountains region of Southern Shaanxi. By applying methodologies inspired by biological cell morphometric analysis (Yu et al., 2013; Losa, 2002; Lobo et al., 2016), this study aims to enhance understanding of the complexities inherent in urban form measurement. The morphological features of these towns are precisely quantified using six overarching indicators—dimensions, shape, spatial distribution, intensity, connectivity, and diversity—and their 15 sub-indicators (Fleischmann and Arribas-Bel, 2022). This meticulous quantification facilitates a comprehensive understanding of the spatial and functional configurations present in the small towns of this region. Advanced deep learning techniques and big data analysis methods are implemented, particularly utilizing the U-Net3+ network model to extract with high precision the architectural footprints of these small towns from remote sensing data (Qin et al., 2022). The U-Net3+ network, selected for its exceptional performance in image segmentation, is extensively applied in urban morphology analysis. Through the application of Python programming for calculating urban morphology indicators, this research quantifies the morphological characteristics of urban settlements at a significant scale. This investigation specifically addresses the coupling relationship between small towns and riverine systems, examining the influence of small watersheds on town morphology. Rivers constitute not only an integral component of the natural terrain but also a crucial consideration in urban development and planning processes. The interaction between rivers and urban settlements reveals the substantial impact of water bodies on urban form, expansion patterns, and spatial organization, particularly in mountainous small towns where rivers function as natural boundaries and ecological corridors, playing an essential role in maintaining ecological equilibrium and promoting sustainable development. Hierarchical clustering analysis of architectural form indicators reveals the spatial and structural nuances characterizing these small towns. Additionally, Grasshopper, a Rhino-based visual programming tool, is employed to refine town planning efforts, with its C# scripting capabilities enabling expeditious urban design developments that are fundamental for harmonizing town-river relationships and preserving ecologically significant areas (Naboni et al., 2019). In conclusion, this research innovatively approaches the study of small town morphology from the perspective of biological cell morphology, integrating deep learning, hierarchical clustering, Python programming, and parametric design tools to conduct an in-depth analysis of the morphological characteristics of small towns in the Qinba Mountain area of southern Shaanxi, while simultaneously exploring the complex coupling relationships between these settlements and their riverine environments, thereby providing scientific foundations and novel perspectives for small town planning, design, and ecological environmental protection.

Plans are foundational to urban planning, defining its identity and advancing the public interest when aligned with community goals. In concept, a well-crafted plan serves the public interest more effectively than urbanization undertaken without planning. Recognizing the importance of plans, scholars have developed well-established principles of plan quality and empirically examined how plan quality shapes urbanization and enhances community outcomes.

However, the increasing volume and complexity of plans make them labor-intensive and challenging to evaluate, limiting their practical use and theoretical advancement. Despite being digitally accessible, their scale deters comprehensive review and comparison. With most plans now online, emerging techniques in text analysis—particularly using Large Language Processing (LLP) models like ChatGPT—offer promising new approaches to analyzing, understanding content, and comparing plans.

This paper extends our prior research by using ChatGPT-4o to automate qualitative coding of plans. We developed a customized ChatGPT (Resilience-GPT) with prompts based on policy definitions and a dictionary of relevant terms to improve its ability to identify policy statements. As the actionable core of urban plans, policies translate broad goals into concrete directives for government action; without them, plans lack the structure and authority needed to guide decisions and drive implementation. We evaluate performance by comparing machine-coded outputs from the customized ChatGPT and ChatGPT model with manual coding across three policy attributes. This approach enhances methodological rigor and enables more scalable evaluations of plan quality.

Using an exploratory approach, we analyze policies included in the comprehensive plans adopted by two coastal cities. We focused on policies that affect community resilience to coastal flooding and sea level rise, a global concern. The analysis examined land use and environmental policies of both plans, assessing three key attributes: (1) Actionable: policy specifies a course of action to advance plan goals (1 = includes a verb; 0 = not actionable); (2) Physical Impact: policy impacts the physical/built environment (1 = impacts on the physical environment; 0 = does not); (3) Spatial: policy references a specific community location (1 = contains a mappable term; 0 = does not).

Resilience-GPT outperformed ChatGPT in most categories when compared to human coders. In League City, Resilience-GPT showed higher agreement for actionable (78.8%), physical impact (76.1%), and spatial (64.6%) attributes, while ChatGPT scored lower, especially for actionable (30.97%) and physical impact (44.2%). In Tampa, Resilience-GPT again performed better for actionable (91.9%) and spatial (70.3%) attributes, though ChatGPT had higher agreement for physical impact (94.6%). Despite these results, reliability measures for Resilience-GPT were below the 80% agreement threshold, except for actionable policies in Tampa. This indicates that while ChatGPT is not yet a viable substitute for human coding, Resilience-GPT shows promise, given the task's complexity.

Our use of ChatGPT for plan quality evaluation reveals the need for refinement. While it performs reasonably well, given the complexity of the task, its accuracy and consistency must improve. The next phase tests Resilience-GPT on a broader sample, building on models trained with data from two cities. By fine-tuning it with targeted plan sections containing policies, we aim to enhance accuracy across diverse plans. Future work will also apply sentiment analysis to evaluate how policies affect hazard vulnerability, training Resilience-GPT with clear definitions to assess whether policies reduce or increase vulnerability.

While not a substitute for human evaluators, customized models like Resilience-GPT offer a promising approach to efficiently and comprehensively assess and compare plans.

This paper has been submitted to the journal of "Landscape and Urban Planning" and is currently under review.

Urban climate and urban heat island effects, resulting from urban development and expansion, significantly impact human health and well-being. Urban forests play a vital role in regulating urban climate by cooling the ambient environment through shade and evapotranspiration, among many essential ecosystem services. Different human communities have distinct abundances, compositions, and patterns of urban forests, leading to varied cooling effectiveness and microclimate outcomes. While the general consensus is that planting more trees yields greater benefits, there is an increasing need to understand and document the forests' varied taxonomical, structural, and biophysical properties at a more granular scale. This understanding is crucial to predicting and comparing the consequent microclimate conditions across communities. In this study, we utilize high-density airborne point cloud data (58 pulses per m²) to differentiate trees based on their vertical and internal structures. We create a tree family and size classification map for all trees in two socioeconomically distinct communities in Portland, Oregon, USA. The Random Forest classifier, using LiDAR-derived metrics, classifies all tree objects into seven classes with an overall accuracy of 67.1%. Using the classified properties, we simulate and compare these forests' combined air temperature cooling effects and test alternative tree composition scenarios with the object-based ENVI-met model. The simulation results indicate that wealthier communities experience a more significant reduction in 1.5-meter-aboveground air temperature than less wealthy ones (0.23K cooler on average). This disparity in benefits is likely to widen further if current forest evolution trends persist. This study demonstrates a comprehensive workflow from generating object-based knowledge on urban trees to high spatial resolution microclimate simulation of the urban forests' composite effects. This approach can aid in practical urban forest quality monitoring and evaluation, supplement urban planning and management practices, and optimize the urban forest to facilitate cross-community ecosystem services equity.

Comparing Planner-Written Versus AI-generated Summaries of Public Submissions

Abstract ID: 1844.0.0.110.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Wayne Williamson [Macquarie University] wayne.williamson@mq.edu.au, presenting author

Large language models (LLMs) such as ChatGPT have drawn significant societal attention, with applications in everyday tasks like knowledge retrieval, text summarization, question answering, and text generation. In urban planning, emerging interest has focused on using LLMs for tasks like reading plans and analyzing public feedback. However, there is ongoing debate regarding the application of LLMs in the planning process. Moreover, researchers must engage planners in the development and testing of AI tools to improve planners' knowledge and perceptions of AI usefulness for planning practice.

The aim of this paper is to contribute to current literature on AI in urban planning with a focus on the research questions: How does a planner-written public submissions summary compare to an AI-generated summary? And What are the linguistic characteristics of planner versus AI-generated summaries? To address these questions, this paper uses linguistic analysis to investigate the similarities and differences between planner- and AI-generated public submissions summaries. By analyzing linguistic attributes such as word groupings, word usage, sentence lengths, and unique or repetitive phrases, this study seeks to identify key differences between the two types of text. Semi-structured interviews were also conducted with planning staff who wrote the public submissions summary to gain insights into how public submission reports are written by planners.

Drawing on 7,932 public submissions received in response to the public exhibition of an Explanation of Intended Effect: Changes to create low- and mid-rise housing by the Department of Planning and Environment (Sydney, Australia) in December 2023, we use ChatPDF to generate a summary of the 10 most common issues raised in the public submissions. ChatPDF (www.chatpdf.com) is an online software platform that utilizes the ChatGPT-4o model to allow users to engage with PDF documents. This recent concept is known as the Retrieval Augmented Generation (RAG) method. In basic terms, the user query or command is combined with relevant content from the PDF file(s), which is then passed to ChatGPT to generate a response. The RAG method is an alternative to the more technical process of fine-tuning an LLM with domain specific knowledge. Linguistic analysis of the planner-written and AI-generated public submission summaries was then undertaken using Nvivo.

The analysis reveals that ChatPDF replicated 4 of the 10 most common issues planners identified in their public submissions report. A further 4 common issues were partially identified but given different titles, while 2 common issues identified by ChatPDF were not discussed by the planners. At the syntactic level, the word length of the planner's summary is longer than that in ChatPDF's summary. The planners used shorter sentences. Both summaries used a similar number of unique words, while planners used more stopwords. The analysis indicates that planners exhibit a more nuanced language structure in their writing. A significant difference between the submission summaries is word usage from the submissions. The AI-generated summary exhibits a more negative tone by using phrases like "perceived failure", "widespread apprehension" and "raised alarms". The planner-written summary does not reproduce negative sentiment verbatim from the public submissions.

The use of LLMs in urban planning research and practice to support routine and repetitive writing tasks is almost inevitable and likely already occurring to some extent. While LLMs such as ChatGPT can produce text that is somewhat like human writing, it is important to understand how AI-generated texts differ from planner-written texts. This paper provides insights into the linguistic characteristic of each.

Computer Vision and GenAI Empowered Urban Design Workflow

Abstract ID: 1844.0.0.1179.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Waishan Qiu [The University of Hong Kong] qiuwaishan@126.com, presenting author

Yuankai Wang [The University of Hong Kong] yuankaiwang108@connect.hku.hk

This paper envisions a novel integration of computer vision (CV) and generative artificial intelligence (GenAI) into urban design (UD) workflow and pedagogy. Urban designers today confront increasingly complex challenges as cities function as dynamic, multi-layered systems—a prevailing concept extensively discussed by scholars yet challenging to incorporate into UD practice. Despite rapid digitalization in other fields (e.g., finance, biology, and even the sibling subject, architecture —where technologies like AR/VR, BIM, and digital twins are widespread) - UD practice continues to rely on "outdated" tools like SketchUp or complicated GIS systems. We propose a new paradigm bridging the gap between UD education and practice by leveraging fine-tuned CV and GenAI applications to streamline and enhance three critical phases of the entire UD workflow (Gan et al., 2024; Jiang et al., 2024): 1) 24-hour site information collection through image generation, 2) user behavior prediction without GIS dataset enabled by customized CV and GenAI models on satellite imagery, and 3) iterative design ideation supported by GenAI. We seek to transform UD curricula and pioneer practical toolkits for educating next-generation urban designers, revolutionizing UD workflow into a collaborative, data-light, and responsive framework, addressing the discipline's longstanding challenges of complexity, data dependency, and slow iteration. It will also cultivate UD students' computational literacy, creative problem-solving, and critical analysis through a human-AI co-design framework.

Context: UD faces increasingly complex challenges due to the multi-dimensional nature of cities - a "complex system" (Batty, 2009) that is constantly evolving and influenced by multiple, often competing factors. With that said, the nature of urban designers' tasks is to work with vast amounts of data and stakeholders, necessitating advanced digital tools being carefully designed and fine-tuned.

Although the concept of Computer-Aided Design (CAD) can be traced back to the 1960s (Negroponte, 1975), it has not fundamentally broken through the built environment discipline's research innovation. Despite advancements in other industries, the digitalization of UD workflows remains low. Many firms continue to rely on outdated tools that require large amounts of data and slow computation times, hindering real-time, evidence-based design decision-making. The rapid adoption of Large Language Models (LLM) such as ChatGPT and GenAI-based tools in the broader design fields is an industrial revolution—one that is inevitable. A stark contrast to the rapid adoption of GenAI technologies in sectors like banking (e.g., GPT in customer service and trading) and even our sibling subject - architecture (e.g., AR/VR, BIM), where technologies such as Stable Diffusion and Midjourney have rapidly proliferated, UD, however, has yet to harness such advances fully.

To bridge the gap, we introduce GenAI tools (e.g., Pix2Pix, CycleGAN, and Diffusion) to modernize the UD workflow, enabling faster iterations, data-driven insights, and creative flexibility, allowing students to predict user behavior, generate day-to-night design transitions, and explore multi-modal design spaces efficiently throughout the entire UD workflow. The project will enable students to expeditiously generate solutions that traditionally require complex GIS simulations or extensive manual data collection. In essence, we envision this integration as the next

evolutionary step, akin to how efforts from Hillier (2015) in introducing Space Syntax broke through the bottleneck between urban studies and computational science.

Decoding Urban Spatial Rhythms: An Integrated Big-Small Data Approach for Activity Pattern Analysis

Abstract ID: 1844.0.0.274.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yinong Liu [Tongji University] liuyn0416@outlook.com, presenting author

Yang Hu [Tongji University] huyang@tongji.edu.cn

As Jane Jacobs famously observed, the essence of vibrant urbanism lies in the complex "ballet of the sidewalk"—the diverse, overlapping patterns of human activity that generate urban vitality. Today, this ballet has intensified and accelerated, fundamentally transforming urban operational mechanisms and daily rhythms globally. Understanding human activities—their spatial distribution, temporal patterns, and interactions—is increasingly critical for sustainable urban planning, as these activities directly shape resource consumption, infrastructure demands, and environmental impacts. Traditional static analytical methods relying on Points of Interest and land use classifications fail to capture the dynamic nature of urban functionality and temporal variations in space utilization.

This study proposes a novel computational approach integrating big-small data fusion techniques to analyze urban spatial rhythms across various spatial units. Our methodology combines the extensive coverage of mobile phone signaling data with detailed insights from time-use surveys, creating a comprehensive technological framework for understanding urban temporal dynamics through advanced spatial analytics.

Using Shanghai as a case study representative of rapidly growing global metropolitan areas, we identified seven distinct daily activity patterns through computational clustering: maintenance and sleep, purchasing commodities, exercise and leisure, employment and education, eating and drinking, medical care, and travel. Through our decomposition algorithm, we extracted activity weights and dynamic population changes across spatial units. Statistical validation showed high goodness of fit ($R^2 = 0.94$) between decomposition results and employment data, while field validation confirmed the method's ability to identify primary activity patterns in specialized functional areas.

Our findings reveal three critical dimensions of urban activity dynamics: (1) spatial distribution patterns showing varying degrees of facility dependency across activity types; (2) temporal evolution of activity intensities demonstrating distinctive urban rhythms; and (3) complex functional combinations forming characteristic patterns of single-functional and multi-functional zones. These insights provide nuanced understanding of how urban spaces transform throughout daily cycles.

This methodology offers particular value for rapidly urbanizing regions in developing countries facing challenges of explosive growth, informal development, and limited planning resources. By leveraging widely available mobile data, our approach provides an accessible solution for cities with constrained technical capacity. The framework can be adapted across international contexts to address challenges of uneven development, infrastructure planning, and resource allocation in Global South megacities. The approach bridges the technological-methodological gap in activity-based urban analysis while offering practical applications in dynamic functional zoning, targeted service provision, and temporally-responsive urban management strategies.

Digital Mapping of Urban Imageability: A GIS-Based Assessment of Urban Image in San Antonio, Texas

Abstract ID: 1844.0.0.510.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Ryun Jung Lee [University of Texas at San Antonio] ryunjung.lee@utsa.edu, presenting author

Nico Molina [University of Texas at San Antonio] nico.molina@my.utsa.edu

Elliott Coleman [University of Texas at San Antonio] elliott.coleman@my.utsa.edu

The image of a city and the characters of its communities are fundamental to social and economic vitality, enhancing livability and attracting residents and visitors. However, market-driven urban sprawl and suburbanization have weakened the character of many urban areas. While communities with a strong character can attract new investments and younger, professional populations, such changes may sometimes disrupt the established community fabric, triggering gentrification. Developing a methodology to quantify the imageability brings the opportunity to examine development patterns in urban fabrics and provide a tool that can be used in diagnosing community characters in diverse urban contexts. The concept of city imageability has been primarily explored through cognitive mapping on five urban form elements – paths, nodes, landmarks, districts, and edges – introduced by Kevin Lynch (1964). Since then, only a handful attempted to digitally measure imageability using advanced tools such as network science techniques and social media analyses, visualizing Lynch's five elements on a digital map (Wessel et al. 2018; Filomena et al. 2019). However, there has not been an attempt to quantitatively diagnose the level of imageability across communities to calculate imageability index scores and analyze their relationship with local economic performance and investment patterns.

This study aims to suggest a new methodology to quantitatively measure urban imageability as a community diagnostic tool and evaluate its relationship with local economic performance and investment patterns through socioeconomic and gentrification measures. The overarching research question is: How does urban imageability, as quantified by Kevin Lynch's five elements, correlate with local socioeconomic characteristics and gentrification patterns in San Antonio? To answer this question, this study developed a GIS-based assessment of urban image and created an imageability index using San Antonio, Texas as a testbed. The imageability index was developed with the Open Street Map (OSM), an open-source data that supports the bottom-up approach Liu (2016) suggested in providing cognitive maps from the public. Another benefit of using OSM was its availability in varying cities globally, which helps to replicate the methodology. Using OSM, an overall Urban Imageability Index was produced by averaging the density values of all five elements at the census tract level using Kernel density analysis, yielding comprehensive scores between 1 and 10. The imageability scores were then compared with socioeconomic and gentrification measures – changes in property values, shifts in demographics (e.g., income and race), and new development patterns. Using multivariate regression models, we examined if socioeconomic characteristics, economic performance, and potential gentrification processes predict the imageability scores.

The results suggest that the overall high imageability score is significantly correlated with older building age and lower single family household proportion. When compared with the socioeconomic characteristics such as race and income, lower income Hispanic communities tend to have a higher imageability score. This reflects San Antonio's current demographic landscape, where historically marginalized Mexican American communities have endured long-term economic challenges. Yet their rich cultural heritage and strong community identity have significantly enhanced the area's imageability. This study offers a robust and replicable index mapping methodology to visually and quantitatively measure urban imageability, as a tool that can diagnose critical urban issues such as

gentrification, economic viability, and social vulnerability. Urban Imageability Index can identify underlying drivers that erode the imageability, providing a basis for targeted interventions to enhance community characters.

Do green space accessibility analyses vary by which data source you use?

Abstract ID: 1844.0.0.453.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Jiyeon Kim [University of Southern California] kimjiyoo@usc.edu, presenting author

Geoff Boeing [University of Southern California] boeing@usc.edu

Jaehyun Ha [University of Southern California] jaehyunh@usc.edu

Ruoyu Chen [University of Southern California] rchen912@usc.edu

Daniele Simon-Thompson [University of Southern California] simontho@usc.edu

Urban parks promote physical activity, public health, and overall well-being. However, measuring accessibility to these green spaces relies on spatial data sources that vary in coverage, accuracy, and digitization standards—potentially introducing bias into accessibility analyses. Due to the uneven representation of different communities in digital data, this bias could particularly undermine our understanding and provisioning of accessibility for underserved and disadvantaged communities.

This study investigates how data source selection influences park accessibility measures by 1) validating the accuracy of several common data sources that are each supposed to be complete and then 2) assessing their impact on calculated accessibility measures. It focuses on large public urban green spaces (LPUGS) and compares three widely used open data sources, OpenStreetMap, the Trust for Public Land (TPL), and Esri, to validate these LPUGS from different data sources against real-world park locations using satellite images and Google Street View. We select three validation study sites - Portland, Buffalo, and Vicksburg - representing variations in size, population, geographic region, and socio-demographic characteristics. Two researchers independently validate each LPUGS in terms of: (1) whether the sample represents a real-world LPUGS at this location using Satellite Images and Google Street View and (2) whether more than one sample represents the same real-world LPUGS. Then we calculate each data source's accuracy through precision, recall, and F1 scores.

After validation, we perform a network-based isochrone analysis at 15- and 30-minute walking thresholds to quantify park access through 1) the cumulative count of parks within each isochrone and 2) the cumulative park area within each isochrone. Then we test how park accessibility measures vary depending on the data source used. We hypothesize that these differences lead to different estimates of the number and total area of accessible parks, affecting how spatial equity is understood by researchers and planning practitioners.

We find that park accessibility measures do vary significantly depending on the data source used, which can bias empirical findings and policy decisions. In particular, OpenStreetMap and TPL capture more real-world parks but also have more false positives, whereas Esri has higher precision but lower recall, potentially underestimating access. These differences lead to different estimates of the number and total area of accessible parks, affecting how spatial equity is understood by researchers. We argue that relying on a single data source may introduce bias, underscoring the need for careful selection in accessibility research. This talk concludes with guidelines for planning scholars and practitioners to improve data source selection and use data-driven methods to mitigate data bias in accessibility analyses to improve park accessibility for all.

Enhancing Home-Work Commuting Prediction for Decarbonized and Climate-Resilient Transport Planning

Abstract ID: 1844.0.0.1043.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yu Han [Department of Land Economy/University of Cambridge] hanyu.bit@gmail.com, presenting author

Li Wan [Department of Land Economy/University of Cambridge] lw423@cam.ac.uk

Understanding home-work commuting patterns is critical for addressing transport planning challenges, including transportation decarbonization, infrastructure resilience, and equitable access to employment (Cabanias-Tirapu et al., 2025; Tsutsumi & Tamesue, 2012). This study addresses two research questions: (1) How do traditional and emerging deep learning approaches compare in predicting home-work commuting flows across UK local authority districts (LADs)? (2) How do socioeconomic variables, spatial dependencies, and network structures shape commute behaviors? By tackling these questions, the research responds to the urban planning imperative of developing robust tools to forecast mobility patterns for sustainable future transport system under evolving demographic and economic changes, and climate disruptions.

The study develops and evaluates three models: a standard gravity model, a spatial econometric model, and a graph neural network (GNN). Data from the UK and Scotland Censuses were harmonized at the LAD level, integrating variables including population, household characteristics, housing rents, travel mode share, and travel times. The gravity model served as a baseline, using population and distance to predict flows. The spatial econometric model extended this by incorporating spatial dependencies between origin-destination pairs (LeSage & Pace, 2008). The GNN model, designed to capture non-linear relationships and network effects, treated LADs as nodes in a graph, with edges weighted by travel times and distances, while integrating node-level socioeconomic features.

Results in this study reveal significant differences in model performance. The GNN model achieved the highest predictive accuracy, highlighting its ability to model complex spatial and relational patterns. The spatial econometric model outperformed the gravity model, underscoring the role of regional interdependencies, such as spillover effects from neighboring areas, in shaping commuting flows. Feature importance analysis in the GNN identified population size, household counts, and private housing rents as critical predictors. Edge features, including travel times and distances, plays significant roles in measuring mobility patterns. These results suggest that commuting flows are shaped by multi-scalar socioeconomic dynamics and spatial network structures.

This study demonstrates the value of integrating machine learning and deep learning approaches for mobility analysis, which could be further applied to measure future commuting patterns under alternative decarbonization and adaptation policies, as well as climate disruptions. For example, future studies could apply these models to predict commuting shifts under scenarios such as increasing telecommuting adoption, accelerated electric vehicle uptake, and intensifying climate-induced risk to public transport systems. The harmonized UK-wide dataset supports data-driven decision-making for the DARE project, which aims to align sustainable transport planning with decarbonization goals and adaptation strategies. A key limitation of this study is the reliance on static census data, which underscores the need for longitudinal, high-resolution mobility datasets to enhance temporal forecasting.

Transportation infrastructure can facilitate the flow of people, goods, and information through cities (Bettencourt, 2021). However, as planners recognize, highways and other large facilities can also create barriers to walkable, accessible, and human-scale neighborhoods (Anciaes et al., 2016). This awareness has influenced a movement towards highway removal in the United States that is complemented by the desire to address the harms caused to communities by federally-funded highway construction (Mohl, 2012).

Between 2022 and 2024, the U.S. Department of Transportation's Reconnecting Communities Pilot (RCP) Program and Reconnecting Communities and Neighborhoods (RCN) Grant awarded approximately four billion dollars to projects that seek to remove, retrofit, mitigate, or replace existing facilities in order to reconnect communities harmed by past transportation infrastructure decisions. At present, however, there are few existing quantitative tools well-suited to assessing prospective and awarded projects based on their impacts on social connectivity rather than their impacts on mobility flows, trip routing, and other more immediate travel effects (van Eldijk et al., 2022). In this paper, we offer an easy-to-use toolset to quantify the impact of transportation barriers on social networks and apply it to 54 planning or capital construction projects financed by RCP and RCN.

Our method involves overlaying a selection of RCP and RCN project-identified barriers with spatial social networks constructed from Twitter mutual followership edges between geolocated users in 32 U.S. Core-Based Statistical Areas (CBSAs). For each site, we calculate a barrier score that compares the number of edge crossings in the real social network to the number of edge crossings averaged over randomized social networks (Aiello et al., 2025). These randomized networks are designed to preserve the location of nodes and the approximate length of edges but to rewire ties based on spatial gravity models that are insensitive to the presence of the highways expected to shape real world social relationships. We then contextualize the barrier scores by exploring associations with local-level data on income distributions, demographics, transit availability, land-use patterns, and more. Focusing on differences that are statistically significant, our findings suggest that some projects may have substantial potential to enhance social connectivity because they target highway segments with high barrier scores, while others seem likely to have a limited impact by this network-based measure.

This approach represents a first step towards a scalable, social network based toolset for policymakers and transportation planners interested in assessing whether existing or planned urban infrastructure projects cause barrier effects or community severance. We briefly discuss software and strategies that may assist in making these analyses faster and more accessible and identify paths for future research based on our exploration of RCP and RCN projects.

Examining the Association Between Urban Form and Carbon Emissions: Evidence From Seoul, South Korea

Abstract ID: 1844.0.0.304.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yuseok Lee [Chungbuk National University] yurakuma@chungbuk.ac.kr, presenting author

Cheolhee Yoo [NASA Jet Propulsion Laboratory] yoclhe13@gmail.com

Minjun Kim [Chungbuk National University] min2412@cbnu.ac.kr

As cities account for a majority of global greenhouse gas (GHG) emissions, understanding how the physical form of urban environments influences energy consumption and carbon intensity is critical to formulating effective mitigation strategies. Despite increasing interest in spatially informed climate policies, existing research often overlooks the role of built form heterogeneity in shaping emission patterns. This study aims to address this gap by integrating high-resolution Local Climate Zone (LCZ) classification with spatial analysis of building-sector GHG emissions in Seoul, South Korea—a megacity characterized by diverse urban morphologies and high energy demand.

To classify LCZ types at scale, we applied a Convolutional Neural Network (CNN) model trained on Landsat 8 imagery and manually validated training areas across the Korean peninsula. The model produced a 100-meter resolution LCZ map with an overall classification accuracy of 83.3%, and particularly high performance for natural-type zones. Using this map, we extracted the LCZ types for 100m grid cells covering the Seoul metropolitan area and spatially linked them to grid-level energy consumption and emissions data. The GHG dataset was constructed from public building-level electricity and city gas usage records, provided via Ecoeye and the Forest Big Data Exchange. Emissions were calculated using standard CO₂ emission coefficients and normalized by the gross floor area (GFA) of each building, allowing us to estimate per-square-meter carbon intensity (CO₂eq/m²) for each grid.

Our results reveal clear spatial and seasonal variation in GHG emissions across different LCZ types. Compact zones (LCZ 1–3), characterized by dense, mixed-use, and vertically oriented buildings, consistently exhibited lower emission intensities across seasons. In contrast, open and low-density LCZ types (LCZ 4–6 and LCZ 9) showed significantly higher emissions, especially during periods of peak energy demand in summer and winter. For instance, LCZ 4 (Open high-rise) recorded the highest electricity-based emissions, while LCZ 5 and 6 demonstrated pronounced increases in gas consumption during colder months. These patterns suggest that urban density and spatial configuration directly influence heating and cooling energy demand, and hence, carbon outcomes.

In addition to within-grid characteristics, we examined the influence of surrounding LCZ environments using spatial regression models. The results confirmed significant spatial spillover effects: grids adjacent to high-emission LCZ types such as industrial or open residential zones showed elevated emissions themselves, even when their own built form was more carbon-efficient. This highlights the importance of considering not only local but also neighboring spatial structures in urban climate planning.

The methodological contribution of this study lies in the use of CNN-based LCZ mapping to overcome the limitations of conventional land cover data, which often lack climate-relevant resolution and functional accuracy. By combining this with normalized GHG emission data and multi-variable Ordinary Least Squares (OLS) regression, we demonstrate a scalable and replicable approach for quantifying the relationship between urban morphology and carbon performance.

Our findings offer practical implications for urban planning and policy. LCZ-based classification enables the identification of high-emission zones, the targeting of climate interventions, and the design of customized carbon reduction pathways that reflect the spatial complexity of real-world cities. As climate mitigation efforts become increasingly spatialized, tools that integrate remote sensing, deep learning, and environmental data will play a central role in shaping equitable and effective low-carbon urban futures.

Expert vs. Data-Driven Bike-Equity Measures: A Granular Analysis for the Bay Area

Abstract ID: 1844.0.0.444.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Ahoura Zandiatashbar [San Jose State University] ahoura.zandiatashbar@sjsu.edu, presenting author

Mona Hashemi-Yazdi [University of Texas at Arlington] mona.hashemi.yazdi@gmail.com

Equity in bicycle infrastructure remains a core challenge for transportation planning, particularly in rapidly urbanizing and economically diverse regions. This study presents a comparative analysis of bicycle equity measures for the San Francisco Bay Area, using a consistent set of 21 indicators applied at the census block group level. These indicators—covering infrastructure, demand, and social vulnerability—were identified through an expert survey involving regional planners, transportation advocates, and equity-focused practitioners.

We develop and compare three different bicycle equity indices: (1) an expert-informed model using weights derived from a Delphi process, (2) a data-driven model constructed using Principal Component Analysis (PCA), and (3) a GIS-based weighted overlay index. The expert-driven model aligns with a supply-demand framework, reflecting practitioner priorities on where infrastructure is most needed and which populations are most underserved. In contrast, the PCA approach extracts latent dimensions purely from statistical variance, without incorporating normative judgments. The GIS overlay model serves as both a spatial synthesis and a communication tool, applying weights in a layered decision-support format that can reflect either expert-defined or equal-weight assumptions.

To statistically compare the models, we apply paired-sample t-tests, Pearson correlation, and spatial autocorrelation techniques such as Local Indicators of Spatial Association (LISA). Our results reveal that equity rankings differ substantially across methods. Notably, block groups in Oakland and East San José consistently rank high in the expert-weighted and GIS overlay models—due to factors like infrastructural gaps, low vehicle access, and income-based need—but receive lower equity scores in the PCA-based index. This suggests that purely statistical approaches may overlook key dimensions of transportation justice when indicator weights are not guided by community-informed values.

This research provides a robust methodological framework for integrating expert knowledge with spatial and statistical tools in transportation equity analysis. For academic audiences, it highlights the epistemological implications of index construction and offers insight into the trade-offs between normative and empirical approaches. For planning practitioners, the findings demonstrate the importance of transparent and context-sensitive modeling methods when prioritizing investments in bicycle infrastructure at fine spatial scales. Together, these approaches offer a path toward more just, data-informed, and actionable transportation planning.

Explaining the “Why” of Urban Perception at Scale: A Context-Sensitive Generative AI Framework

Abstract ID: 1844.0.0.507.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Tim Guangyu Wu [New York University] gw923@nyu.edu, presenting author

ChengHe Guan [NYU Shanghai] cg157@nyu.edu

Understanding how people perceive urban environments is essential for designing safer, livelier, and inclusive cities. To assess these perceptions at scale, planning researchers often rely on deep learning models applied to street view imagery. While effective at predicting scores, these models lack the capacity to explain complex human perception due to their reliance on predefined visual categories and manually crafted indices. Recent efforts to apply large language models (LLMs) for perception scoring offer some interpretability but remain influenced by researcher-defined aspects, providing limited insight into the reasoning behind specific perceptions. To overcome these limitations, we propose a novel approach that uses LLMs with vision capabilities to simulate how humans experience a scene, providing detailed, context-sensitive explanations of ratings to uncover the mechanisms of urban perception.

We applied our method to the widely used Place Pulse 2 dataset and retained 77,006 images after robustness-based filtering. We used LLMs to generate approximately six reasons per image per perception dimension, producing over three million explanations. Using human-voted scores as ground truth, we inferred the contribution and directionality of perception factors and validated the plausibility and coherence of the explanations by comparing them with human annotations. To extract meaningful insights from the large volume of explanations, we utilized BERTopic clustering and part-of-speech tagging to identify common themes and patterns. This systematic analysis organized the unstructured data into a coherent framework of insights. Additionally, we used the open-vocabulary detection model Grounding DINO to validate the presence and prominence of visual elements described in the explanations.

Our analysis produced a hierarchical typology with high-level categories encompassing social, natural, and built environment factors. At a more granular level, we identified more than a dozen thematic factors with adaptable subcategories that reflect regional and contextual variations. The typology also helps resolve contradictions in the literature by illustrating how differences in environmental characteristics shape urban perception. For example, while greenery generally fosters positive perceptions, it can have the opposite effect when poorly maintained or located in socially isolated areas. Similarly, density often enhances vibrancy but may lead to discomfort in overcrowded environments. In addition to clarifying these nuanced effects, our analysis uncovered emerging factors often overlooked in prior studies and revealed significant regional differences and variations along the urban-rural gradient. This flexible typology offers transferable insights across different urban contexts while allowing for localized adaptation, enabling planners to respond to specific needs and feedback.

By introducing a human-centered, explainable framework, our study deepens the understanding of urban perception mechanisms. Our two-stage process first enables LLMs to generate rich, context-specific explanations without restrictive instructions, then applies systematic analysis to extract patterns and transferable insights. This approach addresses key limitations of previous models and provides a flexible framework for further research and transparent, evidence-based decision-making. To mitigate the risk of LLM hallucinations, we incorporated validation and verification throughout our framework. Rather than applying AI to planning as a detached tool, our approach embodies a planning-relevant AI paradigm — a method grounded in urban knowledge that centers human perspectives and directly addresses planning challenges. Our open-source tools will facilitate the adoption

and adaptation of this framework across diverse settings, empowering researchers and practitioners to generate actionable insights and inform context-specific urban design and policy decisions.

Exploring the Potential and Bias of Generative AI in Assessing Pedestrian Safety Perceptions

Abstract ID: 1844.0.0.892.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Xi Guan [Cornell University] xg298@cornell.edu, presenting author

Armita Kar [Department of Geography and Geoinformation Science, George Mason University] akar3@gmu.edu

Pedestrian safety perception plays a crucial role in shaping both community dynamics and individual behavior. However, understanding travelers' perceptions of walking safety typically requires costly, labor-intensive surveys with limited sample sizes. Based on large-scale corpus, Generative AI (GenAI) can quickly and affordably simulate human safety perceptions on a large scale. Despite this potential, the representativeness and accuracy of such simulations remain unknown, especially for minorities and low-income communities.

This research examines the discrepancies between walking safety perceptions collected from GenAI and humans. We conducted a pedestrian safety perception survey based on Google Street View images (n = 331 with 12,596 images) in Columbus, Ohio. We then prompted ChatGPT, a leading Generative AI platform, to simulate the respondents' safety perceptions based on their locations and their demographic profiles. The AI-generated responses were then systematically compared with actual resident feedback. We used a logistic regression model incorporating resident demographics, neighborhood socio-economic profiles, road network characteristics, and built environment features of road segments.

We found that GenAI tends to overestimate walking safety perceptions of White respondents and male respondents. GenAI also tends to underestimate perceived safety in areas with higher population density, better road connectivity, and more regular street layouts. Conversely, GenAI tends to overestimate actual perceived safety in areas with high proportions of commercial land use and greater greenery visible in street imagery.

This study is the first to systematically uncover the potential and biases in generative AI's simulation of pedestrian safety perceptions across specific demographics and urban contexts. It highlights significant socio-economic and urban spatial factors contributing to these biases, emphasizing the need for future research aimed at enhancing the fairness and accuracy of AI-driven urban perception predictions. These insights have critical implications for guiding the equitable integration of AI tools into urban decision-making processes.

Exploring Tipping Points in Commercial Decline: Transitions in Multidimensional Urban Vitality

Abstract ID: 1844.0.0.977.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Jiwoong Jeong [Ulsan National Institute of Science and Technology, UNIST] civil94@unist.ac.kr, presenting author
Jeongseob Kim [Ulsan National Institute of Science and Technology, UNIST] jskim14@unist.ac.kr

Urban spatial change is often nonlinear, with incremental, fragmented shifts accumulating until they surpass a threshold, leading to sudden structural transformations (Batty, 2008). This is observed in both residential neighborhoods (Galster, 2018) and commercial districts, which are central to pedestrian activity and consumption. Early signs of decline, such as store closures or vacancies, may appear transient, but when combined with worsening vacancy, declining activity, and environmental degradation, these factors create a negative feedback loop that accelerates commercial decline (Hollander et al., 2018; Koster et al., 2019).

This decline is not only economic but also visible and social, with vacant storefronts, absent signage, and reduced pedestrian activity indicating the loss of vitality (Zukin et al., 2015). Once a tipping point is crossed, recovery becomes unlikely, and the area may enter an irreversible decline, aligning with nonlinear urban change theory (Hollander et al., 2018).

In this context, this study identifies tipping points in commercial decline by analyzing structural shifts in commercial vitality alongside visual, functional, and economic indicators. The research addresses: (1) Does a tipping point exist in the process of commercial street decline? (2) How do visual landscapes, business composition, and economic activity change before and after these tipping points?

To address these questions, we constructed a multimodal dataset comprising monthly building-level electricity consumption, points of interest (POI) data, employment statistics, and Street View images for major commercial districts in South Korea. Aggregated building electricity consumption at the commercial district level was used as a proxy for commercial vitality, and its validity was confirmed through correlations with pedestrian traffic and gross sales data within these districts. Tipping points of commercial decline were identified using spline regression and Multivariate Adaptive Regression Splines (MARS), methods designed to detect nonlinear shifts in vitality. For each tipping point, we compared changes in physical, economic, and business characteristics before and after the tipping point using t-tests or other statistical methods. Specifically, we analyzed Street View images using GPT-4o-based large multimodal models (LMMs) to classify visual indicators of decline, such as vacant storefronts and the loss of signage. Changes in business diversity and the number of jobs were assessed using POI and employment data.

This study provides empirical evidence of abrupt structural transitions in urban change, as observed in the decline of commercial streets. It also offers a methodological framework and diagnostic tools for evaluating commercial decline. The findings provide new insights for urban planners and policymakers in addressing retail decline and commercial revitalization.

Fine-Tuning LLMs for Online Planning Participation Facilitation

Abstract ID: 1844.0.0.94.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Connor Phillips [The University of Texas at Austin] connorphillips@utexas.edu, presenting author

Junfeng Jiao [University of Texas at Austin] jjiao@austin.utexas.edu

Public participation in urban planning processes remains constrained by technical jargon, power imbalances, and unequal access to participation opportunities. This research addresses the question: How can fine-tuned Large Language Models (LLMs) improve online public participation by making technical information more accessible and facilitating online discussion and idea sharing? While generalized LLMs have demonstrated capabilities in knowledge translation, they lack domain-specific expertise suited to the complex socio-technical challenges of urban planning participation.

This study will implement a novel methodological approach combining LLMs, agent-based AI, and established discursive frameworks. We will fine-tune an LLM using datasets primarily drawn from established community dialogue and facilitator training guidebooks that emphasize inclusive discussion techniques, conflict mediation, and power balancing strategies. These materials will be supplemented with planning-specific content, including technical document translations and planning dialogue transcripts, though the exact composition of planning materials remains flexible as we identify sources. This fine-tuning approach prioritizes enhancing facilitation quality while incorporating domain knowledge.

To evaluate effectiveness, we will conduct controlled experiments using simulated planning discussions with AI agents representing diverse stakeholders engaged in deliberation. These discussions will be facilitated by either a standard LLM or our fine-tuned model. We will employ a guided evaluation (G-Eval) framework—a structured assessment methodology using an independent evaluator LLM to quantitatively score facilitation quality across multiple dimensions. These include facilitation effectiveness, information accessibility, inclusivity metrics, and discussion outcomes. This blind evaluation will compare transcripts from both facilitation conditions using a standardized rubric.

We anticipate discussions facilitated by the fine-tuned model will demonstrate improvements in key metrics: more balanced participation, more accurate translation of technical concepts, greater inclusion of marginalized perspectives, and higher participant satisfaction. The fine-tuned model is expected to develop specialized capabilities in recognizing planning jargon, addressing power imbalances, and contextualizing technical requirements.

This research contributes to planning scholarship by developing quantitative metrics for evaluating participation quality in technologically mediated discussions. While focusing initially on AI-simulated discussions, this methodology establishes a foundation for future research involving human participants, providing a thoroughly tested model before deployment in a community setting. For planning practice, it offers a scalable approach to enhancing public participation that could supplement traditional engagement methods while reaching underrepresented communities. For planning education, it provides insights into communicating technical knowledge across barriers.

Floods that matter? Modelling multiple sources of flash flood reports in New Jersey

Abstract ID: 1844.0.0.492.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Sean Lamb [Rutgers University] sel163@scarletmail.rutgers.edu, presenting author

Bernadette Baird-Zars [Rutgers University] b.bz@rutgers.edu

Amara Thompkins [Rutgers University] ast182@scarletmail.rutgers.edu

Flash floods are particularly thorny to understand: they come quickly, can change course in seconds, and are most sensitive to unevenly enforced terrains of permits, pavements, and pipes. Despite computational and data advances in the fixed inputs typically used by risk modeling, accurate local predictions remain elusive, and officials and impacted frontline communities rarely find models to be of practical use. We draw on recent work on co-produced and community-led epistemologies as well as machine learning models to trace 'backwards' from reported flash flood incidents. Reported events reflect human interest, visibility and privilege of many forms, and we attempt to highlight these biases through signals from local government and frontline communities.

We use a layered mixed-methods approach to identify areas of risk, and also to tease at an underpinning theoretical curiosity: when, how and what types of flash flooding knowledge are used, and by whom? In our machine learning component, we combine events from the US National Oceanic and Atmospheric Administration's Storm Event Database with risk factors and non-flood points to train random forest model, which we evaluate at 300-foot intervals across the state of New Jersey. This builds on literature using crowdsourced data on flash flood hotspot and other hazard events, such as from 311 sources (Liu et al, 2024) or waze data (Esparza et al 2023). Others use community and crowdsourced data primarily to check errors and groundtruth flood forecasting data (e.g. Puttinaovaratt and Horkaew, 2020). We use a random forest model; variations of this have often been found to be most effective for flash flood modelling (Band et al 2020; Liu 2024), or at least relatively similar in accuracy to other approaches (Arabameri 2020; Hosseini et al 2020). This model is then contextualized and critiqued by more precise sources, such as county and municipal alerts, local community-based networks and social media groups. Our initial findings raise further questions on how multiple sources of knowledge can make sense and be of use to a range of residents, decision-makers, and community organizations at the frontlines of flash flood harm and response.

Teng Fei [Wuhan University] feiteng@whu.edu.cn

Yonggai Zhuang [Wuhan University] 2019301030116@whu.edu.cn

People experience the world through multiple senses simultaneously, contributing to our sense of place. Prior quantitative geography studies have mostly emphasized human visual perceptions, neglecting human auditory perceptions at place due to the challenges in characterizing the acoustic environment vividly. Also, few studies have synthesized the two-dimensional (auditory and visual) perceptions in understanding human sense of place. To bridge these gaps, we propose a Soundscape-to-Image Diffusion model, a generative Artificial Intelligence (AI) model supported by Large Language Models (LLMs), aiming to visualize soundscapes through the generation of street view images. By creating audio-image pairs, acoustic environments are first represented as high-dimensional semantic audio vectors. Our proposed Soundscape-to-Image Diffusion model, which contains a Low-Resolution Diffusion Model and a Super-Resolution Diffusion Model, can then translate those semantic audio vectors into visual representations of place effectively. We evaluated our proposed model by using both machine-based and human-centered approaches. We proved that the generated street view images align with our common perceptions, and accurately create several key street elements of the original soundscapes. It also demonstrates that soundscapes provide sufficient visual information places. This study stands at the forefront of the intersection between generative AI and human geography, demonstrating how human multi-sensory experiences can be linked. We aim to enrich geospatial data science and AI studies with human experiences. It has the potential to inform multiple domains such as human geography, environmental psychology, and urban design and planning, as well as advancing our knowledge of human-environment relationships.

From Statehouse to City Hall: Mapping the 50-State AI Regulatory Landscape

Abstract ID: 1844.0.0.522.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yesim Sungu- Eryilmaz [Boston University] yesims@bu.edu, presenting author

Artificial intelligence (AI) has potential to transform urban governance by reshaping how cities manage infrastructure, deliver services, and automating decision-making. However, in the United States, AI regulation is largely decentralized and emerging at the state level—creating a fragmented legal landscape with direct implications for local governments. While cities are often responsible for implementing AI tools, they must do so within the boundaries set by state policy. Despite AI's growing role in urban management, there is limited understanding of how state governments are regulating AI and what this means for cities. This study addresses this research gap by conducting a 50-state content analysis of AI-related legislation to explore how regulatory approaches vary and what these differences imply for urban planning and governance.

The central research question guiding this study is: How are U.S. state governments regulating artificial intelligence, and what are the implications for urban governance and planning? The study aims to (1) map the scope and themes of AI legislation across states, and (2) identify patterns in regulatory focus that may influence how cities govern AI adoption.

Existing scholarship highlights both the opportunities and risks of AI in cities—from improved efficiency to ethical concerns like bias, surveillance, and accountability (Kitchin, 2016; McGuirk et al., 2021). While AI has been widely discussed in the context of smart cities (Sanchez et al, 2023), few studies have systematically examined how U.S. states are laying the legal groundwork that shapes local implementation. Recent research also suggests that political, economic, and demographic factors influence whether and how states regulate AI (Parinandi et al., 2024).

This study employs a qualitative content analysis of AI-related legislation across all 50 U.S. states, using the National Conference of State Legislatures (NCSL) database as the primary source of data. The aim is to identify how state-level legislative activity around AI may enable, constrain, or otherwise shape the governance capacity of urban governments. While prior research has examined the political economy of AI policy adoption (Parinandi et al., 2024), this study builds on that work by focusing specifically on implications for cities and local governance. The legislation is coded along the following dimensions: urban governance relevance (such as mentions of municipalities, etc.), governance impact type (restrictive, enabling, procedural, etc.), theme (privacy, ethics, surveillance, smart cities, etc.), sector (transportation, environment, housing, etc..)

Preliminary analysis reveals wide variation in how states approach AI regulation. Some prioritize consumer protection and transparency, while others focus on economic opportunity and innovation incentives. These differences shape the legal environment within which cities must govern AI technologies—affecting procurement processes, service delivery models, and public accountability structures. Inconsistent or underdeveloped state frameworks may leave cities with limited guidance or protections when adopting AI tools. This study offers a foundational understanding of the evolving AI policy landscape and provides insights for urban planners and policymakers seeking to align local practice with broader regulatory trends

GA-Based Multi-objective Optimization of Pocket Park Renewal in Historical Neighborhoods

Abstract ID: 1844.0.0.266.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Xu Zhang [Southeast University] zxtjtg@126.com, presenting author

Jinze Li [Southeast University] ljz0106@163.com

As China's urban renewal transitions into stock-based development, high-density historic neighborhoods face the complex challenge of balancing cultural heritage preservation, functional enhancement, and public demand. Focusing on Nanjing's Lotus Pond-Diaoyutai district, this study develops an intelligent renewal model that integrates dynamic genetic algorithm (GA) optimization with closed-loop collaborative governance, aiming to reconcile historical authenticity with modern urban vitality through data-driven spatial regeneration.

To address the limitations of existing static protection and unilateral decision-making models that lead to spatiotemporal dislocation, this study introduces innovations at both theoretical and technological levels:

1. Theoretical Innovation – Dynamic Synergistic Governance Framework: Conventional models rely on static protection or unilateral planning, neglecting the integration of technical tools, cultural values, and governance. This study pioneers a framework that combines dynamic GA-based optimization with collaborative governance, introducing the concept of “techno-emotional symbiosis.” A closed-loop system embedding real-time public feedback (demand articulation → AI-aided design → iterative refinement) is established to enable adaptive renewal.
2. Technological Innovation – Multi-objective Co-Optimization: Traditional approaches often emphasize single-objective optimization, overlooking the intricate spatiotemporal interactions characteristic of high-density urban environments. To overcome this limitation, this study proposes a self-optimizing framework leveraging NSGA-III GA-based multi-objective optimization. By incorporating dynamic feedback mechanisms, the framework facilitates continuous iteration, ensuring adaptive, data-driven decision-making in urban renewal processes.

The operational path is as follows:

1. Data Acquisition and Pre-Processing: QGIS is used to create 50-meter dynamic buffers around cultural and conservation units, while Amap API calibrates walking isochrones to ensure data timeliness and accuracy.
2. Preliminary Screening of Candidate Sites: Candidate pocket park sites are identified based on the Effective Green Space Service Area Ratio (EGSR) and land ownership, utilizing spatial topology analysis and buffer zone methods.
3. Multi-Objective Optimization: An NSGA-III algorithm optimizes three objectives—spatial service effectiveness (Voronoi-based 15-minute life-circle coverage), demand response intensity (minimizing the weighted sum of population density and path length), and industry synergy (assessed through a POI-based Functional Activity Ratio). This process yields a Pareto-optimal solution set and reveals non-linear spatial interactions across different parcel scales.
4. Public Participation Mechanism: A participatory framework is established by integrating online/offline surveys and interviews to extract resident demand keywords. Historical street imagery is processed with generative AI tools (e.g., Stable Diffusion) to produce design prototypes, which are then evaluated through real-time public voting via WeChat Mini Programs, forming an adaptive feedback loop.

This study is expected to provide novel insights into the siting and spatial layout of pocket parks in historic districts through intelligent optimization and public collaboration.

By integrating multi-source data fusion, GA-based multi-objective optimization, and collaborative design mechanisms, this study establishes a decision-making framework that bridges digital governance precision with heritage conservation. The proposed framework contributes to the development of a replicable "Nanjing Paradigm" for smart urban renewal.

Generating Street-View Images Towards Global Sustainability Goals via Diffusion Models

Abstract ID: 1844.0.0.1168.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Shenhao Wang [University of Florida] shenhaowang@ufl.edu, presenting author

Yuzhou Chen [University of Florida] yuzhouchen1@ufl.edu

This research investigates how state-of-art diffusion models can generate realistic street-view images explicitly tailored to global sustainability objectives. Addressing the central question: How effectively can diffusion models convert quantitative urban metrics into visually comprehensible scenarios, our study bridges the gap between data-driven sustainability metrics and practical, visually intuitive planning tools, typically hindered by complexity and cost constraints. Urban sustainability planning is critical in addressing environmental impacts, climate resilience, and quality of life improvements amid rapid urbanization. Traditional methods, such as manual surveys and satellite imagery analyses, often suffer from limitations including high costs, insufficient resolution, and limited scalability. Recent developments in generative AI present opportunities to overcome these constraints by producing detailed and realistic urban visualizations. Diffusion models, characterized by their iterative noise-removal process, offer a significant advancement over previous generative frameworks like Generative Adversarial Networks (GANs), providing enhanced stability, controllability, and realism. This aligns with SDG 11 (Sustainable Cities) and the New Urban Agenda's call for innovative planning tools. Our research innovatively integrates diffusion models with spatial conditioning frameworks, enabling planners to visualize specific sustainability scenarios dynamically and accurately. We compiled extensive datasets containing approximately 32,000 street-view images from Chicago and Orlando, systematically sourced from platform of Google Street View. Following data acquisition, we conducted comprehensive preprocessing. We first covert the panorama into standard street-view images in four different directions. Then we split each image into two square images. Therefore, one panorama image can derive eight different street-view images. Semantic segmentation utilizing SegFormer—a Transformer-based model trained on the ADE20K dataset—accurately quantified urban elements such as buildings, greenery, roads, and sidewalks. Proportion of each element are calculated. Furthermore, the YOLOv12 object detection algorithm was integrated to enhance prompt richness by precisely identifying and localizing objects like vehicles, pedestrians, signage, and roads. These combined multimodal analyses informed detailed natural-language prompts, effectively guiding the stable diffusion models integrated with ControlNet to generate realistic urban street-view images reflective of specific sustainability metrics. Initial experiments demonstrated the model's exceptional accuracy in comparing generated and actual street-view images. Sensitivity tests revealed meaningful visual responses to adjustments in sustainability-oriented parameters. For instance, altering vegetation coverage within prompts significantly impacted perceived greenness, while adjustments to pedestrian and vehicle densities visibly modified urban functionality and livability scenarios. These findings affirm the capability of diffusion models to reliably encode and visualize detailed urban sustainability criteria, supporting scenario-based planning and decision-making. This study provides planners and policymakers with a practical, scalable visualization tool, significantly enhancing community engagement and informed decision-making in sustainable urban development. By translating quantitative sustainability metrics into clear visual representations, our method facilitates effective public participation, enabling stakeholders to intuitively grasp potential future scenarios. Future research will expand dataset diversity, refine model accuracy, and explore deeper integration with urban sustainability policy frameworks, reinforcing the practical applicability and broadening the accessibility of these powerful generative AI-driven planning tools.

Generating Sustainable Land Use and Travel Patterns with Density, Diversity, and Design

Abstract ID: 1844.0.0.872.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Qingqi Song [University of Florida] qingqisong@ufl.edu, presenting author

Shenhao Wang [University of Florida] shenhaowang@ufl.edu

Yuzhou Chen [University of Florida] yuzhouchen1@ufl.edu

This research explores how AI models can create realistic urban images that show sustainable patterns based on the 3D framework—Density, Diversity, and Design. We address a key question: How can diffusion models translate urban metrics into visual scenarios to help planners design more sustainable cities? This work fills the gap between quantitative planning metrics and visual planning tools that are often too complex or expensive for many communities.

Urban planning requires balancing social needs, environmental concerns, and infrastructure development. The 3D framework helps evaluate how urban form affects mobility and quality of life. While existing visualization tools are resource-intensive, new AI technologies can create detailed urban images from data. Our research connects AI with urban metrics to help planners visualize different futures and make better decisions.

We train diffusion models using satellite images, land use maps, and urban metrics from Orlando and Chicago. We measured density through building counts and coverage; diversity using Shannon diversity; and design through street patterns and connectivity. Our approach uses diffusion models that create images by gradually removing noise—adapted with ControlNet to ensure the images reflect specific planning metrics. We improved the model's accuracy through specialized training, then tested how changing different urban metrics affects the generated images.

A comparative analysis of 3D metrics reveals substantial differences between Orlando and Chicago. Each city's imagery were collected over 4,800 km² areas centered on downtown, using a 90×90 grid of 1 km² tiles per city. Chicago exhibits a denser urban form with higher building footprint ratios, road density, and land use diversity, reinforcing the link between compact urban development and sustainable mobility. Our specialized training approach significantly improved the quality of generated images, reducing the FID score from 477.41 to 319.16 compared to the baseline ControlNet implementation, indicating substantially better alignment with real urban distributions.

Controlled experiments demonstrate that adjusting individual urban metrics produces meaningful and predictable visual changes in the generated images. When building density was adjusted to regional averages, the resulting images showed more evenly distributed building patterns and more efficient spatial utilization. Adjusting road density parameters resulted in more structured networks, while increasing intersection density created more balanced street grids that could better support sustainable transportation modes.

Further sensitivity analyses with metrics like average block size, road network complexity, and land use diversity revealed distinct impacts on urban form and functionality. For instance, enhanced amenity density visualizations showed improved livability with features such as park-shaped greenways and increased entertainment facilities. These findings demonstrate that diffusion models can effectively encode and visualize urban design principles, offering planners a scalable tool for scenario-based analysis.

This research offers a new way to connect metrics with visual planning tools. By using AI, planners can quickly create images of different development scenarios, making it easier to involve community members in planning discussions. Beyond just creating pictures, this approach can help cities work toward important goals like reducing carbon emissions. The tool can help planners design 15-minute neighborhoods where daily needs are within walking distance, transit-oriented developments, and other forms that reduce car dependency while creating healthier communities. By making advanced planning tools more accessible, more people can participate in shaping their communities. Future work will improve these models and explore how they can support better planning policies.

Generative AI-Driven Insights for AI Regulation, Governance, and Application across Cities

Abstract ID: 1844.0.0.762.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Xiaofan Liang [University of Michigan] xfliang@umich.edu, presenting author

Meixin Yuan [University of Michigan] mayyuan@umich.edu

Jack Bernard [University of Michigan] jackber@umich.edu

Qifan Wu [University of Michigan] qifanw@umich.edu

With the rapid progression of AI development, local governments have started to regulate, govern, and apply AI technologies in the public sector, such as in areas of planning, analytics, security, surveillance, energy, and modeling for decision support, automation, prediction, and service delivery (Yigitcanlar et al., 2024a). These efforts range from AI policy guidelines that outline regulated AI uses, public meeting notes of AI impacts in various sectors and communities, or specific AI use that enhances public services and urban planning (Batty, 2018, Luusua et al., 2023, Peng et al., 2024).

However, tracking these conversations and advancements across cities is difficult because there is no structured data and consistent tracking. The data collection process in prior research relies on manual search through searching engines and academic literature to review AI adoption at the local government level (Yigitcanlar et al., 2024a, 2024b), which is time consuming, and the data could be outdated quickly.

Public documents released by local governments are the perfect raw data to derive these insights, yet processing these data presents both conceptual and technical challenges, such as the defining the fuzzy semantic boundary of “AI-relevant documents”, and robust analyses on grey literature. Grey literature, such as public meeting notes and policy guidelines, is far less structured and hard to filter with straightforward rules.

Our study proposes a Generative AI augmented approach for analyzing text-based public documents (grey literature) released by municipality websites, generating insights into how cities vary in AI regulation, governance, and application efforts. Specifically, we implemented a Retrieval-Augmented Generation (RAG) process with prompt engineering to add tags and topic-specific summaries for each document and then aggregated insights across documents. With this approach, we can identify truly AI-relevant documents that meaningfully discuss the regulation, governance, and application of AI in cities, rather than those that simply mentioned the keyword “AI”. Our design of the RAG approach also ensures that the queries can be done in a cost-effective manner when processing a large number of public documents while minimizing hallucinations.

Our goal is to enable the public to see a high-validity, structured summary for questions like “what does city [name] talks about AI + [subtopic]” with explicit references to documents and paragraph chunks that support the summary. We will also evaluate how well the AI-generated topic and tag classifications and summaries are compared with the human-coded results. Our results will report on which cities have the most “AI-relevant” documents, which indicates their readiness to engage with AI on both policy and application fronts, and what cities have done with AI in regulation, governance, and applications.

Here we describe our methods in detail. First, we queried U.S. city government documents containing the keyword “Artificial Intelligence” between 2017 and 2024 from Overton, the world’s largest database for policy and grey literature (Overton, 2025). File links and meta-data (e.g. issuer, publish dates) for a total of 2,289 documents were identified.

Next, we create paragraph-level text embeddings to cross check with our topic definitions (e.g., AI applications in civic engagement) and add topical tags to documents. By filtering documents that have tags, we can remove documents that do not discuss AI in topic of interests. With the reduced number of documents, we then proceed to generate topic-specific summaries for each document and then use them as an additional input to generate a document-level summary about how AI regulation, governance, and application is discussed.

Urban design is a multifaceted process that demands careful consideration of site-specific constraints and collaboration among diverse professionals and stakeholders. The advent of generative artificial intelligence (GenAI) offers transformative potential by improving the efficiency of design generation and facilitating the communication of design ideas. However, existing GenAI approaches in urban design often fall short in addressing site-specific conditions and integrating expert input, creating a disconnect with real-world practices. Additionally, these approaches typically employ an end-to-end generation process, which overlooks the iterative refinement essential in practical urban design.

To bridge these gaps, this study presents a stepwise generative urban design framework that integrates human expertise with diffusion models. Instead of generating design outcomes in a single end-to-end process, our framework divides the process into three key stages in established urban design workflows: (1) road network and land use planning, (2) building layout planning, and (3) detailed planning and rendering. At each stage, diffusion models generate preliminary designs based on textual human instructions and image-based constraints, which can then be reviewed and refined by human designers. To evaluate the proposed approach, we introduce a comprehensive framework that assesses the fidelity, compliance, and diversity of the generated designs.

Experiments using data from Chicago and New York City demonstrate that our framework outperforms existing baseline models and end-to-end approaches across all evaluation metrics. It generates high-quality outputs with clear geometric boundaries that adhere closely to human instructions, including accurate compliance with road density, land use proportions, building height distributions, and open space ratios. In addition, the framework supports the generation of diverse design alternatives under the same constraints and goals, enabling efficient exploration of design possibilities. It also demonstrates an implicit understanding of urban design principles, such as generating well-connected road networks with reasonable intersections, aligning land use types with road hierarchies, forming continuous street interfaces through building arrangements, and capturing the relationship between land use and building form.

This study underscores the benefits of stepwise generation in preserving human control and facilitating iterative refinement, laying the groundwork for broader applications in context-sensitive urban design solutions. For planners, the framework enables efficient and diverse generation of design alternatives across stages, supporting evaluation, comparison, and iterative feedback. It also enhances public participation in urban redevelopment by providing near real-time visual outputs and an accessible tool for non-experts to explore and express design ideas. Additionally, the framework supports analysis of cross-city design pattern variations and urban style transfer, offering insights into how local context and design language influence planning outcomes.

GeoAI-Powered Traffic Modeling: A Framework for Predictive Spatial Analytics

Abstract ID: 1844.0.0.538.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Anton Rozhkov [New York University] anton.r@nyu.edu, presenting author

Pranav Motarwar [New York University] pm3891@nyu.edu

Rudra Patil [New York University] rp4216@nyu.edu

Traffic congestion remains one of the most pressing challenges in metropolitan areas worldwide (Akhtar & Moridpour 2021). Rapid urbanization, population growth, and increased vehicle ownership place immense strain on transportation systems. The effects of congestion extend beyond daily commutes to broader concerns such as economic productivity, public health, and environmental sustainability. Traditional approaches to traffic management, such as lane expansion and fixed-time traffic signals, are often inadequate in rapidly evolving urban landscapes (Skartland 2023). These methods fail to accommodate fluctuating demand, spatial constraints, and the high costs associated with infrastructure development. As a result, there is a growing need for data-driven solutions that optimize traffic flow and improve urban mobility. The main research question is: how can GeoAI-based approaches optimize transportation infrastructure planning and reduce reliance on traditional reactive congestion management strategies, and what are the broader implications of integrating GeoAI and predictive analytics into the urban transportation planning framework?

This study leverages Geospatial Artificial Intelligence (GeoAI) and machine learning to analyze 15 years of historical traffic data from New York City, uncovering spatiotemporal patterns that inform predictive congestion management (Liu et al. 2024). Using time-series models such as ARIMA to capture seasonal trends and LSTM networks to model non-linear relationships, the research develops robust traffic forecasts for 2025–2029. By integrating geospatial analytics, the study identifies congestion hotspots with clustering techniques, offering fine-grained insights into traffic bottlenecks across boroughs and neighborhoods. In this study, Uber’s H3 Hexagonal Grid System is used to provide a scalable, hierarchical spatial framework that increases the precision of congestion mapping. Beyond predictive analytics, the study introduces an interactive AI-powered query portal powered by the LLaMA model, enabling urban planners and policymakers to explore traffic insights using natural language queries, and fostering a more responsive and adaptive approach to urban mobility management and transportation planning. This developed tool bridges the gap between complex data analysis and real-world decision-making by allowing users to identify congestion trends, evaluate infrastructure needs, and propose strategic interventions dynamically.

The urgency of developing such solutions is further emphasized by the environmental and economic impacts of traffic congestion. Addressing congestion is, therefore, not only a mobility concern but also a key component of broader sustainability initiatives. Many cities are prioritizing less energy-intensive transportation strategies, aligning with global efforts to reduce carbon emissions and promote efficient urban mobility (Kany et al. 2022).

Advancements in machine learning, AI, and geospatial analytics present an opportunity to transition from reactive traffic management to proactive congestion mitigation. Real-time data integration allows for the continuous optimization of traffic signals, route recommendations, and infrastructure planning. This study contributes to the growing discourse on smart urban mobility by providing actionable insights and scalable solutions that can be implemented in New York City and beyond. By combining predictive analytics, geospatial intelligence, and AI-powered decision support, this research paves the way for a future where urban transportation systems are not just reactive but anticipatory, reducing congestion, improving environmental sustainability, and improving the overall efficiency of urban life.

Hierarchical Decoding of Spatiotemporally Stratified Urban Texture Using Deep Learning

Abstract ID: 1844.0.0.227.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Dian Yu [Southeast University] yudianseu2023@gmail.com, presenting author

Jinpeng Yang [Cornell University] jy978@cornell.edu

As a physical manifestation of urban evolution, urban texture plays a critical role in sustaining spatial continuity and vitality in cities. In spatiotemporally stratified cities, functional transformations across historical periods have led to composite urban textures, with fragments from different eras spatially interwoven. These cities face dual challenges: (1) simplistic zoning, such as "old town/new town," fails to capture the complexity of heterogeneous textures, causing policy mismatches; (2) spatial incompatibilities between historical textures and contemporary functional requirements complicate preservation efforts.

To address these challenges, cities require: (1) research into the hierarchical structure and network of urban textures for cross-temporal integration, and (2) exploration of dynamic texture evolution to inform new urban construction. Previous studies show shortcomings in both methodology and theory: Methodologically, expert annotation is labor-intensive and inadequate for large-scale, multi-scalar analysis. Theoretically, image-based and typological approaches lack quantitative analysis, typically focusing on single temporal layers or scales, neglecting cross-era and cross-scale correlations.

This study introduces a "Knowledge- and Data-Driven Deep Learning Approach" for urban texture analysis, specifically tailored for spatiotemporally stratified cities. The approach addresses methodological inefficiencies using deep learning clustering models and overcomes theoretical limitations by integrating large-scale urban data mining and spatial autocorrelation analysis.

The methodology includes four steps: (1) Data processing: Using Nanjing as a case study, urban textures are segmented based on 2025 Google Satellite imagery and GIS-based maps, with expert knowledge and typological analysis used to classify textures from various eras. This forms a temporally-stratified, weakly-supervised dataset with labeled and unlabeled samples. (2) Model training: A hybrid deep learning architecture combining backbone networks (ResNet and Vision Transformer were tested for scale adaptability) and multi-task learning heads is developed. Supervised training on expert-annotated textures ensures domain-specific knowledge is captured, while self-supervised training enhances the model's ability to embed textures. (3) Hierarchical clustering: The DNN model encodes textures into embeddings, which are then hierarchically clustered to identify macro-scale typologies, followed by secondary clustering to reveal subtype variations (e.g., subcategories within Ming-Qing districts). (4) Validation and application: The model's accuracy is validated through comparison with ground-truth data. Spatial autocorrelation analysis identifies significant spatial patterns, which are correlated with urban vitality and functional adaptability indicators through Geographically Weighted Regression (GWR). This analysis helps guide adaptive conservation in modern urban contexts.

The study contributes in three key ways: First, it advances urban texture research by shifting from expert-driven to a knowledge- and data-driven approach, significantly improving efficiency and precision. Second, it reveals the hierarchical structure of urban textures across different eras, bridging temporal and spatial scales, with potential applicability to other cities. Third, it overcomes the static limitations of traditional morphological analysis by correlating hierarchical characteristics with key indicators, offering insights for urban renovation and historical conservation.

High-Resolution Urban Heat Stress Prediction Using a Multimodal Deep Learning Framework

Abstract ID: 1844.0.0.694.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Intensified by the dual forces of climate change and rapid urbanization, summer heatwaves are becoming more frequent and severe, resulting in substantial mortality and economic losses. In response to these growing risks, providing urban shade to limit sun exposure is increasingly recognized as one of the most efficient and cost-effective ways to reduce heat stress. However, empirical studies assessing the provision of urban shade and its direct impact on human heat exposure remain scarce, impeding accurate quantification of individual heat burdens. Additionally, the absence of multimodal frameworks capable of heat burden prediction represents a critical gap, restricting efforts to forecast heat conditions and to design effective optimization strategies.

To address these research gaps, our study employs a two-phase methodological approach. First, we quantify urban shade patterns using high-resolution 3D point cloud models and compute the Universal Thermal Climate Index (UTCI) through the SOLWEIG (Solar and Longwave Environmental Irradiance Geometry) model, integrating meteorological station data across Guangzhou. To overcome the computational limitations of physics-based models in real-time scenarios, we develop an advanced multimodal deep learning framework that integrates satellite imagery, 3D urban morphological metrics, geospatial coordinates, and semantic textual annotations of microenvironments in a unified predictive pipeline. This integrated approach enables high-resolution (1m), real-time UTCI predictions while preserving the physical accuracy of conventional modeling approaches.

The results show significant spatial variation in heat burden within cities, with higher UTCI observed in urban cores and densely built areas, and lower UTCI in vegetated or suburban regions. This highlights the effectiveness of tree canopy cover in reducing heat exposure through shading, while buildings, despite offering some shade, can worsen heat exposure by reflecting and absorbing solar radiation. Our multimodal machine learning model effectively captures these spatial patterns by leveraging the complementary strengths of integrated data sources, achieving high accuracy in predicting UTCI.

The primary contribution of this study lies in the high-resolution identification of urban heat burden hotspots and the development of a scalable, multimodal predictive framework. The findings provide scientific support for urban heat mitigation strategies by enabling precise localization of severe heat exposure areas. The high-resolution heat exposure prediction maps generated by the model offer policymakers and urban planners a quantitative tool to evaluate the effectiveness of interventions, thereby facilitating the design of more efficient climate adaptation strategies. Ultimately, this study provides practical guidance for addressing climate change and lays a foundation for fostering climate-resilient urban development.

Identifying ChatGPT's Preferences for Neighborhoods in London, New York and Rio

Abstract ID: 1844.0.0.454.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Matthew Zook [University of Kentucky] zook@uky.edu, presenting author

A great strength of generative AI systems like ChatGPT is the ability to respond to questions with interpretation and action, or sense-making action in cities. But these responses are based on the data used to create the LLM, and so the bias and preference in these training data are reflected back, albeit repackaged in a technological black box that invites users to interpret as neutral. Therefore, it is essential to make this bias/preference visible and demonstrate how they are a structural feature of generative AI that cannot be transcended.

This is particularly relevant in the context of urban planning, as this bias/preference shapes representations of cities and neighborhoods via responses to common user queries such as “How safe is Harlem for me to live?” or “Which are the best neighborhoods in Detroit for tourists to visit?” or “Which cities are the best places for entrepreneurs?” Urban planners are just starting to grapple with the implications of generative AI in daily practice, and this paper focuses on the representation of cities and neighborhoods that citizens interacting with these systems are likely to encounter.

To achieve this, this paper conducts an algorithmic audit of ChatGPT via a custom-built query engine for ChatGPT’s API (written in Python and shared via GitHub). Through several million pairwise comparative queries (e.g., Is Harlem, NY or Flushing, NY safer?) to ChatGPT’s API, we built a database of its responses when asked to compare U.S. cities with 250,000+ population (n=91) and neighborhoods in London (n=51), New York (n=74), and Rio (n=46). We devised 300+ queries (aggregated into larger meta-categories) on a range of subjective topics around quality of life, safety, and economic/social vibrancy, and used the results to rank cities and neighborhoods. A key element of this methodology is prompt engineering to ensure that ChatGPT provides consistent responses to subjective queries. After experimenting with a range of prompt formats and structures, we selected the one that maximized consistent responses and minimized refusals. We repeated each query multiple times to ensure that the responses were non-random and conducted sensitivity testing on possible factors (order of neighborhoods, length of neighborhood name, etc.).

Our analysis consists of three main parts: (1) analysis of non-standard responses/refusals; (2) ranking and geo-visualization; and (3) analysis of rankings (descriptive stats, correlations, ordinal logistic regression). The first part focuses on the factors associated with ChatGPT’s non-standard responses/refusals that are (based on our preliminary analysis) tied to (a) the subjectivity of the query and the design of ChatGPT to equivocate on “sensitive” questions, and/or (b) lack of data in the underlying LLM related to the query. The second part analyzes a selection of tables and maps documenting ChatGPT’s ranked preferences of cities and neighborhoods across a range of subjective topics. The goal of this is identifying potentially problematic patterns, e.g., minoritized neighborhoods deemed to be more problematic, or that certain places are ranked lower due to lack of data. The third step is identifying possible causal factors for the patterns based on standard demographic characteristics, as well as correlations behind the rankings.

The findings of this research will contribute to a better understanding of generative AI bias and inform strategies for mitigating these biases. Future research will compare ChatGPT responses to other AI models (such as DeepSeek), as well as strategies that cities and planners may use to counteract bias.

Integrating Machine Learning and GIS to Predict Crime Hotspots

Abstract ID: 1844.0.0.389.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Fatemeh Ghobadpour [University Of Memphis] fghbdpur@memphis.edu, presenting author

Abbas Talebi-Fard [K. N. Toosi University of Technology] abbastalebifard@gmail.com

Urban crime analysis plays a critical role in shaping effective crime prevention strategies and informing urban planning decisions. As cities continue to grow and evolve, understanding the spatial dynamics of crime has become increasingly important for resource allocation, policy development, and community safety. Recent studies have demonstrated the significance of spatial and demographic factors in crime patterns. Schaible et al. (2021) revealed a complex interplay where nonprofit concentration may initially elevate crime but eventually contribute to reductions, particularly in crime-focused nonprofits. Similarly, Loukaitou-Sideris, Liggett, and Iseki (2002) emphasized the role of sociodemographic and environmental factors in shaping crime patterns at transit hubs. Hendey et al. (2016) found a positive association between higher concentrations of Housing Choice Voucher holders and property crime in vulnerable neighborhoods, which suggests the importance of understanding spatial dynamics in housing and crime relationships. In addition, Day et al. (2007) noted that while urban design improved pedestrian safety, its effect on crime was more complex, highlighting the need for a broader consideration of environmental and social factors in urban safety planning. Vachuska (2022) found that mobility networks, rather than geographical adjacency, are a stronger predictor of violent crime diffusion.

The literature underscores the need for refined models that incorporate both spatial and environmental factors to better understand crime dynamics. This paper addresses the gap in the literature as a critical urban planning issue by focusing on crime prevention through predictive modeling. Specifically, the authors focus on analyzing crime hotspots in Chicago by integrating demographic, environmental, and spatial factors with machine learning techniques to improve the accuracy and interpretability of crime hotspot predictions. The study aims to answer two key research questions: (1) What demographic, environmental, and spatial factors are most strongly associated with urban crime? (2) How can machine learning and GIS tools improve the accuracy and interpretability of crime hotspot prediction compared to traditional statistical methods?

In answering these questions, we employ a mixed-methods approach that combines Geographic Information Systems (GIS) mapping tools with machine learning techniques. The dataset integrates various sources, including nightlight satellite imagery, street network data, crime incident reports, and demographic indicators. This diverse set of data allows for a comprehensive analysis of factors contributing to urban crime and enhances the overall predictive power of the model.

The methodology consists of three main stages: (1) Data collection and preprocessing, including the filtering of nighttime crime incidents, normalization of spatial data, and processing of nightlight intensity; (2) Exploratory regression analysis to identify correlations between urban characteristics and crime rates, revealing that higher nightlight intensity and population density correlate positively with crime, while higher education levels correlate negatively and (3) Random Forest modeling, which outperformed traditional regression methods with an R^2 of 0.85 and MSE of 0.12, demonstrating its ability to capture complex spatial relationships.

The findings underscore the potential of integrating demographic, environmental, and machine learning-based spatial analysis for crime prediction. Unlike conventional regression models, the Random Forest model not only improves predictive accuracy but also uncovers nonlinear relationships often overlooked by traditional methods.

The model's superior performance indicates its utility in urban planning contexts, particularly for crime prevention strategies and resource allocation.

Integrating Next POI Recommendations to Predict Walking Behavior Changes Post-Development

Abstract ID: 1844.0.0.600.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Jinhong Park [University of Seoul] park21@uos.ac.kr, presenting author

Mingyu Kang [University of Seoul] mgkang23@uos.ac.kr

Walkable cities have become synonymous with sustainable lifestyles due to their positive impact on social, economic, environmental, and health facets worldwide. Consequently, urban policy paradigms have shifted focus from automobiles to pedestrians. This shift has led to the emergence of the concept of pedestrian impact assessment (PIA). PIA serves as a framework for analyzing the effects of development projects on pedestrian movement, allowing predictions of future impacts. Numerous studies have refined PIA evaluation methods using various analysis tools such as ArcGIS, Rhino3D, and Python.

One evaluation approach for PIA is the betweenness analysis, which is part of urban network analysis (UNA). This method provides analytical tools to estimate pedestrian flow at the street level using urban datasets that include sidewalks, buildings, stations, and their attributes. The results of the betweenness analysis are validated against real-world pedestrian traffic, as these results are simulated computationally. However, there are two primary limitations to betweenness analysis. First, the validation process is costly and time-consuming because pedestrian traffic must be collected manually. Second, it cannot detect individual flow, as it only presents aggregated pedestrian flow across regional street networks.

To address these limitations, we propose employing next point-of-interest (POI) recommendation systems to complement UNA and introduce a new method for PIA. The next POI recommendation is a machine learning model that predicts future locations using individuals' location-based social networks, which include contextual information like check-ins, reviews, timestamps, sociodemographic characteristics, and GPS tracks. Typically used in mobile digital advertising, such as taxicab rooftop billboards, we utilize the next POI recommendation in our study to predict changes in walking behaviors following development projects for the first time, integrating both individual and urban environmental factors. This approach allows us to predict pedestrian flow without needing the validation process.

We applied this research to the BostonWalks Study (BWS), a smartphone-based GPS tracking dataset created in collaboration between the Massachusetts Institute of Technology and Northeastern University. The dataset includes extensive GPS trip data and their attributes in the Boston metropolitan area. Unlike other GPS datasets, BWS features the largest walking mode share, making it suitable for developing PIA methodologies. Urban environments adjacent to GPS tracks are also included to train the recommendation model.

Our research addresses the following questions: (1) Do development projects affect individuals' walking behaviors? (2) What are the advantages of analyzing the impact of development projects on walking behaviors? Through these questions, we demonstrate that development projects influence the paths and patterns of walking behaviors by altering urban environments, such as changes in land use, public transit stations, and amenities. Furthermore, our study introduces a new analytical framework for PIA to examine the effects of development projects on walking. Future applications of this assessment can identify significant streets in pedestrian networks and highlight key urban environments that affect people's walking behaviors.

Investigating Misinformation-Sharing Dynamics for Planning Information Integrity on Social Media

Abstract ID: 1844.0.0.818.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Shangde Gao [Department of Urban and Regional Planning, University of Florida] gao.shangde@ufl.edu, presenting author

Yan Wang [University of Florida] yanw@ufl.edu

The public increasingly relies on social media for information, where information about local and regional policies and emerging events circulate rapidly. However, loose content moderation and engagement-driven algorithms exacerbate the spread of online misinformation. With misleading narratives, misinformation can distort public perceptions of planning efforts, undermine trust in planners, and fuel intergroup hostility. These effects pose significant barriers to integrating dissenting voices into participatory planning and hinder the effective implementation of planning policies and actions.

Current planning literature on misinformation has primarily examined issue-specific cases, such as 15-minute cities or false flooding reports during Hurricane Sandy, identifying the drivers of misinformation-sharing (e.g., cognitive dissonance), sentiment shifts, or role of influential users in misinformation diffusion. However, these studies have overlooked the temporal patterns of misinformation-sharing, such as frequency and time lags, or how message content evolves among general public users' sharing behaviors. These knowledges are critical for effective misinformation-mitigation. Also, unlike domains like public health, where misinformation is generated with wide range and large volumes of online activity, planning-related misinformation is typically localized in misinformation content and user engagement, as planning misinformation is usually tied to specific regions, policies, or interest groups. Thus, it remains understudied in terms of misinformation topics and semantic characteristics, and the temporal and collective dynamics of users' misinformation-sharing behaviors. Concomitantly, tools for detecting misinformation are usually designed for general topics, with few tailored to identify or analyze planning-related misinformation at scale within online communication data.

Thus, this study intends to investigate the landscape of planning misinformation on social media and address three core research questions: What are the textual and semantic characteristics of planning-related online misinformation? How can such misinformation and its evolution be effectively detected and monitored on social media? What temporal and network-based patterns characterize online users' misinformation-sharing behaviors?

We begin by compiling a collection of planning-related misinformation from public fact-checking datasets and categorizing it by planning issues (e.g., community design, transportation design, disaster preparedness), distortion types, and misleading textual features. To enable detection and monitoring, we fine-tune pre-trained large language models (LLMs) adopting the Proximal Policy Optimization algorithm with synthetic training data derived from our misinformation collection. Finally, we conduct case studies on real-world social media platforms and characterize user behaviors by analyzing temporal patterns of misinformation-sharing, communication network dynamics, and the association between user characteristics and misinformation-sharing patterns.

The expected outcomes of this study are threefold. The characterization of planning misinformation enables planners and researchers to proactively identify and interpret emerging misinformation trends. The fine-tuned LLMs can provide a scalable and accurate tool for real-time monitoring and early warning of misinformation threats. Furthermore, insights into users' misinformation-sharing behaviors can inform the design of targeted

mitigation strategies aimed at helping the public navigate misperceptions and strengthen trust in planning processes.

This study contributes to integrating the knowledge of online communications into the planning domain by uncovering how misinformation shapes public discussions on planning efforts. It can help planners in anticipating and mitigating misinformation risks that may obstruct planning efforts or crisis response.

Leveraging large language models and generative AI in participatory planning support systems

Abstract ID: 1844.0.0.626.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Steven Jige Quan [Seoul National University] stevenchuan6656@gmail.com, presenting author

Seojung Lee [Seoul National University] seojung.lee@snu.ac.kr

Recent advancements in planning support technologies have heightened interest in participatory planning support systems (PPSSs), aiming to effectively engage diverse stakeholders in urban planning processes. However, existing PPSSs often face challenges in facilitating deeper public participation due to limitations in practical utility and usability for general users. Emerging artificial intelligence (AI) technologies, particularly large language models (LLMs) such as ChatGPT, provide promising opportunities to overcome these barriers through their advanced semantic understanding, reasoning, and natural interaction capabilities. Additionally, deep generative models hold great promise for enabling the public to independently create high-quality, professional-level urban design alternatives, further enhancing stakeholder empowerment in planning processes. Despite their potential, the integration of LLMs and deep generative models into PPSS remains largely underexplored. To address these research gaps, this study proposes a novel web-based PPSS platform integrating ChatGPT and deep generative models into a multi-agent system framework. The platform comprises five interconnected components: (1) process, including problem definition, data analysis, design generation, evaluation, and decision-making; (2) stakeholders, encompassing residents, business owners, planners, and public officials; (3) tools, such as statistical models, GIS, visualization tools, decision-making models, and notably deep generative models that empower stakeholders—regardless of their technical expertise—to actively participate by generating their own urban design alternatives; (4) knowledge, comprising project-specific information, local contextual data, and planning knowledge; and (5) ChatGPT-powered agents, categorized as personalized agents (engaging stakeholders through understanding individual preferences and concerns), task agents (employing tools such as deep generative models to facilitate user-driven data analysis and design generation), persona agents (emulating diverse user perspectives), and a workflow agent (coordinating stakeholder interactions, ensuring effective communication, and building consensus). The proposed system was evaluated through a hypothetical sustainable urban regeneration case, the New Seollo Project in Seoul. Compared to the actual Seollo project, which faced significant criticism due to limited public engagement and controversial design outcomes, the new PPSS platform demonstrated substantially improved stakeholder engagement, greater inclusion of diverse public opinions, and innovative, community-based design outcomes collaboratively generated by stakeholders. The integration of LLMs and deep generative models significantly enhanced the usability and participatory capacity of the PPSS, demonstrating how emerging AI technologies can effectively facilitate meaningful and inclusive stakeholder participation in addressing complex planning challenges.

Mapping Cultural Assets: A Comparative Analysis of Open-Source and Crowdsourced Data in Los Angeles

Abstract ID: 1844.0.0.362.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Norhan Abdelgawad [Virginia Tech] norhan@vt.edu, presenting author

Shalini Misra [Virginia Tech] shalini@vt.edu

Kris Wernstedt [Virginia Tech] krisw@vt.edu

Tom Sanchez [Texas A&M University] twsanchez@exchange.tamu.edu

This study examines the distribution of cultural assets, particularly murals and cultural centers, in Los Angeles using authoritative open-source and crowdsourced data. We address the question, “How do crowdsourced and open-source data vary in their representation of cultural assets?”. It is part of a broader research that examines the effectiveness of using digital data to evaluate spatial justice in cultural planning.

As digital data sources increasingly shape urban decision-making, it is crucial to understand the reliability, completeness, and representation biases in mapping cultural resources and their justice implications. By analyzing both datasets, we examine whether crowdsourced data, shaped by community participation, aligns with or diverges from open-source data maintained by government agencies. This comparison enables us to evaluate the effectiveness of digital data in examining cultural asset spatial distribution by identifying gaps and overlaps in cultural resource allocation.

We selected the city of Los Angeles as our study area because of its cultural vibrancy, diverse communities, and abundance of digital data. Both the crowdsourced and open-source data are spatially related to US census data, where we use the median household income data as a proxy for justice. We aim to understand how resources are allocated through targeted cultural planning efforts in Los Angeles, particularly those led by the Department of Cultural Affairs (DCA) which focus on murals and cultural centers. We collected data from various sources to examine these resources, including the Los Angeles County Open Data Portal, user-generated blogs such as Mural Map LA, and OpenStreetMap (OSM). These different sources reflect different approaches to cultural data collection.

We employed quantitative spatial methods to analyze these datasets, leveraging Geographic Information System (GIS) mapping and R-programming. Our methodology consisted of three key steps. First, we aggregated the cultural asset data with median household income data using GIS. Second, we conducted several GIS analyses, including directional distribution, Moran’s Index, and Getis-Ord Gi* hotspot analysis, to examine the spatial distribution of the cultural resources according to the different datasets and identify clustering and hotspot patterns. Third, we contextualized our findings with an analysis of cultural planning documents.

This analysis provides insights on (1) the spatial distribution of the different cultural resources and (2) the differences between open source and crowdsourced data types, given differences in data structure, and uses the findings to provide recommendations on improving data-driven planning. The results reveal notable disparities in spatial distribution between datasets, with significantly more coverage in mural data from user-generated blogs than open-source data. On the other hand, OSM data on cultural resources is closely aligned with the existing open-source data. Additionally, crowdsourced mural data is focused on tourist-centric regions, whereas OSM data indicated that cultural centers are more evenly spread across various communities. These differences highlight how distinct types of cultural assets are represented and spatially distributed in the city.

The findings reveal data labeling challenges and limitations in open-source and crowdsourced datasets. Further, there is a lack of clear definitions of cultural assets in cultural planning as a field. These discrepancies underscore the need for greater stakeholder collaboration, aligning with LA's cultural strategy. Additionally, the study sheds light on the importance of standardizing data definitions and adopting integrative approaches to cultural data collection and urban policy to ensure a more accurate, representative, and equitable mapping of cultural resources.

Mapping Sociospatial Inequalities: Tourism, Living Heritage, and Urban Livability in Chania, Greece

Abstract ID: 1844.0.0.874.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Areti Kotsoni [Massachusetts Institute of Technology] aretikotsoni.info@gmail.com, presenting author

Tourism-driven growth in historic cities often creates tensions between economic development, urban resource strain, and the protection of living heritage. These conflicts manifest spatially, contributing to the displacement of long-term residents, land commodification, and the prioritization of tourist-oriented investments over everyday infrastructure. When communities are pushed out, customs and daily life rituals fade, weakening a city's living heritage and undermining the very qualities that attract tourists. This paper examines these dynamics in Chania, Crete, Greece—a continuously inhabited historic city now facing unchecked tourism expansion. In 2024, over 1.5 million visitors flew to Chania, a city of just 55,000 permanent residents, yet no regulatory framework exists to mitigate the strain on the environment, infrastructure, or local communities.

This research maps and visualizes the sociospatial inequalities unregulated tourism creates, investigating how it affects the stability and livability of long-term residents. Using a mixed-methods approach—including spatial analysis, fieldwork, interviews, and archival research—it advocates for a visibility-to-action strategy: by making spatial impacts visible, planners and policymakers can better recognize the need for regulatory intervention that protects both residents and living heritage. Data sources include Airbnb listings, rental platforms, public investment records, land-use maps, tax registries, census data, and more, as well as 12 semi-structured interviews with stakeholders ranging from politicians to resident advocacy groups.

To understand variations in the independent variables (e.g., green spaces, housing), the research uses GIS-based visualizations to compare Airbnb proliferation, rental price inflation, public investment distribution, and zoning mismatches across three neighborhoods: Old Town (tourism-dominated), Halepa (gentrifying), and Dikastiria (residential). These maps illustrate patterns of uneven development, inequitable resource allocation, and land-use conflict, illustrating how the city is increasingly shaped by external economic interests rather than residents' needs.

Findings show that short-term rentals are overtaking residential neighborhoods. In the Old Town alone, 794 of 2,072 buildings now host at least one Airbnb listing, while 53 operate as hotels—despite the area's residential zoning and heritage designation. Median nightly Airbnb rates (200 euros) are eight times higher than long-term rents (26.6 euros), creating enormous housing pressure. Essential workers, including teachers and healthcare staff, struggle to afford housing and are displaced or forced to spend over 50% of their income on rent. Ownership analysis reveals nearly half of hosts manage multiple listings, with some operating more than ten units—indicating commercial-scale activity. As one planner observed, "Traditional uses have disappeared since the law stopped protecting them. Knife-making shops are now tourist souvenir stores." Public investments reinforce disparities: urban design projects cluster in touristic areas, while residential districts face neglect, water shortages, and inadequate waste management. One official admitted, "Investors need to see their projects during a short walk in the city center, so we prioritize the parts they walk through."

This research highlights how seasonal volatility, data invisibility, and fragmented policy responses converge to undermine living heritage and urban livability in tourism-dependent cities. Chania is not unique, but part of a broader Mediterranean trend, where cities rely on the Sun-Sea-Sand (3S) tourism model, fueling land-use change, gentrification, and environmental strain. Overreliance on tourism creates monocultural economies, leaving cities

vulnerable to crisis. Without urgent action, cities like Chania risk becoming seasonal enclaves—vibrant for visitors, but uninhabitable for those who sustain it year-round.

Mapping Urban Heat/Cold Thresholds via Social Media and Machine Learning

Abstract ID: 1844.0.0.1120.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Jun Yang [Virginia Tech] juny@vt.edu, presenting author

Shaojiang Zhong [Amazon] shzhong@amazon.com

Mintai Kim [Virginia Tech] mintkim@vt.edu

Extreme temperature events are intensifying across U.S. cities with deadly consequences, from Chicago's 1995 heat wave, which claimed 700+ lives, to Texas' 2021 winter storm, which caused 246 fatalities. While these events highlight growing climate vulnerabilities, traditional temperature warning systems remain constrained by fixed meteorological thresholds that fail to capture how residents actually perceive and respond to temperature extremes. Recent studies by Hondula have demonstrated significant spatial variation in human temperature sensitivity (Hondula et al., 2015), yet the field lacks a comprehensive framework to map these perception-based thresholds at urban scales.

This study addresses three critical limitations of current approaches. First, official warning systems use static thresholds that ignore local acclimatization patterns. Studies have shown that there is a certain gap in the temperature thresholds between residents in hot areas and those in cold areas (Gronlund et al., 2018). Second, while valuable, survey-based studies like the ASHRAE RP-884 database lack the spatial-temporal granularity needed for neighborhood-level analysis. Third, as White-Newsome has documented (White-Newsome, 2021), existing vulnerability indices often overlook important perception disparities in marginalized communities.

This study develops an innovative methodology to bridge these gaps through three key objectives. First, we quantify perception-based heat and cold thresholds by analyzing over 300,000 geotagged social media posts from social media (2014-2024) across 10 representative U.S. cities. We categorize posts along a 5-point thermal sensation scale using advanced NLP classification with a BERT model. Second, we employ adapted breakpoint analysis to identify precise temperature thresholds where post-frequency increases significantly. Third, we develop gradient boosting models that predict these thresholds by integrating multiple data streams: meteorological variables from PRISM climate data, urban form metrics from NLCD land cover, and socioeconomic factors from ACS 5-year estimates.

Our analysis reveals several important findings with direct policy implications. We document substantial regional variation in heat discomfort thresholds, ranging from 82°F in humid climates to 92°F in arid regions - a striking contrast to NOAA's uniform 90°F advisory threshold. The urban heat island effect emerges as a significant factor, with thresholds consistently lower in high-density neighborhoods compared to suburbs. Most critically, we find communities with higher poverty rates demonstrate heat sensitivity at temperatures lower than more affluent areas, highlighting important equity dimensions in climate vulnerability.

These findings support three key policy recommendations. First, we propose developing dynamic warning systems incorporating our threshold-adjusted approach to improve heat wave preparedness, particularly in sensitive neighborhoods. Second, our ML mapping identifies priority zones for targeted interventions like cooling centers and strategic urban forestry. Third, we introduce a new equity framework for evaluating climate justice in municipal heat action plans. This research aligns with multiple ACSP tracks, offering technological advances in ML/NLP for urban analytics, new indicators for housing quality assessment, and practical applications for climate adaptation planning.

ML and GIS for Housing and Park Equity: Advancing Environmental Justice in Metro Atlanta

Abstract ID: 1844.0.0.621.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yan Duan [University at Georgia] yd40901@uga.edu, presenting author

As urban environments grow increasingly complex, machine learning (ML) and geospatial data science have emerged as critical tools for addressing environmental management challenges related to housing, equity, and spatial resource distribution. This study presents an integrated analytical framework combining ML-based housing price prediction with spatial equity assessment of urban green infrastructure. Using regression-based ML algorithms—including Random Forest, Naive Bayes, and Neural Networks, the study models housing prices by incorporating diverse predictors: structural property attributes, socioeconomic and economic indicators, walkability scores, urban morphological metrics, and smart location variables such as proximity to transit and employment centers. Model performance is evaluated using RMSE and R^2 , with feature importance analysis revealing key spatial-economic determinants of property value.

Concurrently, the study investigates spatial inequities in access to green spaces by integrating park quality evaluation scores with demographic, environmental, and morphological data. Advanced GIS-based techniques—including Getis-Ord G_i^* spatial clustering, spatial regression models (GWR, SEM), and landscape metrics (fragmentation, connectivity, patch cohesion)—are employed to identify and quantify disparities in park access and quality across socioeconomic strata. The spatial configuration of the built environment is analyzed using urban morphology indicators such as block size, street network density, and building coverage ratios, which are linked to walkability and environmental accessibility. These components are further enhanced through the inclusion of walkability indices and smart growth criteria, providing insight into the environmental performance and sustainability of urban areas.

The results are visualized through interactive spatial equity dashboards and predictive surface models, offering transparent and actionable tools for policy and planning. By combining ML, spatial statistics, and landscape analysis, this research delivers a robust framework for urban environmental management. It enables planners and decision-makers to anticipate real estate dynamics, identify spatial injustices in green space provision, and support equitable and sustainable land use strategies. This dual-focus approach advances integrative environmental planning by promoting a balanced distribution of ecosystem services and socio-spatial opportunities in urban systems.

Mobility Disruption and Risk Perceptions During and After Hurricane Helene

Abstract ID: 1844.0.0.1151.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Zihui Ma [University of Maryland] zma88@umd.edu, presenting author

Qian He [Rowan University] he@rowan.edu

Songhua Hu [MIT] hsonghua@mit.edu

Behnam Tahmasbi [University of Maryland] behnamt@umd.edu

Hurricanes pose profound challenges to urban and regional infrastructure, particularly transportation systems that are vital for everyday functioning and emergency response (Washington et al., 2023; Swanson & Guikema, 2023). Disruptions from flooding, power outages, and damaged road networks can hinder access to healthcare, food, and shelter—especially in marginalized neighborhoods (Logan, 2006; Cutter et al., 2013; Fothergill & Peek, 2014). While prior research has documented infrastructure vulnerabilities and evacuation behaviors, less is known about how individuals' perceptions of risk influence mobility responses and how such responses vary across urban and rural contexts. This study investigates the urban and regional mobility patterns following Hurricane Helene, a Category 4 storm that made landfall on September 26, 2024, resulting in over 230 fatalities and widespread devastation across six southeastern states. We analyze spatial patterns of human movement during and after the hurricane by integrating real-time mobility data from CUBEQ GPS tracking with sentiment analysis from social media platform X (formerly Twitter). National Weather Service data—including precipitation levels and wind speeds—serve to control for local variations in storm severity. We ask two central questions: (1) How do post-hurricane mobility shifts reflect spatial patterns of resilience and vulnerability across different communities? (2) How do public sentiments—captured in real-time during the disaster—correlate with observed changes in mobility?

Findings highlight that while evacuation orders increased overall mobility, their effectiveness was uneven. Communities with higher income and educational attainment showed greater mobility adaptation, suggesting higher levels of adaptive capacity. In contrast, Black and rural communities demonstrated lower mobility response, underscoring persistent barriers to evacuation, such as transportation access, housing insecurity, and historical underinvestment in infrastructure. The severity of the storm—particularly wind and flooding—was negatively associated with mobility, indicating physical constraints on movement despite official evacuation efforts. Sentiment analysis revealed spatially patterned emotional responses. In areas where mobility declined sharply, sentiment data pointed to heightened distress or disruption, while stable or increased mobility often coincided with neutral or resilient sentiment, suggesting coping strategies or better access to recovery resources. This combined analysis of movement and emotion provides a richer, more nuanced understanding of how communities respond under crisis.

For urban planners, these insights offer actionable knowledge about how infrastructure, information flows, and social vulnerability shape post-disaster accessibility. Our findings suggest that physical mobility metrics alone cannot fully capture the capacity of a place to withstand and recover from disaster. Incorporating sentiment data allows planners to distinguish between distress-driven movement and adaptive responses, informing the design of more equitable and responsive emergency management strategies. By highlighting where and why mobility breaks down—and who is most affected—this study advances planning scholarship on disaster resilience, accessibility, and social equity. The integration of geospatial mobility data, public sentiment, and hazard intensity creates a novel framework for assessing and addressing spatial inequality in disaster contexts. Urban planning practitioners and researchers can leverage this approach to better identify at-risk populations and prioritize equitable recovery planning.

Modeling Energy Consumption in Residential Buildings Using Micro-level Data

Abstract ID: 1844.0.0.448.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Emre Tepe [University of Florida] emretepe@ufl.edu, presenting author

Jean-Michel Guldmann [The Ohio State University] guldmann.1@osu.edu

Urban areas play a significant role in global energy consumption and greenhouse gas emissions, with residential buildings among the largest energy consumers in urban settings. Assessing the energy demand at the residential level is crucial for planning urban areas effectively. Residential building energy consumption depends on various factors that can be grouped into five categories: macroclimate, microclimate, building structure, users' behaviors, and energy sources.

The macroclimate influences regional energy demand, which changes over time. Seasonal weather variations correlate positively with outdoor temperature and residential electricity use (X.-X. Li, 2018). Perera et al. (2018) explore how climate change indirectly affects urban energy consumption. The microclimate also impacts building energy use significantly. Toparlar et al. (2018) show that areas near parks are cooler than dense urban zones, with an average temperature difference of 2.85 °C and corresponding differences in cooling energy demand. Trees improve the microclimate by providing shade and evapotranspiration, thus reducing land surface temperature (LST) and thereby lowering cooling energy needs (Aboelata & Sodoudi, 2019; Chen et al., 2021; Wang et al., 2016). Urban form influences the urban microclimate and energy consumption: denser structures raise LST, leading to higher cooling demands (Bruyns et al., 2021; Gracik et al., 2015; C. Li et al., 2019; Navamuel et al., 2018; Silva et al., 2017). The Urban Heat Island (UHI) is the resulting phenomenon that contrasts higher temperatures in urban centers as compared to temperatures in the rural hinterland (Boehme et al., 2015; Chun & Guldmann, 2014; Duan et al., 2019; Hu et al., 2020). Construction materials also impact energy use. Gunawardena et al. (2019) show that lightweight insulation materials can lower energy demand. Building ventilation (Pappaccogli et al., 2020) and insulation (Mutani & Todeschi, 2021) are critical. User behavior significantly influences energy use, with Mashhoodi (2020) examining how age, rental occupancy, and household size affect energy expenditure. Energy sources, pricing, and policies also play significant roles in energy consumption.

The above review shows the importance of conducting a comprehensive investigation to identify the factors influencing residential energy consumption. This study focuses on these factors, using curated building-level data for Washington, D.C. This dataset includes privately-owned buildings with gross areas exceeding 50,000 square feet and encompasses various factors related to the neighboring built environment (building density, green spaces, land uses), the microclimate (land surface temperature), and the socio-economic characteristics of residents, all captured within circular buffers centered on each building. The comprehensive data is curated using various sources, including Landsat remote sensing images, Lidar imagery, the American Community Survey, and municipality-level building data, which encompasses energy consumption records. Total building energy consumption is computed by combining electricity, gas, and oil consumption. Both regression and machine learning methods are applied to examine the complex relationship between building energy consumption and these factors. Initial findings based on regression analyses point to the significance of microclimate, building materials, and some socio-economic factors. By employing machine learning algorithms in conjunction with the Shapley values approach, non-linear relationships are explored, and a residential energy consumption model is developed that can be used to inform policy decisions and development.

Negotiating Exceptions: Instruments for Zoning Variance in Local Public Meetings

Abstract ID: 1844.0.0.546.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Xuanyi Nie [University at Buffalo] niexuanyi@gmail.com, presenting author

Lauren Fischer [University at Buffalo] lf44@buffalo.edu

Dingliang Yang [University of Minnesota] yang@umn.edu

Research Question and Significance: This study investigates the instruments used by residents and developers in requesting zoning variances during public meetings across 280 U.S. cities (2006–2023). Drawing on 6,400 transcripts and leveraging Large Language Models (LLMs), we examine the legal, rhetorical, and procedural strategies deployed in these negotiations, as well as the influence of stakeholder groups and project types. The project evaluates how variance decisions reflect power asymmetries and whether public participation challenges or reinforces exclusionary zoning practices. Zoning is the legal framework shaping urban form in the U.S. Variances allow property-specific exceptions to zoning codes, typically reviewed in public meetings. While intended to democratize planning, such meetings often reinforce privilege. Scholars argue that affluent residents shape land use by opposing unwanted developments (Einstein, 2021), while others emphasize institutional dominance in decision-making (Checkoway, 1981; Moore & Caporale, 2025). Zoning variances have also become tools for protecting elite interests through uneven civic engagement (Fischer et al., 2022), often to the detriment of inclusive housing policies. This study contributes to zoning and governance research in two ways. First, it uncovers the specific rhetorical and legal tactics used in variance petitions (e.g., economic hardship, public benefit, and neighborhood compatibility), offering a detailed account of how stakeholders frame their claims. Second, it examines how different actors (e.g., individuals, developers, and advocacy groups) shape zoning outcomes, revealing intra-community power struggles and institutional bias in public processes.

Approach and Methodology: Using LLMs, we analyze 6,400 public meeting transcripts from LocalView. We first filter and classify variance cases through keyword detection, then consolidate related transcripts and categorize projects by type (e.g., single-family, multifamily, commercial, public infrastructure). Variance outcomes (granted/denied/pending) are tracked, and projects with unknown results are excluded. Next, we extract structured data on key actors: who filed the request, who opposed it, which third-party groups were involved, and their positions. Topic clustering and sentiment analysis then classify rhetorical themes and emotional tones (e.g., concern, anger, optimism) across three contexts: residents vs. institutions, residents vs. stakeholders, and resident vs. resident.

Expected Findings: We anticipate revealing common tactics used in variance negotiations and identifying systematic patterns in who influences zoning decisions. The study will highlight how exclusionary practices persist through institutional bias and disparities in civic power. By mapping discourse and sentiment, we aim to expose how planning meetings mediate public voice and policy outcomes.

Relevance: This work contributes to planning scholarship on zoning, participatory governance, and legal mechanisms, offering insights into more equitable planning practices. It advances planning pedagogy and scholarship by integrating LLM methods with governance analysis, offering new insights into how public forums function and often fail as equitable decision-making venues. This project deepens our understanding of institutional power, zoning law, and citizen participation, with practical implications for fairer urban development.

With accelerating urbanization across the Global South, informal urban settlements—particularly urban villages—have become vital habitats for grassroots communities, providing affordable housing and supporting diverse livelihoods. These areas often develop spontaneously in the gaps of formal planning systems, playing a key role in absorbing migrant populations and sustaining urban labor forces. However, they typically suffer from spatial fragmentation, inadequate infrastructure, limited public services, and social marginalization. Despite their significance, urban villages are frequently excluded from mainstream urban planning discourse, and there is a lack of scalable, data-driven methods to evaluate and improve their public spaces from the perspective of actual users. This gap underscores the urgent need for context-sensitive, quantitative approaches that bridge built environment analysis with community-level spatial perception. This study addresses the following research questions: How do built environment features influence residents' spatial perception in informal urban areas? And how can these insights inform targeted design interventions in high-density contexts?

This study proposes a comprehensive evaluation framework for public space perception, integrating street view data, built environment data, and Point of Interest data. Using ResNet-50 and DeepLabv3+ technologies, physical indicators such as green coverage, interface permeability, and facility visibility are automatically extracted from street view images. These data are further combined with building metrics to assess the quality of the built environment in urban village public spaces.

Furthermore, given the distinctive temporal dynamics of urban villages—characterized by minimal daytime activity and heightened nighttime vitality—NPP-VIIRS nighttime light remote sensing data has been utilized to capture patterns of human activity intensity. Through radiometric normalization and urban boundary masking, this data reveals patterns of lighting intensity, serving as a proxy for economic vitality and spatial activity distribution.

Building on this, the study employs the SHAP-ICE dual-driven explanation framework to examine the key factors and non-linear effects shaping spatial performance, uncovering the intricate relationship between actual activity intensity and residents' spatial perception. The analysis further reveals that the topological integration of alleyways significantly enhances perceived safety, while activity intensity exerts a dual influence on both spatial functionality and social interaction—playing a pivotal role in space utilization and optimization. Moreover, K-means clustering is applied to identify three distinct spatial unit types: day-dormant, balanced, and night-active. For each typology, tailored design strategies are proposed, including tide-responsive street furniture and segmented lighting schemes to accommodate varying usage patterns.

This study validates the non-linear transmission relationship between the physical environment and social perception in urban villages, providing scientific quantitative evidence and a reference framework for the progressive renewal of high-density built environments. It also offers a transferable methodology and practical experience for planning and designing informal spaces in Global South cities.

Performance-based Application of Alternate Coding Methods to Study Plans

Abstract ID: 1844.0.0.30.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Pranjali Rai [Washington State Department of Commerce] pranjali88@gmail.com, presenting author

Content analysis using manual coding is an established method to study plans based on a predefined protocol (Norton, 2008). It involves human coders that read plans, often multiple times, to identify references related to predefined criteria or concepts. This method is highly resource-intensive, and hence, most plan analyses are limited to small samples that affects generalizability of their results. Recently, researchers have started experimenting with application of alternate methods to read plans. Specifically, some studies have used Natural Language Processing (NLP) techniques for topic modelling to determine key themes in large datasets of plans (Brinkley & Stahmer, 2021; Fu et al., 2023). However, there are still gaps in knowledge related to application of alternate methods for conducting content analysis based on a pre-defined protocol. In this research, we propose a performance-based application of alternate methods to code plans for increasing efficiency. We demonstrate this application by identifying references related to water conservation concepts in 114 comprehensive plans from drought-prone small communities across the U.S. We use term frequency-inverse-document-frequency (TF-IDF) and Boolean Query-based methods to code plans. Our analysis provides a methodology to test and apply alternate coding method and illustrates the utility of Efficiency and Convergence metrics for studying performance of these methods. Findings indicate that the suitability of methods used in this research depend on the accuracy required for the study context and the amount and nature of discussion (i.e. the vocabularic consistency and number of references for each concept). Future research involving plan analysis can replicate our methodology for an informed application of alternate coding methods to identify references in large datasets. Researchers can also use findings from this study to determine the suitability of TF-IDF and Boolean query-based methods for their analysis. They should note that these methods are not completely devoid of human effort and require measures to ensure accurate manual coding for training and precise checking of retrieved references.

Planning for Subjective Well-Being Using Social Media Data: The Non-Linear Impact of Accessibility

Abstract ID: 1844.0.0.303.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yuanzhao Wang [University College London] yuanzhaowang93@gmail.com, presenting author

In recent years, scholars across economics, psychology, sociology, political science, and urban planning have increasingly shifted their focus toward subjective well-being (SWB), happiness, and life satisfaction—a movement often described as the “happiness turn.” This shift emphasizes mental health, emotional experience, and overall quality of life over traditional indicators such as economic output or productivity, which promotes people-centered urban policies, including the rise of “healthy cities” and “happy cities.” Despite increasing attention to SWB in diverse urban contexts, the specific factors that shape SWB within different urban environments—and how they interact—remain unclear. This study examines the relationship between the built environment and SWB by analyzing social media data from Jiaxing, China. We proposed an innovative method to employ Gradient Boosting Decision Tree (GBDT) models, and sentiment analysis of Weibo posts to reveal complex, non-linear relationships between SWB and different accessibility to urban amenities. The findings demonstrate that linear models fail to capture these nuanced dynamics, as the effects of accessibility on SWB exhibit threshold effects and context-specific variations. A further contribution of this study is the integrated use of both shortest distance and shortest travel time as measures of accessibility. This dual-dimensional approach provides a more comprehensive understanding of how individuals interact with urban amenities and underscores the need to differentiate the nature of various urban activities. It offers detailed insights for planners, emphasizing the need for targeted, context-sensitive strategies to enhance livability and subjective well-being in diverse urban settings.

Platform Intersections: Food Delivery Networks and BPO Clusters in Makati

Abstract ID: 1844.0.0.969.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Nasha Virata [Rutgers University] nasha.virata@rutgers.edu, presenting author

This study investigates the spatial reconfiguration of urban environments through platform capitalism, specifically examining how food delivery apps interact with labor geographies in a rapidly developing urban context. The research addresses critical questions at the intersection of digital infrastructure and urban planning: How are spatial patterns and labor relations affected by digital consumer platforms in Makati, Philippines? In what ways do these digital infrastructures interact with established global outsourcing networks? And what are the implications for urban governance and spatial justice?

Using a case study of the food delivery app Foodpanda and its operations in Makati City, Philippines, this paper builds on previously presented research to document how such platforms function as "infrastructures of extraction" (Sadowski, 2020), converting urban mobility into financialized assets while simultaneously responding to the socio-spatial requirements of transnational labor arrangements.

Quantitative geospatial techniques and computation analyses reveal the geography of digital consumption while qualitative interviews with executives and BPO managers provide context to offer insight into how delivery platforms are shaped by and responsive to local labor and consumption patterns.

This dynamic reflects what Jin (D. Y. Jin, 2025; D. Yong Jin, 2015) calls "platform imperialism" and contributes to a broader understanding of trans-urban infrastructures (Cuppini et al., 2022), where platform operations are governed by global capital flows but materialize through deeply localized social and economic relations.

These findings hold significant implications for planning policy and practice. First, they necessitate regulatory frameworks addressing the temporal asymmetry of platform-mediated urban services, particularly regarding transportation infrastructure, public space management, and safety provisions during non-standard hours. Second, they highlight the need for data governance policies requiring platforms to share operational data with municipal authorities to enable evidence-based planning interventions. Third, they suggest opportunities for integrating platform logistics considerations into zoning practices, including designating micro-logistics zones, rider rest areas, and dedicated delivery infrastructure in high-density commercial districts.

This research also contributes to planning scholarship by providing both conceptual tools and empirical methods for understanding the socio-spatial implications of platform urbanism. It advances theoretical understandings of how digital infrastructures reshape urban territories while offering practical approaches for integrating platform dynamics into planning practice.

By illuminating the complex interrelationships between global labor systems and localized platform operations, this study provides a foundation for developing more equitable governance models that address the structural inequalities reinforced or exacerbated by digital platforms in rapidly developing urban contexts.

Predicting Human Perception of Streetscape Quality with Attention-Enhanced CNN

Abstract ID: 1844.0.0.1153.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Donghyun Kim [UNIST] hyunurban@unist.ac.kr, presenting author

Minji Ryu [UNIST] rmj1115@unist.ac.kr

Gi Hyoung Cho [Ulsan National Institute of Science and Technology] gicho@unist.ac.kr

Urban environments are dynamic systems that critically influence pedestrian experiences, urban livability, and community well-being. Traditional research methods, primarily field observations and surveys, have provided valuable insights into how streetscape design affects human perception. However, these approaches are often limited in scope due to the high cost and time required to conduct extensive studies, making it difficult to generalize findings across diverse urban settings. In 2016, Dubey et al.'s seminal work, which leveraged a deep learning model trained on the globally sourced PlacePulse dataset, paved the way for inferring urban perception at scale and has since inspired a broad range of applications in the field.

Despite extensive work on visual perception and urban quality, significant gaps remain in the literature. Existing approaches typically offer limited interpretability for deep learning models used for predicting human perception and often lack the capacity to pinpoint which specific urban elements drive visual engagement. Moreover, many studies overlook the explanatory potential of integrating attention mechanisms to provide objective, fine-grained insights into how pedestrians visually process urban environments. These limitations highlight the need for methods that not only predict perception with greater accuracy, but also elucidate the underlying visual drivers that shape pedestrian experience.

In this study, we propose an attention-enhanced convolutional neural network (CNN) framework to predict human perception of streetscape quality. Our model is built upon the ConvNext architecture, a state-of-the-art deep learning model that incorporates self-attention modules. This design enables the model to focus on the most important parts of an image. We further enhance interpretability with GradCAM, a technique that generates visual "heat maps" to highlight the areas of an image that most influence the model's predictions. The model is trained on the PlacePulse2.0 dataset, which offers a globally diverse collection of urban images paired with human perception ratings.

For validation, we conducted an experiment with 87 subjects who evaluated 100 urban images using a pairwise comparison method across six perceptual dimensions (safe, lively, beautiful, wealthy, depressing, and boring). During the experiment, eye-tracking devices recorded the subjects' gaze patterns and created heat maps representing where and how long pedestrians looked at various elements in a scene. Following data collection, we compared these eye-tracking heat maps with our GradCAM-derived attention maps. To facilitate this comparison, we employed several evaluation metrics, specifically, the Dice score, Pearson correlation, and the Structural Similarity Index (SSIM), which measure the overlap between the two sets of highlighted areas, the linear relationship between them, and their structural similarity, respectively. Additionally, we overlaid these heat maps with semantic segmentation outputs, classifications of different image regions into meaningful categories, and performed regression analysis to explore how the attention ratios of specific urban elements relate to the corresponding perception scores, using segmentation-derived element ratios as a baseline.

Our findings show that integrating attention mechanisms into CNN-based models significantly enhances interpretability by revealing which visual elements, particularly building façades, sidewalk and greenery, most

strongly influence human perception of streetscape quality. These insights provide urban planners with a data-driven basis for identifying the key elements that capture pedestrian attention. For instance, the model can inform decisions on where to prioritize improvements in building design or green infrastructure, ultimately contributing to the design of more attractive, pedestrian-friendly, and sustainable urban environments.

Public Transit Route Design Using Reinforcement Learning with On-demand Micro transit Data

Abstract ID: 1844.0.0.712.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Qing Hou [University of Florida] houqing@ufl.edu, presenting author

Rapid urbanization coupled with dynamic demographic characteristics has created a temporal mismatch between the adaptability of public transit networks and emerging travel patterns, leading to increased reliance on point-to-point transportation options. These modal shifts toward private vehicles and ride-hailing services, characterized by direct connectivity but suboptimal passenger-to-vehicle ratios, subsequently exacerbate urban congestion. Addressing this challenge necessitates systematic identification of core travel needs and service gaps to enhance regional transportation efficiency by increasing public transit ridership. However, traditional transportation planning typically relies on static historical data and assumptions or limited surveys, necessitating substantial human and economic resources. This conventional approach inhibits efficient responsiveness to the dynamic and evolving urban mobility demands in contemporary metropolitan contexts. Therefore, this research utilizes four years (2016-2019) of origin-destination (OD) data from Tampa's downtown on-demand micro-transit service "Downtownner" to propose a methodological framework employing reinforcement learning (RL) for the automatic generation of optimized public transit routes. This reinforcement learning methodology transforms low-occupancy transportation OD travel patterns into practical public transit solutions, facilitating comparison with existing bus routes and offering new possibilities for future public transportation planning.

This research employs a data-driven approach to construct optimized public transit route networks directly from micro transit OD data. The methodological framework encompasses three principal phases: data preprocessing, route generation, and performance evaluation. First, temporal and spatial analyses are conducted on four years of Downtownner micro transit service data to identify primary travel patterns and demand densities. Subsequently, reinforcement learning algorithms are applied to integrate these discrete point-to-point demands into continuous route candidates, wherein the agent optimizes route configurations by maximizing passenger coverage while minimizing operational costs (Yoo & Lee, 2023). The RL model implements an adaptive reward mechanism that balances passenger coverage, walking distance, route length, and transfer convenience across multiple dimensions. Finally, the generated routes are comparatively analyzed against Tampa's existing transit network, evaluating differences in coverage, service efficiency, and responsiveness to travel demands. This "clean-slate" route design approach provides an objective benchmark that, through comparison with existing networks, not only precisely identifies service gaps in current systems but also provides data-driven support for route adjustments and system optimization based on actual travel demands. Through this methodology, the research demonstrates how dispersed point-to-point travel demands can be transformed into efficient public transit services, thereby reducing dependence on low-occupancy transportation modes and alleviating urban congestion.

By combining micro transit data with reinforcement learning, this research offers a viable pathway toward establishing more inclusive and sustainable urban transportation systems. Furthermore, this methodology demonstrates broad applicability across diverse urban contexts, particularly in regions experiencing rapid urbanization and evolving travel patterns, requiring only parameter calibration to accommodate specific local conditions and constraints.

Vivian Wong [University of Florida] vivian.wong@ufl.edu

Post-earthquake housing reconstruction faces a key challenge: damage assessments are reported gradually over time, while conventional scheduling methods assume that complete information is available at the start. This discrepancy can lead to inefficient resource allocation and delays in recovery. In this study, we address the research question: Can an adaptive (dynamic) scheduling approach—one that continuously updates reconstruction priorities as new information arrives—outperform a traditional static schedule in reducing recovery delays? We introduce PyRebuild, a Python-based simulation framework that models the temporal dynamics of damage report arrivals and dynamically allocates reconstruction resources. The framework employs a discrete event simulation approach and tests three scheduling algorithms: Longest Job First (LJF), Shortest Job First (SJF), and random assignment. Using data from the 2018 Lombok earthquakes reconstruction initiative, we evaluate these strategies under both static (complete initial information) and dynamic (gradual information arrival) conditions. Our validation metric is the Root Mean Square Error (RMSE) between predicted values and observed values. Our analysis shows that in five of seven regions dynamic scheduling yields lower RMSE, while in two regions static methods perform slightly better. These results indicate that the optimal scheduling approach depends on local damage patterns, emphasizing the need for adaptive planning in post-disaster reconstruction.

Qualitatively-Informed Machine Learning for Thematic Coding of Large-Scale Text Data in Planning

Abstract ID: 1844.0.0.944.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Madison Lore [Cornell University] madiclore@gmail.com, presenting author

Holly Caggiano [University of British Columbia] holly.caggiano@ubc.ca

William Gao [University of British Columbia] wgao23@student.ubc.ca

Noisy information environments present a complex challenge for planners - competing narratives, misinformation, and information overwhelm complicate the development and implementation of equitable planning solutions. While qualitative methods have traditionally been the most effective way to analyze such complexity in discourse, the volume of data generated on a daily basis is too large for traditional qualitative methods to handle. This creates a fundamental challenge: how can planners leverage large-scale data while preserving the depth and contextual nuance of qualitative analysis? Advances in computational text analysis, including natural language processing (NLP), offer powerful tools to bridge this gap, yet most automated methods struggle to replicate the rigor and interpretability of human-led thematic coding, especially with deeply contextual topic modeling. In particular, while supervised NLP models—trained with human-labeled examples—often outperform fully unsupervised approaches, it remains unclear how much human coding is necessary. While planning research excels in qualitative thematic coding to extract deep insight from textual data, methods for embedding this expertise into the creation of automated models are poorly understood.

We ask, how can well-developed qualitative thematic coding methods inform supervised NLP methods? This paper evaluates leading supervised topic modeling techniques and proposes a framework for defining the complexity of research tasks of interest to planners. We apply this approach to a multi-case study analyzing language used to support or obstruct renewable energy transitions. Drawing on 5,000 press releases from major oil companies, 250,000 media transcripts, and climate action plans from 96 cities, we hand-code a sample of each dataset using inductive, deductive, and abductive coding approaches. These codebooks serve as a foundation for defining task complexity—based on topic breadth, depth, and specificity—and for assessing the accuracy of supervised NLP models in identifying these themes. We then introduce a novel topic modeling method that applies triplet loss, a technique that refines document embeddings by distinguishing between similar and dissimilar examples traditionally used in computer vision. By structuring topics hierarchically, we create increasingly complex positive and negative training examples, improving model performance on nuanced classification tasks.

Our results reveal that both supervised models built from pretrained models (i.e., BERT) and from scratch (i.e., neural network with cross entropy loss) struggle to discern topics that are highly specific from similar language describing more general terms. However, training a topic model with triplet loss and increasingly complex examples leads to decreased false positive rates across all topics. This mirrors traditional methods of qualitative thematic coding, in which human investigation is able to discern irrelevant labels.

This paper offers three primary contributions to planning research and practice. First, it contributes to the growing literature on the use of NLP in planning research. While some applications are well-suited by out of the box large language models, we show these methods struggle with highly nuanced contexts which are common in planning problems. Second, this paper provides a clear framework for defining complexity in planning topic modeling tasks to aid researchers in choosing the appropriate NLP method. The criteria in the framework provide clear recommendations for the level of automation and amount of training data necessary for nuanced topic modeling. Finally, this paper proposes a novel method of using context informed triplet loss in topic modeling to reflect, but

not replace, human methods of qualitative coding. As computer-based methods of topic modeling become easier to use in planning contexts, planners and researchers need guidelines for matching NLP methods with research goals.

Quantifying the Influence of the Built Environment on Our Emotion Using Geographic Explainable AI

Abstract ID: 1844.0.0.265.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Liwei Zhao [Southeast University] 230248017@seu.edu.cn, presenting author

Understanding the intricate relationships between the urban built environment and public emotions is crucial for promoting human-centered urban planning strategies and sustainable social development. Although existing studies have provided valuable insights, the nonlinear mechanisms and threshold effects of multidimensional built environment factors on public emotions remain underexplored due to the limitations of research methodologies. This study developed a multimodal data analysis framework, incorporating social media data, machine learning modeling, and spatial statistical techniques. Using Shanghai, China, as a case study, we examined the spatio-temporal variation characteristics of public emotions and how different aspects of the built environment affect public perception. Specifically, we collected 122,054 Sina Weibo check-in data points posted in Shanghai from 2024, which were quantitatively analyzed using Natural Language Processing (NLP) to obtain sentiment scores. Furthermore, geocoding and spatial statistics techniques were employed to explore the spatial distribution and clustering patterns of public emotions across different times (weekdays and weekends, and different seasons). We constructed a Geographic Explainable Artificial Intelligence (GeoXAI) framework based on XGBoost and GeoShapley models. Partial dependence plots were utilized to analyze the nonlinear influence mechanisms and threshold effects of physical environment, visual landscape, and service facility factors on public emotion in different areas of Shanghai. Additionally, SHAP interaction values were used to interpret the interaction effects among built environment factors. The main findings are as follows: (1) Shanghai's public emotion was unevenly distributed spatially and displayed certain fluctuations temporally. (2) In the overall effect analysis, built environment, visual landscape, and service facility factors all exerted significant influences on public emotions, although the specific influence mechanisms and threshold effects differed. (3) Building density, subway accessibility, and business office density have the most significant impacts on public emotion on weekdays, whereas green visibility, visual diversity, and third space density have the most significant impacts on weekends. (4) In terms of spatial scale, park accessibility and financial and legal facility density have more pronounced effects in the urban central area, while building density and road network density have stronger effects in the broader area. (5) The degree of importance, nonlinear trends, threshold effects, and interaction effects of the same factor varied across different regions. This study contributed to a more nuanced understanding of the intricate relationships between multidimensional built environment factors and public emotions. The results can provide a scientific basis for the fine-tuned regulation of built environments at different scales, thereby promoting the development of human-centered healthy cities.

Introduction-Urban underground space (UUS) development has become crucial as cities face increasing surface space limitations. Metro station underground spaces serve as vital transportation and commercial hubs but often experience imbalanced utilization with congested and underutilized areas coexisting. This study examines Shanghai's Jing'an Temple Metro Station using an integrated approach combining Space Syntax analysis with data-driven methods to evaluate and optimize underground space performance, addressing the complex challenge of balancing pedestrian flow efficiency with economic benefits in UUS design.

Methods-This research employed Space Syntax analysis to quantify spatial properties of Jing'an Temple Metro Station's underground spaces, using Integration and Choice metrics to assess connectivity and identify central areas, while Visibility Graph Analysis evaluated visual accessibility. Data-driven methods supplemented this approach through: (1) field surveys measuring pedestrian flows; (2) user experience questionnaires; and (3) agent-based simulations modeling passenger movements under various spatial configurations. These methods enabled comprehensive assessment of spatial characteristics and user behaviors, informing optimization strategies validated through simulation testing.

Results-Space Syntax analysis revealed strong correlations between Integration/Choice values and pedestrian flow efficiency, with high-value areas functioning as critical distribution hubs. Visibility Graph Analysis showed highly visible spaces attracted greater passenger dwell time and enhanced user satisfaction. Agent-based modeling demonstrated that strategically positioned commercial areas amplify pedestrian gathering effects, with well-designed open dining areas effectively capturing pedestrian flows. The findings indicate that locating visible commercial hubs at secondary nodes along major pathways achieves an optimal balance between transportation functions and retail opportunities.

Discussion-This research contributes an innovative framework for underground space optimization by integrating Space Syntax with data-driven methodologies. The findings suggest three key strategies: enhancing Integration and Choice values of major corridors to improve flow efficiency; strengthening visual design of nodes to create clearer spatial networks; and prioritizing retail facilities in high-visibility areas to maximize commercial revenue. This study advances theoretical understanding of underground behavioral patterns while providing practical guidance for UUS optimization in high-density urban environments, with future applications potentially leveraging artificial intelligence to further refine spatial behavior analysis in smart city development.

Urban retrofitting is a fundamental approach for achieving sustainable and resilient urban development in the face of contemporary challenges. The increasing prevalence of urban big data presents an opportunity to establish a robust analytical

framework for urban retrofitting, enabling more effective comparative studies and informed decision-making. This paper introduces a comprehensive 5R framework—Re-inhabitation, Re-building, Re-transportation, Re-capitalization, and Re-greening—to provide a multidimensional perspective on urban retrofitting. The 5R framework facilitates a holistic understanding of urban transformation processes and establishes standardized metrics for analyzing urban retrofitting initiatives using diverse urban big data sources. To demonstrate the adaptability and effectiveness of the 5R framework in a real-world context, we conduct a case study of Charlotte, North Carolina. By applying innovative methods for the integration and analysis of extensive datasets, our study offers new insights into the evaluation of urban retrofitting efforts, such as transportation accessibility, micro-scale building improvements, investment patterns, green space enhancements, and overall livability. This approach addresses existing research gaps by providing a structured set of indicators that assess each dimension of urban transformation comprehensively. Beyond academic advancements, the 5R framework offers practical tools for policymakers and urban planners to evaluate retrofitting interventions, quantify their outcomes, and understand the dynamics of evolving urban spaces. The insights gained through our research highlight the importance of using big data to enhance the scope and impact of urban development strategies, ultimately bridging the gap between theoretical concepts and real-world urban retrofitting applications. Our findings demonstrate the potential of the 5R framework to serve as a guiding model for more sustainable, data-driven urban growth and revitalization.

Route Choice Behaviors for Shared Bike Users: Visual Streetscapes and Gender Differences

Abstract ID: 1844.0.0.246.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Seung Jae Lieu [Georgia Institute of Technology] slieu3@gatech.edu, presenting author

Donghwan Ki [The Ohio State University] ki.17@osu.edu

Gulsah Akar [Georgia Institute of Technology] gulsah.akar@design.gatech.edu

This study utilizes computer vision techniques with street view images and GPS trajectory data to understand bicyclist route choice behavior. Prior studies have shown that cyclists often prioritize safety and comfort over distance, favoring dedicated bike lanes and separated paths (Broach et al., 2012; Sener et al., 2009). While gender differences in cycling preferences are well established, with women typically displaying greater sensitivity to safety features compared to men (Hardinghaus & Weschke, 2022), several critical research gaps remain unexplored. First, the impact of street level visual elements such as urban greenery, sky visibility, and parking facility entrances has received minimal attention in bikeability literature. Second, the extent to which gender specific preferences influence trade-offs in route decisions remains underexplored, particularly under different departure times. Third, most existing research has concentrated on regular cyclists, leaving the unique behavioral patterns of shared bike users largely uncharacterized (Cubelles et al., 2023).

Our study addresses these limitations by combining computer vision techniques with street view images and GPS trajectory data to analyze shared bike user behavior in Seoul. Utilizing a Path Size Logit model and a constrained enumeration method, we generated plausible alternative routes for each observed trip. Street attributes include both traditional built environment features (e.g., bike lane, traffic road type, and intersection) and streetscape features derived from computer vision analysis of street-view imagery. These include greenness and sky visibility, features commonly examined in walkability research (Lieu & Guhathakurta, 2025), as well as parking facility entrances identified as potential safety interruption points where vehicles might cross cycling infrastructure. By integrating trip departure time and user gender, and applying a trade-off framework within utility function, we estimated the additional distance users would tolerate to avoid or seek specific route attributes

The results reveal that shared bike users generally prefer routes with bike lanes, increased sky visibility, more commercial land use, and higher greenery, while avoiding intersections without signals and minor traffic roads. Women exhibit stronger preferences for visual openness and environmental quality, favoring greenery, commercial density, and clear sky views. They are more deterred by illegal car parking and building entrances that interrupt curb continuity—factors associated with perceived risk. Interestingly, several route preference variables lost statistical significance during off peak hours, highlighting the temporal variability of cyclist decision making.

By integrating urban computing methods with discrete choice modeling, this research emphasizes the critical need for gender sensitive, perception aware cycling infrastructure design. More broadly, our study demonstrates how image-based analytics and behavioral modeling can collaboratively inform more inclusive and effective active transportation systems.

Seeing "HAI": Human Activities and Interactions Detection from Streetviews through LLMs

Abstract ID: 1844.0.0.808.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Liu Liu [Massachusetts Institute of Technology] lyons66@mit.edu, presenting author

Freya Tan [Massachusetts Institute of Technology] freya117@mit.edu

Andres Sevtsuk [Massachusetts Institute of Technology] asevtsuk@mit.edu

Observational studies have historically played a crucial role in urban research, offering deep insights into human behaviors within public spaces, as exemplified by seminal works of scholars such as Jan Gehl and William H. Whyte. Understanding these human dynamics is particularly significant in today's context, where societal divisions appear to be deepening, influenced by digital echo chambers and increasingly segmented interactions. Against this backdrop, the concept of the "Town Square," articulated by Richard Sennett, becomes even more essential, highlighting the importance of public spaces that facilitate encounters among diverse groups.

In contemporary urban research, computer vision (CV) techniques have become increasingly prominent. However, their application has largely diverted towards relatively simplistic and less socially insightful metrics, such as the Green View Index (GVI), neglecting the nuanced complexities of human social behavior. Recognizing the inherent difficulty of observing and interpreting diverse human behaviors through traditional CV methods alone, this research leverages advancements in Large Language Models (LLMs) to address these challenges, aiming for incremental yet significant improvements in detecting social interactions.

Responding to these needs, the study introduces the concept of Human Activities and Interactions (HAI), defined as observable behavioral patterns within pedestrian environments. HAI encompasses a broad spectrum of social behaviors including various postures, visible actions, implied actions, group dynamics, and engagement modes, providing a structured taxonomy to systematically capture the complexity of human interactions in public spaces.

To operationalize the HAI concept, the research proposes a systematic, multi-step pipeline integrating CV with multimodal LLMs: (1) traditional object detection models first identify individuals within street-level images; (2) multimodal LLMs subsequently assess social groupings among detected individuals through relational reasoning; and (3) further LLM-based inference classifies specific activities and interaction modes within identified groups. Extensive, timestamped street-view datasets from diverse urban contexts underpin this spatial-temporal analytical approach.

It is important to note that this project is still a work-in-progress, and achieving accurate identification across the entire HAI taxonomy remains challenging. Nonetheless, substantial progress has already been made in specific areas such as group detection and activity recognition. Through customized annotation datasets and fine-tuning of multimodal LLMs (specifically Qwen-VL), our approach has demonstrated superior performance compared to general-purpose models like GPT-4o.

Preliminary results indicate that this integrated methodology effectively enhances the accuracy and detail of automated observations of human interactions. Ultimately, this innovative approach provides valuable tools and data resources for urban design researchers, enabling richer and more contextually informed explorations of social dynamics, thereby offering significant potential for future urban observational studies.

Seeing What Matters: A New Metric for Understanding Pedestrian Visual Attention in Urban Crossings

Abstract ID: 1844.0.0.1186.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Wenwen Zhang [Rutgers University] wenwen.zhang@ejb.rutgers.edu, presenting author

Shiyu Ma [Rutgers University] sm2758@scarletmail.rutgers.edu

Where pedestrians direct their visual attention while walking is critical to understanding perceived safety, informing infrastructure planning, and guiding urban design. Eye-tracking studies often rely on the percentage of fixation duration on predefined Areas of Interest (AOIs) to gauge feature salience. However, findings are inconsistent, partly due to methodological limitations—such as limited control in naturalistic settings, treating foveal vision as single points, and failing to account for AOI size and visibility. As Gadsby et al. (2022) note, higher fixation percentages may reflect an AOI's size or visibility rather than a greater influence on perceived safety.

To address these limitations, this study proposes a novel eye-tracking metric: Size-Weighted Conditional Fixation Duration (SWCFD), which accounts for both the time spent fixating on an AOI and its relative size in the visual field. To evaluate this metric in real-world settings, we conducted a naturalistic eye-tracking experiment with 30 participants walking a 1.2-mile route, encompassing 15 intersections with varied built environment features. Participants wore Tobii Pro Glasses 3 to record their gaze behavior. We employed PSPNet (Zhao et al., 2017), a deep learning-based semantic segmentation model, to automatically annotate AOI categories and sizes across each fixation frame.

Compared to the traditional percentage fixation duration, we found the SWCFD metric more effectively highlights AOIs relevant to the crossing—such as people, vehicles, and poles/signs—objects that require active attention. In contrast, the traditional metric often emphasizes large or visually dominant AOIs like buildings, roads, and sidewalks, which are generally large in size but are less task-relevant. SWCFD also avoids aggregating fixations into discrete crossing events, preserving a larger sample size and enabling continuous analysis across different crossing phases. Using linear mixed-effects models, we found that both built environment features (e.g. signals, spatial openness, crossing distance) and individual factors (e.g., age, gender, route familiarity) influence gaze patterns.

By accounting for both fixation time and AOI size, our Size-Weighted Conditional Fixation Duration metric offers a robust and innovative indicator for AOI saliency and pedestrian alertness. This advancement enhances our understanding of pedestrian safety and supports data-driven urban design and infrastructure planning decisions.

Small-Area Estimation for Local Business Dynamics: Insights from Business Dynamics Statistics Data

Abstract ID: 1844.0.0.1013.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Keuntae Kim [Institute for Transportation Studies, University of California Davis] kimprins@hotmail.com, presenting author

Despite the increasing availability of high-quality, longitudinal firm-level datasets, much research on business dynamics remains constrained to relatively coarse geographies—such as states or large metropolitan statistical areas (MSAs)—and access to the business-level microdata has been limited because most of them are commercial databases. As an attempt to address this data gap, this study explores the application of small area estimation (SAE) techniques to the U.S. Census Bureau’s Business Dynamics Statistics (BDS) at the county and MSA levels, with the aim of producing more granular measures of firm births, survival rates, and job flows. By combining BDS aggregates with auxiliary data from the American Community Survey, County Business Patterns, and other local administrative records, this study aims to explore how SAE methods can generate robust and reliable estimates of business dynamism at sub-county scales, including neighborhoods, census tracts, business improvement districts, and so on.

Our methodological framework centers on three complementary goals. First, we develop an SAE-based approach to “shrink” higher-level BDS indicators—such as establishment entry, exit, and net job creation—down to fine-grained localities, addressing the critical data-scarcity problem for small domains. Second, we validate the resulting estimates using multiple cross-checks, including comparisons with known ground-truth samples in populous counties and consistency checks across time-series data. Third, we incorporate spatial correlation structures to capture local patterns—such as clusters of entrepreneurship—that standard county- or MSA-level analyses may obscure.

In applying this framework to select urban regions across the United States, this study expects to find that localized estimates of business activity reveal significant intra-urban disparities. Some disadvantaged neighborhoods exhibit systematically lower rates of firm creation and survival, even when the surrounding areas show robust entrepreneurial activity. Such findings resonate with prior evidence suggesting that place-based factors—such as land-use regulations, transportation infrastructure, and neighborhood socioeconomic conditions—shape local firm dynamics (Haltiwanger, Jarmin, & Miranda, 2013; Decker et al., 2014). By linking small-area estimates to these contextual factors, this study highlights some entry points for targeted policy interventions, such as micro-finance initiatives and zoning reforms.

Beyond addressing methodological gaps, the results underscore SAE’s potential to transform how urban planners can measure and interpret business vitality at highly granular levels. Drawing on canonical work in SAE (Rao & Molina, 2015) and building on the extensive research on BDS, this study demonstrates a replicable approach for researchers and practitioners seeking to pinpoint both entrepreneurial “hot spots” and economic distress zones within metropolitan regions. This study argues that improving the spatial precision of business-dynamics metrics can spark new evidence-based policy debates—particularly around equity, localized economic shocks, and targeted growth strategies. By integrating cutting-edge statistical methodology with an underutilized depth of BDS data, this study hopes to contribute an actionable toolkit for analyzing local economic ecosystems. The findings of this study have implications for scholars, policymakers, and community stakeholders, illustrating the considerable promise of SAE methods to inform more equitable and effective urban economic development strategies.

With the rapid advancement of AI technology, urban planners and designers are increasingly exploring the use of AI tools to enhance citizen engagement in urban development. Given the conversational nature of chatbots, many public agencies have begun employing specialized chatbots to facilitate communication with residents, addressing their needs and answering their inquiries (Senadheera et al., 2024). Recent AI-powered chatbots, ChatGPT, demonstrate significant potential for understanding natural language and human interaction in cities (Ferrara et al., 2019). This capability opens new opportunities for rethinking the role of AI chatbots in encouraging individuals to share their thoughts and experiences regarding public spaces and services, thus enhancing public participation in urban issues (Hasan et al., 2023; Dortheimer et al., 2024). This paper investigates the feasibility of using AI chatbots to gather public opinions in urban spaces and discusses their potential applications in urban management. Using Washington Square Park in New York as a pilot study, we aim to develop an AI chatbot that encourages visitors to share their experiences and provides insights from public input for future park improvements. In this project, we created an AI-powered chatbot named 'ParkGen,' which utilizes a large language model (LLM), specifically Google's Gemini (chat-bison@001 model), to generate dynamic responses based on user input. ParkGen centers on 12 key questions aimed at engaging participants, including: "What motivates you to choose Washington Square Park over other locations for these activities?" and "Would you like to meet new people in Washington Square Park?", among others. Additionally, we used a rule-based chatbot, lacking advanced intelligence, as a control group to evaluate participants' preferences for interacting with ParkGen. The study was conducted in July and August 2024, recruiting 50 visitors to Washington Square Park aged 18 and over by approaching them in the park. Participants were invited to spend 10 to 15 minutes interacting with both chatbots about their experiences in the park, followed by a questionnaire assessing their interactions with each chatbot (e.g., willingness to share thoughts, trust in chatbot, perceived empathy and positive feelings). After data collection, the textual data obtained from these interactions, which mainly refer to 'user input', were analysed using natural language processing (NLP) techniques to extract public insights about their visit motivations and improvement concerns. By mapping the word cloud and calculating the TF-IDF scores, the results show that the visit motivations are around 'people watching', 'meeting friends', 'walk', 'music', 'sit' and 'eat', while the most common terms related to park improvement are 'drugs' and 'cleaning'. In addition, t-test results also show that participants have higher positive feelings and willingness to share their visits and thoughts with AI-powered chatbots compared to the rule-based chatbot. These findings show the potential of using AI-powered tools such as chatbots to encourage people to share their thoughts about the urban space during their visits, which could enrich people's experience in urban public spaces and enhance their participation in future urban management. However, this paper also found that people's interest in talking to the AI

chatbot decreased over time as they spent less time on each question, suggesting that user engagement may decrease as the novelty of the technology wears off, which is consistent with the findings of Dorteimer et al. (2024). This also inspires us to consider how the conversational intelligence of generative AI can be used to communicate urban issues to improve people's sustained engagement in public participation.

Spatial Vulnerability Analysis of Historical Districts under Multi-Risk Scenarios

Abstract ID: 1844.0.0.311.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Wenting Zhou [Chongqing university] f5week@163.com, presenting author

Yunyan Li [Chongqing university] liyunyan@cqu.edu.cn

With the acceleration of urbanization, cities are facing increasing risks. In this context, historical districts have become areas of high vulnerability in cities due to their aging infrastructure, spatial constraints, and inadequate risk preparedness. These areas are not only important carriers of urban history and culture but also key targets for urban safety and resilience construction. However, existing research has mostly focused on vulnerability analysis under a single risk scenario, with less exploration of the impact of multiple risk superposition; in addition, discussions on vulnerability usually focus on a comprehensive perspective, with less in-depth analysis from a spatial dimension, which makes it easier to ignore the essential impact of physical space on vulnerability. Therefore, by exploring the spatial vulnerability of historical districts in the context of multi-risk scenarios, this study aims to provide a new theoretical framework for the prevention and control of risks in historical districts.

This study focuses on the historical district of Ciqikou in Chongqing—a representative historic area with complex terrain and dense urban fabric, constructs multiple risk scenarios from both natural and man-made risks, and identifies the vulnerable areas of the historical district under various risks by simulating the spatial vulnerability performance under different risk scenarios. On this basis, the spatial autocorrelation analysis method is further applied to explore the spatial distribution characteristics of vulnerable areas, revealing their spatial vulnerability features and distribution patterns. The research results indicate that the spatial vulnerability of historical districts is significantly enhanced by the combination of natural and human risks, and some areas have become hotspots of vulnerability due to issues such as aging building structures, materials, and infrastructure. Based on the analysis results, this study proposes targeted disaster prevention and mitigation strategies, providing a scientific basis for the protection and renewal of historical districts, as well as theoretical support for urban resilience construction and sustainable development.

Spatio-Temporal Heat Stress at Bus Stops in Philadelphia: Microclimate Modeling and Explainable AI

Abstract ID: 1844.0.0.65.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Shengao Yi [University of Pennsylvania] shengao@upenn.edu, presenting author

Xiaojiang Li [University of Pennsylvania] jianglix@design.upenn.edu

Donghang Li [Massachusetts Institute of Technology] donghang@mit.edu

The Urban Heat Island (UHI) effect poses significant risks to public transit users, particularly those waiting at bus stops, where prolonged exposure to extreme heat can lead to thermal discomfort, heat exhaustion, and severe health outcomes. While existing studies have analyzed urban heat exposure using coarse-resolution Land Surface Temperature (LST) data, few have examined hyperlocal heat stress at bus stops and its relationship with the surrounding urban environment. This research aims to answer three key questions: (1) How does heat stress vary spatio-temporally around bus stops? (2) What urban and socioeconomic factors influence these variations? and (3) How do these factors exhibit nonlinear relationships and threshold effects?

To address these questions, we integrate high-resolution, multi-source geospatial data with microclimate modeling to generate hourly 1-meter resolution Universal Thermal Climate Index (UTCI) data across Philadelphia for July 2020, typically the hottest month of the year. This dataset enables a fine-scale analysis of pedestrian-level heat stress rather than relying on conventional 30m LST data, which fails to capture variations in street-level thermal conditions. We analyze heat stress from two perspectives: (1) a 3-meter buffer around each bus stop, representing hyperlocal exposure, and (2) a 400-meter pedestrian walkshed, reflecting the cumulative heat exposure during a typical 5-minute walk to or from the stop. Furthermore, we employ an explainable machine learning framework, integrating Random Forest (RF) and SHapley Additive exPlanations (SHAP) analysis, to uncover the nonlinear relationships and threshold effects between heat stress and both socioeconomic and built environment variables.

Our results reveal substantial spatio-temporal disparities in heat stress across Philadelphia's bus stops: (1) Heat stress exhibits strong diurnal variation, peaking at midday and remaining consistently high until the late afternoon, with some stops experiencing prolonged extreme conditions beyond critical thermal stress thresholds. (2) Bus stops in socioeconomically disadvantaged areas are disproportionately exposed to high heat stress, particularly those in high-poverty neighborhoods. Conversely, stops in affluent areas with higher median household values show significantly lower heat stress exposure. (3) Green View Index (GVI) and Enclosure are the strongest mitigators of heat stress, offering effective shade and cooling benefits. (4) Urban environment variables exhibit complex nonlinear threshold effects, indicating that heat mitigation strategies should be targeted and equity-focused rather than applying uniform interventions.

This study underscores the urgent need for equity-driven urban planning interventions to mitigate heat stress for transit users, particularly in high-risk and socioeconomically disadvantaged neighborhoods. Our high-resolution heat stress mapping approach provides actionable insights for planners to prioritize interventions at bus stops facing extreme heat exposure. By bridging microclimate modeling, explainable AI, and urban planning, this research contributes to the growing discourse on climate-resilient cities and equitable public transportation systems. The methodological framework developed here can be replicated in other cities to inform sustainable and inclusive transit planning in the face of climate change.

Spatiotemporal Impacts of Purpose-Specific Human Mobility on Air Pollution

Abstract ID: 1844.0.0.19.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Wenrui Xu [Tsinghua University] wenruixu@outlook.com, presenting author

Xinyue Gu [The Hong Kong Polytechnic University] xinyue.gu@connect.polyu.hk

Human mobility exerts significant influences on urban air pollution. Regrettably, most existing studies treated mobility as a homogeneous entity, neglecting that its effects may vary by travel purposes due to distinct spatiotemporal patterns. To address this gap, this study utilizes a trip purpose inference algorithm to classify mobility based on Beijing's three-month taxi trajectory data and examines its impact on air pollution using interpretable XGBoost-SHAP models. The correlational analysis indicates the substantial contribution of wind, temperature, and precipitation to air pollution. Human mobility's contribution is less significant than that of natural environments but greater than built environments. In the long term, the negative correlation between work- and home-purpose mobility and pollution challenges the assumption that more mobility always increases pollution. This study provides valuable experiences for sustainable urban planning and management globally, including promoting mixed-use development and work-residence integration, creating urban wind corridors and open green spaces, and adopting low-emission transportation while avoiding blanket traffic restrictions. Future research could examine causal relationships to understand the underlying mechanisms of these findings further.

Planning research and practice is often compartmentalized into quantitative and qualitative work. Local and indigenous knowledge can augment fact-based planning, especially through participatory approaches that recognize alternative knowledge and power in space-making, but rarely is the citizen resourced or empowered to leverage geospatial or statistical tools. In today's consultant-dominated ecosystem, asymmetries in data access and technical capacity favor those who can pay. This puts planners at a crossroads: Most state- and corporate-led planning lean on quantitative methods; community-based efforts rely on qualitative approaches. This methodological divide mirrors broader inequities in planning knowledge.

Forester (1989) called on planners to combat information inequity. Today, the proliferation of data and analytics techniques have created new possibilities—and responsibilities—for planners to build tools that democratize knowledge, bridge epistemic divides, and support collective agency. This paper presents a collaboration of quantitative and qualitative researchers, teaming up to create a framework for public-interest data praxis supporting grassroots planning advocacy in Goa, India. Using urban informatics tools to generate quantitative evidence, and interrogate land use planning, we demonstrate how technology informed by grounded issues can empower local actions. We highlight how the collaboration itself—between distinct methodological traditions—enabled new forms of planning practice. Flipping the “street science” model (Corburn 2005), in which planners qualitatively gather and interpret community perspectives, we shift toward enabling communities to independently produce research that informs their advocacy.

Our case examines the rezoning process in Goa, a coastal Indian state where residents contest investments in second-home developments fearing loss of future homeownership. To obtain a rezoning, developers must justify why their properties are fit for construction. Rezoning reports, prepared by private consultants, sideline community concerns by deploying technocratic language and selectively framed quantitative evidence. Institutional decision-makers tend to prioritize over villager-concerns. This left local residents at a disadvantage, not only being unfamiliar with planning jargon and protocols, but also vulnerable to manipulated data favoring clients over integrity. The Goa case thus exemplifies the information inequity: Those who can pay can play.

To address this challenge, we introduce our suite of tools:

amche.in, an open-source publicly accessible zoning atlas, hosts isolated maps owned by different municipalities to aid understanding of land use across the state.

Amche.Slope, an open-source slope map, classifies slopes according to statute, helping citizens interpret topography and verify claims.

CV4LandUse, a computer vision application, classifies and quantifies land uses from over 100 scanned land use maps. It applies pixel-based analysis to calculate land use percentages with speed and consistency, automating a process previously done manually in AutoCAD.

Project 39A, an online platform that tracks, simplifies, and maps rezonings statewide. A standardized spreadsheet and online training support a volunteer network: social workers relay the latest map and policy updates to villagers in their districts, while researchers assist them remotely in responding to rezoning reports.

More than a technological intervention, the toolkit operationalizes a hybrid methodology bridging quantitative applications with grounded, place-based insight. It illustrates how community advocates, equipped with analytical capacities typically reserved for institutional actors, can produce data-driven arguments that meet planning standards without losing local priorities. This offers a transferable model for participatory planning that reconfigures the engagement between expertise, evidence, and advocacy.

Striking a Pose: Using Pose Estimation Enhanced Computer Vision Models to Measure Public Life

Abstract ID: 1844.0.0.660.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Minwook Kang [MIT Leventhal Center for Advanced Urbanism] minwook@mit.edu, presenting author

Sarah Williams [Department for Urban Planning, MIT] sew@mit.edu

Observing and measuring public life is essential for designing successful public spaces. As William H. Whyte famously noted, “The best way to know how people are using a space is to simply watch them.” His seminal work, *The Social Life of Small Urban Spaces* (1980), revolutionized urban design by using emerging technologies to observe and quantify human activity in public environments. While Whyte relied on manual video analysis, advancements in open-source computer vision (CV) have made automated observation widely accessible. Today, with just a camera, a small computer, and open-source software, anyone can extract actionable insights that once required extensive manual effort.

Despite this increased accessibility, most urban studies utilizing CV tools for public space measurement are focused on transportation and fail to capture the nuanced ways people interact within urban environments—such as socializing, sitting, or sports activities. This gap exists because most CV algorithms struggle to accurately detect these types of behaviors. In this study, we test the combination of pose estimation with CV recognition to improve the accuracy of activity detection.

To integrate this model into public space sensing, we developed a sensor system called the Public Life Sensor Kit (PLSK)—a freely available, open-source tool designed specifically for measuring public life. The kit was tested during a public space improvement project in Sydney, Australia, where it was evaluated against the Viva Sensor, a transportation-focused, off-the-shelf CV sensor kit, as well as traditional human observation methods. The results demonstrated that PLSK not only made data easier to acquire but also offered greater accuracy in cataloging key activities such as pedestrian movement, sitting, and socializing. Our study highlights the potential of pose detection for measuring public life and suggests that future sensors should incorporate these techniques.

Emily Raider [Clemson University] emilyraider18@gmail.com

From 2003 to 2019 Americans steadily reduced out-of-home time; this trend then accelerated sharply during the pandemic and has never reversed. Comparing 2023 to 2003, Americans on average spend about 80 fewer minutes per day out-of-home. This has important planning implications, including potentially less need for commercial and retail space, greater demand for spacious housing, and less justification for difficult or costly transportation interventions. The most obvious explanation for less out-of-home time is the increasing use of information and communications technology (ICT), such as smartphones, streaming video, social media, videoconferencing, and high-definition television, all of which are mostly done in the home and might lessen the appeal of going out. However, prior research on ICT and out-of-home time has reached inconsistent findings and has not observed post-pandemic behavior. To fill these gaps, we use data from the Centre for Time Use Research UK Time Use Survey, March 2023. It collected 3,784 one-day time diaries from 2,179 adults. We created variables measuring daily minutes spent on television, communication (social media, texting, and phone), computer games, and internet/other computer use. Our outcome variables are out-of-home time and travel time. We also include sleep as a benchmark variable to distinguish between substitution effects (e.g., social media replacing in-person socializing) and time budget effects (ICT reducing other activities because there is limited time in the day). We assume sleep duration has little impact on the propensity to leave home versus stay in, which we confirmed using seemingly unrelated regression: since sleep's coefficients across models of both in-home and out-of-home time are statistically indistinguishable, we conclude that sleep presents only a time budget constraint with respect to leaving home. By comparing our sleep and ICT coefficients in models of out-of-home and travel time, we can infer whether ICT is a substitute for going out (if ICT coefficients are significantly more negative than sleep's) or a complement to it (if ICT coefficients are significantly more positive). Using OLS regression with demographic controls, we find television and computer games are strongly and negatively associated with out-of-home time, suggesting both substitution and time budget effects. However, the coefficients for both communication and internet/other computer time are significantly more positive than sleep's, suggesting complementarity. ICT time in general is negatively and significantly associated with out-of-home time, but the magnitude of the relationship is similar to sleep's, suggesting only a time budget effect. Travel is negatively associated with TV and games, but this is likely only due to time budget effects, while internet/other computer use has a stronger negative effect that suggests substitution. Communication's coefficient, which is significantly more positive than sleep's, suggests complementarity with travel. Television, internet/other computer time, communications, and overall ICT time are all negatively associated with social time, with television time particularly substituting for in-person contact. People with children, higher-income people, the unemployed, retirees, and Black Britons are more likely to stay home if they play more computer games, and unemployed people are more likely to stay home if they watch more TV. We find no evidence that the relationship between ICT use and out-of-home time varies based on sex, marital status, age, or education. In sum, ICT appears to explain some of the long-term decline in going out, but the relationship varies by ICT type (communication technology might actually promote leaving home) and demographics. There is a very strong possibility of endogeneity in our findings, since ICT may lead to less out-of-home time but causality likely also runs in the opposite direction. Future research should address this limitation.

The overall impact of working from home (WFH) on transportation emissions remains a complex issue, with significant implications for policymaking (Choo et al., 2005; O'Brien and Aliabadi, 2020). This study matches socioeconomic information from American Community Survey (ACS) to the global carbon emissions dataset for selected Metropolitan Statistical Areas (MSAs) in the US (Huo et al., 2022). We analyze the impact of WFH on transportation emissions before and during the COVID-19 pandemic. Employing cross-sectional multiple regression models and Blinder-Oaxaca decomposition, we examine how WFH, commuting mode, and car ownership influence transportation emissions across 141 MSAs in the United States. We find that the prevalence of WFH in 2021 is associated with lower transportation emissions, whereas WFH in 2019 did not significantly impact transportation emissions. After controlling for public transportation usage and car ownership, we find that a 1% increase in WFH corresponds to a 0.17 kilogram or 1.8% reduction of daily average transportation emissions per capita. The Blinder-Oaxaca decomposition shows that WFH is the main driver in reducing transportation emissions per capita during the pandemic. Our results show that the reductive influence of public transportation on transportation emissions has declined, while the impact of car ownership on increasing transportation emissions has risen. Collectively, these results indicate a multifaceted impact of WFH on transportation emissions. This study contributes to the policy debate by advocating for WFH as a strategy to reduce transportation emissions. Concurrently, policymakers can mitigate its unintended consequences by promoting public transportation and encouraging the adoption of environmentally friendly commute modes.

The Influence of Surrounding Amenities on the Elderly Neighborhood Park Visits in Seoul, South Korea

Abstract ID: 1844.0.0.588.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Alam Hasnan Habib [Ulsan National Institute of Science and Technology] alamhasnanh@unist.ac.kr, presenting author

South Korea is on the brink of becoming a super-aged society, with the elderly population, aged 65 and older, expected to surpass 30% of the total population by 2036 and 40% by 2050. This demographic shift presents a significant challenge that requires effective response. Notably, the fact that two-thirds of Korean elderly do not meet the recommended physical activity levels outlined in the National Guidelines. As result, diseases linked to the insufficient physical activity among the seniors - such as cardiovascular and cerebrovascular diseases - are among the leading causes of the mortality among South Korea's elderly population, alongside cancer, COVID-19, and pneumonia as reported in 2024. Frequent park visits have been shown to promote physical activity, reduce sedentary behavior, enhance mental health, and foster social interactions among the elderly. Therefore, encouraging park visits among older adults can be seen as an appealing strategy for the South Korean government. Promoting park visits can help seniors meet the recommended physical activity levels while also contributing to the economy by reducing healthcare costs. It is understood that the park visit is influenced by the intrinsic and extrinsic factors of the park. The intrinsic factors include the park size and the availability of the park's internal facilities. The extrinsic factors, which relate to the surrounding environmental characteristics, also play a critical role. The observed key extrinsic factors include the land use diversity, average of the surrounding building age, and transport facilities which are represented by the bus stop density and proximity to subway stations. While these factors are well-documented, the influence of the park's surrounding characteristics on the visits remains under researched and inconclusive. The presence of open-source data and mobile phone data has led to a trend of research in investigating the surrounding facilities' effect on the park visits. Utilizing Point of Interest (POI) data and mobile phone trip data, several studies have suggested that the presence of amenities near parks can attract more visitors. Subsequently, parks located near convenient amenities and areas with high vitality are found to experience an increased number of visits. These findings suggest that the presence of surrounding facilities encourages park visits by offering greater convenience and contributing to a more vibrant atmosphere. However, despite these findings, no research has explicitly demonstrated a direct relationship between park visits and the utilization of surrounding amenities and leaves an open question as to whether surrounding facilities influence park visitation or vice versa. To address this gap, our research leverages aggregated mobile phone data, represented in Origin - Destination matrices which record the people trips, to analyze mobility patterns among the elderly park visitors in Seoul, South Korea. This research focuses specifically on the neighborhood parks in Seoul, South Korea which are commonly equipped with outdoor gyms, walking tracks, and other facilities designed to encourage physical activity. Through statistical analysis, this research aims to confirm whether the presence of surrounding facilities influences the elderly park visits—or, conversely, whether the elderly park visits impact the utilization of nearby facilities. This research contributes to strengthening the understanding of the interrelationships between the parks' surrounding amenities with the elderly park visits. Additionally, this research helps to provide insights into sound strategy for increasing the park visits among older adults - an underrepresented segment in recent trends on park visits studies.

The Production of Spaces and Places by Urban Food Delivery Platforms in Kolkata, India

Abstract ID: 1844.0.0.1129.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Triparnee Kushari [Rutgers, The State University of New Jersey] triparnee.kushari@rutgers.edu, presenting author

Food delivery platforms not only enable interactions between food businesses and consumers and facilitate exchange (Langley & Lehson, 2017; Srnicek, 2016), they also act as portals of information exchange and tools for value extraction from locations unfeasible for traditional food businesses (Bauriedl & Strüyer, 2022). Using Cresswell's (2009) understanding of place, these platforms can be seen as aiding in the making and unmaking of "place" by reshaping the digital and physical experience of place through alternative representations of the city and by influencing changes in land use patterns. In this paper, I aim to reveal how these platforms produce pockets of disconnected spaces and disadvantaged places through platform affordances in the city of Kolkata, India.

I focus on the workings of Zomato, the leading food delivery company in India. As food businesses are highlighted in this "space of flows" (Castells, 2020) to maximize economic exchange, information that situates businesses in the physical world or "space of places" is de-emphasized. This enables the commercial exploitation of urban land unsuitable for traditional food business on the platform and makes it unnecessary for the business to be attractive to traditional consumers as they are tailored for delivery. I use restaurant location data scraped from Zomato's sitemap, online survey of cloud kitchen companies operating in the city, and field observations of a chain of restaurants and cloud kitchens in the city to identify locations that are adversely affected by these platform affordances.

Preliminary findings reveal that the combination of high platform visibility and low physical or local visibility of food businesses leads to the production of disconnected lots in disadvantaged neighborhoods. Their attractive virtual business-fronts conceal invisible 'ghost kitchens' in non-commercial neighborhoods. These areas not only bear the externalities of a commercial kitchen but are also robbed of the economic and social vibrancy that traditional food businesses bring to a street.

Time Profile of U.S. Neighborhoods: Datasets of Time Use at Social Infrastructure Places

Abstract ID: 1844.0.0.437.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Yan Wang [University of Florida] yanw@ufl.edu, presenting author

Ziyi Guo [University of Florida] ziyiguo@ufl.edu

Social infrastructure plays a critical role in shaping neighborhood well-being by fostering social and cultural interaction, enabling service provision, and encouraging exposure to diverse environments. Understanding time use offers a unique lens into population well-being, economics, social equity, and even poverty, as it reveals how individuals allocate their most finite resource—time—across various activities. Particularly, time spent at places like community centers, churches, meal sites, and cultural markets emerges as a vital indicator of social interactions and community engagement, underpinning social capital and meaningful relationships within neighborhoods. Thus, comprehensive knowledge of social infrastructure time use patterns is critical for informing urban planning and public health interventions.

Despite growing awareness of the importance and accessibility of social infrastructure, little is known about actual time use at these locations due to the absence of spatially-resolved national datasets. Existing national datasets, such as the American Time Use Survey (ATUS), have extensively explored demographic variations in time use but lack integration of spatial dynamics, leaving significant gaps in understanding spatial patterns of time allocation across neighborhoods. The predominant method for capturing time-use data relies on self-reported surveys, which often challenged for its respondent biases and limited spatial resolution. These limitations can hinder advancements in both time geography and public health, while impede comprehensive analyses across diverse geographic scales.

Existing knowledge body of time geography have emphasized human contacts and spatial accessibility, yet they predominantly focus on travel-time to locations rather than dwell time. Interdisciplinary studies examining the relationship between built environment and health highlight the importance of neighborhood contexts and daily activities for residents' well-being but rely heavily on self-reported data with inherent biases.

There is a lack of detailed spatial and temporal descriptions of how people engage with social infrastructure at the neighborhood level. This requires scalable, objective, and spatially explicit time-use data integrating both are needed to better inform urban policy and health research.

This study we develop four Social-infrastructure Time Use (STU) measures, and propose novel datasets spanning multiple geographic scales—from census tracts to metropolitan areas—across the 49 continental U.S. states from 2019 to 2024. Our STU measures incorporate three critical dimensions: length and depth of engagement, activity diversity, and spatial inequality. These datasets leverage anonymized and aggregated foot traffic data, enabling scalable, objective, and precise analyses of neighborhood-level social-infrastructure engagement. Preliminary analyses reveal significant variances in STU across time, space, and socio-demographic characteristics. Validation efforts confirm the robust population representativeness of the STU datasets, aligning well with existing national surveys while uncovering previously unrecognized nuanced patterns.

The novel dataset and measures offer comprehensive, comparable, and consistent benchmarking of time poverty in social infrastructure places across the U.S. This open opportunities for future studies to link STU with diverse public health, urban dynamic and environmental outcomes, providing vital insights for targeted interventions aimed at enhancing population well-being. Ultimately, our work offers scalable empirical evidence to advance

social infrastructure planning, improve health equity, and inform policy decisions aimed at fostering resilient, vibrant, and equitable urban environments.

Understanding the impact of GenAI on planning and design: A survey targeting faculty and students

Abstract ID: 1844.0.0.1177.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Sicheng Wang [University of South Carolina] sichengw@mailbox.sc.edu, presenting author

Generative artificial intelligence (GenAI) applications, such as ChatGPT, DeepSeek, Midjourney, Stable Diffusion, and DALL-E, are emerging as a transformative force in urban planning and design. These technologies are trained based on huge existing data through large language models (LLMs) and can rapidly generate contents texts, charts, images, and videos for a variety of creative tasks that used to be completed by highly skilled professionals who have systematic training in planning and design. This starts reshaping how planners and designers conceptualize, visualize, and communicate urban solutions. Teachers and students in planning programs are facing a problem how they should deal with the immersion of GenAI. However, the interaction with GenAI in urban planning education and practice remains uneven, and perceptions of its value and potential consequences are not well-documented. In this study, we aim to explore the attitudes, usage, and perceived impacts of GenAI among faculty and students in urban planning programs provided by institutions in multiple countries and regions, including the US, the UK, Korea, the Netherlands, Mainland China, Hong Kong, and Macau. The study addresses three primary research questions: (1) What is the level of familiarity and actual usage of GenAI among planning faculty and students? (2) How do planning faculty and students perceive the impact of GenAI on job opportunities and requirements in planning? (3) How do planning faculty and students perceive GenAI influencing creativity, efficiency, originality, and overall quality of planning works? (4) What ethical and practical concerns are associated with the integration of GenAI into urban planning education and practice?

To address these questions, we use a structured online survey distributed to faculty and students across diverse urban planning programs at undergraduate and graduate levels. The survey captured scales on familiarity and frequency of GenAI usage, as well as measures regarding perceived benefits, workforce impact, risks, limitations, and ethical implications. The survey also includes open-ended questions capturing qualitative data on attitudes and perceptions. Our analysis combines statistical methods to assess patterns of AI adoption and thematic analysis to interpret qualitative responses.

The findings contribute new empirical insights into an emerging technological trend within urban planning and design education and practice. The paper highlights the necessity of thoughtful integration strategies, highlighting that careful consideration of ethical guidelines, training protocols, and inclusive access are critical to establishing a framework that integrates AI in planning and design. These findings will advance understanding of technology adoption in educational settings; it informs practice by clarifying practical benefits and pitfalls; and it supports planning and design education by providing evidence-based recommendations for curriculum development and instructional strategies. As urban planning continues to evolve rapidly in response to technological advances, this study offers valuable guidance for balancing innovation with ethical and practical considerations.

Universality in Urban Street Networks

Abstract ID: 1844.0.0.61.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Geoff Boeing [University of Southern California] boeing@usc.edu, presenting author

Planning scholars and practitioners model street networks to understand or predict many phenomena, including traffic dynamics, accessibility to daily living needs, and the resilience and sustainability of urban forms. These analyses use various topological and geometric indicators to measure important street network characteristics: node degrees reveal streets' connectedness, betweenness centrality concentrations identify network chokepoints, straightness suggests network efficiency or lack thereof, orientation entropy indicates the consistency of its spatial organization, etc. Much research in recent years has sought to identify differences between different cities' urban street network characteristics, for example by developing morphological typologies to identify planning paradigms, or by using variation to explain walking or resilience outcomes. This paper instead argues that these indicators of street networks' geometric and topological form actually show remarkable universality—i.e., convergent homogeneity—across cities of drastically different origins and planning paradigms.

To test this, we model the street networks of every urban area in the world using 2025 Global Human Settlement Layer boundaries and covariates plus 2025 OpenStreetMap data via OSMnx. Then we calculate each street network's straightness, orientation entropy, average node degree, and the Gini coefficient of its weighted node betweenness centralities. Next, across all urban area street networks, we calculate each indicator's coefficient of variation (CV), a standardized measure of the dispersion of each's probability distribution. Then we compare these CVs to those of urban "size" indicators (population, built-up area, total street length, intersection count) and other urban characteristics (average built height, average elevation, population greenness exposure, air pollution concentration), selected to cover a variety of ratio scale probability distributions.

We find that urban street networks' geometric and topological form is consistently far more homogenous (CVs = 0.02 to 0.10) than the size indicators (CVs = 2.80 to 3.45) and the other urban characteristics (CVs = 0.28 to 1.58). Further, these patterns and differences hold across a variety of underlying probability distributions and rescaling (normalization). In other words, these properties are largely independent of the details and dynamics of the underlying urban system. Cities of drastically heterogeneous types and vintages converge on a consistently homogenous narrow set of universal indicator values. This "universality" tells us that many underlying processes—many kinds of cities and planning paradigms—converge to generate similar street network forms. Regardless of the location of the city or the size of its network, there is homogeneity among indicators of street networks' geometric and topological form, which we do not see in other urban characteristics.

These findings contribute a new understanding of universality in street network planning to urban science's quest for universal theory. We propose some candidate explanations for—and real-world implications of—the underlying process. Street networks' spatial embedding and quasiplanarity constrain their geometric and topological properties in ways that do not apply to other urban characteristics. More importantly, many but not all street networks are shaped by central planning. Yet urbanization that is centrally planned versus organically self-organized, urbanization from different historical eras, and urbanization in different world regions may generate very different cities and modes of urban living—yet they converge on a homogenous set of street network form characteristics. This universality is seen in other complex systems and contributes to complexity theories of cities and planning.

Urban Analysis of Shared Streets: Evaluating Pedestrian-Vehicle Conflict via Deep Learning Video

Abstract ID: 1844.0.0.1000.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Hyemin Na [Ulsan National Institute of Science and Technology] hyemin23@unist.ac.kr, presenting author

Jeongseob Kim [Ulsan National Institute of Science and Technology, UNIST] jskim14@unist.ac.kr

In urban environments, streets serve as critical infrastructure shared by both pedestrians and vehicles, fundamentally shaping the spatial scale of cities. Pedestrian safety is influenced by a combination of built environment characteristics and individual behaviors, while street design directly affects pedestrian-vehicle interactions through factors such as visibility, traffic volume, and speed (Stoker et al., 2015).

To enhance pedestrian safety and create more flexible traffic environments, planners have introduced the concept of shared space, which minimizes conventional traffic rules and promotes self-regulated interaction among road users, thereby transforming streets into more human-centered social spaces (Methorst et al., 2007).

South Korea's Pedestrian Priority Streets adopt this concept by allowing pedestrians and vehicles to jointly use the entire road space. However, post-implementation evaluations have primarily relied on qualitative surveys or manual counting of traffic flow and speed (Oh & Park, 2018), while most existing research on shared spaces has focused on developing methodologies for behavior or conflict analysis rather than on-site empirical evaluation (Orsini et al., 2023).

This study aims to overcome these limitations by developing an automated, AI-based analytical framework for quantitatively assessing pedestrian safety in pedestrian-priority streets and applying it to real-world urban street environments.

We conducted a comparative analysis using pedestrian-priority streets with both one-way and two-way traffic as the experimental group, and conventional streets of the same width (8 meters) as the control group. Pedestrian and vehicle movements were extracted from video footage using the YOLO object detection algorithm, and actual speeds and distances were estimated via homography techniques. Key indicators analyzed include spatial sharing between pedestrians and vehicles, frequency and location of potential collisions, and spatial patterns of avoidance behaviors.

Data were collected using 360-degree cameras across various time periods, including weekdays, weekends, rush hours, and lunch hours. Additionally, pedestrian characteristics such as age and gender were considered to examine differences in interaction patterns and avoidance responses.

By shifting away from traditional survey- or observation-based approaches, this research demonstrates the potential of video-based quantitative analysis to provide objective, evidence-based insights for evaluating the effectiveness of pedestrian safety policies. Ultimately, the framework offers a valuable tool for evidence-based urban planning centered on pedestrian-friendly design.

Urban Morphology and Compound Exposure: Unraveling the Temperature-PM2.5 Link

Abstract ID: 1844.0.0.186.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Lu Liang [University of California, Berkeley] lianglu@berkeley.edu, presenting author

While the effects of urban landscapes on singular environmental exposures have been widely studied, few investigations consider the compounded exposures people experience in daily life. This study examines two prominent environmental challenges in urban areas: urban heat and air pollution. Specifically, we analyze (1) the spatial and temporal dynamics of the air temperature (T)–PM2.5 relationship and (2) the influence of urban morphology on this association. To capture ground-level air T and PM2.5, we deployed co-located, systematically calibrated low-cost sensors across 50 sites in Denton County, Texas. To represent the diverse urban morphology, we integrated high-resolution satellite-derived land use and land cover maps alongside local climate zone (LCZ) maps, which account for both physical and structural attributes, providing a more comprehensive view of urban form. Over 200 landscape metrics were generated from these datasets to characterize urban patterns using traditional circular buffers and wind-wedges to account for wind effects on heat retention and pollution dispersal. Our modeling results reveal strong seasonal variations in the air T–PM2.5 relationship and identify key landscape variables that help mitigate compounded environmental exposures. These findings offer insights on the critical role of urban design in shaping air quality and thermal environments.

Using Daily Mobility to Predict Residential Mobility

Abstract ID: 1844.0.0.140.2025

Track 13: Technology, Society and Analytical Methods

Pre-Organized Paper Presentation

Lance Freeman [University of Pennsylvania] lancefre@design.upenn.edu, presenting author

Differences in economic resources, residential preferences, and discriminatory practices have been the primary explanations for how households sort themselves across neighborhoods along dimensions of class and race (Galster and Godfrey 2005; Ellen 2000). Demographers have further unpacked these explanations to show that economic disparities experiences with discrimination and especially preferences are mediated through social networks and day-to-day living experiences. Maria Krysan and Kyle Crowder are perhaps the most influential proponents of this latter approach developing the Structural Social Sorting Perspective (SSSP) (Krysan and Crowder 2017). They argue racial-ethnic differences in daily activities and geographic experiences are important predictor of segregated residential patterns (Krysan and Crowder 2017, 183).

Facets of the SSSP have been tested using qualitative interviews that ask respondents about their experience and knowledge of other neighborhoods and how that influenced subsequent moves. Researchers have typically relied on respondent recall to infer how daily experiences impact subsequent choices (McDaniel 2025). Such an approach is certainly informative, however, suffers from several shortcomings. First respondents' recall is fallible. Second, respondents might attach more salience to some experiences than others. This could be due to respondent error or quite the questions failing to prompt the appropriate answers. Finally, the sample sizes used in previous research didn't allow researchers to infer the strength of the connections between different neighborhoods. We reason in neighborhoods with stronger connections, as evidenced by a greater volume of daily visits between two neighborhoods, residential mobility connections between those neighborhoods will be greater as well.

In this paper we utilize two relatively novel data stats to examine how daily mobility experiences might inform future residential mobility. We use smartphone data to document patterns of daily mobility. Our smartphone data is derived from 45,000,000 devices across the U.S., aggregated to the census block group from 2019 to the present. From this data we construct network pairs that show how linked to census block groups in a city are to other block groups. This allows us to infer the degree of daily exposure between two census blocks groups. We then use information on the strength of these connections to predict residential mobility flows based on consumer reference data also aggregated to the census block group level. Consumer reference data from Infutor include individuals' first and last names, date of birth, residential location and start date, as well as inferred demographic information. The data include around 80- 90 percent of the population (Ramiller et al. 2024).

Our research will be among the first to demonstrate how daily mobility patterns influence subsequent residential mobility. In doing so our research will make two important contributions. First, we will demonstrate the utility of both smartphone data, and consumer trace data for studying patterns of daily and residential mobility. Second, we will show how daily mobility patterns are linked to patterns of residential mobility. In doing so we will further our ability to understand patterns of neighborhood change.

Individual Paper Presentation Submission

Florina Dutt [Alabama A&M University] florina.dutt@aamu.edu, presenting author

This research investigates the relationship between the built environment and the intangible qualities of Sense of Place (SoP) and Sense of Community (SoC) in Huntsville, Alabama, using geo-located Instagram posts as a novel methodological framework. Building on prior exploratory studies, we analyzed data from over 450 points of interest (POIs) within Huntsville and its adjacent two-mile radius. The study introduces a scoring system that decomposes SoP and SoC into measurable components, allowing for a deeper understanding of how urban spaces influence mental well-being and community engagement.

The scoring system operationalizes SoC through four dimensions: membership (a sense of belonging), influence (the ability to impact one's community), fulfillment of needs (access to resources), and shared emotional connections (collective experiences). Similarly, SoP is evaluated through four elements: place attachment (emotional ties to a location), social bonding (interpersonal connections fostered by the space), place dependence (functional reliance on a location), and place identity (the role of a place in shaping self-expression). These constructs were quantified using text mining algorithms applied to Instagram posts, comments, and captions generated through image classification techniques. Image analysis employed Faster R-CNN Inception ResNet V2 for object detection and BLIP (Bootstrapping Language-Image Pre-training) for image captioning, enabling the identification of urban features such as public art, seating areas, green spaces, and pedestrian infrastructure.

The results revealed significant correlations between components of SoP and SoC. Place attachment exhibited a very high correlation with place identity ($r = 0.959$), indicating that individuals who strongly identify with their place are also likely to feel deeply attached to it. Membership showed a strong correlation with social bonding ($r = 0.925$), suggesting that individuals who feel a sense of belonging in their community are more likely to experience interpersonal connections in shared spaces. Influence demonstrated a significant connection with place identity ($r = 0.839$), reflecting how individuals who perceive agency in shaping their environment often express stronger identification with their locale. However, fulfillment of needs showed weaker correlations with other factors, suggesting it may operate independently of socio-emotional constructs like attachment or identity.

Additionally, the analysis highlighted similarities between highly frequented POIs and lesser-known locations. Underutilized spaces often share visual features with high-scoring areas, such as mixed land use, pedestrian-friendly designs, or public art installations. This finding underscores the latent potential of lesser-known spaces to foster community engagement and enhance urban livability.

This research offers a practical methodological approach for urban planners by leveraging publicly curated image and text data from Instagram to quantify intangible qualities like SoP and SoC. The novelty lies in using text mining and image classification techniques to evaluate mental well-being expressed in social media posts. By mapping these attributes across Huntsville, this study enriches our understanding of the interplay between the built environment and mental well-being while providing actionable insights for designing inclusive urban spaces that promote social cohesion.

What and Where Are the Problems? Revealing Walkability Inequity Using Street View Images and ChatGPT

Abstract ID: 1844.0.0.386.2025

Track 13: Technology, Society and Analytical Methods

Individual Paper Presentation Submission

Donghwan Ki [The Ohio State University] ki.17@osu.edu, presenting author

Zhenhua Chen [The Ohio State University] chen.7172@osu.edu

A better understanding of walkability conditions in minority neighborhoods requires close attention to streetscape features that often pose significant barriers to walking in these communities (Adkins et al., 2017; Koschinsky et al., 2017). However, assessing such features across large geographic areas remains challenging due to the high cost of field audits and the limited scope of off-the-shelf computer vision models. Specifically, these models can capture only typical environmental features (e.g., greenery) and their quantitative attributes (e.g., amount), which are insufficient for a comprehensive evaluation of walkability (Liu & Sevtsuk, 2024; Park et al., 2025).

To address this gap, this study leverages Google Street View (GSV) and ChatGPT to conduct an automated and comprehensive walkability assessment in the City of Los Angeles, California. Recent studies have begun to explore the use of ChatGPT in interpreting visual information for built environment evaluation, highlighting its emerging potential in urban analytics (Crooks & Chen, 2024). The study aims to identify detailed walkability issues and examine their spatial distribution, with a particular focus on minority neighborhoods. For each GSV image, ChatGPT is prompted to generate both a numeric walkability score and a narrative description of observed walkability issues. These large-scale textual outputs are then analyzed using natural language processing techniques—specifically, Latent Dirichlet Allocation topic modeling—to extract structured, topic-specific walkability problems.

Findings reveal that minority neighborhoods not only exhibit lower walkability scores but also disproportionately experience issues such as unkempt streetscapes, deteriorated sidewalk conditions, and a lack of traffic calming measures. Validation using both human raters and semantic segmentation models confirms the reliability of ChatGPT-generated walkability assessments. By providing a scalable and nuanced evaluation of walkability, this study offers critical insights to inform more equitable planning interventions and resource allocation.

Beyond Objective Metrics: Interpreting Multi-dimensional Park Perceptions with Large Language Models

Abstract ID: 1842.0.0.644.2025

Track 13: Technology, Society and Analytical Methods

Research-in-Motion Presentation Submission, Research currently in process

Qiwei Song [The Chinese University of Hong Kong] qiwei.song@link.cuhk.edu.hk, presenting author

Jeroen van Ameijde [The Chinese University of Hong Kong] jeroen.vanameijde@cuhk.edu.hk

Siyu Tian [The Chinese University of Hong Kong] sijyu.tin@link.cuhk.edu.hk

Understanding the general public's perceptions of urban amenities is critical for effective urban management to enhance residents' livability. Conventionally, the park evaluation relies heavily on objective measures that quantify available resources (e.g., tree coverage) or through labor-intensive survey methods to solicit subjective feedback. More recently, emerging crowdsourced user-generated reviews on social media platforms offer a cost-effective alternative for capturing users' opinions and experiences in a scalable manner. Nevertheless, previous data-driven research was limited to assessing the users' sentiment within parks; its narrow focus often rendered it challenging to identify targeted strategies for park amenity enhancement for governance. Various other dimensions, including accessibility, functionality, attractiveness, or maintenance, could derive direct implications for park management, which is poorly addressed in the existing literature.

To address the research gap, this study systematically compares, for the first time, three types of deep learning models—Contrastive Language-Image Pre-training (CLIP) models, text embedding-based models, and Large Language Models (LLMs) for predicting three dimensions (perceived accessibility, functionality, and attractiveness) of urban parks using manually curated labels derived from Google Maps reviews. Leveraging the model with optimal performances, over 66 thousand user reviews were subsequently analyzed to quantify multi-dimensional perceptions across 158 urban parks in Hong Kong. Secondly, by integrating the park perceptions, we innovate existing walking accessibility to parks measurement with a quality-based Enhanced Two-Step Floating Catchment Area (E2SFCA) approach. The bivariate Local Indicators of Spatial Association (LISA) analysis allows comparison between quality-based and the prevailing size-based accessibility metric to identify neighborhoods demonstrating disparities in actual experiences and supplied park capacities. Finally, to uncover the underlying impact pathways of each dimension, it further examines the influence of various characteristics, including park interior features (e.g., specific facilities), built environment attributes (e.g., land use mix), street qualities (e.g., aesthetics), as well as the nearby sociodemographic profiles and temporal factors.

This study demonstrates that the finetuned domain-specific LLM achieves optimal predictive performance—yielding accuracy between 83% and 91% across different perception categories—outperforming zero-shot and few-shot prompted LLMs and other models. The subsequent spatial equity analysis uncovers insights often overlooked in conventional accessibility assessments focused solely on park capacity. Despite minor variations caused by different network buffer settings, clusters of low-quality yet high-capacity were consistently identified in several northern neighborhoods of Sha Tin and Yuen Long Districts, offering new perspectives for park provision and management in Hong Kong. Lastly, the study enriches the literature by elucidating the nonlinear effects of environmental attributes on public perceptions.

To summarize, this research proposes a comprehensive analytical framework that leverages state-of-the-art LLMs to advance the evaluation of public park perceptions. Integrating user-generated data and advanced AI techniques enables the identification of priority areas for park improvements through perception-driven, data-informed analysis to advance spatial equity assessments. Most importantly, the findings offer evidence-based recommendations by highlighting key characteristics that shape park perceptions, thereby informing policy decisions and guiding long-term park management strategies to improve urban quality of life.

Generative AI for Urban Planning: Opportunities and Challenges

Abstract ID: 1842.0.0.657.2025

Track 13: Technology, Society and Analytical Methods

Research-in-Motion Presentation Submission, Critique related to a hot topic in planning research

Junghwan Kim [Virginia Tech] junghwankim@vt.edu, presenting author

This presentation explores the potential opportunities and challenges of Generative AI (GenAI) for urban planning by presenting key empirical findings from recent work conducted by our research group, Smart Cities for Good at Virginia Tech. Since the release of ChatGPT in November 2022, an increasing number of urban planners and GIScientists have begun examining how GenAI tools might be integrated into planning practice (e.g., Ye et al., 2025a, 2025b).

In a recently published study (Jang and Kim, 2025), we employed two widely used multimodal large language models (LLMs)—OpenAI’s GPT-4o and Google’s Gemini 1.5 Pro—to assess their ability to identify built environment features such as sidewalks and streetlights from street-view imagery. We compared the GenAI-based results with those produced by a conventional deep learning-based computer vision method. The findings underscore the considerable potential of GenAI for built environment auditing—an essential but often resource-intensive task for planning agencies such as Metropolitan Planning Organizations (MPOs). Importantly, unlike conventional deep learning approaches, which typically require substantial computing resources (e.g., high-performance computing) and technical expertise (e.g., coding skills), GenAI-based methods may broaden participation in advanced urban analytics. With user-friendly interfaces such as interactive chatbots, GenAI offers a more accessible entry point for planners and practitioners to engage with AI-assisted tools.

At the same time, our findings reveal a critical limitation: the uneven geographic performance of GenAI tools. A series of empirical studies conducted by our group have examined GenAI’s spatial capabilities, including its ability to extract location-specific environmental issues (Kim et al., 2024) and respond to spatial queries (Renshaw et al., 2025). These studies consistently show that GenAI performs better in densely populated, affluent urban areas than in sparsely populated, economically disadvantaged rural regions. These geographic differences highlight potential ethical concerns (e.g., biases) in the use of GenAI for urban planning.

Drawing on these findings, I will discuss the ethical implications and the importance of responsible GenAI use in both research and practice. As AI technologies continue to evolve rapidly, it is crucial for planning professionals and scholars to be prepared for this new technological landscape. In this context, I will introduce the concept of AI literacy and explore how planning education can adapt to better prepare students. Specifically, I will share insights from a newly developed course at Virginia Tech, GenAI Applications in Social Science, designed to foster critical engagement with GenAI in urban planning contexts.

Overall, this presentation offers a timely opportunity for planners to critically reflect on both the potential and limitations of GenAI in urban planning. This presentation will stimulate meaningful discussions among planning researchers and practitioners on this critical and evolving topic in the AI era.

Graph neural networks for travel demand choice: an alternative graph with nest structures

Abstract ID: 1842.0.0.839.2025

Track 13: Technology, Society and Analytical Methods

Research-in-Motion Presentation Submission, Research currently in process

Yuqi Zhou [University of Florida] yuqizhou@ufl.edu, presenting author

Shenhao Wang [University of Florida] shenhaowang@ufl.edu

Zhanhong Cheng [University of Florida] zhanhong.cheng@ufl.edu

Discrete choice models (DCMs) have been a cornerstone for travel mode choice analysis. These models provide a sound analytical framework for explaining individual decisions and deriving behavioral indicators. A family of DCMs widely used for decades is based on random utility maximization, including the multinomial, nested, and mixed logit models (MNL, NL, and MXL). However, these conventional models are commonly restricted by their computational efficiency and handcrafted utility specification. To address the limitation in handcrafted utility specification, deep neural networks (DNNs) have been adapted for choice analysis in many recent studies, which have demonstrated their capacity of automating utility specification and improving predictive performance upon conventional DCMs. However, a critical missing in existing DNNs is the ability to capture the correlations among alternatives.

To address the challenges, this study proposes an alternative graph to represent the relationships among travel mode alternatives, thereby reframing the conventional discrete choice model by graph neural networks (GNNs). Firstly, we use the designed nested alternative graph to represent the alternative correlations between utilities rather than directly adapting sufficiently flexible neural networks into an existing GEV model. We categorize the seven travel modes into three components: vehicle, active, and public transit. Within the vehicle component, the driver, taxi, and passenger nodes are fully connected. The active component includes bike and walk, while the public transit component consists of bus and metro. Let's name a one-layer graph neural networks with an alternative graph consisting of disconnected components with full connectivity in each component as nest-specific utility (NSU) GNN. We can replicate the key choice probability form in the nested logit model due to the additive nest-based aggregation form. The NSU-GNN generalizes the existing automatic feature learning capability of DNNs to further account for correlations between alternatives with compound utilities. We then apply NSU-GNN alongside benchmark models, including DNN architecture with alternative-specific utility functions (ASU-DNN), MNL, and NL, to predict travel mode choice in datasets collected from 2018-2019 Chicago My Daily Travel Survey and 2019 Tampa Bay Regional Travel Surveys. Results demonstrate that NSU-GNN consistently outperforms all benchmark models in terms of prediction accuracy for travel mode choice.

This study makes contributions in two main areas. Theoretically, the NSU-GNN generalizes the MNL, NL, and ASU-DNN models in terms of model representation and substitution patterns, while retaining the utility-based interpretation. It introduces utility maximization theory to establish novel theoretical foundations for incorporating deep learning techniques, such as GNNs, into travel behavior analysis. This paper further explores the hierarchical relationship among NSU-GNN, ASU-GNN, MNL, and NL, showing that NL is a special case of NSU-GNN, while MNL is a special case of ASU-GNN. This approach integrates traditional discrete choice models with GNNs, bridging classical econometric methods with modern machine learning techniques. Empirically, the NSU-GNN significantly outperforms the benchmark models, and addresses key limitations of existing DNN-based choice models in differentiating properly the substitution patterns for correlated/non-correlated alternatives. NSU-GNN retains the strengths of DNNs, like automatic utility specification and high predictive performance, while effectively modeling relationships among choice alternatives. Overall, this study introduces deep graph choice models (DGCMS) and

designs NSU-GNN towards an interpretable, robust, and transparent computational choice modeling framework for more reliable decision support.

Investigating the Impact of Urban Morphologies on UHI

Abstract ID: 1842.0.0.231.2025

Track 13: Technology, Society and Analytical Methods

Research-in-Motion Presentation Submission, Research currently in process

Xuyang Chen [Southeast University, School of Architecture] chenxy_seuarch@163.com, presenting author

With the advancement of global climate change and urbanization, the issue of urban heat island(UHI) in high-density areas has become increasingly severe, posing significant threats to human health and urban sustainability. Urban form has been recognized as a key factor influencing the urban heat island, as it determines the environmental structure of buildings and microclimates. Therefore, understanding the relationship between urban two-dimensional and three-dimensional forms and the thermal environment is crucial for developing effective urban heat island mitigation strategies. However, few studies have considered the significant impact of differences in urban functional areas on research outcomes, while urban location factors are often overlooked. In this study, we innovatively constructed an interpretable analytical framework combining geographically weighted regression (GWR) with causal machine learning. This framework explores the differential impact of urban form on the thermal environment across different urban functional areas by identifying these areas, addresses the influence of location differences through GWR, and reveals the intervention effects of urban form on the thermal environment using causal machine learning. The results show that: (1) The mechanisms by which urban form influences the thermal environment vary significantly across different urban functional areas. In commercial areas, factors such as MBH, FAR, and RESI have a strong positive impact on the thermal environment, while factors like BO and BH have a more significant impact in residential areas. (2) The influence of urban form on the thermal environment exhibits significant spatial variability. This is of critical importance for formulating differentiated urban heat island mitigation planning and policies. (3) The heterogeneity of causal effects reveals the sensitive thresholds and nonlinear response patterns of urban form regulation. By generating a library of urban form optimization schemes based on potential outcome models, we quantify the cooling potential of urban form adjustments in different functional areas to mitigate future urban heat island effects and promote healthy urban development. The findings provide new insights into the complex mechanisms by which urban form affects the thermal environment in urban functional areas and offer quantitative guidance for the planning of urban form updates in high-density areas to alleviate future urban heat island effects and foster sustainable urban development.

Listen to the Land: Multicultural, Multimodal AI for Scientific & Indigenous Knowledge Sharing

Abstract ID: 1842.0.0.1085.2025

Track 13: Technology, Society and Analytical Methods

Research-in-Motion Presentation Submission, Research currently in process

Xiao Shi [University of California San Diego] xis024@ucsd.edu, presenting author

Feiyang Sun [University of California, San Diego] f1sun@ucsd.edu

This multi-year project investigates how Artificial Intelligence (AI) can support inclusive, culturally grounded communication and planning at the intersection of climate adaptation, health equity, and land governance. It centers on the development of context-aware language databases and small language models that translate across scientific, traditional ecological knowledge (TEK), and local knowledge systems in the transboundary Cali-Baja bioregion. Encompassing Southern California, Northern Baja California, and the lands of Indigenous Nations, Cali-Baja is shaped by overlapping histories of Indigenous stewardship, colonialism, and migration, as well as the highest biodiversity in the continental U.S. Its plural ecologies and governance structures make it an ideal testbed for developing multilingual, multimodal AI planning tools for knowledge sharing and communication that respect and reflect the diversity of epistemologies, spatial practices, and socio-ecological systems that inform local decision-making.

The project responds to two key challenges. First, AI systems—particularly those trained on large, generalized text corpora—struggle to interpret the linguistic complexity and epistemological richness of Indigenous and place-based knowledge systems. This includes polysynthetic language structures, semantically dense terminology, and storytelling as a primary mode of governance and planning. Second, conventional climate and health planning tools often privilege urban-centric, technocratic frameworks, marginalizing rural and Indigenous communities that are most affected by ecological change yet least equipped with inclusive communication technologies.

Methods: To address these challenges, the project adopts a phased, participatory methodology. It begins by co-developing a multimodal corpus (i.e. text and other formats of data used to train AI systems) through workshops, incorporating oral histories, climate plans, scientific articles, and visual materials such as maps and hand drawings. Language data will be annotated with spatial, ecological, and cultural metadata reflective of the Cali-Baja bioregion. From this, we will train small language models using a hybrid architecture and curated, domain-specific outputs. These models aim to generate accurate, respectful, and context-sensitive translations between technical and community-based planning concepts, expressed in multiple languages and modalities (e.g., images, maps, and narrative forms).

Expected Results: The project's end deliverables include a bioregion-specific knowledge corpus, a suite of lightweight translation models, a knowledge sharing platform, and policy recommendations for integrating culturally grounded AI into local governance systems. Crucially, the project is governed by a community-led data stewardship protocol that upholds Indigenous data sovereignty and cultural specificity. Model outputs will be evaluated through iterative workshops with community partners, ensuring that AI tools remain responsive to the lived priorities of those navigating climate and health challenges on the ground.

Significance: This project advances existing AI methodology by integrating multimodal techniques to capture the linguistic and epistemological structures of Indigenous and local knowledge systems. It contributes to a new paradigm of storytelling-centered knowledge creation and decision making that bridges the humanities and climate science and lays the groundwork for a durable, interdisciplinary alliance that can be replicated in other bioregions

globally. Most importantly, it restores the rightful place of local narratives, languages, and wisdom traditions in shaping our collective future.

Seniors' Use of Autonomous Vehicles and Implications for Access to Social Networks and Wellbeing

Abstract ID: 1842.0.0.317.2025

Track 13: Technology, Society and Analytical Methods

Research-in-Motion Presentation Submission, Research currently in process

Rababe Saadaoui [Arizona State University] rsaadaou@asu.edu, presenting author

Aging is a global trend, with many countries experiencing a rise in both the number and proportion of older adults. This demographic shift presents significant challenges, including major life transitions such as retirement, the loss of loved ones, and living alone. In addition, health-related mobility limitations put seniors (aged 65+) at risk of social isolation, restricting their ability to maintain social networks beyond their immediate surroundings, which can negatively affect their wellbeing.

Autonomous Vehicles (AVs) are an emerging technology with the potential to reshape seniors' mobility by enhancing access to social networks. Scholars suggest that AVs can support healthy aging by promoting mobility, fostering social interactions, and enabling aging in place (Booth et al., 2022; Curl et al., 2018; Sohrabi et al., 2020; Zandieh & Acheampong, 2021). AVs could be especially beneficial for seniors who are still relatively active but face driving challenges due to physical or cognitive decline. By maintaining mobility independence, seniors may continue engaging in social activities and sustaining social connections—key contributors to overall wellbeing. However, challenges such as difficulties adapting to AVs, trust issues, and safety concerns remain significant (Booth et al., 2022).

While most existing research on AVs and seniors focuses on anticipated outcomes, this study explores seniors' actual experiences with AVs. Specifically, it examines both the opportunities and challenges AVs present, with a focus on access to social networks, a critical factor for seniors' wellbeing. The research questions are: What are the characteristics of social networks among seniors, and how do the quantity and quality of these networks vary by income level and car ownership status? How do seniors access their social networks? How does the introduction of AVs impact seniors' access to social networks and their wellbeing? Does the experience of using AVs lead to sustained changes in access to social networks and wellbeing among seniors? If so, how and to what extent? If not, why not?

To address these questions, the study focuses on the Phoenix region, a leading hub for AV technology. The study employs semi-structured interviews and travel diaries across three phases. Phase I establishes a baseline understanding of seniors' social networks and the role of transportation in accessing them. In Phase II, participants receive vouchers to use AVs and reflect on their experiences, assessing the impact on their social networks and wellbeing. Phase III focuses on assessing any long-term changes in social network access and wellbeing following AV exposure. A mixed-methods approach will be used for analysis. Travel diaries will be quantitatively assessed to evaluate shifts in travel behavior, the nature and frequency of social interactions, and AVs' impact on social network access. Thematic coding of interview transcripts will identify key patterns related to AV adoption, mobility independence, and wellbeing implications.

This study provides critical insights into how emerging transportation technologies influence seniors' access to social networks and wellbeing. By examining real-world experiences, it highlights both the benefits and challenges of AV adoption for seniors. The findings will inform discussions on integrating AVs into systems that support healthy aging and contribute to policy and urban planning initiatives focused on improving mobility solutions for seniors.

Smart City Infrastructure and Clean Energy Adoption and Access Equity: Evidence from New York City

Abstract ID: 1842.0.0.191.2025

Track 13: Technology, Society and Analytical Methods

Research-in-Motion Presentation Submission, Research currently in process

Saeed Esfandi [University of Delaware] sesfandi@udel.edu, presenting author

John Byrne [University of Delaware, Foundation for Renewable Energy & Environment (FREE)] jbnov@yahoo.com

As part of its sustainability agenda, New York City (NYC) has launched a range of initiatives advancing digital infrastructure, decarbonization, and energy efficiency in recent years. The city was ranked the number one smart city in North America in 2023 (Sat & Maynard, 2023). Annual solar energy production from NYSERDA-supported projects rose from 71,956 MWh in 2015 to 506,180 MWh in 2023, a sevenfold increase (NYSERDA, 2024). During the same period, American Community Survey 5-year estimates indicate that the number of housing units using clean energy (solar or electricity) for primary heating grew by 60%, from 324,475 (10.4% of total housing) to 517,077 units (15.6%). While these city-wide metrics reflect notable progress, less is known about how smart city infrastructure relates to clean energy adoption rate (CEAR) and clean energy access equity (CEAE) at the local level. This study uses 2023 data to conduct a census tract-level analysis addressing two research questions:

1. How is the concentration of smart city infrastructure related to CEAR and CEAE levels?
2. Do tracts with elevated levels of smart city infrastructure and solar capacity demonstrate higher CEAR and CEAE levels?

CEAR was defined as the proportion of housing units using clean heating fuel, CEAE as an adjusted measure of CEAR that accounts for socioeconomic disadvantage, and “Solar Capacity” as annual solar energy production (kWh) per housing unit of each tract. A Smart City Index Score (SCIS) was developed by aggregating eight indicators: fixed broadband Internet and computing device access, densities of telecommunications poles, Wi Fi kiosks, 5G towers, EV chargers, distributed energy storage capacity, and the ENERGY STAR score of benchmarked residential buildings. Spearman’s rank correlation was used to assess pairwise relationships among key variables. Census tracts were grouped according to their levels of solar capacity and SCIS to evaluate variations in CEAR and CEAE across different infrastructure contexts. Kruskal–Wallis tests with Dunn’s post-hoc comparisons were then used to identify statistically significant differences among these groups.

Results show a moderate positive correlation between SCIS and both CEAR and CEAE, indicating that tracts with more smart city infrastructure tend to have greater clean energy adoption and equitable access. Kruskal–Wallis results confirmed significant differences in clean energy outcomes across the groups. Post-hoc comparisons further indicated that tracts characterized by relatively high levels of both smart city infrastructure and solar capacity consistently outperformed other groups. While these findings do not establish a direct causal relationship and further investigation is warranted, they suggest that increasing installed solar PVs alone may be insufficient to enhance local clean energy use or equitable access. This underscores the critical role of enabling technologies and smart infrastructure in advancing more just and effective energy transitions (Byrne & Taminiau, 2018; Esfandi et al., 2024).

Based on the integrated assessment of smart and solar infrastructure characteristics, we identified distinct tract groups and mapped their spatial distribution across the city, offering planners and policymakers in NYC a foundation for more targeted interventions. Depending on the conditions of each tract or cluster of similar tracts, strategies may include: (1) expanding solar deployment in areas with untapped potential; (2) initiating building retrofits focused on electrification and smart technologies; (3) enhancing the distribution of smart city

infrastructure; and (4) developing virtual power plants and local microgrids to enable on-site consumption or storage of locally generated solar energy (Hoang et al., 2021; Esfandi et al, 2024). This planning approach can support NYC in advancing energy justice, lowering household and utility costs, strengthening grid reliability, and narrowing the digital divide.

Contested Claims, Divergent Discourses: Case Studies of Transportation Planning

Abstract ID: 1840.0.0.933.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Session Summary

Session Includes: 1844.0.0.390.2025, 1844.0.0.391.2025, 1844.0.0.503.2025, 1844.0.0.556.2025, 1844.0.0.925.2025

Kate Lowe [University of Illinois Chicago] katelowe@uic.edu, organizer

Papers in this session utilize case study research to explore evolving and contested claims about equity and justice in transportation planning. Despite frequently invoked technical objectivity in the field of transportation, these case studies illuminate the highly politicized and normative nature of transportation debates and policy processes across contexts. Case studies provide an opportunity to examine transportation processes and claims in context by providing thick description and critical evaluations of the causal processes that shape transport systems. Authors examine a variety of transportation planning interventions, from highway repurposing and covid-era streets programs to international bridges and rail trails, united by theoretical frameworks that emphasize justice and equity. Cases will provide transferable insights into concepts of equity, racial justice, and the provision of collective goods within transportation planning infrastructure, funding, and programming.

Learning Objectives:

- Attendees at this session will gain critical insights into the politicized and normative nature of transportation debates.

Corridors of Cooperation and Conflict: Contesting Transport Justice in Buffalo, NY.

Abstract ID: 1844.0.0.390.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Lauren Fischer [University at Buffalo] lf44@buffalo.edu, presenting author

Camden Miller [University at Buffalo] camdenmi@buffalo.edu

Grace Wiseman [University at Buffalo] gracewis@buffalo.edu

Tendaji Ya'Ukuu [University at Buffalo] tendajiy@buffalo.edu

Transportation infrastructure's influence on urban development and neighborhood change make it a key component in both enabling and hindering a "right to the city" for all. Recent federal initiatives such as the Reconnecting Communities program and the Justice 40 initiative support projects that address racial inequality and other transportation-related injustices. Implementation of these policy initiatives are contested locally, by state actors and emergent community organizations, whose normative claims to justice are mediated by existing organizational networks and rationalities (Flyvbjerg 1998; Kimble 2024). This paper analyzes two planning efforts in Buffalo, NY to redesign and repurpose highway infrastructure along the RT198/RT33 corridor, an interconnected highway serving demographically different neighborhoods. Utilizing participant observation, structured interviews with policymakers, document analysis and workshops with neighborhood residents, we document a variety of perspectives and claims to justice across each project. We then conduct a comparative analysis of the community planning processes to identify how procedural, recognition, restorative and epistemic justice (Sheller 2018, Martens 2016) are contested and constructed by different stakeholders over time. Our analysis identifies learning and organizational capacity as key mediating factors that shape differential outcomes of each planning process. In addition, we identify processes of selective learning whereby stakeholders strategically emphasize lessons drawn from previous planning interventions to uphold and challenge existing rationalities of power. In the discussion, we explore how planning interventions aimed at enhancing justice and equity interact with organizational and discursive factors to shape contemporary transportation planning processes.

Blank Checks and Bailouts? A Discourse Analysis of Chicagoland's Public Transit Funding Crisis

Abstract ID: 1844.0.0.391.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Kate Lowe [University of Illinois Chicago] katelowe@uic.edu, presenting author

Transit agencies across the United States faced ridership collapses during covid shutdowns, and ridership has generally not fully rebounded. Federal covid relief funding offset some of the resulting farebox losses for many agencies. For systems that heavily rely on farebox revenue—typically those serving large metropolitan areas—the exhaustion of covid funds is leaving considerable budget gaps and precipitating funding crises. However, these funding crises are not the first time public transit has faced shortfalls, and public transit has been underfunded for many decades (Bloom, 2024).

In metropolitan Chicago, the exhaustion of federal covid support in early 2026 will leave a \$771 million operations shortfall for the three agencies serving the region; this gap is termed the fiscal cliff. Addressing the impending fiscal cliff has become entangled with dissatisfaction with the three agencies serving the region and ideas of restructuring them, including agency consolidation as a means of improving service and finding (projected) spending efficiencies.

This case study will analyze framings in the entangled conversations of funding and reform, such as one prominent legislator's stance against a "blank check". The discourse analysis will draw on document review—capturing framings from agencies, lawmakers, advocates and business actors. The genesis of the analysis was through participant observation, which will also serve as a source for the analysis. The paper will contextualize framings within broader discourse on government consolidations (Savitch et al., 2010), critiques of the state, narratives around inefficiency in the public sector and the provision of collective goods (Todd-Breland, 2018; Freemark & Rennert, 2023).

Two Wards and Two Paths in the Pursuit of Transportation Equity: Slow Streets and Washington D.C.

Abstract ID: 1844.0.0.503.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Angela Johnson-Rodriguez [Rutgers University] adj67@scarletmail.rutgers.edu, presenting author

COVID-19 shook the foundation of mobility, and in their haste to keep people moving during the public health crisis, some cities' slow street implementations heightened long-simmering resentments within Black communities, accompanied by fears that these street-level changes begin with the streets and end with the people (Anguelovski et al., 2021). Those fears manifested in Washington D.C.'s Black-majority Southeast neighborhoods, where, for the first time in the District, Ward 8 withdrew from the citywide Slow Streets program while neighboring Ward 7 remained. This is a qualitative case study of power, fear, and engagement through the actions of two Black councilors in a Black city overseeing Black communities during Washington D.C.'s Slow Streets program (2020 - 2021). Through this program, I pose two overarching yet connected questions: Why did Ward 7 stay, and why did Ward 8 leave?

To address these questions, I employed a mixed-methods approach that combined in-depth interviews and document reviews from 2019 to 2022. I conducted four semi-structured, confidential interviews and exchanged correspondence with three local transportation advocates and former staff from the District Department of Transportation in Washington, D.C. The Slow Streets program in D.C. operated for just one year, from May 2020 to May 2021. Due to its brief duration and rapid dismantling, I utilized document reviews to reconstruct the narrative of Slow Streets, identify fundamental problems in neighborhood transportation policy, and analyze the political factors that contributed to the differing approaches in Ward 7 and Ward 8. Data collection followed a semi-structured interview protocol, and all interviews were conducted via videoconferencing. Additional communication occurred through emails, with advocates requesting anonymity. Interviews were open to staff of transportation advocacy organizations, the District Department of Transportation (DDOT), and citizen advisory councils in Washington, D.C.

The results reveal a series of external power struggles between DDOT, the Council, the Mayor, and District residents on the issue of equitable transportation strategies and engagement. The councilor's divergent paths match their politics: Ward 7 Councilor and former Mayor Vincent C. Gray has supported most transportation treatments in D.C. and his ward. Ward 8 Councilor Trayon White has mainly opposed transportation treatments, specifically bike lanes, due to fears of gentrification. Those fears led to his removal of Ward 8 from the program. The DDOT also struggled internally with overtaxed DDOT staff caught between unsupportive Leadership and distrustful residents stemming from historic ostracism and now the novel coronavirus.

This study contributes to the literature on the politics of equity, particularly regarding underserved communities. Demographically similar communities may interpret transportation equity in various ways due to the influence of local-level politics and residents' identities (Brand, 2015). Thus, this study also offers insight into opposing viewpoints that cities must navigate in the pursuit of transportation equity. Finally, this research examines politicized transportation modes, specifically bicycles, and their impact on local politics. There are prevailing perceptions of how bicycle infrastructure and related transportation treatments impact gentrifying Black communities and communities of color (Lubitow et al., 2016) but less about how these perceptions shape political decision-making (Gibson, 2015). This latter topic remains an area that is still under-explored.

Impossible Sidewalks: How History, Policy, and Politics Block Walkability

Abstract ID: 1844.0.0.556.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Matthew Palm [University of North Carolina Chapel Hill] palmmatt@unc.edu, presenting author

Ashley Hernandez [UNC Chapel Hill] ashleych@unc.edu

Danielle Spurlock [University of North Carolina at Chapel Hill] dspurloc@live.unc.edu

Popular urban planning agendas treat walkability as the heart of urban living. For instance, walkable neighborhoods are understood as a foundational component of smart growth (Smart Growth America, 2025). Over 1,700 U.S. jurisdictions have embraced “Complete Streets” policies to provide space on roads for pedestrians and cyclists (Smart Growth America & National Complete Streets Coalition, 2025). Dozens of U.S. cities have signed onto Vision Zero, a movement that seeks to end all traffic fatalities. These frameworks offer planners in small and mid-sized cities practicable means of promoting sustainability, safety, equity, and economic development. For example, The Vision Zero network holds up the efforts of Bellevue WA, and Alexandria VA, as proof that mid-sized cities can achieve a ‘big impact’ with a Vision Zero approach (Fox, 2020).

Providing safe infrastructure for pedestrians remains a persistent challenge, particularly around building and maintaining sidewalks. Many cities place responsibility for sidewalk maintenance on property owners, leading to less maintenance in communities with higher poverty rates (Rajaei et al., 2021). Municipalities that manage repairs report specific barriers that make the process relatively more difficult than road repair, including damage from tree roots and lack of knowledge among contractors (Jane Gibson & Marshall, 2022). Sidewalk repair is often complaint-driven, which can exacerbate inequalities in service provision. While researchers have explored barriers to sidewalk maintenance, no studies have documented the barriers to provisioning sidewalks on existing, occupied streets.

We report on the efforts of a community-led partnership to advocate for sidewalk installation in two historically redlined communities in Durham, North Carolina. Our data include twelve interviews with community organizers and planning staff, field notes from over 20 community meetings, recordings of city council meetings, and a database of local news articles.

We find that legacies of segregation, redlining, and past transportation planning injustices stymie present efforts to find space on the street for Durham’s pedestrians. Planners report that roads in these historically redlined areas are more difficult to install sidewalks on as they require more flood mitigation. Adhering to AASHTO guidelines would require aggressive right-of-way acquisitions, but community members who lost childhood homes to highways do not trust agencies to compensate them fairly. Aggressively anti-urban and anti-pedestrian state legislation limits funding sources while forcing advocates into a reactive posture of pushing for change whenever state-owned roads happen to come up for periodic repainting. Victories come more easily around new, peripheral development as residents can pressure the city to require developers to install sidewalks, but these wins provide no improvements to longtime residents’ own streets.

Community members advance progress on sidewalk justice with a variety of tactics. They build coalitions across different neighborhoods, cultivate relationships with key city staff, leverage both formal and informal mechanisms of public feedback, and “just show up randomly to keep them on their toes.” Their efforts teach us that capitalism won’t pay for sidewalks without a fight, but mobility justice cannot exist without a safe space for pedestrians to move.

Connecting Nations, Dividing Communities: Impacts of US-Canadian Cross-Border Bridge Projects

Abstract ID: 1844.0.0.925.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Robert Pfaff [Iowa State University] robpfaff@iastate.edu, presenting author

In 2018, the foundations were poured for the Gordie Howe Bridge project. The international bridge is the second to cross the Detroit River, linking the cities of Detroit, Michigan and Windsor, Ontario at a cost of \$5.7B. Currently, the Detroit-Windsor trade connection is served almost entirely by the four-lane Ambassador Bridge, completed in 1929, which is listed as the busiest North American crossing by trade volume. Approximately 25% of the trade between the US and Canada crosses in Detroit, and was estimated to impact 150,000 jobs and \$13B in economic output. The project was almost entirely funded by the Canadian Government, and represents the culmination of nearly 25 years of efforts to further expand trade linkages between the United States and Canada that began in the early 2000s. The process of beginning construction was delayed nearly a decade by a host of legal battles mounted by private citizen and billionaire Matthew “Matty” Moroun. The Moroun family owns a controlling interest in the Ambassador Bridge, which he acquired in 1979, making a personal profit from toll revenue collected from the nearly 28M yearly vehicle crossings, as well as duty-free fuel revenue, and facilities rentals for shipping companies that are maintained on both the Canadian and US sides of the border.

The history of the Gordie Howe Bridge Development from 2000 - 2025 represents a series of unique challenges for planning infrastructural connections for trade, traffic, and transit, and is emblematic of political values that pervade ostensibly “neutral” projects. The legal battles, mounted by the Moroun family and companies in which they control an ownership stakes, represent a legal saga that stretched nearly a decade to include rampant property speculation, lawsuits over eminent domain, a failed constitutional referendum, a vetoed state law, “good-faith” blight redevelopment, false eviction notices, and a personal appeal to a new President - all of which were fruitless. The Gordie Howe International Bridge is set to open in 2025.

Despite the billionaire legal opposition, community groups in the Detroit neighborhood known as Southwest also opposed the bridge, and are bracing for the customs plaza to open alongside a dense residential area, populated by minority residents, and low-income communities. The EIS found a disproportionately high and adverse effect, and the US Government agreed to fund \$30M USD to provide community development, support, and mitigation, including constructing a wall near the customs plaza to mitigate noise from the estimated ~10,000 semi-trucks that are projected to navigate the crossing daily upon its completion. This research uses qualitative methods, including case study analysis, historical textual analysis, and secondary research to explore the history of the Detroit River International Crossing. In total, the new international bridge across the Detroit River represents a multi-billion dollar bi-national infrastructure investment with repercussions in US and Canadian economies. The Gordie Howe Bridge, upon opening later fall 2025, is a fascinating case study to explore contested politics of public infrastructure, including fraught legal battles, billionaire influence in geopolitical affairs, and resident organizing for environmental justice in the face of globalized trade, traffic, transit, and of course, tariffs.

Introducing the Tools of the Road Lobby

Abstract ID: 1840.0.0.846.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Session Summary

Session Includes: 1844.0.0.280.2025, 1844.0.0.366.2025, 1844.0.0.801.2025, 1844.0.0.664.2025

Orly Linovski [University of Manitoba] orly.linovski@umanitoba.ca, organizer

While there is increasing interest in transportation as a political problem (e.g. Kent and Harris 2024; Marsden and Reardon 2017; Mattioli et al. 2020), there has been limited examination of the traditional elements of political influence, such as lobbying, discourses and campaign donations. Actors such as trade associations, industry groups, and professional lobbyists spend substantial amounts to shift legislative priorities (Brulle and Downie 2022), often mobilizing diverse groups and strategies to achieve political goals (Dahan 2009). The papers in this session examine the actors, strategies, and discourses used to advocate for road expansion and the implications for understanding the political context for transportation investments.

Learning Objectives:

- Participants will learn about the political context and strategies used in advocating for transportation investments.

Building Consensus for the Road Lobby with the ASCE Infrastructure Report Card

Abstract ID: 1844.0.0.280.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Kelcie Ralph [Rutgers, the State University of New Jersey] kelcie.ralph@ejb.rutgers.edu, presenting author

Nicholas Klein [Cornell University] n.klein@cornell.edu

Americans across the political spectrum largely agree that our infrastructure is crumbling. In an age of partisan rancor, how did this consensus materialize? While there are many potential factors at play, we focus here on one specific tool: the Infrastructure Report Card, a product of the American Society of Civil Engineers (ASCE) that assesses the nation's infrastructure every four years and offers solutions for improving the nation's near-failing grades. Some observers may minimize the report cards' influence, noting that "Asking civil engineers whether America needs to invest in infrastructure is like asking a barber whether you need a haircut." (White, 2012) Yet a complete dismissal is too hasty.

We argue that the Infrastructure Report Card merits careful inspection as a tool of the road lobby, one used strategically by the ASCE to raise awareness about infrastructure conditions and build a consensus for increased funding. The report cards' core message enjoys considerable air-time in the media and serves as a frequent talking point in the halls of power.

We conduct a content analysis of eight editions of the report card from 1998 to 2025 to answer two research questions: 1) How does the ASCE describe the problems and solutions for U.S. infrastructure? 2) What rhetorical tools does the Report Card use to build consensus around infrastructure issues? We focus on two categories of infrastructure: roads and bridges.

Collectively, the report cards make three foundational claims: our infrastructure is crumbling, the cause of our woes is inadequate funding, and the solution is greater investment. Throughout, the ASCE builds credibility for their claims by describing the central role of engineers and the robustness of their methods (despite providing few details or documentation). The ASCE builds consensus through vivid imagery (i.e., "deteriorating", "crumbling", "failing", and "crisis" and by describing all infrastructure spending as "investments" and "needs." Finally, the ASCE presents their results at a level of aggregation that precludes prioritization, analysis of tradeoffs, or reviews of rates of return. ,

While the ASCE presents their claims as commonsensical and beyond reproach, outside critics have taken issue with each one. To make sense of competing claims, we supplement the content analysis of the report cards with a summary of key critiques from the academic and gray literature. A contribution of our work is to synthesize these oft-siloed critiques in a single location.

Throughout, we contextualize the report card historically, starting with an important precursor--the Fragile Foundations report, which was congressionally commissioned in 1988--and ending with the release of the eighth edition of the Report Card in March 2025. During this period, the policymaking context shifted considerably: costs per lane mile soared, infrastructure funding as a share of Gross Domestic Product declined steadily, high-profile bridge collapses periodically captured the attention of the fickle American public, and the Highway Trust Fund went

from running a surplus to the brink of insolvency. We trace the rise in the influence of the report card (i.e., how often it is mentioned in the media and in policy discussions) and track polling numbers illustrating growing awareness and concern about infrastructure.

Finally, because the existing Report Cards are a poor foundation for meaningful public debate, we close by speculating briefly about what a more useful infrastructure report card might look like. Future iterations should embrace greater methodological transparency, present disaggregated findings, engage more deeply with economic considerations, and pay more attention to effective tools for managing demand.

There has been little scholarly attention paid to the interest groups advocating for increased investments in roads. These groups are broad and diverse, with industry associations that represent all aspects of road design (engineers and consultants), construction (materials and labour) and end users (automotive, trucking, and logistics). Despite the significant role that industry associations have in influencing policy in other areas (Brulle and Downie 2022; Kowal 2018), systematic analysis in the transportation field has been limited (Dudley and Richardson 2001; Hamer 1987). This research aims to explore the strategies and discourses that trade associations use in advocating for increased investment in road infrastructure. Our research aims to answer three questions: What is the “road lobby” and who participates in it? What specific issues and policies do they target? What strategies and discourses do they employ to influence policies and investments?

We answer these questions using critical discourse analysis to understand what strategies and the types of discourse and rhetoric that are used. Focusing on U.S. national organizations, we analyzed trade associations that (1) had explicit mention of road and infrastructure investment in their advocacy documents; (2) lobbied federal road-related agencies (i.e. Department of Transportation, Federal Highway Administration, Environmental Protection Agency); and, (3) spent money on federal lobbying (OpenSecrets, n.d.). The eight associations that met the criteria represent a variety of road-related interests. We collected and analyzed publicly-available documents produced by these organizations, including letters to elected officials, policy briefs, and legislative toolkits, and targeted at different audiences.

We find that organizations have a wide variety of materials aimed at influencing political decision-makers, including policy briefs, position papers, and model legislation, as well as efforts to mobilize members through lobbying tours or “fly-ins” to meet with legislators. We describe and analyze the different strategies that these organizations use, such as public media campaigns, advocacy funds, and direct engagement with politicians. Lastly, we delve into the positions, values, and priorities of the organizations involved in road investment lobbying. We examine how these organizations frame their priorities, the language they use to advocate for them, and the values they seek to promote within the political discourse surrounding transportation policy. By examining the rhetoric used by road lobby organizations and the ways they position themselves within broader political debates, this research will identify the key values that drive their lobbying efforts and the underlying strategic goals they pursue.

Who Drives Highway Expansion? A Roadmap of the Highway Coalition

Abstract ID: 1844.0.0.801.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Amy Lee [UCLA] amyee@ucla.edu, presenting author

Why do highways continue to get built and expanded despite their myriad negative impacts? Substantial empirical literatures describe the impacts of highway capacity on air quality, environmental justice, displacement, community severance, greenhouse gas emissions, and induced vehicle travel that erases any congestion improvements. Despite the relatively meager benefits compared to costs, governments continue to abundantly plan and program new road and highway capacity (Taylor et al. 2023, Lee 2023).

An oft-cited reason for highway expansion is the political one. Politicians may advocate for large infrastructure projects for electoral reasons and to showcase their political acumen, and there is a powerful “highway lobby” of industry interest groups that exerts influence on these lawmakers for transportation funding and desired policy outcomes (e.g., Finer 1958, Dunn 1995, Murphy 2020). But why does this building and construction lobby advocate so successfully for highways and not for, say, capital investments in dams and schools?

This research empirically measured the members and policy beliefs of the coalition that advocates for highway expansion. Via in-depth interviews with 49 policy actors—state and local elected official, local transportation planners, state Department of Transportation (DOT) officials, regional transportation agency staff, consulting engineers, academics, lobbyists, and advocates—I explored the transportation policy arenas that surround three large case study highway expansions in California. Specifically, I investigated who holds power and influence, their policy beliefs, and the resources and strategies they use to propel or advocate for highway expansion.

Interviews showed that the network of policy actors in the highway expansion coalition is much more complex than just interest groups lobbying politicians. This paper provides detailed case studies about how these nuances play out across the multileveled and polycentric system of transportation governance. It confirms previous scholarship that politicians and interest groups – e.g., construction and building industries, real estate interests, labor organizations – do indeed play an influential role, and, crucially, expands on prior work to show how members of the highway coalition are embedded in institutions and agencies at all levels of government and in all stages of the transportation planning process. These included local and regional planners, travel modelers, finance and programming staffs, consultants, and DOT staff. That is, politicians and interest groups have a powerful coalition ally in the DOT and other transportation agencies, who advocate for highway expansion from within the transportation institution.

Theodore Yanos [Rutgers University] twf21@scarletmail.rutgers.edu

Robyn Dong [Rutgers University] bsd59@scarletmail.rutgers.edu

Ballot box planning and financing play an increasingly large role in transportation policy. A primary use of ballot measures in the transportation arena is to levy taxes to generate revenues for transportation projects at the state and local levels in the form of local option sales taxes. Transportation scholars have analyzed several aspects of ballot initiatives: their role in transportation finance, expenditure lists, successes, and failures. This research focuses on the large sums of campaign donations that these ballot initiatives garner. For example, campaign contributions totaled over 52 million dollars for a 2018 California ballot proposition, with over 90 percent of campaign donations opposing the proposition (Lee, 2023).

We analyze campaign donations for local and state ballot initiatives to expand the road and highway system. We argue that these campaign donations are one way the “road lobby” exerts influence in the transportation planning and political process to expand automobile infrastructure. Campaign donations are a tangible way for researchers to study how interest groups influence public policy, but they are far from the only avenue of influence (Brulle and Downie, 2022).

We investigate campaign donations in eight case studies of transportation ballot measures across the US. We limit our case selection to ballot initiatives in elections from 2015 through 2024, where a majority of their revenues go to roads and highways and where campaign donation data is available. The eight case studies include five state and three county ballot initiatives, which would have raised between 80 million and 50 billion dollars and received between 50,000 and 52 million dollars in campaign donations. We use campaign finance data from state secretaries of state, campaign disclosures, and Open Secrets to analyze the broad spending patterns focusing on total spending, who is using their money to influence policy, and what they spend their money on.

Our research shows that a substantial share of contributions to support generating more transportation dollars—for sales tax measures and against the repeal attempt, in the case of California’s gas tax legislation—come from firms and organizations that have material interests in building heavy infrastructure projects, as well as from nearby businesses and real estate interests. These include construction companies, construction materials companies (e.g., sand and gravel companies, aggregate and concrete producers), building trades organizations, labor organizations, engineering consultancies, and chambers of commerce, and these findings build on evidence from scholars such as Lee (2023) and Linovski (2018).

Shifting to the Safe System Approach: Principles, Interventions, and Paths Forward

Abstract ID: 1840.0.0.727.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Session Summary

Session Includes: 1844.0.0.141.2025, 1844.0.0.154.2025, 1844.0.0.478.2025,

Weijing Wang [University of California, Davis] weijingw@ucdavis.edu, organizer

Traffic crashes in the U.S. alone claim nearly 40,000 lives, with a total cost of over \$470 billion each year. The Safe System approach represents a holistic vision to bring traffic deaths and severe injuries to zero through prioritizing system-level changes like the built environment and transportation infrastructure. This pre-organized session brings together scholars and researchers to dialogue about the Safe System approach in the U.S.: theories and methods, implementation challenges, and opportunities. We will discuss safety countermeasures addressing the built environment features and roadway infrastructure design. We will examine traffic safety outcomes of the Vision Zero initiatives, while also addressing challenges and pitfalls in policy implementation across diverse contexts. The session will provide insights into theoretical advances and policy implications of the Safe System approach, as well as exploring the future directions for research, policy, and collaboration.

Learning Objectives:

- Describe the Safe System approach and its distinguishing principles
- Identify countermeasures to reduce deaths and severe injuries on the roadways, citing research-based applications
- Apply the Safe System approach to future research and policy agenda, encouraging the field toward safer systems

The Effects of Curb Extensions on Traffic Collisions and Injuries

Abstract ID: 1844.0.0.141.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Erick Guerra [University of Pennsylvania] erickg@upenn.edu, presenting author

Yihong Hu [City of Philadelphia Office of Transportation and Infrastructure Systems] yihong.hu@phila.gov

Marco Gorini [City of Philadelphia Office of Transportation and Infrastructure Systems] marco.gorini@phila.gov

Ariel Ben-Amos [City of Philadelphia Water Department] ariel.ben.amos@gmail.com

Curb extensions, also known as bump-outs or bulb-outs, are widely implemented as a traffic-calming measure aimed at improving pedestrian safety and managing vehicular traffic. By extending the sidewalk into the roadway, curb extensions reduce pedestrian crossing distances, enhance visibility, and encourage slower vehicle speeds by reducing vehicle turning radii. Policymakers have credited a combination of physical curb extensions and lower cost plastic delineators to block off space for pedestrians with helping Hoboken, NJ, a dense city of 50,000, with cutting its traffic fatality rate to zero. Despite widespread adoption, there is limited direct study into the effects of curb extensions on crashes or traffic injuries. The Federal Highway Administration has identified research into the effects of curb extensions on crashes as a high priority area for empirical research. In this paper, we examine the effects of curb extensions on traffic safety through their implementation as part of a stormwater management program in the City of Philadelphia.

As part of its stormwater management program, the Philadelphia Water Department has been planning, designing, and constructing a portfolio of green stormwater infrastructure systems over the past dozen years. These systems capture, filter, and store stormwater run-off utilizing sub-surface trenches, and vegetated features, from raingardens to street trees, mimicking natural processes where possible. As part of this program, the water department built 156 curb extensions with vegetated areas that protrude into the street at mid-block and intersection locations between 2013 and 2022. The water department plans to build another 342 curb extensions over the next 5 years.

By comparing the effects of these curb extensions over time relative to similar roadways where curb extensions have not yet been installed, this study offers a causally valid approach to identifying the effects of curb extensions on traffic safety. Although pre-existing crash data featured in the selection of treated locations, the focus on stormwater management and long list of treated and untreated intersections provide unique, quasi-experimental conditions under which to examine the effects of curb extensions. Although curb extensions are widely accepted roadway design interventions in the fields of traffic calming and traffic safety, little is known about their effects on crashes or how these effects may vary by roadway conditions, location, or other features.

After matching curb extensions to intersections and removing midblock interventions, we create a dataset of 84 treated intersections and 313 control intersections. We matched these spatially to annually aggregated crash data from 2012 to 2023. We also matched these to data on the width of roadway, roadway class, and expected acres of drainage associated with stormwater management. All three were used to help determine the suitability of bump-out construction. Preliminary analysis suggests that curb extensions reduced the incidence of serious crashes by around 50% on arterials. The effects on local roads were likely smaller and were not statistically different from zero with 95% confidence.

Examining a Lost Decade for Traffic Safety in Large US Cities: Lessons for a Safer System

Abstract ID: 1844.0.0.154.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Robert Schneider [University of Wisconsin-Milwaukee] rjschnei@uwm.edu, presenting author

Henry Barbee [University of Wisconsin-Milwaukee] hmbarbee@uwm.edu

Kyle Nelson [City of St. Louis, MO] nelsonk@stlouis-mo.gov

Xiao Gu [Penn State University] xgx5152@psu.edu

Despite setting goals to improve traffic safety for pedestrians, bicyclists, and motorists, large US cities experienced a surge in traffic fatalities since the Great Recession, making the US an outlier among higher-income countries. Comparing 2008-2012 with 2018-2022, the traffic fatality rate per 100,000 population increased by more than 33% across the 100 most populous US cities (from 6.97 to 9.28) versus less than 5% in all other parts of the country (from 12.03 to 12.59). This lost decade for traffic safety cost lives. If the change in traffic fatality rates across the 100 largest cities would have simply matched other parts of the country, 6,438 fewer people would have died during 2018-2022.

While many studies have examined traffic safety trends at national and state levels, relatively few focused on cities. City-level analyses have been conducted in New York, where traffic safety improvements have been attributed to Vision Zero (VZ) actions, such as redesigned streets, reduced speed limits, and automated speed enforcement (Karaye et al. 2023; Dragan & Glied 2024). Ferenchak (2023) analyzed fatalities between 2007-2019 in 18 US cities that adopted VZ policies and found better outcomes in cities with higher population densities; higher shares of walking, bicycling, and transit commuting; and automated enforcement programs. Stimpson et al. (2014) examined 29 years of fatality data in the 100 largest US cities during 1982-2010 and showed that lower traffic fatality rates were associated with more public transit miles traveled per person. Ferenchak and Marshall (2024) compared seven smaller cities with high-bicycling commute mode shares and seven with lower-bicycling mode shares during 2010-2019, finding lower traffic fatality rates in cities with more bicycling, more compact urban form, and higher incomes. However, none of these studies have examined traffic fatality outcomes in the largest 100 cities over the last decade to see which communities might provide a template for safer systems nationwide.

To help fill this gap, we investigated traffic fatality trends in the 100 most populous US cities by comparing two five-year periods: 2008-2012 and 2018-2022. We asked the following research questions: How did traffic fatality patterns change within large cities? What characteristics, including VZ commitments, were associated with traffic fatality increases and decreases?

We used data from the Fatality Analysis Reporting System, American Community Survey, and vehicle travel monitoring sources to explore traffic fatality counts and rates within these 100 large cities. Descriptive statistics showed that traffic fatalities increased the most between 6:00-11:59 pm, on arterial and collector roadways, on state and US highways, in low-income neighborhoods, and for pedestrians and bicyclists, highlighting growing disparities in fatality outcomes. Multilevel models showed that fatality rates were positively related to total automobile commuters but negatively related to population density and city median income. The 17 cities that adopted VZ between 2012-2016 experienced a smaller increase in fatality rates than the other 83 cities, but the difference between VZ and non-VZ cities fell just short of statistical significance when controlling for other socioeconomic and land use variables. Lower-income cities tended to have higher fatality rates, underscoring the importance of state and national policies to target safety initiatives in areas with fewer local resources.

The paper will also provide insights from interviews with planners in cities that had relatively better traffic safety outcomes. We investigate factors in these cities that may have been beneficial, such as traffic safety advocacy groups, safety plans, multimodal street redesign projects, and safety-oriented land use and public transit planning. Lessons from this paper can support safer systems and reduce traffic fatalities in US cities.

Investigating Factors Associated with Various Types of Behavioral Violations

Abstract ID: 1844.0.0.478.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Weijing Wang [University of California, Davis] weijingw@ucdavis.edu, presenting author

A paradigm shift to the Safe System approach opens up new avenues for research and policy to bring traffic deaths to zero. Street networks and areas with the highest concentrations of fatalities and severe injuries, namely, the High Injury Networks (HINs), remain a key strategy for implementing safety countermeasures and allocating resources (Custodio et al., 2021; U.S. DOT, 2025). Despite the wide adoption, using the HINs approach does not capture variations in causes of fatalities and severe injuries, resulting in high uncertainty in the outcomes of policy interventions (Khan et al., 2024; Wang and Barajas, 2025). This study addresses these issues by asking and answering the following research questions: (1) What are the factors associated with various types of behavioral violations resulting in traffic fatalities and severe injuries? (2) What are the characteristics of behavioral violations that disproportionately affect people using active transportation (vs. automobiles)? (3) Where do these behavioral violations occur?

To answer the questions, I analyzed nearly one million traffic crashes occurred in California from 2015 to 2019, drawing on the Statewide Integrated Traffic Records System (SWITRS) database. I used indicators of whether a behavioral violation acts as the predominant factor of deaths and severe injuries to estimate the likelihood of different behavioral violation types, and the factors associated. SWITRS data provided nine types of behavioral violations that are computed from the California laws, automobile right-of-way, driving or bicycling under the influence (DCUI), unsafe speed, improper turning, wrong side of the road, unsafe lane change, traffic signals and signs, pedestrian right-of-way, and pedestrian violations. I measured the crash, person, mode, road, and place characteristics using four data sources, the Statewide Integrated Traffic Records System, the OpenStreetMap, the American Community Survey, and the National Household Travel Survey. I used multinomial logistic regression and logistic regression modeling.

The results reveal that the most common behavioral violations in fatal and severe crashes are DCUI (18%), unsafe speed (18%), improper turning (17%), and pedestrian-related reasons (15%) (including pedestrian right-of-way and violations). After controlling for other factors, fatalities and severe injuries are a lot more likely to be due to traveling on the wrong side of the road (212%), and automobile right-of-way, unsafe speed, and improper turning (100%), relative to pedestrian-related reasons. Similarly, fatalities and severe injuries are 42% more likely to be due to DCUI and 8% - 11% more likely to be due to unsafe lane change and traffic signals or signs (vs. pedestrian-related reasons), respectively.

Sociodemographic characteristics are associated with behavioral violation types. In a fatal and severe crash, compared with their white peers, Hispanic travelers are 24% more likely to be killed or severe injured due to violations of traffic signals or signs; at the same time, Black and Hispanic travelers are 50% and 15% less likely to be killed or severely injured due to DCUI (vs. pedestrian-related reasons), respectively. While walking, pedestrians are 2.3 times more likely to be killed or severely injured due to drivers violating the pedestrian right-of-way, compared to pedestrians violating traffic regulations. Pedestrians aged 65+ are at least 3.5 times as likely as adults aged 18-24 to be killed or severe injured when they have the right-of-way (vs. violating traffic regulations). Pedestrian fatalities and severe injuries in nonrural areas with a population size of 10k-25k are 70% more likely to be due to drivers violating the pedestrian right-of-way than other areas. Findings highlight the likelihood of various types of

behavioral violations, the persons affected, and the factors associated, which merit attention and targeted policy interventions under the Safe System approach.

The Theoretical Mismatch of High Injury Networks: Critiques and Recommendations

Abstract ID: 1844.0.0.651.2025

Track 14: Transportation and Infrastructure Planning

Pre-Organized Paper Presentation

Rachael Panik [Georgia Institute of Technology] rtpanik@gatech.edu, presenting author

David Ederer [Georgia Institute of Technology] dederer3@gatech.edu

High-injury networks (HINs) are commonly developed as part of Safe Systems programs (e.g., Vision Zero) in the United States. HINs apply safety hot-spotting; once developed, they are a collection of corridors that contain the network's highest concentrations of severe- and fatal-injury crashes [Kronenberg et al., 2015]. The methodologies for developing HINs vary, and there is no widely accepted practice for creating them. The intended purposes of HINs, though, are consistent: they are purported to help agencies funnel resources to most effectively reduce roadway injuries and fatalities.

HINs are now central to roadway safety planning in the U.S. For example, the U.S. Department of Transportation's "Safe Streets and Roads for All" FY24 grant program requested that applicants identify whether a proposed project is on the city's HIN, highlighting the importance that HINs currently hold in our safety planning approaches [USDOT, 2024]. Their widespread adoption makes sense, as the logic of HINs is appealing. But this work proposes that there is a theoretical mismatch between a hot-spotting approach and the reality of latent risk that pervades the transportation system.

Several issues are cited. First, it seems likely that crash concentrations are a result of numerous confounding variables, including of traffic volumes [Elvik, 1997]. Most HINs are developed using crash rates that are not normalized by traffic volumes or other confounding variables, and crash concentrations may be the result of residual confounding risk rather than high risk. HINs inherently assume that the severe concentration is because roadways in the HIN differ from other roadways in the system. Thus focusing countermeasures on the HIN will reduce most serious injuries and deaths. While it is true that many corridors in HINs have design characteristics that are highly correlated with roadway crashes and VRU injuries and fatalities (e.g., long crossing distances), these characteristics are often present in many other roads in the network that do not have the same concentration of crashes [Elvik, 1997]. Therefore, high risk is still present in the system.

Second, the beliefs that injury risk manifests in the system that are inherent to HINs are not supported by theoretically or causally. Epidemiological approaches to risk [Dumbaugh and Li, 2010, Ederer et al., 2023] state that more effective than hot-spotting is addressing risk factors, which are underlying conditions that increase the probability of an injury occurring. Instead of identifying concentrations of symptoms (i.e., crashes), it is more effective to identify latent pathogens (i.e., causal risk agents) of injuries and then systematically address them throughout the network.

And finally, because HINs are not causally-informed, their prescriptions may not be resilient to the rapidly changing transportation system. These single-corridor investments identified through hot-spotting may not be as important long-term; as the system changes with new forms of mobility, long-term travel patterns (e.g., exposure) will change. If HINs are mostly an artifact of exposure and other latent risks, HINs will simply shift to different places over time without reducing the population-level burden of deaths and serious injuries.

Given these many problems with the practice hot-spotting in generally and HINs specifically, "fixing" some corridors will not address overall system risk and thus may reduce overall injury, which is the goal of Safe System/Vision Zero planning. To highlight these assumptions and theoretical mismatches, we further expound upon the assumptions

about risk inherent to HINs. We also explore those assumptions with HIN and crash data in the U.S. We propose an alternative approach to Safe Systems implementation, one that identifies causal elements of the system that increase risk, and then addresses them network-wide.

Track 14 Roundtables

Celebrating the Legacy of Donald Shoup (1938-2025), and Next Directions in Parking Research

Abstract ID: 1843.0.0.1187.2025

Track 14: Transportation and Infrastructure Planning

Roundtable Submission, Panel Interviews

Daniel Hess [University at Buffalo, State University of New York] dbhess@buffalo.edu, organizer

Evan Iacobucci [Missouri State University] eiacobucci@missouristate.edu

Evelyn Blumenberg [University of California, Los Angeles] eblumenb@ucla.edu

Brian Taylor [UCLA] btaylor@ucla.edu

Michael Manville [University of California, Los Angeles] mmanvill@g.ucla.edu

Overview

This roundtable commemorates the urban planning scholarship of Professor Donald Shoup. Panelists will elucidate the many contributions made by Shoup to research and practice about urban parking policy. The panelists and audience members will discuss new directions in research about parking and outline research needs related to parking, access, and creating finer cities. This session will (1) celebrate Shoup's decades-long contributions to research, practice, and education and demonstrates how parking reform can support affordable housing development, lessen air pollution, and reduce automobile dependency, and (2) forge a new set of research directions about parking policy.

Donald Shoup

Donald Shoup, distinguished Professor Emeritus of Urban Planning, whose decades of teaching and scholarship at UCLA greatly influenced the field of land-use planning as well as generations of scholars, students and urban planners, passed away following a short illness on February 6, 2025, in Los Angeles. He was 86.

Shoup, a titan in the field of urban planning and specifically parking reform, is renowned for his pathbreaking research into how cities manage, or mismanage, parking spaces. This work, which demonstrated that seemingly mundane provisions in zoning codes had rendered many places overly dependent on driving, brought him academic accolades and made him an unlikely hero for a generation of urbanists determined to repair American cities.

Over the course of his career, Shoup won numerous awards. He was a fellow of the American Institute of Certified Planners, a select group of professional planners nominated by their peers in recognition of their "significant and transformational improvements to the field of planning and the communities they served." In 2017, he received the Distinguished Educator Award from the Associated Collegiate Schools of Planning. The award, presented biennially, is the highest honor bestowed by the organization in appreciation of significant contributions that have made a difference to planning scholarship, education and practice.

Parking Research

Shoup has spent his career encouraging everyone to rethink relationships between parking and the built environment, traffic congestion, energy consumption, and local economic development. Shoup's recommendations

for reforming parking policy center on three recommended actions. First, remove off-street parking requirements. Second, use market prices to manage on-street parking. Third, spend the parking meter revenue to fund added public services on metered blocks. These parking reforms can align individual incentives with collective objectives and produce enormous benefits at low or no cost. All these benefits will result from subsidizing people, not parking. Shifting the cost of parking to the parkers will make cities more expensive for cars and more livable for people.

A new generation of researchers—many were Shoup’s research collaborators or former students—have taken up the mantle and expanded on Shoup’s research in new context and settings. Some of these researchers will appear as panelists.

The Roundtable

This roundtable will be of interest to scholars, planning practitioners, and citizen advocates who are passionate about reducing automobile dependency and creating more sustainable and vital cities. Audience members will: (1) learn from the panelists about the impacts of Shoup’s research on parking policy; (2) share memories about Shoup; (3) reflect on the current state of research about parking policy; (4) collaborate with the panelists in identifying pathways for future research on parking policy. The latter will take into account various considerations, including equity and inclusion, affordable housing, development pressures, governance, and climate change.

Equitable and Co-Designed Solutions for Transit Workforce Shortages

Abstract ID: 1843.0.0.172.2025

Track 14: Transportation and Infrastructure Planning

Roundtable Submission, Topical Discussions

Nichola Lowe [University of Minnesota] nlowe@umn.edu, organizer

Sylvie Guezeon [University of Minnesota] gueze002@umn.edu

Jamaal Green [University of Pennsylvania] jamaalg@design.upenn.edu

Jacob Wasserman [University of California, Los Angeles Institute of Transportation Studies]

jacobwasserman@ucla.edu

Mehri Mohebbi [University of Florida] mohebbmi@gmail.com

Public transportation systems across multiple cities and regions in the United States are struggling with chronic worker shortages and high employee turnover rates. While the specific positions with the greatest shortages can differ from one agency and region to another and shift with time, most public transit agencies face ongoing and intensifying workforce challenges that need focused attention. These shortages impact the ability to operate the transit system safely and reliably. Beyond that, they prevent cities and regions from meeting climate action targets by limiting the expansion of transit services.

This existing challenge allows planning scholars to exchange ideas supporting replicable workforce solutions and share those insights with the regions and institutions they support and engage. This roundtable responds to this opportunity by bringing together researchers from two planning sub-fields: transportation and economic development planning. We aim to open a conversational and interpretive space for knowledge sharing, deepening our collective understanding of current and emerging workforce needs while leveraging panelist knowledge about co-designed strategies that center worker and community voice. The panel will identify actionable solutions to be tested and adapted within multiple cities and communities. We hope this conversation will spur interdisciplinary collaboration to support more inclusive workforce practice.

The panel will open with an overview of current transit workforce challenges, both nationally and within our respective regions, focusing on positions that are currently hardest to fill. As part of that discussion, we will consider who typically holds these “high-churn” positions and which communities and segments of the population are currently underrepresented and why. Panelists will also reflect on related workforce shortages. For example, many cities and counties struggle with an acute shortage of school bus drivers—in certain regions of the country, driver shortages affect other aspects of infrastructure development and maintenance, such as snow removal, waste management, and the movement of critical building materials, most notably ready-mix concrete. Broadening the focus to include these and other related worker shortages will help to motivate multi-industry, multi-scaler responses.

The second half of the panel will focus more centrally on actionable solutions, drawing from both current and emerging workforce initiatives within and beyond the transit sector. Rather than treating workforce development as a short-term hiring challenge, the discussion will emphasize long-term career pathways that support worker mobility, particularly in historically overburdened communities. Panelists will explore models from adjacent industries—such as construction, green infrastructure, and manufacturing—to examine how structured apprenticeships, upskilling initiatives, and co-designed training programs can create sustainable transit careers, not just jobs. The conversation will also highlight strategies for worker retention by investing in reskilling opportunities, enabling frontline workers—such as operators, mechanics, and maintenance staff—to adapt to automation, electrification, and other technological shifts without displacement. By grounding solutions in community-driven

workforce development, the panel will propose a forward-looking approach that ensures transit agencies do not just react to workforce shortages but actively build equitable, future-ready career pipelines.

Panelists from the economic development sub-field include: Jamaal Green (University of Pennsylvania) and Nichola Lowe (University of Minnesota); from transportation planning: Mehri Mohebbi (University of Florida) and Jacob Wasserman (UCLA). The panel will be moderated by University of Minnesota doctoral student and transportation scholar, Sylvie Guezeon.

Navigating the Complex Dynamics of Accessibility, Safety, and Mobility for Vulnerable Road Users

Abstract ID: 1843.0.0.79.2025

Track 14: Transportation and Infrastructure Planning

Roundtable Submission, Panel Interviews

Xiaoxia Dong [University of Pennsylvania] xiaoxiad@design.upenn.edu, organizer

Anne Brown [University of Oregon] abrown33@uoregon.edu

Joshua Davidson [Oberlin College] jhdavids@oberlin.edu

Robert Schneider [University of Wisconsin-Milwaukee] rjschnei@uwm.edu

Michael Smart [Rutgers University] mike.smart@rutgers.edu

Jasmine Siyu Wu [University of Pennsylvania] jsiyuwu@design.upenn.edu

For decades, planners have been searching for the magic recipe for enhancing transportation accessibility, safety, and mobility for vulnerable road users- groups of individuals at increased risk of experiencing the inefficiency, inequity, and undesirable outcomes of the transportation system. These users often include, but are not limited to, pedestrians, cyclists, children, seniors, women, and racial minorities. Adequately addressing the needs of vulnerable road users, however, presents significant challenges for two reasons. First, the unique transportation needs of certain vulnerable road user groups have not been widely acknowledged by planners and decision-makers. Second, strategies to improve one aspect of transportation planning can conflict with or even undermine another. For example, while 28 U.S. states require teens to practice with a certified instructor before getting a junior driver's license- a policy aimed at ensuring safe driving practices- this requirement can inadvertently exclude teens who cannot afford such training, thus denying them the mobility and access to educational and economic opportunities that come with a driver's license.

This roundtable will focus on the multifaceted challenges facing specific vulnerable road users and explore planning interventions tailored to their particular transportation needs. Panelists will delve into the experiences of novice drivers, cyclists, pedestrians, queer transit users, minorities, low-income residents, among others, all while navigating the complex dynamics of accessibility, safety, and mobility.

Since the 1990s, Urban Studies has published a growing body of empirical research highlighting the social dimensions of urban transport, supporting the paradigm shift from viewing transport primarily as physical and spatial entities to emphasizing the complex social dynamics that underpin the functional aspects of transport systems (Attoh 2017; Bickerstaff and Walker, 2005; Wood, 2022; Blumenberg and Smart, 2014). Building on existing studies on this topic and the Urban Studies call for papers (Fan, Wood, and Blumenberg, 2024), this roundtable brings together authors and editors affiliated with the Urban Studies journal to critically reflect on this intellectual evolution and spark new conversations about how social, cultural, and political forces shape—and are shaped by—urban transport systems.

Participants in this session will explore the long arc of theoretical developments that conceptualize urban transport as a social construct, and the growing urgency of these perspectives in light of several contemporary urban trends—including persistent social disenfranchisement and exclusion, post-COVID transformations, the rise of digital transport economies, the escalating impacts of climate change and the Anthropocene, and the resurgence of authoritarian regimes alongside the deepening of neoliberalism. Moreover, drawing on a diverse array of empirical cases—from open-air markets reshaping mobility in post-COVID Paris, to the interplay of transport and rezoning in Denver, to informal adaptations of Bogotá's gondola system—the discussion will examine how transport systems are embedded with social meaning, political power, and historical legacies. Transport infrastructures and policies often reflect the values and ideologies of those in power, reinforcing social inequities and spatial injustice.

This roundtable seeks to critically examine the current landscape of transportation studies and foster a more nuanced perspective that transcends conventional technical or economic analyses. It aims to situate the understanding of urban transport within the broader socio-political context that defines urban life. Through a shared inquiry into transport's role as a complex socio-political force that structures inequalities, reinforces or challenges power dynamics, and shapes the lived realities of urban life, the event will cultivate a socially grounded and justice-oriented perspective on urban transport. The goal is to pave the way for research that not only analyzes but also seeks to transform the social dimensions of urban transport.

Zhengyang Wei [Stanford University] zywei@stanford.edu

Jianxi Gao [RPI] gaoj8@rpi.edu

Jenny Suckale [Stanford University] jsuckale@stanford.edu

This study provides the first global evaluation of direct and indirect flood hazard impacts on urban road transportation networks. We construct topological road networks for 2,564 human settlements, representing over 14 million kilometers of urban roads. We assess their exposure to pluvial and fluvial flood risks under ten scenarios, corresponding to different flood intensities (1:5 to 1:1000 year return periods). Under each scenario, we analyze direct infrastructure exposure and assess the indirect effects of flood-induced mobility disruptions: route failures, travel delays, and travel distance increases. Our results document a positive relationship between flood return period and flood impact (both direct and indirect). Compared with direct flood hazard exposure, the indirect effects of floods on mobility is more prominent and heterogeneous. The average share of the road network that is flooded by at least 0.3 meters is 3.64% (or 24.84%) under the 5-year (or 1000-year) return period—yet 11.58% (or 65.67%) of simulated trips fail in the same scenario. The results enable comparisons of exposure and vulnerability of road networks to flood hazards across countries, allowing the identification and prioritization of urban transport resilience measures. Our study builds a comparative understanding of the vulnerability of road networks to flood hazards under ten distinct return periods by identifying the spatial heterogeneity in mobility loss due to travel speed reduction and road closure. We call attention to particular world regions where targeted initiatives for flood mitigation and adaptation measures in the transportation sector are most critical while also recognizing areas where large-scale interconnected road network failures might occur. We explore explanatory variables that can capture the variation observed in the indirect impact of floods on mobility and point to three governing features: exposure, network connectivity, and travel pattern. We evaluate their relative importance in different geographic regions and make policy-relevant recommendations for increasing network resilience. This effort facilitates the development of region-specific hazard mitigation objectives and investment plans, effectively reducing the indirect repercussions of floods.

A Theoretical Framework for Induced Travel

Abstract ID: 1844.0.0.355.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Robert Noland [Rutgers University, Bloustein School] rnoland@rutgers.edu, presenting author

Induced travel remains a controversial issue despite a large empirical literature developed over the last 25 years demonstrating that increases in lane-mile capacity leads to increases in vehicle-miles of travel (VMT). The controversy, while typically not explicitly stated, is over how cities should grow. That is, those who argue that new road capacity will increase VMT (or not be effective at reducing congestion), are typically concerned about the negative impacts of new road capacity and advocate for different ways to address mobility and accessibility concerns (e.g. public transit and active modes of travel). Those who diminish the impact of induced travel argue that new capacity is needed to meet current and/or future demands for vehicle mobility.

Much of the recent controversy is generated by the availability of easy-to-use “induced travel calculators”, originally developed in California. Some have argued that these calculators over estimate induced travel effects and this is partly due to assuming elasticity measures of VMT with respect to lane-miles based on old data (generally before 2005). There is evidence that VMT per capita peaked about this time, with a shock due to the great recession, improved communication technologies, and more recently the Covid pandemic leading to increased working at home. Other factors, such as more home-delivery, may also play a role. The other concern is that the calculators do not consider localized contexts, such as existing levels of congestion or its non-existence, background exogenous levels of growth and economic development, and transit availability. I base these observations from discussions occurring in the Minnesota Technical Advisory committee on which I sit and as a member of an NCHRP project team working on developing guidance on how state DOTs can estimate and address induced travel.

What is lacking in these discussions is a clear theoretical framework for how these factors may lead to different levels of response to new capacity. There is a desire to define “typologies”, that is, under what circumstances is induced travel a concern? I will present a brief overview of recent literature, including an attempt to define different typologies. How can consideration of different conditions inform the theory of induced travel, also known as “the fundamental theorem of road congestion”? Within this focus is the tension between those who oppose highway construction and those that see it as their duty to provide as much as possible.

A Travel Time-Based Evaluation of Public Transport Competitiveness in Chinese Megacities

Abstract ID: 1844.0.0.979.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Siying Li [Tongji University] 2859855342@qq.com, presenting author

Haixiao Pan [Tongji University] panhaixiao@tongji.edu.cn

In rapidly urbanizing megacities, the “public transport priority” policy is regarded as a key strategy to alleviate congestion and improve urban mobility efficiency. However, while widely emphasized in policy discourse, its actual effectiveness remains to be verified. To explore this issue, the study introduces the Travel Time Ratio (TTR) between private cars and public transport as a core metric to assess whether transit is truly prioritized in everyday commuting.

Time-based accessibility has become a critical indicator for evaluating public transport (PT) competitiveness. Unlike spatial proximity, travel time captures the full commuting cost—walking, waiting, transferring, and in-vehicle time—reflecting both system efficiency and user perception. Although many metro station areas are nominally served by transit, limited surface-level connectivity often leads to functional inaccessibility. Recent studies emphasize the importance of evaluating accessibility not only in terms of efficiency but also equity, as high travel times disproportionately affect low-income and peripheral populations.

This study evaluates PT competitiveness across eight Chinese megacities—Shanghai, Beijing, Shenzhen, Guangzhou, Chengdu, Chongqing, Tianjin, and Wuhan—focusing on TOD areas defined as 1-kilometer buffers around metro stations. Travel time data for both cars and PT are collected via API queries during peak and off-peak hours, incorporating walking, waiting, congestion, and mode-specific travel segments. A Generalized Journey Time (GJT) framework is applied to assign differentiated weights to each travel component, capturing perceived time costs more accurately.

Results show that core urban areas and metro corridors exhibit strong PT competitiveness, with TTR values close to 1.5. However, suburban and peri-urban areas show significantly weaker performance, with TTRs exceeding 2.5. Inter-city comparison reveals clear differences in transit efficiency, shaped by metro network coverage, land use integration, and urban structure.

The study provides evidence-based insights for TOD policy by identifying spatial patterns of weak PT competitiveness and proposing targeted strategies for service optimization and land-use coordination. The GJT-based framework offers a replicable and transferable approach for benchmarking PT performance across cities. Ultimately, this research supports the development of inclusive and sustainable mobility systems in rapidly urbanizing regions.

Adapting Multimodal Travel Behavior to Extreme Heat: A Tale of Two Cities

Abstract ID: 1844.0.0.1090.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Rounaq Basu [Georgia Institute of Technology] rounaq@gatech.edu, presenting author

Jay Mulay [Georgia Institute of Technology] jay.mulay@gatech.edu

Rudra Gopal [Georgia Institute of Technology] rgopal32@gatech.edu

Extreme weather events are becoming more commonplace and yet increasingly more unpredictable. Heatwaves, in particular, are found to occur more frequently, last longer, and be more intense. Extreme heat, grimly referred to as the ‘silent killer,’ has severe consequences not just for people’s mobility but also health and quality of life. From a mobility perspective, people who do not have access to a car face the brunt of extreme heat as they move about urban areas walking, biking, and using transit. Many people adapt their activity-travel patterns in various ways on extremely hot days. For example, they can choose not to make a trip at all (by working from home or deferring a trip). They may choose to use their car, if available, since it offers air conditioning. They may choose to shorten their trips to reduce heat exposure or perhaps make longer detours to use routes that offer more shade and are cooler. However, for many, adapting their travel patterns is not an option. They may not have access to a car or find public transportation too expensive, thereby needing to walk or bike regardless of how hot it is. They may not also have the luxury of working from home or being able to adjust where and when they go.

The examples listed above are but a handful of the myriad ways in which people adapt to, or are unable to adapt to, extreme heat. The different adaptation mechanisms and constraints impeding adaptation start to paint a complex picture of how travel behavior and activity-travel patterns are affected by extreme heat. The literature on this topic is fairly nascent, with only a handful of studies examining this relationship but with limited scopes. Extreme heat has been found to significantly affect both time use and activity-mobility patterns (Batur et al., 2024). Some studies have focused on the effects of extreme heat on specific transportation modes, such as walking (Basu et al., 2024), bikesharing (Li et al., 2024), public transportation (Miao et al., 2019), and ridehailing (Gebresselassie et al., 2025). However, we do not yet have a comprehensive understanding of how activity-travel patterns are affected across all modes. Additionally, we have limited evidence of how individual-level shifts in behavior may differ from population-wide shifts.

Through this study, we seek to address these two gaps in the academic literature. First, we use a multi-day mobility diary dataset from Boston, US that contains daily activity-travel data for multiple residents of the Boston metropolitan region who were recruited to participate in the mobility tracking study. The ‘usable’ sample of repeat observations for the same person across a set of extreme heat days (as treatment) and not-so-hot regular days (as control) contains around 200 unique individuals. Second, we use a ‘big’ dataset from Milan, Italy that contains daily activity-travel data for millions of people (represented through devices) sourced through location-based services. We adopt a similar strategy to track changes in activity-travel patterns between extreme heat days (treatment) and not-so-hot regular days (control), but at the population-level this time.

Preliminary results confirm several of the hypotheses stated earlier about adaptation mechanisms. We also observe some heterogeneity across our sample in Boston, for which we have socioeconomic data; the Milan sample is unfortunately anonymized. We aim to continue exploring these differences across the two types of datasets and contexts through behavioral models, which will inform a choice-based vs. necessity-based heat adaptation framework that can be used for integrated climate resilience and sustainable transportation planning.

Analyzing Commuting Inequalities in the Spatial Mismatch Hypothesis Using Machine Learning

Abstract ID: 1844.0.0.423.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Qisheng Pan [University of Texas at Arlington] qisheng.pan@uta.edu, presenting author

Jianling Li [University of Texas at Arlington] jjli@uta.edu

Subham Kharel [Lehigh Valley Planning Commission] sxk7802@mavs.uta.edu

Soheil Sharifiasl [Houston Galveston Area Council] sxs8675@mavs.uta.edu

Lijuan Tang [University of Texas, Arlington] lxt7115@mavs.uta.edu

The Spatial Mismatch Hypothesis (SMH) emerged from Kain's (1968) observation of the negative impact of residential segregation and the decentralization of suburban employment on the job opportunities of African Americans in inner-city areas. It has been extended to address the mismatch between the residential locations of minorities in central cities and the suburbanization of employment. (Holzer 1991, Ihlanfeldt & Sjoquist 1998).

Commuting distances often reveal the nuanced patterns of inequality. Blumenberg and King (2019) found that lower-income workers experienced disproportionately longer commute distances than high-income groups, with such effects being more pronounced for low-income workers compared to high-income groups. Commuting distance is especially relevant when transportation mode disparities are considered. Kawabata and Shen (2007) demonstrated significant differences between car and public transit users in commute distances and times, revealing systemic inequities.

Housing affordability and public transportation availability are critical variables together impacting spatial mismatch. Rising housing costs in job-rich urban areas have pushed low-income households to job-poor locations, exacerbating transportation-related inequalities (Levine, 1998; Benner & Karner, 2016). As cities face growing housing demand, opposition to affordable housing developments in urban cores has increased, pushing low-income families to areas farther from employment centers (Whittemore & BenDor, 2019). This displacement often results in longer commutes and higher transportation costs for affected communities (Raphael & Stoll, 2010; Blumenberg & Wander, 2023). Addressing spatial mismatch, therefore, requires integrating housing affordability and transit availability into planning frameworks

Numerous modeling approaches have been used to explore spatial mismatch, ranging from linear regression to spatial econometric models. Linear regression models such as Ordinary Least Squares (OLS) were common for examining commute patterns and their relationship with job accessibility (Kawabata & Shen, 2007; Blumenberg & Wander, 2023). Since the relationships between the built environment, socio-demographics, and travel behavior are often non-linear (Abdollahpour et al., 2024), relying on traditional statistical models that assume linearity may lead to biased estimations and inferences. Machine learning models, with their capability to capture non-linear relationships and predict outcomes with reduced error, are gaining increasing attention in causal statistics (Balzer & Westling, 2023; Fuhr et al., 2024).

To shed some light on how commuting distance as a measure of spatial mismatch interact with various socio-demographic factors across three income-level jobs, we propose to apply a two-stage Extreme Gradient Boosting (2SLSXGBoost) model to each income group and compare the impact of built environment, urban form, and socio-economic, and transportation variables across each income group in the state of Texas. Our research questions include: 1) How do various socioeconomic and built environment factors differently impact the commute distances of high-, medium-, and low-income workers? 2) How does a two-stage Extreme Gradient Boosting (2SLSXGBoost))

model perform in predicting commute distances and spatial mismatch compared to its traditional counterpart? 3) What are the implications of these findings from applying AI-driven approaches to address spatial and socioeconomic disparities in urban planning?

The answers to these questions will provide insights into understanding the driving forces of spatial mismatch for different groups, especially the low-income minority group, and facilitate the reduction of community inequity through policy recommendations for affordable housing, job locations, and transportation options.

Analyzing Driver Earnings, Utilization, and Market Regulation in Toronto's Ride-Hailing Industry

Abstract ID: 1844.0.0.282.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Mashrur Rahman [University of Toronto] mashrur.rahman@utoronto.ca, presenting author

Mischa Young [Université de l'Ontario Français] mischa.young@utoronto.ca

Steven Farber [University of Toronto] steven.farber@utoronto.ca

Ride-hailing platforms (also known as Transportation Network Companies or TNCs) have expanded rapidly over the past decade, raising concerns about driver earnings, labor conditions, and urban congestion. As a result, many jurisdictions are exploring regulatory interventions, including license caps, minimum earning standards, utilization rate targets, congestion pricing, and environmental incentives. However, it is not clear how these policies may impact driver welfare. In this study, we examine the effects of possible license caps and subsequent change in utilization rate (defined as the portion of each driver hour that includes a fare-paying passenger in the vehicle) on drivers' earnings in Toronto.

Our data include 84 million TNC trips between January 2023 and April 2024, accounting for 75,208 TNC drivers licensed in Toronto. We calculate drivers' net earnings by applying the TNC platform's rate card formulas and deducting vehicle expenses, including both fixed and variable cost items unique to each vehicle's specific make, model, year, and ride-hailing mileage. Next, we develop a two-stage fixed effect model to analyze how various factors, including the utilization rate, affect driving earnings per in-app hour, where the in-app hour consists of all logged-in time on the platform, including deadheading. Given that the utilization rate may be correlated with unobserved driver-specific characteristics such as drivers' skills, experience, and familiarity, we employ an instrumental variable approach. We use the number of daily active drivers as an instrument for utilization rate based on the assumption that the number of daily active drivers in Toronto only affects drivers' earnings through the utilization rate.

The data reveals that between 2023 and 2024, the utilization rate of TNC drivers in Toronto fell from 61.4% to 54.4%, and the median hourly net earnings decreased from \$7.94 to \$5.97. Our model identifies a significant negative association between driver supply and utilization rate after controlling for other variables, including the demand and weather (temperature, rain, and snow): specifically, a 10% increase in the number of daily active drivers in Toronto is associated with a reduction of utilization rate by 7.5%. We also find a significant variability in drivers' earnings. The model shows that a 10% increase in the utilization rate raises the hourly earnings by 38%, suggesting a strong practical significance of the utilization rate on drivers' earnings.

Other important factors affecting earnings include the number of trips, trip location, time, vehicle types, and service types. Net hourly earnings increase with the number of daily trips, as fixed vehicle costs are spread over more working hours. However, downtown trips yield lower earnings compared to non-downtown trips, suggesting the negative effect of downtown congestion on driver earnings. Additionally, drivers who offer premium services, operate an electric vehicle, drive during night shifts, and use both apps earn more compared to their counterparts.

Our findings have important implications for gig workers' welfare and transportation equity, particularly given that 95% of TNC drivers in Toronto earn below Ontario's minimum wage. The results strongly suggest that unregulated growth in driver supply is significantly reducing utilization rates and adversely affecting drivers' hourly earnings. To mitigate income inequality among drivers, metropolitan areas, especially those with large ride-hailing markets, should actively consider strategies to manage driver supply. Policy mechanisms such as temporary pauses on new

licenses or dynamic caps in congested areas could help counter the oversupply. Moreover, any supply-side regulations must be bundled with minimum pay standards equivalent to the minimum wage, pushing TNC platforms to internalize costs associated with deadheading and ensuring a fairer overall wage structure for drivers.

Analyzing Urban Walkability and Pedestrian Safety Using Location-Based Service Data

Abstract ID: 1844.0.0.1029.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Yunwoo Nam [University of Nebraska-Lincoln] ynam2@unl.edu, presenting author

The increasing popularity of active transportation modes, such as walking and biking, supports key planning goals around public health, environmental sustainability, and active living. However, this shift also raises critical safety concerns: pedestrians continue to experience disproportionately high rates of injuries and fatalities in traffic-related incidents. Addressing these issues requires a more precise understanding of travel behavior and exposure, which has historically been limited by the lack of detailed and reliable data on pedestrian volumes.

This study introduces a novel approach that leverages Location-Based Services (LBS) data—sourced from StreetLight Data Inc.—to estimate pedestrian, bicyclist and vehicle volumes at finer scales (street segment level) and examine spatiotemporal patterns of activity and crash risk. Through the application of random forest models and integration of multiscale spatial datasets, the research offers a data-driven framework to support more precise safety analysis and urban planning.

Key findings include: First, by integrating LBS data and GeoAI tools into planning practice, this approach offers a scalable, data-driven method for assessing pedestrian safety, identifying high-risk areas, and informing infrastructure investments. Second, traffic volume emerged as the most critical predictor of safety risk across pedestrian, bicyclist, and vehicular modes. Third, pedestrian safety varies significantly by spatial scale, with place-based infrastructure-level characteristics offering the most actionable insights. Fourth, the spatial-temporal analysis of 2019–2021 traffic volumes highlights changes in pedestrian and vehicle activity during COVID-19 and seasonal changes, particularly in downtown and recreational areas.

This research advances planning knowledge by bridging data innovation and pedestrian safety analysis. It demonstrates how emerging mobility data sources can fill critical gaps in exposure measurement, enabling more accurate and equitable safety assessments. It offers practical implications for planners seeking to develop safer and vibrant communities. The results offer valuable insights for urban planners, designers, engineers, and policymakers aiming to design safer and sustainable communities.

App-based Ride-hailing in the Global South and its Impact on Destinations: A Case Study of Bengaluru

Abstract ID: 1844.0.0.287.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Shubhayan Ukil [University of Michigan Ann Arbor] ukilshub@umich.edu, presenting author

App-based ride-hailing use has grown over the past few years in Bengaluru, India, and other Global South cities, enhancing people's mobility and catering to travel needs in urban areas. As the Information Technology (IT) sector grows in the city and population levels continue to rise, ride-hailing services have helped bridge the increasing travel demand when public transportation has not kept up (Mukherjee et al., 2017). However, these services also contribute to traffic congestion, which has significant environmental, economic, and health consequences. Many studies have taken a mobility-centric focus to understand the environmental outcomes of ride-hailing services and proposed policy suggestions that make ride-hailing use environmentally friendly (Hasselwander & Bigotte, 2023). I contend that to make ride-hailing use more sustainable; we need to take an accessibility-centric approach and understand not only the influence on mobility outcomes but also destinations. People generally seek to maximize their accessibility benefit- the utility gained from participating in activities at various locations, such as home or work, while minimizing the costs of the transportation services required to reach these destinations (van Wee, 2011). I investigate the impact of ride-hailing services on residential locations and social/recreational destinations in Bengaluru, as ride-hailing is predominantly used for commute and recreational travel in the city.

Using a mixed-methods approach, I conducted semi-structured interviews with key transportation stakeholders in Bengaluru and performed thematic analysis to understand the identity of app-based ride-hailing users and the diversity in ride-hailing modes in Bengaluru. My analysis revealed that apart from being young, high-income adults, many ride-hailing users are also migrant IT workers and women who use ride-hailing due to not owning a personal vehicle, unfamiliarity with the transportation system, and safety concerns. Through thematic analysis, I also generated causal mechanisms about possible ride-hailing influences on residential and social/recreational destinations. While most interviews felt that ride-hailing services only influence social/recreational destinations by eliminating parking issues, some reflected an indirect effect of ride-hailing services on residential locations. In rapidly expanding Bengaluru, housing costs are higher near office spaces, especially IT parks. Ride-hailing services enable people to live in areas with more affordable housing in peripheral parts of the city or other areas that may have developed due to economic growth and growing population levels but do not have reliable public transportation. Following this, I conducted an intercept travel survey and ran Structural Equation Modeling with the data to test the causal mechanisms. The model results confirmed that people living in locations they found affordable or farther from their workplace would likely change their residential location if ride-hailing services become unavailable. However, if people live in affordable areas farther from their workplace, they are unlikely to change residential locations, indicating people's long-term residential location decisions. The statistical models also confirmed that ride-hailing services influence people's social/recreational destinations by reducing the stress of driving and parking, enabling access to locations they perceive safe, especially for women and lower-income groups. These findings reinforce the interdependent transportation-land use relationship and how it influences travel patterns. In the short term, urban planners and policymakers must work towards strengthening the public transportation system by integrating ride-hailing services as a last-mile mode for sustainable travel. Long term, they also need to plan for more affordable housing around IT parks and other office spaces in Bengaluru to reduce travel distance and increase equity in accessibility.

Application of Correction Factors to Improve the Accuracy of Automated Non-motorized Counter Data

Abstract ID: 1844.0.0.745.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Md Shazalal Tushar [Virginia Tech] shazalaltushar@vt.edu, presenting author

Vahid Bakhshi [Virginia Tech] vahidbakhshi@vt.edu

Ralph Buehler [Virginia Tech] ralphbu@vt.edu

Steve Hankey [Virginia Tech] hankey@vt.edu

Accurate data of bicycling and walking is important to make the proper resource allocation and plan for a safe environment for bicycling and walking which may help increase physical activity for individuals and the population. Leveraging permanent automated counters to collect active travel data has gained popularity as it is helpful to collect data over a longer period to inform decision making. Counting pedestrians and cyclists is more complex than counting motorized vehicles because non-motorized traffic includes- occlusion events, bypassing the counter events. Automated bicycle and pedestrian counters are sensitive to weather conditions (e.g. precipitation, snowfall). As a result, count data obtained from the automated bicycle and pedestrian counters require further adjustment and validation to reduce errors. One common approach to addressing the overcounting or undercounting issues of automated bicycle and pedestrian counters is to develop site specific correction factors. However, previous studies do not explore the improvements of the automated count data after applying the correction factor for a larger network of counters. The goal of this study is to identify the benefits of applying correction factors for accuracy improvements to the automated count data. This study describes the results of applying correction factors to improve data accuracy of 40 automated bicycle counters and 27 automated pedestrian counters in the Washington D.C. region with a large counter network (n= 150).

We collected video recordings for at least 30 hours during daytime from each automated counter using a recording device. Once we collected the video recordings, we watched the videos and extracted the hourly manual counts for each automated counter which serves as the ground truth data. Implementing a subsampling approach, we developed the correction factor with 15 random hourly time bins (training set) using an Ordinary Least Square (OLS) model. Once we developed the correction factor, we applied it to the automated count data excluding the hourly bins used for the development of the correction factor (test set). We iterated the process 1000 times and calculated the error before and after applying the correction factor in each iteration for the test set. For the error calculation, we used the absolute percentage error of aggregated 15-hour count before and after applying the correction factor.

The developed correction factor for pedestrian counters ranged from 0.47 to 1.26 while it was 0.33 to 1.56 for bicycle counters. The range of the magnitude of corrections illustrates the need to develop factors to reduce error of the automated count data. About 28% of the bicycle counters and 37% of the pedestrian counters had an error of less than 5% prior to applying the correction factor. For these counters, the error difference was minimal as the correction factor was close to 1 indicating automated count data had better accuracy. We found that the average difference of error before and after applying the correction factor for automated bicycle count data was about 12% where the maximum difference was about 151%. For the automated pedestrian count data, the average error difference was about 8% with a maximum error difference of about 48%.

Findings of this study suggest the importance of correction factors. For planners and engineers, corrected data can help identify locations for infrastructure enhancements for pedestrians and/or cyclists, such as trail/infrastructure widening or improved pedestrian and bicycle friendly intersections and roadway crossings that meet engineering

minimum active travel thresholds. Furthermore, this study provides guidance on when to apply the correction factor for the accuracy enhancement of the automated count data based on the error obtained from counter validation.

Applying Big Data to Analyze Internal Trip Capture in Station Area Neighborhoods

Abstract ID: 1844.0.0.33.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Louis Merlin [Florida Atlantic University] lmerlin@fau.edu, presenting author

Mary Asumang [Florida Atlantic University] masumang2023@fau.edu

The concept of the 15-minute city has reinvigorated the discussion surrounding the benefits of local accessibility or proximity-based planning for residents as well as for promoting more sustainable urban forms. Cities across the globe have adopted a wide range of plans and planning practices centered on the 15-minute planning concept. At the same time, the concept of local accessibility is an older concept with a more extended research history, and many academics have discussed the complementary functions of regional and local accessibility for enhancing livability and access to opportunity.

The purpose of this study is to examine whether neighborhoods surrounding transit stations in metropolitan areas with high-quality metropolitan transit systems provide sufficient levels of local accessibility and to investigate what features of the built and social environment support adequate levels of local accessibility. For this paper, evidence of high-quality local accessibility is indicated by the travel behavior variable of internal trip capture. The analysis of internal trip capture has a significant historical use as a travel behavior outcome variable. Much of the previous work on internal trip capture has focused on the characteristics of mixed-use developments. Still, the same methodology has recently been adopted at larger scales and applied to the 15-minute city concept.

For this study, we examine 1-mile neighborhoods around 96 transit stations in Portland and 96 transit stations in metropolitan Washington, DC. The outcome variable of interest is the percentage of internal trip capture, defined as the percentage of trips with both trip origins and trip ends located within these 1-mile neighborhoods. The independent variables include a wide range of built and social environment variables, including various measures of street network connectivity, the concentration of jobs and population, jobs disaggregated by job type, a variety of mixed-use variables, median income, and transit and auto regional job accessibility. Portland and Washington DC provide an interesting contrast as both are considered relatively high-quality metropolitan transit systems in the US context.

The study incorporates two key innovations over previous work on internal trip capture. Firstly, rather than relying on travel behavior surveys with relatively low levels of trip counts, this study relies on the big data vendor StreetLight to calculate the internal trip capture variable. The use of a big data source means that the internal trip capture variable is based on thousands of observations instead of dozens, ensuring a much higher quality statistical analysis. Secondly, we also employ machine learning models to understand the thresholds and non-linear effects of independent variables. We identify the critical minimum and maximum values over which internal trip capture is sensitive for each independent variable.

Preliminary results suggest that total employment in the station area neighborhood is the most important variable in determining internal trip capture, as the total number of jobs is a strong proxy of the availability of local destination accessibility. Street network variables also appear to be predictive of ITC, though less so. Mixed-use variables show little marginal value once total employment counts are controlled for, contrary to previous research. Finally, regional transit accessibility to jobs positively correlates with internal trip capture, which is a novel and unexpected result.

In terms of planning practice, our results will help local land-use planners understand what types of land-use planning can facilitate local accessibility around transit station areas. By adding thresholds provided by machine learning models, planners can obtain guidance for land-use planning targets for key local design features such as employment density or street network connectivity.

Assessing Infrastructure Resilience and Emergency Access After the Francis Scott Key Bridge Collapse

Abstract ID: 1844.0.0.1007.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Mansha Swami [Morgan State University] mansha.swami.civil@gmail.com, presenting author

Daeyeol Chang [Morgan State University] daeyeol.chang@morgan.edu

Mansoureh Jeihani [Morgan State University] mansoureh.jeihani@morgan.edu

The sudden collapse of the Francis Scott Key (FSK) Bridge in Baltimore has brought into focus the resilience of urban infrastructure and the equitable delivery of emergency services during major disruptions. This study addresses the research question: To what extent did pre-existing transportation systems and emergency services support community resilience in the aftermath of the FSK Bridge collapse, and how can future planning improve equitable access to critical services during crises?

Focusing on the pre-event and disruption phases, the study evaluates essential services—such as emergency medical services (EMS), fire, and healthcare access—alongside transportation logistics, including transit connectivity, passenger rail access, alternate fueling stations, and emergency evacuation routes. These metrics are assessed within neighborhoods upstream of the bridge, comprising approximately 56,292 residents, 14% of whom live below the poverty line and 4% of whom are unemployed, as per 2018–2022 ACS data.

Employing a multidisciplinary methodology, the research integrates spatial analysis, demographic profiling, policy evaluation, and community-engaged data collection. A ZIP code–level “resilience type” database will be developed using ACS and National Household Travel Survey (NHTS) data to analyze travel behavior and infrastructure accessibility. To assess preparedness and capacity, we incorporate the National Risk Index (NRI) and Homeland Infrastructure Foundation-Level Data (HIFLD), allowing for a geographically grounded understanding of vulnerabilities.

Emergency response data from the Maryland Department of Transportation (MDOT) and the Baltimore City Office of Emergency Management will be analyzed to evaluate service delivery trends following the collapse—particularly response times and resource deployment. These data will be compared against pre-event baselines to identify breakdowns, delays, or successful interventions.

Complementing the quantitative analysis, a qualitative review of city, regional, and state resilience plans—including Baltimore’s Long-Range Transportation Plan—will be conducted to uncover planning gaps and assumptions that may have hindered disaster response. In addition, targeted community surveys will be conducted across impacted ZIP codes to document residents’ experiences regarding access to emergency services, transportation challenges, and recovery support, with a focus on equity across income, racial, and age groups.

Survey responses will be analyzed using spatial autocorrelation in ArcGIS Pro to identify patterns between demographics, infrastructure presence, service performance, and satisfaction levels. This spatialized approach allows for a nuanced understanding of which communities were disproportionately impacted and why.

Preliminary findings suggest areas with limited multimodal connectivity and fewer emergency service nodes tend to experience longer response times, primarily affecting low-income and transit-dependent populations. These outcomes indicate a pressing need for adaptive, short-term response planning and long-term resilience investment, especially in underserved areas.

This study contributes to planning scholarship by positioning transportation resilience within the broader context of social equity and spatial justice. For practitioners, the research offers actionable recommendations for enhancing infrastructure redundancy, expediting emergency response protocols, and integrating community-informed data into planning. For educators, it provides a robust case study for teaching integrated approaches to urban resilience and equity.

Ultimately, this research seeks to advance equitable resilience planning by bridging empirical analysis with lived experience. The findings aim to guide cities toward inclusive, anticipatory strategies that support all communities—especially the most vulnerable—during crises.

Assessing Vehicle Miles Traveled (VMT) Tools for Climate Planning in California

Abstract ID: 1844.0.0.1183.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Serena Alexander [Northeastern] se.alexander@northeastern.edu, presenting author

Shams Tanvir [Cal State Long Beach] shams.tanvir@csulb.edu

One central challenge of climate planning in California is the lack of consistent methods for measuring vehicle miles traveled (VMT) impacts of transportation projects. Using qualitative and quantitative data, this research: (1) evaluates existing VMT calculators and other methods to assess climate impacts of transportation projects in alignment with state climate goals, and (2) analyzes transportation professionals' perspectives on VMT as a metric and the effectiveness of VMT tools. Findings indicate that the consistency, contextual relevance, complexity, data accuracy, and user-friendliness of VMT tools vary significantly based on design and methodology. Each tool has distinct advantages and limitations, making it suitable for specific uses but not necessarily for others. The recommendations include: 1) Improve access to accurate, validated data for VMT modeling; 2) Develop context-sensitive tools that capture local conditions and changes over time; 3) Foster collaboration between jurisdictions to share best practices, data, and tools; and 4) Promote an integrated approach to VMT analysis by combining multiple tools and datasets to enhance decision-making.

Automobile LOS Clings to Life Despite California's Increased Focus on VMT

Abstract ID: 1844.0.0.1144.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Jamey Volker [University of California, Davis] jvolker@ucdavis.edu, presenting author

Elisa Barbour [University of California, Davis] esbarbour@ucdavis.edu

Automobile level of service (LOS) has been the most commonly used metric of transportation system performance in the United States since it was introduced in the 1965 Highway Capacity Manual. However, as transportation and land use planning agencies focus more on reducing car dependence and greenhouse gas emissions, they are increasingly reconsidering how they use LOS. California kickstarted the most sweeping changes to date when it enacted Senate Bill (SB) 743 in 2013, which eliminated LOS and replaced it with vehicle miles traveled (VMT) as the primary transportation impact metric for land development projects under the California Environmental Quality Act (CEQA). Actual implementation of the LOS-to-VMT shift was left up to lead agencies, primarily local governments, with a requirement to start using VMT-based metrics by July 1, 2020.

Previous research suggests that VMT could be a more appropriate and effective metric than LOS for achieving sustainability goals, such as reduced greenhouse gas emissions, improved public health and safety, and streamlined infill development. However, the LOS-to-VMT shift was also expected to create numerous challenges for transportation analysts, given the often limited resources of local governments, the ingrained nature of LOS in transportation impact analyses, and the perceived lack of established practice with respect to VMT impact analysis, and the uncertain synergies or conflicts between LOS and VMT standards and mitigation measures. With those concerns in mind, we surveyed planners from 94 responding cities and counties about implementing SB 743 and, in particular, whether and how they are continuing to use LOS outside of CEQA in project-level analyses and/or higher-level plans and policies.

We found that most jurisdictions continue to use their pre-SB 743 LOS metrics and standards – they just apply them outside of CEQA, e.g., in general plans, project-level development standards, and traffic operations decisionmaking. At the project level, only 15% of localities have reduced LOS requirements, and associated costs to developers. We also found that, on average, combined costs to developers for both VMT and LOS analysis and mitigation do not appear to have changed since SB 743 went into effect. Most jurisdictions reported the combined costs to be about the same (18% of respondents) or slightly higher (40% of respondents) than pre-SB 743 costs. About 26% of localities consider the combined costs to be much higher, while 16% consider the costs to be much lower. Unsurprisingly, the combined costs tend to be lower in denser and more urban locations.

While LOS remains prominent in both local government plans and project-level analysis requirements, VMT has concurrently been infiltrating into plans and policies beyond CEQA. Some localities have started to integrate VMT-reducing strategies into policies, plans, and programs operating at a jurisdiction-wide scale, such as through goals and standards incorporated into general plans and associated programs such as impact fees imposed on developers for transportation purposes. However, that has not resulted in many corresponding changes to plan-level LOS standards. As a result, approximately two-thirds of respondents indicated that their jurisdiction's plan-level VMT and LOS standards conflicted.

Collectively, the survey findings confirm that implications of SB 743 vary by community type. For many, the expected pattern is occurring, in which the type and location of development projects requiring mitigation has shifted to lower-density localities, and within localities, to lower-density, less transit-proximate parts of town. VMT

mitigation requirements in the most urban areas can be minimal, sharply contrasting with the situation in rural cities and towns, where few projects may escape mitigation requirements.

Beyond the State: Rethinking Transportation Justice in the Anti-DEI Era

Abstract ID: 1844.0.0.842.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Alex Karner [The University of Texas at Austin] alex.karner@utexas.edu, presenting author

Jonathan London [University of California, Davis] jklondon@ucdavis.edu

Dana Rowangould [University of Vermont] dana.rowangould@uvm.edu

Understanding how transportation policy and investments can be made more fair is the province of transportation justice research and practice. Historically, efforts to advance transportation justice have appealed to state institutions. Transportation infrastructure investments are costly, and policy or design changes typically require legal or regulatory shifts, making state involvement essential.

In prior work, we identified a spectrum of approaches that can be used to advance transportation justice goals, ranging from state-centric (e.g., agency-sponsored analyses) to society-centric efforts (e.g., community organizing) (Karner et al. 2020). While approaches at these extremes rely on the state to ultimately deliver infrastructure and services, the difference lies in the source of the impetus and its direction—is it the agency itself, an external law or regulation, or the communities most affected by policy decisions?

The environmental justice literature has long wrestled with the contradictions inherent in the state's role in justice struggles (Pulido, Kohl, and Cotton 2016; Harrison 2023; Pellow 2017). While state interventions have occasionally led to major victories—preventing disproportionate burdens and mandating equity assessments—these gains have been fragile, dependent on shifting political winds. In the U.S., transportation justice has traditionally relied on legal frameworks rooted in civil rights and environmental justice law. With Supreme Court precedent limiting direct civil rights claims, executive agencies have become the primary arbiters of environmental and transportation justice, making them vulnerable to partisan control. In some cases, the state has been passive or even an opponent to overburdened communities in their struggles for transportation justice. Recent frameworks have identified strategies that range from within, against, and beyond the state (Angel and Loftus 2019).

The second Trump administration appears poised to permanently reshape the landscape. Civil rights offices are being shut down, regulatory enforcement is being dismantled, and legal interpretations are shifting to treat any consideration of race or ethnicity as discriminatory on its face. Unlike previous cycles of political change, where one could anticipate some redress under a different administration, the active dismantling of state capacity may make future reversals nearly impossible. If these changes become codified into law, they will fundamentally undermine the ability to use legal strategies to challenge transportation injustices. Even the partial victories achieved by the transportation justice movement are now at risk.

Given this reality, this paper argues that transportation justice must shift its primary focus from legal frameworks and state-based advocacy to grassroots organizing and other non-state strategies (sometimes called “beyond the state.”). Drawing on critical environmental justice studies and international research on democratic backsliding, we contend that the future of transportation justice depends more than ever on building power outside the state in addition to (or instead of) appealing to it. Using both academic literature and a handful of case studies drawn from practice, the paper describes how organizing efforts—historically a crucial but sometimes secondary component of transportation justice—must become central, examining emerging strategies for advancing justice in the face of state hostility.

Boon or Bane? Regional Transportation Planning in the Vehicle Electrification Era

Abstract ID: 1844.0.0.34.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Shengxiao (Alex) Li [National University of Singapore] alexli@nus.edu.sg, presenting author

Yufei Wang [National University of Singapore] e1509275@u.nus.edu

The US is ambitiously accelerating electric vehicle (EV) adoption to reduce greenhouse gas emissions and promote economic development. Two recently approved federal bills, the Infrastructure Investment and Jobs Act (IIJA) and the Inflation Reduction Act (IRA), have created unprecedented opportunities for cities and regions to consider how to integrate EVs in transportation planning. Still, scholars and practitioners often criticize EVs' unanticipated impacts on equity (Yu et al., 2023), vehicle dependence (Liang et al., 2023), and revenue loss (Lewis and Clark, 2021). How do Metropolitan Planning Organizations (MPOs) plan for EVs? There is an extensive literature on EVs, but no publication has explored regional responses. This study uses a mixed-methods design including topic modeling and content analysis to examine 50 MPOs' understanding of vehicle electrification and policy tools. The results show that MPOs recognize the environmental benefits of EVs and the funding and infrastructure challenges. However, only 16 MPOs set clear EV-related goals. MPOs' EV planning strategies are well aligned with the IIJA, with a focus on charging infrastructure development, public transit electrification, and capacity building, such as regional collaboration and staff training. The IIJA and IRA provided generous support to expand charging infrastructure in the US, but policymakers should be aware of the potential impacts of such expansion on car dependence and social equity. They should seriously consider properly taxing EV drivers through EV-related registration fees and distance-based charges in lieu of gasoline taxes. The electrification of urban transportation systems should also include heavy-duty vehicles, such as trucks and buses, and the integration of EV technology into shared mobility systems to maximize the environmental benefits of EVs.

Individual Paper Presentation Submission

Shengxiang Jin [UC Irvine: University of California Irvine] shengxj2@uci.edu, presenting author

Douglas Houston [University of California, Irvine] houston@uci.edu

Paul Ong [UCLA] pmong@ucla.edu

Chhandara Pech [UCLA Center for Neighborhood Knowledge] cpech@luskin.ucla.edu

In recent years, federal and state governments have adopted policies, developed programs, and allocated funds to redress the past and contemporary harms caused to disadvantaged populations and communities by the construction of highway and transportation infrastructure. In the 20 years after the passage of the Federal Highway Act of 1957, over 475,000 households were displaced during the construction of the interstate highway system in the United States, with disproportionate dislocations occurring in low-income areas and communities of color. The legacy of these impacts has been amplified by exclusionary housing and urban renewal policies that have further undermined the accumulation of generational wealth and related economic and educational advancement.

In January 2021, the Biden administration launched the Justice40 initiative to ensure that at least 40% or more of the benefits of climate and clean infrastructure investments were directed to “disadvantaged communities” defined by low-income status, high household costs, and exposure to environmental, health, and climate burdens. This criteria was used to allocate over \$4 billion in funding from the Infrastructure Investment and Jobs Act (2021) and the Inflation Reduction Act (2022) towards the federal Reconnecting Communities Program (RCP) administered by the U.S. Department of Transportation (USDOT) between 2022 and 2024. RCP funded capital construction and planning grants across the nation including projects to remove and replace highways with community-supportive infrastructure, construct safe highway crossings that support pedestrians and cyclists, and build freeway cap parks. Around 88% of grants and 95% of funding were allocated to disadvantaged communities. However, in January 2025, the Trump administration froze funding for RCP projects and adopted new criteria for allocating transportation funding based on marriage and birth rates and compliance with federal immigration policy. Early evidence suggests the new USDOT 2025 criteria will shift transportation funding priorities towards areas that are more white and have greater transportation resources and away from lower-resourced communities of color that experience greater travel burdens and barriers.

We evaluate the implications of this shift in federal funding criteria for transportation investments for RCP-selected projects by examining their geographic locations relative to Justice40 and 2025 DOT criteria. We use parity analysis to assess whether 204 funded RCP projects and 813 projects not selected for funding were distributed equitably in each region. The analysis focused on projects located in urban areas with a population over 100,000 and compared average parity indices for projects based on whether funding was awarded, the grant type (capital construction vs. planning), urban area size, and infrastructure type (freeway removal, safe crossing, vs. cap parks). Results based on Justice40 criteria indicate that RC projects were, on average, located in areas with a higher composition of people of color and persons in poverty compared to their region. Results based on USDOT’s new 2025 criteria indicate that RC projects were located in areas with a lower marriage rate but that projects were on average located in areas at parity with their region relative to birth rates.

These findings (and additional results regarding differences by project characteristics and historic population dynamics near project sites) suggest that (if funding is unfrozen) RC projects awarded based on Justice40 criteria could help address some of the past and ongoing harms for lower-resourced communities of color that experience

greater travel burdens and barriers due to highway construction and operations. However, we find that usage of the new USDOT 2025 criteria to allocate infrastructure funding would substantially alter the distribution of improvements and undermine the goals of reconnecting communities programs.

Background - Public transit not only facilitates mobility but also influences how people perceive interact with their neighborhood environments. These perceptions, in turn, affect their daily activities and transportation choices [2, 3]. Although evidence suggests that transit-oriented environments promote active travel and benefit public health [1], few studies have investigated how neighborhood perceptions vary among various transit user groups and affect transit use after the opening of new bus rapid transit (BRT) lines. Understanding these differences can contribute to developing strategies that promote transit use and enhance public health outcomes.

Methods - This study used the data collected between 2017 and 2020 from an NIH-funded project in El Paso, TX, USA, that included surveys and 7-day travel logs. The surveys assessed participants' perceptions of neighborhood walkability, safety, and infrastructure, as well as barriers to transit use. The travel logs documented a total sample of 1699 trips from 190 participants, which included the number of trips, travel modes, and trip purposes, providing. The baseline period captured neighborhood perceptions and travel behaviors before the opening of the new BRT lines, and the follow-up data were collected after the opening. Users were classified as non-transit users, occasional transit users, frequent transit users, captive transit users, or choice transit users. Bivariate analyses examined group-level differences in perceptions, barriers, and travel patterns. Multivariable models, zero-inflated negative binomial regression models, were applied to isolate the effects of user type, neighborhood perception, and time phase on transit use and walking behavior, after controlling demographic variables such as car ownership, age, BMI, education level, and mobility difficulties.

Results - The findings highlight differences in travel behavior and neighborhood perceptions across user groups and phases. The statistical models showed significantly higher perceptions of transit quality, comfort, safety, and pedestrian infrastructure, particularly among frequent and captive transit users. However, after the BRT opening, we found an unexpected decline in actual bus use and active transportation usage across most user groups, accompanied by increased reliance on private vehicles. Car ownership emerged as a major barrier to transit use ($\beta = -1.984$, $p < 0.001$). Additionally, positive perceptions of traffic safety ($\beta = 0.643$, $p < 0.001$) were associated with increased bus use. Older age groups showed a trend toward reduced bus usage ($\beta = -1.400$ for ages 20-29, $p = 0.051$), indicating age-related barriers in transit adoption.

Discussion - The results underscore the importance of considering user type and intervention timing when assessing the impact of new transit infrastructure. Positive perceptions of transit improvements alone may not be sufficient for achieving sustained ridership increases. The findings emphasize the need for integrated urban planning strategies that simultaneously address transit infrastructure, traffic management, car dependency, and pedestrian environments. Such comprehensive approaches are essential to translate improved perceptions into lasting behavioral changes and equitable urban mobility outcomes.

Clean Cars for Some: Scalar Politics, Spatial Networks in California's ACC II Regulation

Abstract ID: 1844.0.0.891.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Jeannine Marie Pearce [University of California Irvine] jeannimp@uci.edu, presenting author

California's Advanced Clean Cars II (ACC II) regulation mandates that 100% of new vehicle sales be zero-emission by 2035, positioning the state as a national climate policy leader. Framed as an environmental and racial equity milestone, ACC II was developed amid calls to address long-standing transportation injustice. Yet despite equity commitments like Executive Order N-16-22, the final rule lacked binding measures to ensure access or benefits for historically marginalized communities. This raises a central puzzle: Why, despite legislative mandates and strong environmental justice (EJ) advocacy, did the California Air Resources Board (CARB) fail to embed enforceable equity mechanisms?

This question is especially pressing given California's unique authority under the federal Clean Air Act. A waiver allows it to set stricter emissions standards, which other states may adopt under Section 177. As of 2024, seventeen states have opted into ACC II, giving CARB's decisions national impact. Yet equity provisions remained narrowly state-focused, limiting grassroots actors' ability to shape how equity would—or would not—be implemented across jurisdictions. The result is a nationally diffused policy with locally bounded justice.

To unpack this dynamic, I draw from a growing body of scholarship that reorients the study of social movements and governance around space, scale, and networks. As Nicholls (2016) argues, movement scholarship has long been shaped by “methodological nationalism” (Beck, 2000), which assumes nationally bounded movements and treats local struggles as derivative. This framing underestimates the political salience of geography—not only where movements act, but how spatial position mediates access to institutions and shapes coalitional strategy. The “spatial turn” in movement research emphasizes that place is not a passive backdrop but an active force in structuring opportunity and exclusion (Nicholls, 2008). Diani and McAdam (2004) extend this by showing how network structure matters: strong local ties foster trust and internal capacity, while weak ties—especially across institutional or geographic divides—are critical for scaling demands and securing influence (Diani, 1997).

I argue that scalar positioning and network architecture jointly shape which actors influence governance. In ACC II, EJ advocates had procedural access—serving on advisory boards and attending hearings—but were peripheral to multistate regulatory networks. In contrast, automakers, utilities, and fossil fuel interests activated longstanding infrastructures across extraction, production, and deployment sites, shaping technical elements like credit trading while avoiding redistribution.

This study draws on three methods: a policy and power analysis of ACC II; an organizational mapping of EJ groups, including demographics, reach, funding, and coalition roles; and qualitative data from focus groups and interviews with CARB officials, advocates, and industry actors. These approaches trace how equity claims were negotiated, reframed, or sidelined within networked governance.

I advance the hypothesis that scalar asymmetry in governance structures advantages countermovement actors over grassroots coalitions. To theorize this, I introduce the Contested Equity Governance Arena—a space where procedural inclusion coexists with structural exclusion, and where fragmented authority disperses responsibility without redistributing power. As ACC II spreads nationally, this framework helps assess when climate policy facilitates equity—and when it replicates exclusion.

Closing the Gap: Transportation Accessibility for Adults with Disabilities

Abstract ID: 1844.0.0.748.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Aisling O'Reilly [University of Southern California] agoreill@usc.edu, presenting author

Genevieve Giuliano [University of Southern California] giuliano@usc.edu

This research addresses the critical issue of transportation accessibility for individuals with disabilities in both urban and rural settings, with a focus on Los Angeles County and Tulare County in California. Approximately 25.5 million Americans with disabilities face significant barriers to travel outside their homes, impacting essential aspects of life such as healthcare, employment, housing, and social interactions. Despite the prevalence of disabilities, there is little research on the challenges faced by these individuals, particularly in considering the difference in accessibility in urban and rural settings.

The purpose of this research is to understand the constraints on travel of those with disabilities and its consequences. People with disabilities – those who have hearing, visual, cognitive, or physical limitations – make fewer trips and travel fewer miles than the general population (Brumbaugh, 2018). We will address the following questions: 1) what is the accessibility gap for populations with disabilities relative to the general population, 2) how do individuals navigate the transportation system, and what needs and challenges do they face, and 3) what are the impacts on social exclusion and well-being?

The proposed research will have two parts. The first part will generate accessibility measures to compare the accessibility of those with disabilities with those who do not have mobility constraints. The second part will conduct small group interviews to explore and understand the lived experiences and transportation challenges of those with disabilities, including impacts on social exclusion and well-being. The research will be conducted in two California counties, Los Angeles and Tulare, in order to include a broad range of populations, local geographies, and support services.

Commuting Time Distributions Before and After COVID-19: Assessing Long-Term Changes

Abstract ID: 1844.0.0.799.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Seunggwon Park [University of Texas at Austin] park.sg@utexas.edu, presenting author

Ming Zhang [University of Texas at Austin] zhangm@utexas.edu

The COVID-19 pandemic precipitated considerable disruptions to daily travel patterns, leading many people to adopt telecommuting arrangements, shift typical commuting times, or reduce weekly travel. Yet it remains unclear whether these changes are fleeting or signal a long-term reconfiguration of commuting habits. This study addresses two core research questions: (1) How have commuting time distributions and schedules evolved, and how much time do workers spend commuting—and when? (2) Are these changes temporary, or do they appear to be likely to continue?

Prior to 2020, standard transportation planning practices frequently assumed two relatively stable peak-time periods to guide transit services, manage roadway capacity, and design congestion mitigation. However, if current behaviors diverge substantially from earlier patterns—such as a broader range of travel times or more flexibility in whether, when, and how people commute—these assumptions may need to be revisited. This underscores the importance of strategic planning, resource allocation, and policy design in the field of transportation. Confirming whether such developments represent short-lived adaptations or more durable shifts is therefore vital for the future of our field.

Recent research consistently highlights telework growth, altered departure times, and lower in-person activity since COVID-19. Many studies, however, rely on narrower or regional datasets that are not easily generalized, focus only on early-pandemic observations, or emphasize select aspects like telework without systematically assessing trip durations and peak periods. Some discussions present findings on the major shifts in commuting but offer limited exploration of deeper factors shaping those trends. By examining data at a broader scale and over multiple years, this project clarifies whether these observed changes are temporary or not in terms of transition.

This study utilizes two national datasets. The National Household Travel Survey (NHTS) from 2017 (pre-pandemic) and 2022 (post-pandemic) offers a comparative view of commute duration, departure times, and mode choice. The American Time Use Survey (ATUS) from 2017 through 2023 supplies annual data of out-of-home activity. Both sources are aligned to ensure that each individual's 24-hour day is verified for total travel time alongside in-home activities. The analysis begins with studying commute durations, the proportion of longer-distance travel, and departure-time distributions across survey and demographic groups. Differences in average and median commute lengths help reveal whether telework or altered work schedules have significantly reduced or reshaped conventional rush hours. Regression and multivariate methods then control for factors like age, income, employment type, and urban/suburban location to distinguish between short-term and sustained behavioral changes. Finally, the ATUS data are examined longitudinally to confirm whether noteworthy changes in commute times or scheduling persist, stabilize, or gradually return to previous norms over multiple years.

By studying baseline commuting patterns from before and after the coronavirus outbreak, agencies or policymakers can better adapt networks in response to future disruptions or unexpected changes in travel demand. Broadening service coverage throughout the day can safeguard against sudden peaks and ensure continuity for all users, even when work patterns change rapidly. Capturing how schedules evolve over time also enhances the ability to scale or pivot service levels, apply robust demand-management strategies, and strategically allocate resources. By using

these insights, planners can flexibly respond to future public health events or economic shocks while maintaining a resilient and effective transportation system.

Consideration for Freight in Complete Street, Vision Zero, and Curb Management Policies

Abstract ID: 1844.0.0.179.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Evan Iacobucci [Missouri State University] eiacobucci@missouristate.edu, presenting author

Kelly Gregg [University at Buffalo] kgregg@buffalo.edu

Camden Miller [University at Buffalo] camdenmi@buffalo.edu

The widespread adoption of Complete Streets (CS), Vision Zero (VZ), and curb management (CM) policies over the past decade has promoted the expectation that streets are becoming safer for all users. Shifting from an auto-centric perspective, they emphasize the vulnerabilities of pedestrians, cyclists, and transit users. As demand for curb and street space has intensified, especially following the COVID-19 pandemic, there remains a critical gap in consideration of urban freight, delivery services, and emergency vehicles among these policies.

Research has demonstrated that urban freight uses may conflict with other street users—especially vulnerable road users (VRU)—thus it is assumed that CS, VZ, and CM policies seek to manage these conflicts and safety risks in some way. It remains unclear however, the extent to which these policies are directly addressing the potential conflicts between freight and delivery uses and VRU. To better understand the policy development of CS, VZ, and CM policies, we conducted an evaluation of the policies content where we critically questioned:

To what extent are local level CS, VZ, and CM policies across the US and Canada addressing demands for: urban freight, delivery, and emergency vehicle uses within the street right-of-way, and how do these provisions differ across the three policy types?

To address these questions, we conducted an analysis of transportation policies produced over the past ten years. Specifically, we developed a sample of Complete Streets, Vision Zero, and Curb Management policies based on lists maintained by the National Complete Streets Coalition and the Vision Zero Network, as well as systemic searches of professional literature and municipal websites. We developed inclusion criteria based on policy completeness, city size, recency, and several other factors which yielded a final collection of over 100 policies from across 35 municipalities for analysis. To analyze these documents, we produced a coding scheme that captured information about the documents including their goals, details on the uses and contexts they did/did not address, the users they accommodate, and key interactions between these categories. The results of this process yield both important quantitative information about the sample and qualitative insights about how policies accommodate uses (or not).

We find that while policy documents across each policy type have become more comprehensive over time, provisions for freight and emergency vehicles are typically either absent or underdeveloped. Curb management policies are the most likely of the three types to explicitly address freight and delivery accommodations, while Vision Zero policies are least likely. In many cases, Complete Streets policies prioritize non-motorized users, often without clear guidelines on integrating commercial vehicle operations. Where accommodations for freight and emergency vehicles are sometimes mentioned, they tend to be superficial, lacking prescriptive measures for curb space allocation, loading zone management, and operational conflicts with vulnerable road users.

The research highlights the growing safety and operational challenges posed by inadequate urban freight planning, and underscores the need for a more holistic approach to policy development that balances the needs of all users—including freight operators and emergency responders—within the broader goals of urban safety and sustainability. We recommend that municipal policies incorporate provisions for freight and emergency vehicles, establish clear curb management strategies, and integrate these considerations into broader street safety

initiatives. By recognizing freight and emergency services as essential components of the urban transportation ecosystem, cities can create more inclusive and functional streetscapes that enhance safety, efficiency, and mobility for all users.

Crisis, Response, Resilience: What Planning for 'COVID Streets' Teaches Us About Future-Ready Cities

Abstract ID: 1844.0.0.244.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Tabitha Combs [University of North Carolina at Chapel Hill] tacombs@live.unc.edu, presenting author

Lindsay Oluyede [Arizona State University] loluyede@asu.edu

In response to the COVID-19 pandemic, transportation professionals worked to meet heightened demand for pedestrian, cycling, and outdoor commerce space by reallocating portions of public roads for non-driving uses (Abdullah et al., 2020; De Vos, 2020). The rapid implementation of these “COVID Streets” challenged conventional notions that transportation infrastructure changes are costly, time-consuming, and often politically unpalatable. An international scan of COVID Streets research, which sought to understand the motivations and implementation approaches cities used to adapt street space during the pandemic, called for further investigation into what enabled these rapid responses and how these experiences are shaping post-pandemic transportation planning practices (Oluyede, Combs, and Pardo, 2024).

This paper responds to that call by examining the experiences of transportation planners and engineers who were actively involved in planning, implementing, and evaluating COVID Streets responses in 36 US cities and towns. Data were collected through online questionnaires and in-depth semi-structured interviews between 2021 and early 2024. These data were collected as part of the Shifting Streets project, which sought to document the myriad changes to the transportation planning landscape around the world during the pandemic (Combs and Pardo, 2021).

Through narrative content analysis of interview transcripts and questionnaire responses, we draw new insights about lessons transportation professionals learned through their experiences with COVID Streets and ways in which municipal transportation practices and policies have evolved based on these experiences. We also identify keys to success—defined by respondents in terms of response speed, longevity, public sentiment, and quantitative data—of COVID Streets programs across US municipalities.

Our analysis has identified several common elements of successful COVID Streets programs, including (1) strong interdepartmental coordination, (2) pre-identification of public assets that can be deployed or adapted in emergencies, and (3) programs for in situ public engagement and data collection. Many respondents noted these elements could be established before future disruptive events as part of comprehensive resilience strategies.

An emphasis on the rational nexus between the pandemic’s impacts and the types of street space changes implemented emerged as a fourth element in some cities. Preliminary analysis suggests a correlation between this rational nexus, characterized by a focus on transparency and responsiveness in planning, and programs’ public acceptability and longevity—in contrast to more opportunistic approaches driving many less successful COVID Streets efforts early in the pandemic.

Regarding practice changes, transportation professionals described a near-universal increase in confidence in and appetite for using pilot programs with robust in situ public engagement to inform transportation planning. Many respondents also described a sense that attitudes have shifted among both professionals and elected officials: that changes to public road space to support non-driving uses have broad public appeal and need not be expensive or time-consuming undertakings.

The experiences documented in this paper will provide a valuable framework for building more resilient, future-ready cities. While many, if not most, of the original COVID Streets in the US have been dismantled, the true

impacts of the COVID Streets era lie not in specific interventions but in new practices, new perspectives on street space, and new understanding about the relationships between transportation planning and resilience.

Denver Metro's Rail System at 30: What Explains Low Ridership, and Can It Be Improved?

Abstract ID: 1844.0.0.1131.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Carrie Makarewicz [University of Colorado Denver, Dept. of Urban & Regional Planning]

carrie.makarewicz@ucdenver.edu, presenting author

The Denver Regional Transit District (RTD) rail transit system is among the newer systems in the U.S., with 84 stations, 10 lines, and 115 miles of track. The first line opened in 1994, making some lines 30 years old. In a region of 3.09 million people covering a 2,345-square-mile service area, what type of ridership should we expect? Is a four percent regional commute share by transit acceptable? To what extent is the low commute share explained by local zoning, track alignment of least resistance, so-called "Western," culture, and ample auto infrastructure? The system's incremental construction in an existing urbanized area, its alignment decisions, the presence of enforced TOD policies, and other political and social contexts offer an opportunity to study the multiple factors that influence station construction and ridership. As other regions consider expanding or introducing fixed rail transit lines amidst metropolitan politics and the shifting nature of work, the Denver region's case offers multiple lessons.

Drawing from prior research on the region's system (Nelson & Hibbert, 2021; Bhattacharjee & Goetz; Katz, 2013), and the evaluation of the Bay Area Rapid Transit system at a similar age (Cervero & Landis, 1997), our paper asks three questions: (1) How has the Denver region's light rail system performed over the last 30 years and how does ridership vary by station and jurisdiction? (2) How does the region's rail commute-share compare to systems of similar age, such as those in Minneapolis, Salt Lake City, and Los Angeles? (3) Considering the local politics and opposition that influenced the system design, how might Colorado's recently passed laws for densities near transit and more funding for affordable housing and transit affect ridership?

We employ a mixed-methods approach, informed by qualitative analysis of local documents, literature, and interviews, combined with quantitative analyses of the system and land use, to assess the challenges facing the system's performance amidst operational challenges, i.e., safety, frequency, and reliability. At the block group level, we analyze the half-mile station areas in terms of households, density, and jobs, and document the zoning influences. For each jurisdiction, we score their plans for actions and goals aimed at fostering affordable and attainable transit-supportive housing and walkability. We use GIS to construct walksheds for each transit area, given less than ideal station locations. We then delve into the politics and vote-making surrounding the allocation of rail access to municipalities and neighborhoods, as well as the process by which line locations were finalized and funded.

Our findings highlight several design, political, and financial factors that contribute to low ridership. First, resistance to land use changes that would have supported both major destinations and dense origins at more stations, as well as the Federal Transit Administration's requirements for large park-and-rides, significantly affect ridership. Additionally, macro-scale decisions about line locations and track alignment also impact ridership. These outcomes reflect the politics of getting rail built; Denver's light rail was embraced as a middle-class amenity of a "world-class city" made possible with broad-based regional coalition building. Effectively building this coalition of majority-suburban municipal leaders across the eight counties required a focus on more affluent commuter municipalities that rely less on transit rather than transit-dependent neighborhoods that are also low-income and minoritized. Furthermore, reliance upon a sales tax and the farebox to pay off bond debt makes the system reliant on high fares. While the region is celebrated for building its system, our analysis reveals the unfortunate outcomes of

neighborhood appeasement over proven transit and land-use design principles that result in robust ridership and equitable access.

Disaster Resilience for Public Transit: Learning from 50 Largest Transit Agencies

Abstract ID: 1844.0.0.866.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Nawshin Tabassum [University of Utah] u1424030@utah.edu, presenting author

Alessandro Rigolon [University of Utah] alessandro.rigolon@utah.edu

Reid Ewing [University of Utah] ewing@arch.utah.edu

Introduction. Extreme weather events pose serious challenges for public transit services, such as transit operation and service disruption, infrastructure damage, deterioration of service quality, and public safety threats. For example, subways are affected by waterlogging due to extreme precipitation. Transit users are more vulnerable to extreme heat than people driving, as they spend significant time outdoors. Transit agencies seeking to increase transit ridership as an efficient transportation measure must adapt to disasters. Few studies to date have focused on the proactive initiatives undertaken to adapt public transit to these disasters.

Research goal. We examined how public transit agencies include disaster resilience strategies in their strategic plans, long-term transportation plans, transit plans, sustainability plans, and other similar plans.

Methods. As part of a project funded by the U.S. Department of Transportation, we conducted the first national-level study exploring transit agencies' proactive efforts toward disaster-resilient transit facilities. We focused on the 50 largest transit agencies in 2021 based on ridership ("annual Unlinked Passenger trips") from the National Transit Database (NTD) by Federal Transit Administration (FTA). Understanding that disaster-resilient public transit includes efforts by several planning sectors, we collected strategic plans, transit plans, long-range transportation plans, sustainability plans, and similar plans for those transit agencies. In total, we identified 93 plans. Then we used combinations of keywords to identify relevant paragraphs about disaster resilience for public transit facilities within those plans. Subsequently, we conducted content analysis for relevant paragraphs to identify different disasters affecting public transit and disaster resilience strategies adopted by the transit agencies.

Results. We found that transit agencies facing frequent disaster events are actively working towards providing disaster-resilient public transit facilities, whereas agencies with lower disaster risks include less resilience content in their plans. Risks mentioned included floods, sea level rise, heavy rainfall, coastal floods, tropical storms, and extreme heat. Some agencies are working towards providing reliable and flexible transit services during extreme weather conditions.

Transit agencies adopt various short-term and long-term strategies for disaster resilience based on the type of public transit facilities and disaster experience. For rail services, transit agencies build sea walls, elevate critical facilities (e.g., electrical substations), relocate or harden critical infrastructure, install power transformers and sensitive power equipment, and implement other strategies.

Transit agencies are also working to provide comfortable bus stops, stations, and subway services for riders. To deal with the extreme heat, transit agencies provide proper air conditioning and ventilation in subway stations, and shade infrastructure (e.g., tree planting) at bus stops. For stormwater management, transit agencies are prioritizing green infrastructure (e.g., rain gardens with native plants and swales) and permeable pavements at stations.

To implement these strategies, transit agencies focus on pre-seasonal and preventive maintenance, vulnerability assessment of infrastructure, increasing system redundancy, collaboration and coordination with other agencies

and institutions, and other initiatives. Transit agencies are also adopting disaster forecasting tools (e.g., on-demand flood simulations) and early warning systems, emergency protocols, and management plans.

Implications. This study can help planners and policymakers understand the major disasters that transit agencies face, their associated impacts, and the strategies used to address these issues. Planners working in public transit can learn about funding opportunities and barriers to implementing disaster resilient public transit.

Eva Kassens-Noor [Technische Universität Darmstadt] ivv@verkehr.tu-darmstadt.de

The replacement of conventional diesel trucks with alternative drive technologies has the potential to contribute to climate-friendly road freight transport (Gnann et al., 2025). A range of technologies are currently being tested, including battery-electric trucks with stationary or dynamic charging, vehicles with hydrogen combustion engines, and trucks with hydrogen fuel cells. However, there is often a lack of practical experience with the alternative drive technologies and there are different levels of maturity in terms of both vehicle technology and the refueling and charging infrastructure (Peters et al., 2021; Pfoser et al., 2018). Therefore, one of these alternative drive technologies, the dynamic charging of electric trucks using overhead lines (eHighway system), was tested in a field test (Boltze, 2020). Between 2019 and 2024 transport companies operated various types of overhead line trucks (O-trucks) on a public test track for overhead lines. The real-world operation was scientifically monitored with the research focusing on two main questions: How mature and resilient is dynamic charging with overhead catenary lines? Can dynamic charging with overhead catenary lines be the solution for road freight transport?

To evaluate the potential and technological maturity of the eHighway system, comprehensive data was collected and evaluated as part of the accompanying scientific research during the six-year real-world operation. The operational data collected from the overhead line system and the O-trucks provided a basis for evaluating technical maturity and feasibility. The O-truck data was also used to determine energy consumption, energy demand and the reduction of greenhouse gas emissions. The potential for integration into the fleet of transport companies was determined based on O-truck data and supplemented by several surveys of management and drivers. In addition, traffic and accident data provided information on possible changes in traffic flow and impact on road safety due to the eHighway system. Furthermore, two surveys were conducted to determine the social perception of the eHighway system.

Our analysis shows that the overhead line system works safely and reliably and has been integrated into existing traffic management processes. In real-world operation, the system's availability was continuously increased, and measures to maintain a high level of availability were derived. It was determined that neither traffic flow nor road safety were negatively impacted by the overhead line infrastructure or the operation of the O-trucks. The O-trucks have been found to meet the technical requirements of the transport companies and can be integrated into existing transport processes without causing additional downtime. Drivers have also provided favorable feedback, perceiving the O-truck as enjoyable and expressing satisfaction with the O-truck. Even though the usage of the pantograph requires increased attention of the driver at the beginning, it decreases with growing driving experience. From an ecological point of view, the tested O-trucks enable a reduction in well-to-wheel greenhouse gas emissions compared to conventional diesel trucks between 30 and 53% – depending on the electricity mix and usage profile. Notably, acceptance by the public and politicians was identified as a particular challenge. However, their involvement is essential for a successful expansion.

The results of the accompanying research on the real-world operation of the eHighway system demonstrate its technological maturity. Concurrently, this study offers pivotal insights that must be considered in the future implementation of the eHighway system. The findings provide a solid foundation for politicians, transport companies, and vehicle as well as overhead line infrastructure manufacturers to pave the way for the further expansion and broad introduction of the technology.

Dynamics of Neighborhood Change and Gentrification: The Impact of Multiuse Trail Openings and Use

Abstract ID: 1844.0.0.605.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Yunlei Qi [School of Government, Sun Yat-sen University] qiyunlei@mail.sysu.edu.cn, presenting author

Problem: Advocates of multiuse trails highlight their benefits, such as improving access to recreation and active transportation in underserved urban neighborhoods, contributing to broader goals of environmental justice and sustainable development. However, critics argue that these trails might trigger unwanted changes like gentrification and displacement in surrounding neighborhoods, and become “disruptive green landscapes” (Triguero-Mas et al., 2022) or “green locally unwanted land use” (Anguelovski, 2016; Anguelovski et al., 2022). Scholars often describe this phenomenon as “green (space) paradox” (Wolch et al., 2014). Previous studies have found heterogeneous conclusions regarding the incidence of gentrification or broader neighborhood changes, triggered or accelerated by these multiuse trails across different cities and metropolitan areas (e.g., Anguelovski et al., 2022; Qi & Lindsey, 2024). Despite the growing body of literature, few studies have explored the dynamics of trail-induced neighborhood change, particularly gentrification, across different time periods, and investigated the role of trail use in these processes.

Research strategy and findings: Using the Ohio-Kentucky-Indiana (OKI) region as the case study, we tested the dynamic impacts of multiuse trail openings and use on neighborhood change, with a particular focus on gentrification. Our analysis includes two parts. First, we apply a Difference-in-Differences (DiD) design with variations in treatment timing to evaluate the dynamic impacts of multiuse trail openings on their surrounding neighborhoods in terms of housing and residential characteristics. Second, we further investigate whether trail use affects the probability of neighborhood change, particularly gentrification, in neighborhoods adjacent to these multiuse trails.

Our findings show that both gentrifiable and non-gentrifiable neighborhoods experienced more neighborhood changes associated with multiuse trail openings after 2010, particularly during the 2015-2020 period, compared to the previous three decades (1980-2010). Before 2010, gentrifiable neighborhoods experienced more changes due to trail openings compared to non-gentrifiable neighborhoods; whereas the impacts became similar between the two groups during the 2010-2020 period. Additionally, the impact of trail use on gentrification followed an “inverse U-shape” pattern in gentrifiable neighborhoods; whereas trail use showed little effect on neighborhood change in non-gentrifiable neighborhoods.

Takeaway for practice: This study highlights the complex interactions between multiuse trails and neighborhood change, and emphasizes the need for urban planners and policymakers to ensure community engagement during trail planning and targeted strategies to mitigate gentrification risks. Additionally, planners should not only prioritize the development of multiuse trails but also consider strategies to manage trail use levels, ensuring that trails serve all residents without initiating or accelerating gentrification. Policies that promote affordable housing preservation, community engagement, and equitable access to trails are critical to mitigating potential displacement, ensuring that the benefits of green infrastructure are equitably accessible and that urban development remains inclusive, sustainable, and responsive to the needs of diverse communities.

Effects of Vehicle Restriction Policies on New Energy Vehicle Sales and their Broader Implications

Abstract ID: 1844.0.0.131.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Ke Song [College of Architecture and Urban Planning, Tongji University] ksong_stu@tongji.edu.cn, presenting author

Mi Diao [College of Architecture and Urban Planning, Tongji University] diaomi@tongji.edu.cn

Driving and purchasing vehicle restriction policies have been widely adopted to address urban transport challenges by curbing the excessive usage of private cars. In recent years, some governments have introduced unbalanced restriction policies that favor new energy vehicles (NEVs) over conventional internal combustion engine vehicles (ICEVs) to promote the electrification of vehicles. These vehicle restriction policies reshape the vehicle market and bring unknown impacts on urban transportation systems, potentially undermining the effectiveness of the restrictions themselves. While existing research has predominantly focused on the impact of restriction policies on traditional ICEV ownership and usage and environmental outcomes (e.g. traffic congestion and air quality), few studies assess the effects of such unbalanced restriction policies on NEV adoption and their broader implications for urban transport systems.

In this study, we investigate the combined effects of two distinct but interrelated policies in Shanghai: (1) a plate-auction based purchasing restriction policy that applies exclusively to ICEVs, and (2) a driving restriction policy that limits the entry of non-local license vehicles into certain urban areas during peak hours. Using monthly vehicle sales data for NEVs and ICEVs, we apply a sharp regression discontinuity design to empirically evaluate the changes in NEV sales and their market share in response to the driving restriction policy.

The results show that the driving restriction policy significantly boosts NEV sales, with an increase of 112.1%-150.7%, while the proportion of NEVs in total vehicle sales rises by 12.5%-17%. This surge is primarily attributable to the unbalanced regulatory burden imposed by the two vehicle restriction policies: ICEVs face substantially higher license acquisition costs through the auction system, whereas NEVs qualify for free green license plates. Concurrently, the driving restrictions, which affected approximately 1.7 million non-local license vehicles (representing one-third of Shanghai's total vehicle fleet in 2019), generated substantial demand for license plate replacements. Given the higher operating costs associated with ICEVs, NEVs emerged as the dominant choice for both new vehicle purchases and license replacement scenarios.

Furthermore, employing monthly second-hand housing transaction sales as an instrumental variable, we explore the broader implications of the NEV sales surge on traffic congestion and air quality. The results indicate that the policy-driven increase in NEV sales is associated with elevated concentrations of PM_{2.5}, PM₁₀, and CO by 11.5%, 13%, and 19.6%, respectively, and has also led to a 10.9% increase in urban traffic congestion. These findings suggest that although the unbalanced restriction policies have played a positive role in promoting NEV adoption, it may have adverse effect on traffic congestion and air quality. On the one hand, the low driving cost of NEVs may encourage individuals who previously relied on public transport or non-motorized options to switch to private vehicles, thereby worsening congestion. On the other hand, the elevated PM_{2.5} and PM₁₀ levels could stem from upstream NEV manufacturing processes, while the disproportionate CO increase may reflect heightened coal-fired electricity generation to meet growing NEV charging demands.

This study provides a new perspective on the impact of unbalanced vehicle restriction policies on NEV adoption and urban transport systems. The research findings offer useful policy implications for optimizing urban traffic management and environmental governance.

Evolving Patterns of Large Vehicle Ownership in the U.S. Over the Past 30 Years

Abstract ID: 1844.0.0.1148.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Nicole Corcoran [Arizona State University] ncorcor1@asu.edu, presenting author

In recent years, rising concerns have emerged about the growing size of vehicles in the United States., a trend commonly known as "car bloat." This phenomenon refers to the increasing dominance of larger, heavier vehicles, particularly Sport Utility Vehicles (SUVs), which are now the most popular vehicle type in the U.S. auto market. The rise of large, heavy vehicles amplifies many of the externalities associated with automobile use. Such vehicles contribute to more severe injuries and fatalities among pedestrians and cyclists, exhibit lower fuel efficiency, occupy greater space within our urban environments, and demand more resources. Despite the rapid expansion of the SUV market and its far-reaching consequences, there remains a limited understanding of how large vehicle consumers have evolved in the wake of their popularity.

Research on ownership characteristics has been relatively scarce since the early 2000s. The majority of the existing literature, covering the late 1990s to early 2000s, indicates that households owning SUVs were predominantly affluent, young adults, and families with children. However, the demographic profile of large vehicles has likely evolved significantly with the expansion of the large vehicle market. Moreover, the literature on large vehicle consumers remains fragmented, with the use of disparate datasets from different subregions and time periods, varying vehicle classification methods, and diverse modeling approaches. These inconsistencies limit the ability to make meaningful comparisons across studies, and therefore, across time.

Understanding the characteristics and evolution of large vehicle owners is crucial for making informed urban planning decisions aiming to reduce vehicle-related externalities. This research seeks to provide a comprehensive analysis of how consumer demographics related to vehicle body type, size, and weight have shifted during the past three decades. By employing consistent data types, methodologies, and vehicle classifications, this study aims to provide a clear and comprehensive picture of how household vehicle holdings have shifted during the three decades of rapid auto market changes. The following three research questions are addressed:

1. How have household vehicle holdings evolved in the past three decades in terms of weight, size, and body type?
2. Has the SUV consumer demographic disseminated throughout demographic populations within the past three decades? In what way? How does this vary geographically?
3. How are SUVs utilized in comparison to other vehicle types, and how has this changed overtime?

The National Household Travel Survey (NHTS) datasets from 1990, 1995, 2001, 2009, 2017, and 2022 are used to answer the research questions. For urban planners, vehicle size and weight are critical factors in assessing their impact on communities, influencing safety, infrastructure demands, and environmental effects. To better capture SUV variation, this research introduces SUV subclassifications based on size and weight (i.e. compact SUVs, large SUVs, etc.), with use of the Canadian Vehicle Specification dimension data. Descriptive statistics are used to examine changes in household demographics associated with vehicle ownership across NHTS datasets, providing insights into how vehicle ownership by body type, size, and weight has evolved over time. These statistics are compared across survey years and geographic factors such as region and population density, along with vehicle trip characteristics like commuting patterns and household mileage. Simple logistic regression models are also used to

understand evolution of SUV ownership trends, with demographic, geographic, and time variables as independent factors, with the benefit of controls. Lastly, more robust models are used to examine differences in demographic trends across SUV subclassifications.

Fare-Free Transit for Seniors: A Quasi-Experimental Study of Montreal's 65+ Program

Abstract ID: 1844.0.0.1156.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

João Pedro Figueira Amorim Parga [University of Toronto] parga.joao@gmail.com, presenting author

Matan Singer [University of Toronto Scarborough] matan.singer@utoronto.ca

Matthew Palm [University of North Carolina Chapel Hill] palmmatt@unc.edu

Christopher Higgins [University of Toronto Scarborough] cd.higgins@utoronto.ca

Steven Farber [University of Toronto] steven.farber@utoronto.ca

In 2023, Montréal implemented the Free 65+, a fare-free policy for its seniors residents (65 years old or above). The policy addresses seniors' transportation needs, i.e., mobility and accessibility declines derived from aging, the interconnectedness between transportation accessibility and social inclusion (and the risk of exclusion), and issues of affordability [4]. Fare-Free Public Transit (FFPT) programs, as the Free 65+, refer to the total elimination of public transit tickets for all individuals or the distribution of zero-fare tickets for some specific groups [1]. By providing unconditional access to collective transport regardless of one's ability to pay, FFPT are tied to egalitarian concerns - thus making them an appropriate vessel to the evaluation of theories of justice and the social exclusion approach to transportation [2], [5]. However, the literature on FFPT has not clearly defined the causal links between free transit passes and social exclusion, let alone empirically investigated the policy's effect on activity participation.

Thus, we asked: is Montréal's Free 65+ achieving its main objectives after one year of its implementation? More specifically, has the free transit pass significantly impacted seniors' travel behaviour, changed their perception on activity participation (thus reducing the risk of social exclusion), and/or affected their relationship to the fundamental cost of using public transit (fares)? Furthermore, are these impacts distributed equally throughout seniors or is any particular social group (e.g., immigrants, different cohorts among seniors, visible minorities, etc.) disproportionately affected by the policy?

We use a quasi-experimental research design. We collected data before and after the intervention through a survey conducted by the Mobilizing Justice Partnership. Besides socio-demographic and geographical information, we asked individuals about our main outcome variables related to the policy's objectives - their travel behaviour (frequency, destination, and mode used), their subjective perceptions on transit fares' affordability, and their satisfaction with activity participation. We use propensity-score matching (PSM) to define treatment (seniors in possession of the pass after the intervention) and control groups (counterfactuals who represent what would have happened to treatments had they not acquired the pass). Moreover, we use appropriate metrics, before and after the intervention, to evaluate its equity considering recent discussions of distributive justice in transportation [3].

Our expected contributions to the field of transportation planning are the following. First, by evaluating a concrete FFPT policy in light of its reported objectives, we expect to provide substantial evidence about its short-term effects, which can be used in future policy improvements. Thus, we anticipate the analysis to be a source of discussion between the stakeholders involved in its implementation (transit agency, policymakers, and users) which could ultimately steer Montréal towards a more just transit system. Second, by mapping the causal links between a free-pass transit policy and the three outcomes cited – travel behaviour, transit affordability, and activity participation – we expect to help future research to avoid common perils of causal inference estimation (e.g., omitted variable bias, confounder bias, etc.). In a context where association studies form the basis of empirical evidence on FFPT, we expect the research based on causality to deliver meaningful insights otherwise neglected or

hidden on common methodologies. Finally, by examining the equity impacts of the program, we discuss how egalitarian-driven policies might generate unexpected results through a distributive justice lens.

Governing Electrified Micromobility Expansion: Lessons from Four Decades of Adoption in China

Abstract ID: 1844.0.0.897.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Chenhao Zhu [Massachusetts Institute of Technology] chzhu@mit.edu, presenting author

Electrified micromobility has matured into a sustainable alternative to automobiles for short-distance trips, serving as a key solution for decarbonizing car-centric development (Abduljabbar et al., 2021). Despite its potential benefits, the rising penetration of electrified micromobility presents significant governance challenges for cities seeking large-scale implementation, such as safety risks, sidewalk obstructions, and visual disorder (Leszczynski et al., 2024; Fearnley, 2020). In response, proactive policy measures are essential for anticipatory governance of electrified micromobility expansion. Although many studies have explored this issue from operational, managerial, and user perspectives, fewer have examined the evolving policy measures related to the built environment (BE) to accommodate electrified micromobility expansion (Zhang et al., 2023). Even fewer studies have linked specific BE-related governance challenges and solutions to distinct phases of electrified micromobility expansion from a spatiotemporal perspective.

To fill this gap and provide timely guidance for global cities navigating the uncertainties of electrified micromobility expansion, China's 40 years of governance and policymaking experiences offer valuable lessons on regulating this disruptive technology to maximize its benefits while minimizing negative impacts (Zuev, 2020). Since their debut in 1985, the number of electric bicycles in use has surpassed 350 million, according to 2024 data from the Chinese government. While many cities are only now beginning to navigate these challenges, major Chinese cities have long grappled with the externalities of large-scale micromobility implementation through consistently modifying BE regulations and corresponding infrastructure. To analyze 40 years of Chinese governance efforts in managing electrified micromobility expansion, this study employs a mixed qualitative approach at both national and municipal levels, focusing on three key BE elements: micromobility nodes, links, and networks. Laws and regulations at both national and local level are mapped to corresponding challenges across different phases of electrified micromobility expansion. Meanwhile, the spatiotemporal changes of micromobility-related BE elements in the three cities with the largest electrified micromobility fleets, Shanghai, Tianjin, and Chengdu, are analyzed through onsite observations, interviews, and archival research.

The findings reveal that the evolution of national regulations reflects a progressively more sophisticated approach to governing electrified micromobility and its related BE elements. For example, policy has shifted from treating all electrified micromobility uniformly to classifying vehicles by speed and specifications, with tailored BE regulations for each category. The examination of local policies reveals more nuanced insights into the disparities among cities in addressing electrified micromobility expansion. For instance, while some cities promote micromobility hubs for their role in enhancing aesthetics and accessibility in public spaces, others mandate them to ensure charging facilities are sited away from buildings to reduce the risk of deadly fire hazards. Building on these findings, an adaptable policy checklist is developed to help cities proactively prepare the built environment, navigate uncertainties, and mitigate potential negative impacts associated with electrified micromobility expansion.

Reliable transportation plays a critical role in ensuring healthcare access for vulnerable populations, referring to Medicare and Medicaid beneficiaries who often face socioeconomic barriers and may have functional limitations (Flynn et al., 2021; Wolfe et al., 2020). Public transit facilitates this access, particularly for individuals without private vehicles (Jin et al., 2022). Assessing healthcare accessibility via public transit helps identify spatial inequities contributing to delayed care and poor health outcomes (Jin et al., 2022; Wolfe et al., 2020). Spatial inequities can be defined as avoidable or remediable differences in the geographic distribution of opportunities to access healthcare services among different groups (Jin et al., 2022).

Studies globally highlight transportation's crucial role in healthcare accessibility, revealing disparities for vulnerable groups. For example, low-income individuals in Shanghai, those with disabilities and poor mental health in Toronto, and older adults in Ghana experience significant transportation barriers (Jin et al., 2022; Lyeo et al., 2023; Oduro Appiah et al., 2020). However, research is limited on how transit impacts healthcare access for publicly insured populations within U.S. metropolitan areas (Jin et al., 2022; Lyeo et al., 2023). This study seeks to understand how public transit influences healthcare access for Medicare and Medicaid beneficiaries in the DFW region by addressing two key questions: (1) How does geographic location shape the experience of transportation barriers to healthcare? and (2) How are socioeconomic factors, such as insurance type, income level, and age, associated with the prevalence and type of transportation-related barriers?

This study will employ network-based spatial accessibility analysis within a Geographic Information System (GIS) framework to evaluate healthcare access via public transit for Medicare and Medicaid beneficiaries in the Dallas–Fort Worth (DFW) metropolitan area. Building on methods proposed by Luo & Wang (2003) and Liu et al. (2022), the analysis emphasizes travel time impedance rather than simple distance, capturing the real-world complexity of public transportation. Using digital transit data, including routes, schedules, and stop locations, the study will apply a time-dependent shortest path algorithm (e.g., Dijkstra's) to estimate minimum travel times between residential locations and healthcare facilities (Jin et al., 2022). Accessibility calculations will integrate factors such as walking distances to transit stops, waiting times, transfer penalties, and, in some cases, real-time delays, enhancing accuracy beyond schedule-based models (Liu et al., 2022). Accessibility will be measured using the Two-Step Floating Catchment Area (2SFCA) method, which jointly considers healthcare provider capacity and demand within travel-time catchments of 30, 45, and 60 minutes (Jin et al., 2022; Chen et al., 2023). This method will incorporate public transit travel times and healthcare provider capacity, making it ideal for identifying spatial access disparities among transit-dependent populations. The unit of analysis will be the census tract, using data sources that include GTFS transit feeds from DART, healthcare provider data from CMS, and demographic and socioeconomic variables from the American Community Survey (ACS).

Based on the literature, it is expected that lower-income populations are more likely to rely on public transit and experience delays or missed appointments (Jin et al., 2022; Oduro Appiah et al., 2020). The role of age is expected to be complex, reinforcing findings from Lyeo et al. (2023), older adults, especially those over 85, may encounter mobility limitations, although some may benefit from car access or specialized transit services. This study aims to

reinforce and localize these patterns by highlighting disparities in transit-based healthcare access among Medicare and Medicaid beneficiaries in DFW.

Housing and Transportation Costs and Residential Relocation: A Study of California Movers

Abstract ID: 1844.0.0.968.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Jesus Barajas [Department of Environmental Science and Policy] jmbarajas@ucdavis.edu, presenting author

Movers, Housing and transportation comprise households' two largest expenses. Housing cost burden remains a major challenge for California. Over half of the state's households pay more than 30% of their income on housing costs, with higher burdens among households in poverty and people of color-disparities likely widened by the Covid-19 pandemic (PolicyLink 2022; Nobari, Anderson, and Whaley 2022). Meanwhile, some locations with the lowest transportation costs because of available transit and multimodal infrastructure also face the strongest displacement pressures due to high housing costs and a deficiency of affordable housing (Chapple, Thomas, and Zuk 2021). This study asks (1) whether housing and transportation costs are associated with residential relocation, and (2) whether moves are to areas that generate higher vehicle miles traveled (VMT). The study examines these questions for the state of California.

This study relies on two key data sources. The first is the University of California Consumer Credit Panel (UC-CCP). The UC-CCP dataset is a longitudinal panel consisting of a nationally representative 2% sample of US adult consumers and 100% of Californians with credit histories, plus people who shared an address or an account with individuals in the sample. We use the UC-CCP to construct a database of movers with a limited set of demographic characteristics provided in the sample. The second is tract-level information about housing and transportation costs and VMT generation. Housing and transportation costs are calculated using a state-specific version of the H+T model developed by the Center for Neighborhood Technology (CNT). VMT estimates are calculated using the inputs to the VMT model, which are drawn from vehicle odometer reading estimates from another state calibrated to a sample of California odometer readings.

We have constructed a database of movers and have begun to calculate descriptive statistics on these movers, though the results are not yet ready as of the time of writing this abstract. We will report a descriptive summary that compares VMT estimates in sending neighborhoods to receiving neighborhoods for movers, stratifying by equity-priority communities. We will also report results from a statistical model that estimates the likelihood of moving as a function of housing and transportation costs, controlling for other personal characteristics.

Results will be relevant to planners seeking to understand how housing and transportation costs contribute to potentially unwanted moves or to excess greenhouse gas emissions as a result of residential concentration in high car-use areas.

How Caregiving Shapes Daily Travel Choices: Analyzing Determinants of Children-Accompanied Tours

Abstract ID: 1844.0.0.981.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Dawon Oh [Harvard University] dawon_oh@gsd.harvard.edu, presenting author

This study examines how caregiving responsibilities, particularly traveling with children, shape caregivers' daily travel choices. While existing research broadly explores caregiving's impact on travel behavior, this study focuses specifically on how caregiving influences whether caregivers travel with children.

Prior research on mobility of care highlights the significant impact of caregiving roles on travel behavior (de Madariaga, 2016; de Madariaga & Zucchini, 2019). Caregivers navigate constraints related to travel time, distance, frequency, and mode of transport, often dictated by children's schedules and needs (Chica-Olmo & Lizárraga, 2022; He & Giuliano, 2015; McDonald & Aalborg, 2009). However, less is known about how factors such as household composition, caregivers' personal traits, and urban environment influence caregiving-related travel decisions.

This study categorizes travel into three tour types: All Children-Accompanied Tours, Partly Children-Accompanied Tours, and Children-Free Tours. A "tour" consists of multiple trips forming a closed loop, returning to the original starting point. An All Children-Accompanied Tour includes children on every trip, a Partly Children-Accompanied Tour includes some trips with children, and a Children-Free Tour involves no child accompaniment.

The study aims to analyze how household and trip characteristics affect the likelihood of choosing each tour type. Using a discrete choice model, it estimates the probability of each tour type based on various influencing factors. The analysis leverages 2017 National Household Travel Survey data from the United States and Denmark, enabling a cross-cultural comparison of how caregiving dynamics, shaped by cultural and urban contexts, influence travel decisions. This comparison considers differences in urban design, transportation infrastructure, and caregiving norms.

The model incorporates key variables reflecting household and trip characteristics. Household factors include the number and age of children, single-parent status, and multi-generational living arrangements. Trip characteristics such as travel time, trip purpose, and transportation mode capture the constraints and flexibility caregivers experience in their travel choices.

The findings highlight two key trends. First, women caregivers from lower-income households are more likely than men to accompany children on their trips, reflecting the gendered nature of caregiving responsibilities. Limited access to alternative caregiving support and workplace flexibility may further reinforce this trend, particularly in resource-constrained households. Second, child-accompanied tours (both partly and entirely) in both US and Denmark rely more on private vehicles for longer trips, while shorter trips in Denmark favor active modes such as walking and cycling. This suggests that time efficiency, safety, and convenience influence longer-distance travel, whereas walkable urban environments facilitate active travel for shorter trips.

While caregiving-related travel patterns may seem intuitive, this study provides empirical evidence to quantify these trends, uncover underlying mechanisms, and explore context-specific differences that inform policy and planning. By analyzing travel survey data from the U.S. and Denmark, it examines how cultural and infrastructural factors shape mobility. Beyond confirming broad trends, the study investigates who is most affected and under what conditions—such as whether lower-income caregivers choose active travel out of necessity or preference and

how walkability influences private vehicle use. These insights contribute to a deeper understanding of how household composition, trip characteristics, and urban infrastructure interact to shape caregiving-related mobility.

How Do Mobility Patterns Affect Extreme Heat Exposure While Walking and Biking?

Abstract ID: 1844.0.0.473.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Hojung Yu [Georgia Institute of Technology] hyu483@gatech.edu, presenting author

Rounaq Basu [Georgia Institute of Technology] rounaq@gatech.edu

Kavya Venkateswaran [Georgia Institute of Technology] kvenkate3@gatech.edu

Exposure to extreme heat significantly affects quality of life and poses health risks, with effects varying across different neighborhoods. Climate inequities are often structural, disproportionately affecting vulnerable groups who experience harsher environmental conditions and have lower access to mitigation resources. Researchers have found a relationship between socioeconomic attributes of neighborhoods and urban heat island effects, whereby non-White and lower-income communities are subject to elevated heat levels. While green spaces can help mitigate urban heat, their distribution is also often inequitable, with higher-income neighborhoods with a larger proportion of White residents having access to more green space compared to lower-income neighborhoods.

While prior research has examined the disproportionate spatial distribution of urban heat at the scale of neighborhoods, there remains a gap in our understanding of how heat stress affects vulnerable groups while walking and biking. Since urban heat risk can change by time-of-day and is related to mobility patterns, a more careful exploration of how heat risk is affected by human mobility above and beyond residential location is needed. Where we live and who we are matter, but where we go and how we travel also matter just as much, if not more.

This study aims to provide a nuanced understanding of urban heat inequity by analyzing both ambient temperature disparities and potential heat exposure during travel by walking or biking. We focus on the Atlanta and Boston metropolitan regions to quantify heat exposure at a very high (1-meter) spatial resolution, emphasizing two key dimensions - socioeconomic inequity and environmental inequity, through the mediating effect of activity-travel patterns. We compute a thermal comfort measure called the Universal Thermal Climate Index (UTCI), which represents the perceived “feels-like” temperature, across neighborhoods to evaluate urban heat risk. We also use additional environmental indicators related to urban greenery—such as the Normalized Difference Vegetation Index (NDVI) and Enhanced Vegetation Index (EVI)—that are derived from Planet Imagery datasets. First, we confirm the findings from prior research by examining the relationships between socioeconomic indicators and urban heat and urban greenery at the neighborhood (Census block group) level. We then extend the literature by examining urban heat risk at the network-link level to explore variations in exposure while walking or biking. We use population-level mobility data provided by Replica for summer and fall, which include socioeconomic attributes as well. Finally, we integrate both components to compute total heat and greenery exposure experienced by people during their daily walking and biking trips, along with disparities in heat and greenery exposure across socioeconomic groups. This approach moves beyond using the residential location as a point of reference, offering a more comprehensive understanding of how individuals experience heat risk while moving through urban environments.

Our findings contribute to ongoing discussions on urban climate resilience and sustainable mobility by identifying and quantifying critical disparities in heat exposure across neighborhoods and sociodemographic groups. While sustainable mobility advocates push for mode shifts to non-car options, these efforts may be stymied by extreme heat effects or accentuate heat exposure without supportive mitigation efforts. This study provides evidence to support the integration of heat resilience into transportation planning through targeted interventions such as expanding green infrastructure and adding shaded transit shelters, among others. Overall, our work aims to

support the development of more resilient and equitable cities where threats to sustainable transitions such as extreme heat do not disproportionately affect vulnerable populations.

Impacts of Free Fare Policy on Public Transit Ridership

Abstract ID: 1844.0.0.105.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Luyu Liu [Auburn University] luyuliu@auburn.edu, presenting author

Harvey Miller [The Ohio State University] miller.81@osu.edu

Fare-free public transit has been explored as a policy intervention to increase ridership, promote social equity, and reduce car dependency. However, quantified, empirical evidence on its effects remains limited, particularly in the United States. This study examines the impact of a temporary fare-free policy implemented by the Central Ohio Transit Authority (COTA) in Columbus, Ohio, from March 2020 to January 2021, which provides a unique opportunity to analyze transit demand and ridership changes in a controlled setting. Using high-resolution trip planning app usage data from the Transit App and automatic passenger counts data from the public transit system, we conduct spatiotemporal analyses and Differences-in-Differences regression to identify shifts in ridership patterns and assess the policy's implications for social equity. The findings contribute to understanding whether fare-free policies stimulate latent demand, particularly among low-income populations, and offer insights into their potential role in shaping more accessible and sustainable urban transit systems.

Influence of Travel Mode and Heat Sensitivity on Streetscape Preferences Related to Thermal Comfort

Abstract ID: 1844.0.0.837.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Gulsah Akar [Georgia Institute of Technology] gulsah.akar@design.gatech.edu, presenting author

Chaeyeon Han [Georgia Institute of Technology] chan303@gatech.edu

Seung Jae Lieu [Georgia Institute of Technology] slieu3@gatech.edu

Shinah Park [Georgia Institute of Technology] shinah.park@gatech.edu

Rising temperatures negatively impact outdoor travel experiences, which are crucial to mobility and health outcomes. In transportation planning efforts aimed at improving outdoor thermal comfort, studies have commonly emphasized the need to mitigate heat stress during non-motorized travel to increase walkability (Basu et al., 2024; Xi et al., 2023). Traditional approaches have relied on simulations or travel records to identify where and who is more likely to be exposed to extreme heat during outdoor travel (Karner et al., 2015).

Although we now understand which built environment features help mitigate heat stress on streets, we lack a clear understanding of how preferences for these features vary based on individuals' travel behaviors and attitudes toward traveling under heat. People have different thermal comfort levels for traveling based on their physical or sociodemographic contexts. To address this gap, we developed a survey on heat exposure during travel, which we designed into two sections to examine whether individuals' main mode of travel is associated with their street environment preferences, considering their attitudes toward travel under extreme heat conditions.

Section 1 asked about participants' attitudes toward traveling in high temperatures and their views on the role of cities in addressing extreme heat. It also asked how they travel across different modes throughout the week and their sociodemographic characteristics. Section 2 assessed visual streetscape preferences under heat. Participants were shown several image pairs that represented a variety of streetscapes. For each image pair, respondents selected the one they would prefer to walk in during high temperatures.

A significant benefit of using our survey is the ability to understand attitudes toward heat, which are an underlying factor that impacts people's travel outcomes. We offer a novel framework by connecting this attitudinal and travel information to the understanding of thermal environment needs (Jia et al., 2022). Through the analysis, we test these hypotheses: 1) individuals have different attitudes toward traveling under heat, 2) heat stress experiences vary by individuals' main travel mode, and 3) preferences for heat-mitigating streetscapes (such as trees) depend on factors such as heat sensitivity and primary mode of travel.

For statistical analysis, we categorized 150 respondents based on their attitudes toward heat and recorded travel patterns. In the process, we applied factor analysis and PCA to summarize these variables. Additionally, we modeled the 1,200 pairwise image choices using a conditional logit model to understand the factors affecting their street preferences. Our results indicate that preferences for street environments, such as greenery, are closely related to travel behavior. The preference for green streetscapes is stronger for those who mainly walk than for those who drive. Additionally, differences exist between individuals who are more likely to be affected by heat and those who are not. For instance, female travelers and zero-vehicle households are more likely to reduce or avoid travel during the heat.

The findings from this survey contribute to both the literature and planning practice by guiding where and what types of interventions to implement for mitigating heat, based on individuals' varying travel patterns. Since travel outcomes are closely related to the built environments around them, this study provides guidelines on how and

where to enhance environments for thermal comfort based on travel behavior in the region. Our findings offer valuable insights for creating street environments that support sustainable mobility and inform mitigation strategies in transportation planning for the future of healthy cities.

Infrastructure Disruptions and Recovery: Focus on Rural Households after 2018 Hurricane Michael

Abstract ID: 1844.0.0.161.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Diana Mitsova [Florida Atlantic University] dmitsova@fau.edu, presenting author

Ann-Margaret Esnard [Georgia State University] aesnard@gsu.edu

Monica Escaleras [Florida Atlantic University] mescaler@fau.edu

Alka Sapat [Florida Atlantic University] asapat@fau.edu

Lilah Besser [Florida Atlantic University] lmb9767@med.miami.edu

The uneven distribution impact of natural disasters across different communities in the United States has been well documented in academic research. However, there remains a noticeable gap in the literature regarding recovery outcomes, particularly in rural areas that often face unique challenges (Jerolleman, 2020; Marshall, 2024). Our study aims to address this gap by providing a comprehensive, longitudinal analysis of self-reported household recovery outcomes in rural communities in the Florida Panhandle following the catastrophic 2018 Category 5 Hurricane Michael, which caused widespread destruction across the region.

We analyzed data from 909 survey responses, collected approximately five months after Hurricane Michael made landfall. These responses were gathered from the fifteen counties designated by FEMA as eligible for both individual and public assistance. A follow-up survey was disseminated 17 months after the landfall. It was completed by 156 respondents who were matched across both phone surveys. To analyze the factors influencing recovery outcomes, we employed a random-intercept logistic regression model.

The survey results revealed a complex picture of recovery, with a significant portion of respondents reporting varying degrees of progress. Five months after the storm, 40% of participants indicated that they had fully recovered from the disaster, while 22% reported that they mostly recovered. Another 24% of respondents said they had somewhat recovered, and 10% indicated that they had not recovered at all. This data underscores the varied experiences of recovery, with some households reporting a swift return to normalcy, while others faced prolonged challenges. The follow-up survey revealed that 64% of those recontacted had recovered, while 34% reported that they had not. Overall, 32% of respondents experienced electrical outages lasting more than seven days, while 28% reported losing cell phone and Internet service for the same duration. When asked what facilitated their return to normal daily routines, the vast majority in both baseline and follow-up surveys cited power restoration as the key factor, followed by the restoration of cell phone and Internet services. The timelines for restoring electrical power, especially in rural areas where utility companies have limited capacity and resources, are crucial for both household and community recovery (Mitsova et al. 2018).

The results from the statistical modeling identified several key factors that significantly impacted recovery. The severity of the damage to homes and infrastructure had a strong negative association with recovery, as did extended power outages, income loss, and difficulties in accessing basic necessities such as food, fuel, and essential services. These challenges created additional barriers for households trying to rebuild their lives. In contrast, having homeowners' insurance was found to have a highly significant positive association with recovery, suggesting that financial resources played a critical role in facilitating faster and more successful recovery efforts. The survey results also highlighted the role of disaster assistance in the recovery process. Compared to those who received disaster assistance, individuals whose applications were denied or were still pending at the time of the survey had significantly lower odds of recovering. This finding underscores the importance of timely assistance in promoting equitable recovery, particularly for vulnerable populations in rural areas.

Overall, the findings provide valuable insight into the long-term trajectory of recovery and highlighted the significant hurdles that many rural communities continue to face even well after the immediate aftermath of a disaster. These results emphasize the need for tailored interventions that address the specific needs of affected populations and ensure that all communities, regardless of their location, have an equal opportunity to recover and rebuild.

Integrating Survey Data into Large-scale Choice Models for Mobility Hub Impact Assessment

Abstract ID: 1844.0.0.302.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Xiyuan Ren [New York University] xr2006@nyu.edu, presenting author

Joseph Chow [New York University] joseph.chow@nyu.edu

Rapid urbanization and growing travel demand have intensified challenges such as traffic congestion, increased carbon emissions, and exacerbated services disparities, significantly impacting urban sustainability and livability. Mobility hubs emerge as critical interventions in this context, offering nodes of connectivity that seamlessly combine public transit, active mobility, and shared services to encourage transit ridership, reduce car usage, and facilitate convenient transfers.

Identifying optimal locations for mobility hubs becomes an essential and strategic task for policymakers and relevant authorities. Previous studies on hub location selection either employ Multi-Criteria Decision Making (MCDM) methods or formulate optimization models. However, these studies highly depend on the assumed demand, expert judgment, or proxy indicators. An empirical assessment of how mobility hubs impact travelers' mode choices is lacking. Inadequate consideration of hub-specific parameters, heterogeneities in user preferences, and intercity travel patterns constrain the scalability of existing models and limit their practical contributions.

Estimating behavioral models that account for both large-scale travel patterns and user preferences of mobility hubs is challenging. On the one hand, citywide or regional travel data typically do not include multimodal trips involving the use of mobility hubs since most hubs are still in the conceptual stage, and few have been implemented. The lack of real-world usage data makes it difficult to obtain user feedback and accurately capture user preferences regarding mobility hubs. On the other hand, although hub usage data can be collected through on-site investigations, these data are often limited in both spatial and temporal scope. Mobility hubs involve diverse mode combinations as well as numerous potential trips, which cannot be fully represented by surveys with small sample sizes.

This study proposes a novel data fusion approach to integrate mobility hub usage data into a mode choice model estimated with large-scale information and communication technology (ICT) data. The mode choice model quantifies mode shares for a wide range of trip origins to destinations (OD) pairs, segmented by age, income level, and employment status. The hub usage data provide direct insights into how travelers use mobility hubs, enabling the calibration of hub-related parameters not included in the initially estimated model. The data fusion approach involves two key steps. First, we identify trips potentially impacted by mobility hubs and generate a revised choice set that includes multimodal trip options. Second, we calibrate hub-specific parameters within the pre-estimated choice model using survey and ground-truth data. With this hub-usage-enhanced modeling framework, it becomes possible to quantify the behavioral impacts of mobility hubs, which are crucial to hub deployment strategies but rarely measured. Such impacts include changes in transit ridership, vehicle miles traveled (VMT), carbon emission, and consumer surplus in the post-pilot scenario.

We apply this method to a case study in Capital District, NY, using data from a survey conducted by the Capital District Transportation Authority (CDTA) and a mode choice model estimated using Replica Inc.'s synthetic data. The two implemented hubs—located near UAlbany Downtown Campus and in Downtown Cohoes—are projected to generate 8.83 and 6.17 multimodal trips per day, reduce annual VMT by 20.37 and 13.16 thousand miles, and increase daily CS by \$4,000 and \$1,742, respectively. An evaluation of potential hub candidates in the Albany-

Schenectady-Troy metropolitan area demonstrates that hubs located along intercity corridors and at urban peripheries, supporting park-and-ride (P+R) patterns, yield the most significant behavioral impacts.

Investigating Heat Exposure for Paratransit Users in the Denver Metropolitan Region

Abstract ID: 1844.0.0.896.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Abigail Cochran [University of Nebraska–Lincoln] acochran@unl.edu, presenting author

Rounaq Basu [Georgia Institute of Technology] rounaq@gatech.edu

Prashanth Venkataram [Cambridge Systematics, Inc.] pvenkataram@camsys.com

Manish Shirgaokar [University of Colorado Denver] manish.shirgaokar@ucdenver.edu

Weather patterns are shifting globally with varying effects at the local level. Heatwaves, for instance, are getting longer, more frequent, and more intense. The literature examining the intersection of travel behavior and extreme weather, while relatively nascent, has been growing in recent years. Researchers have investigated how heat exposure is associated with travel behaviors broadly (Li, et al. 2023), with a specific focus on active travel modes (Colaninno, et al. 2024) and public transit (Ahmed, et al. 2024). The policy implications of heat exposure on activity-travel patterns extend to public health and infrastructure planning and design. Several local jurisdictions in the United States are beginning to recognize this emergent need to proactively plan for changing local weather patterns.

Local government entities in the Denver Metropolitan Region along with the Regional Transportation District (RTD), which provides para/transit services in the region, are a unique case study for expanding this literature for people with disabilities. RTD provides a paratransit service, Access-a-Ride, across the Denver Metropolitan Region (Akceek, et al. 2023). Relying on a dataset from RTD that includes timestamped paratransit trip start and end locations, we are exploring the overall geography of demand on extreme heat days during 2019 and 2020. We are comparing trips undertaken by people using paratransit during extremely hot days (i.e., treatment days) with control days—within the same 10-day period—when temperatures remained within normal ranges. We plan on overlaying a heat exposure model built, calibrated, and verified for extreme heat days in the Denver metropolitan region at a 30-meter spatial resolution (Ibsen, et al. 2022). In this paper, we aim to identify locations where paratransit users are relatively more exposed to extreme heat, in addition to highlighting where demand shifts at a micro-geographic scale. We anticipate our analysis will shed light on the extent and location of systematic changes in paratransit demand during extreme heat days. Our findings can inform policy strategies to expand weather-resilient travel options for people with disabilities who rely on paratransit services.

Life Without Cars: Why Some Americans Are Choosing Car-Free Neighborhoods

Abstract ID: 1844.0.0.512.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Huê-Tâm Jamme [Arizona State University] hjamme@asu.edu, presenting author

Deborah Salon [Arizona State University] dsalon@asu.edu

Rababe Saadaoui [Arizona State University] rsaadaou@asu.edu

Aurelie Knecht [Arizona State University] amknecht@asu.edu

Emerging literature suggests a sizable unmet demand for car-free living in America, i.e., for living in places where it is possible to not own a car. Corcoran et al. (2024) estimated that 18% of the U.S. urban and suburban population currently living in car-owning households are interested in car-free living. While existing studies on car-free and carlite neighborhoods have largely focused on Europe, Asia, or Australia (e.g., Baehler & Rérat, 2020; Basu & Ferreira, 2020; Pajmans & Pojani, 2021; Selzer & Lanzendorf, 2022), our paper addresses three key research questions in the U.S. context: 1) Who is interested in car-free neighborhoods? 2) What motivates this interest? 3) How do these individuals anticipate overcoming mobility challenges in a car-dependent environment?

We collected data in 2022 and 2024 from a group of people (N=503) who showed a strong interest in the car-free neighborhood concept by paying a \$100 deposit to reserve a unit at Culdesac Tempe before construction began. Often described as the first car-free neighborhood in the U.S., Culdesac Tempe is located near rail transit in Phoenix, AZ, one of the most car-dependent regions in the world. This private development has received significant attention in the popular media for its groundbreaking parking policy: there are no options for residents to park privately owned vehicles on-site or nearby. Instead of residential parking, the Culdesac model offers many on-site amenities and abundant open space. As of spring 2025, approximately 300 residents live at Culdesac Tempe (renters only). The population is expected to reach about 1,000 upon completion of 700 units.

We invited all Culdesac depositors to participate in a survey and other research activities. Our response rate was 17% of complete survey responses (n=87). Some respondents also participated in a focus group discussion (n=16), a follow-up interview coupled with a seven-day travel diary activity (n=6), and an additional interview after moving to Culdesac (n=2). We used a mix of descriptive statistics and thematic analysis to identify patterns in our data.

The survey results highlight some distinctive transportation preferences among Culdesac depositors. They favor sustainable transportation modes, especially walking, the electric bicycle, rail transit, and the regular bicycle (in decreasing order of preference). When choosing a place to live, they highly value a walkable neighborhood and proximity to shops and services. Nevertheless, most of them have access to a car and live in neighborhoods that are not particularly walkable. They drive often, but not always. In terms of sociodemographic characteristics, Culdesac depositors are a rather diverse group in terms of income, gender, and race. However, young professionals aged 20-30 are overrepresented in the sample, as well as people having the option to work from home, likely influenced by the timing of data collection during the later phases of the Covid-19 pandemic.

The interviews and focus groups revealed five profiles of people interested in car-free living: 1) The Retiree Seeking Connection, 2) The Avid Bicyclist Seeking Community; 3) The Lifelong Car-Free Individual; 4) The Pioneer Forging a New Path; and 5) The Anti-Car Advocate. Despite their differences, participants shared common experiences, such as having traveled to walkable and bikeable cities around the world, and experiencing feelings of loneliness and isolation. They identified two factors critical for their satisfaction with living in a car-free neighborhood: the

emergence of a strong sense of community, and the availability of reliable alternative mobility options, especially rail transit and cars on demand.

We conclude with recommendations for planners and developers to embrace car-free living as a multidimensional concept rather than a housing type. The provision of car-free living options must prioritize a community-oriented design and an alternative mobility package.

Linking Accessibility and Transport Poverty using Two Canadian National Datasets

Abstract ID: 1844.0.0.934.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Matan Singer [University of Toronto Scarborough] matan.singer@utoronto.ca, presenting author

Ignacio Tiznado-Aitken [University of Toronto] i.tiznadoaitken@utoronto.ca

Steven Farber [University of Toronto] steven.farber@utoronto.ca

Disparities in the level of accessibility to destinations across socio-demographic and racial/ethnic groups are well documented (Shen, 1998), as are the links between low levels of auto-ownership and (transit) accessibility on the one hand and transport poverty on the other (Lucas et al., 2016). Specifically, lack of (affordable) transportation options has been linked to social exclusion manifesting in lower ability to find and maintain a job, missing medical appointments, low levels of activity participation, and lower well-being. However, a core question remains whether and to what extent does accessibility alleviate transport poverty. Understanding the relationship between accessibility and transport poverty is crucial for providing planning agencies with the evidence needed for future transport and land use decisions that can help improve equity and sustainability outcomes.

In this study we examine the relationships between transport accessibility and transport poverty in Canada using two unique datasets. A novel national survey of over 27,000 residents in all Canadian metropolitan and rural areas is used to develop transport poverty indicators based on stated levels of activity participation, perceived accessibility, transport costs, and foregone trips. The survey data were collected between July 2023 and November 2024 through an online form using a professional survey firm. The data collected also includes extensive socio-demographic information about the household situation of the sampled population. The sample size collected seeks to capture individual and household level data from different income levels (i.e., low and middle-high income households), urban, suburban, and rural and equity-seeking groups in vulnerable populations from across Canada.

Accessibility measures are developed to determine, for predefined population groups, how far above or below a sufficient level of accessibility by a specific transport mode that population group is (Karner, et al., 2024; artens, et al., 2022). We use Statistics Canada's Spatial Access Measures (SAM) to calculate gravity-based accessibility to seven destination types (K–12 schools, employment, health care, sport and recreation, culture and arts, post-secondary institutions, and grocery store) via walking, biking, and public transit at the dissemination blocks (DBs; equivalent to the census block group in the US) across Canada's 41 Census Metropolitan Areas (CMAs). Based on the SAM accessibility scores, we calculate the levels of accessibility below which a population group is deemed 'accessibility poor' (also known as the Foster-Greer-Thorbecke (FGT2) measure (Karner, et al., 2024) or the Accessibility Sufficiency Index (Martens, et al., 2022)). We defined low access DAs as those in the bottom 25% of SAM accessibility scores and rescaled the scores, for each metropolitan area separately, to derive the 25% threshold. The rescaled scores range from 0-1, with 0 indicating that the population is above the threshold and 1 indicating that the population is below the threshold.

Bivariate and multivariate analyses are employed to uncover the links between being below the accessibility threshold and experiencing different transport problems across different urban settings and transport systems. Specifically, being below the accessibility threshold is associated with, among other things, making fewer trips than one would like, spending more time and longer distances travelling, reaching less destinations than one needs, and spending more money on transport than one would like. These outcomes highlight the importance of evaluating transportation and social outcomes in the context of the transportation options that people have available to them and the level of accessibility to destinations they provide. Understanding these relationships is key for making

informed decisions about the future of our cities while accounting for the full impacts that transportation has on our lives.

Longitudinal Analysis of Transit's Land Use Multiplier in Three U.S. Regions

Abstract ID: 1844.0.0.766.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Guang Tian [University of New Orleans] gtian@uno.edu, presenting author

Jiahao Shi [The University of New Orleans] jshi4@uno.edu

Reid Ewing [University of Utah] ewing@arch.utah.edu

Andrew Trtich [University of New Orleans] atritch@uno.edu

Longitudinal Analysis of TransiCities in the United States and around the world have made expensive investments into fixed guideway transit (e.g. light rail, metro, bus rapid transit) with the goal of reducing vehicle miles traveled (VMT) and in turn the negative externalities associated with VMT such as increased traffic congestion. Investments in transit infrastructure can also lead to land use changes through the creation of transit-oriented development (TOD) which are dense, compact, mixed-use built environments that are pedestrian friendly and encourage the use of public transportation (Cervero, et al., 2004). These land use changes spurred by rapid transit can lead to greater location efficiency which can encourage people to take trips by walking and biking or lead to shorter automobile trips. This can lead to decreases in VMT beyond what is expected from the direct substitution of automobile trips to transit trips, which are known as “indirect” impacts. This effect is known in the literature as the “transit multiplier” and is often defined as the number of total VMT reduction per passenger mile on transit. This study examines the magnitude of the transit multiplier and changes in travel behavior using household travel surveys conducted before and after the construction of light rail in three U.S. cities: Seattle, Salt Lake City, and Sacramento. This makes this study one of the first to evaluate the transit multiplier using longitudinal data and a quasi-experimental study design in multiple regions, which are preferred due to their greater ability to discern causal impacts.

Previous studies have been conducted which evaluate the transit multiplier effect across a variety of transit modes and urban contexts. Holtzclaw (2000) analyzed 28 communities across California and found that the magnitude of the transit multiplier varied between 1.4 to 9 depending on the community analyzed with the transit multiplier effect being most pronounced in denser urban environments such as San Francisco. Ewing and Hamidi (2014) conducted a longitudinal study which examined the effects of Portland’s Westside MAX light rail extension and found the value of the transit multiplier to be 3.04. Sabouri et al. (2024) utilized household travel survey data at the trip level in 31 diverse U.S. metropolitan regions and found that the value of the transit multiplier to vary between 6.1 to 9.54 depending on the region, and that the majority of the variation in this study was attributable to indirect land use impacts of transit rather than the direct substitution of automobile trips to transit trips.

Based on the studies highlighted above, we expect to find similar results in the three regions analyzed in this study. Suggestions for maximizing the potential multiplier effects of rapid transit on VMT reduction, and therefore the economic impacts that come from the more efficient movement of people and freight are presented. These include additional investments into pedestrian and cycling infrastructure around transit stations, coordinating land-use changes simultaneously with the construction of new rapid transit lines, and redeveloping underutilized parking structures at transit stations into mixed-use and walkable developments.

Memphis' Inaccessible Transit Vision: Planning, Austerity and Inequity in a Neoliberal Utopia

Abstract ID: 1844.0.0.707.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Andrew Guthrie [University of Memphis] guthrie1@memphis.edu, presenting author

Mahdis Modaresi [University of Memphis] mmdaresi@memphis.edu

This paper explores the divergence between planning and implementation for the transit system in Memphis, Tennessee as an example of austerity in planning and its consequences for regional accessibility as well as social and racial equity. We also examine those planning and implementation processes through the lens of the local political economy which helps define them: Neoliberalism triumphant. Memphis represents an extreme case of neoliberal urbanism applied to transit planning, with the Transit Vision component of the Memphis 3.0 comprehensive plan developed primarily by a civic booster nonprofit and private consultant. We trace the planning process which led to Transit Vision and its partial implementation without the major funding and frequency increases it calls for, placing it in the historical context of local, national, and international urban governance trends. To quantify the realized impacts of that partially-implemented vision, we also conduct system-wide, place- and person-based cumulative opportunity job accessibility analyses of the Memphis Area Transit Authority system when Transit Vision was produced, at the height of efforts to partially implement it and at the present time, along with a counter-factual scenario representing full implementation of the plan. We find a process fitting theoretical understandings of neoliberal urbanism in terms of depoliticization, elite technocratization, and extraction of value from the public commons. The result is a transit system providing poor accessibility to employment under real-world conditions and showing significant accessibility disparities by race and class in all realized networks. The full implementation scenario shows improvements in all measures, providing a proof of concept for the network recommended by Transit Vision but has no organized, popular constituency to compel its implementation—or even to aggressively resist service cuts. We close by recommending future system redesigns include equity-focused accessibility analysis, be led by public agencies with deep participation of riders and potential constituencies of support, be funded as called for in planning and that transit planners critically examine relationships with the private and nonprofit sectors in constituting planning processes.

Mobility & Racial-Spatial Isolation in Suburbs: A Qualitative Exploration

Abstract ID: 1844.0.0.452.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Madeline Wander [UCLA Urban Planning] mwander@ucla.edu, presenting author

In recent decades, the traditional racial-spatial divide in U.S. regions has blurred, with an unprecedented growth of low-income residents of color in suburbs. Increased racial diversity in suburbs, however, have been accompanied by increased racial segregation therein. Of course, suburban landscapes differ from urban ones, particularly in terms of the vast dispersion of land uses and activities—which shape people’s ability (or inability) to move through space and reach destinations. Amidst complex and changing regional terrains, it is important to consider whether the expansion of low-income people of color to increasingly segregated and dispersed suburbs has introduced additional or different dimensions of racialized disparities in mobility and access.

Toward this end, my larger research project uses a mixed methods approach to explore the relationship between mobility and racial-spatial isolation in suburbs. My regression analysis shows that as mobility (measured by car access) decreases, Latinx and Black isolation increases—a relationship that is even stronger in suburbs compared to urban areas. Building on my quantitative findings, this paper uses a qualitative methodology to understand how the relationship between mobility and racial-spatial isolation operates in suburbs—specifically, how it affects people’s mobility experiences and economic and social outcomes.

To explore this question, I conducted in-depth interviews, including cognitive mapping exercises, with a random sample of 30 people of color living in economically-distressed suburbs in Southern California’s Inland Empire. Using a thematic analysis, I find that, even in the suburbs, car ownership is out of reach for many—20% of interviewees have no car access—and so they often rely on public transportation, specifically buses. Such reliance, however, hinders their mobility as suburban buses run infrequently and have limited geographic coverage. Unlike their urban counterparts, who often report overcrowded and uncomfortable conditions, participants had no complaints about the actual bus ride; indeed, buses provide an air-conditioned and clean environment in which riders can charge their phones. What makes public transportation so unpleasant in the suburbs is the waiting, resulting in extremely long travel times. Because of this, many resort to walking, but this greatly limits place access.

And so, interviewees largely view car access as the primary means of removing restrictions on mobility. As a result, among those with car access, there is pervasive stress about losing it. Many fear car accidents, not necessarily because of harm to their body, but because of harm to their vehicle. Additionally, the cost of gas and maintenance means participants must choose between travel and meeting other basic needs, like housing and food, leading many to forgo trips altogether. Additionally, the threat of auto-related police violence, particularly when driving through whiter and wealthier suburbs, causes anxiety and stifles travel. Due to these mobility constraints—transportation access, transportation costs, and safety concerns—participants’ activity spaces are relatively small, leading some to feel cut off from job opportunities in nearby suburbs.

This paper is relevant to both planning scholars and practitioners. In terms of scholarship, by focusing on suburbs, my project expands the spatial scope of the transportation planning field, which traditionally focuses on the urban—particularly when considering racialized transportation disparities. In terms of practice, this research identifies emergent transportation conditions with which planning agencies must contend—and raises the importance of spatial isolation when considering how to remove barriers to mobility and access. Indeed,

interventions to improve mobility and access will be quite different in dispersed suburban environments than in dense urban ones.

Mobility Wallet Effects on Individual Life Outcomes: A Longitudinal Study in South Los Angeles

Abstract ID: 1844.0.0.880.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Tamika Butler [University of California, Los Angeles] tamikabutler@g.ucla.edu, presenting author

Madeline Brozen [University of California, Los Angeles] mbrozen@g.ucla.edu

Madeline Wander [UCLA Urban Planning] mwander@ucla.edu

Evelyn Blumenberg [University of California, Los Angeles] eblumenb@ucla.edu

Transportation is a common barrier to accessing opportunities, particularly for low-income families. Scholars have examined strategies to reduce transportation barriers through approaches like improved transit or car access and ownership programs. However, fewer interventions directly target issues of transportation affordability. In 2023, Los Angeles joined a small but growing number of cities aiming to address this gap by piloting a Mobility Wallet program. This novel approach has the potential to not only affect travel behavior and mobility outcomes, but also assist with helping low-income people meet basic needs outside of transportation.

This paper draws from English and Spanish-language interviews with thirty-one Mobility Wallet program participants conducted before, during, and after the one-year program. The interviewees are diverse in age, gender, car access, household composition, and employment status. All interviewees identify as people of color. During and after the program, interviews captured data on how the wallet affected the interviewees' travel behavior (modes, destinations, and frequency of travel) and how changes in travel behavior affected their quality of life. Quality of life indicators included material hardship, stress and well-being, social connections, and feelings of independence and autonomy. This longitudinal, qualitative approach allowed the research team to explore, in detail, the effect of the mobility wallet on people's lives.

Our results demonstrate that flexible transportation subsidies are promising solutions for meeting the diverse transportation needs of low-income travelers and improving their quality of life. The wallet's most prominent and lasting effect was its role in decreasing material hardship and providing financial support. Because interviewees covered large portions of their transportation costs with wallet funds, they were then able to reduce financial stress. They described purchasing material items like clothing or school supplies for their children, catching up on bills, or contributing towards growing their savings.

We also found quality-of-life benefits stemming from increased social interactions. Interviewees described how having a mobility wallet increased their social connections and strengthened their relationships. They used their wallets to participate in more social activities, take kids or families on outings, visit family members, and connect with others for celebrations. The wallet increased the demand for social activities and provided the necessary financial resources for travel. These increased social connections were a source of joy for interviewees.

Finally, interviewees discussed increased independence and autonomy. They were able to support their own transportation needs and decrease their reliance on friends and family for transportation. In some cases, interviewees described being able to support the transportation needs of others in their lives by covering their transit or ridehailing costs. This personal independence and caregiving provided interviewees with a source of pride.

This research highlights the promise of flexible interventions in transportation affordability on improving low-income people's lives, but their shortcomings when conducted as short-term approaches.

Qisheng Pan [University of Texas at Arlington] qisheng.pan@uta.edu

In the United States, car crashes cause over 100 deaths daily (CDC, 2024), with 5.2 million injuries in 2022. The economic cost is \$340 billion annually, or \$1,035 per person (Blincoe et al., 2023; NHTSA, 2019), representing 0.7% to 3.6% of state per capita income. In Texas, crashes caused a \$28.9 billion loss, or \$998 per person (NHTSA, 2019). Social impacts include lost productivity, medical expenses, and reduced quality of life (Blincoe et al., 2023).

Most traffic crash studies focus on built environment- such as road networks, land use, and population density (Abdel-Aty et al., 2013; Obelheiro et al., 2020; Pirdavani et al., 2014). Other studies focus primarily on driver behavior such as drunk driving, speeding, and inattention (Alghnam et al., 2018; Al-Wathinani et al., 2021; Farooq et al., 2019; Rahman et al., 2020). However, research often overlooks the combined influence of these factors, alongside demographics and environmental conditions (weather, light, surface). A key question is whether crashes are driven by a single factor-or do they result from the complex interaction of multiple factors? Moreover, there is a gap in linking safety policies with crash data. Texas reports over 3,500 traffic fatalities annually (NHTSA, 2021), highlighting the need for better policy alignment. While cities like Austin, Houston, and San Antonio have Vision Zero initiatives, the NCTCOG region lacks a coordinated safety strategy (Mobility 2045). We specifically ask:

- (1) What is the relationship between different contributing factors and injury crashes at the road segment level?
- (2) How do interactions between independent variables (e.g road type and weather conditions) influence injury crash rates?
- (3) What specific human factors (violations, speeding, intoxication and so forth) should be addressed in safety policies to reduce injury crash on different road segments?
- (4) What interventions can reduce injury crashes based on road, environmental, demographic, and human factors?

We examine the relationship between injury crash counts—fatalities and all injury types—and four independent variables: (i) driver behavior (speeding, lane changes, unsafe turns, distractions, violations, intoxication); (ii) built environment (road functions, speed limits, intersections, lanes, road types); (iii) demographics (age, gender, ethnicity); and (iv) environmental factors (weather, surface, light conditions). It analyzes TXDOT data from 2016–2024 for the NCTCOG region, a key area for shaping road safety policies due to its diverse road environments, and significant traffic volumes.

We hypothesize that injury crashes in the NCTCOG region result from road characteristics, environmental conditions, demographics, and human behavior. Factors like inattention, intoxication, speeding, and violations impact crash severity differently across road segments. Effective planning strategies, (Vision Zero, improved road design, and awareness campaigns), are crucial for preventing crashes to enhance road safety.

We used Multilevel Negative Binomial regression to analyze the impact of variables on injury crashes while accounting for variations across road segments and time. This method is effective in crash research, addressing

overdispersion and hierarchical data structures across segments and time (Basu & Saha, 2017; Dong et al., 2014; Kwayu et al., 2020; Park et al., 2022).

Initial findings reveal injury crash variations across road segments, highlighting how each of the independent variables affect crash outcomes verifying their effects and extent. The study identifies notable interaction effects, (for example: road type and violations) on crashes. Findings align with prior research (Ahmadi et al., 2020; Behnood & Mannering, 2017; Dingus et al., 2016; Precht et al., 2017; Huang et al., 2018; Oviedo-Trespalacios, 2018; Maasalo et al., 2019;). The results will provide evidence for our research questions and discuss policy implication and future research.

Moving from an Ethos of Cars to an Ethics of Care: Urban Planners as Urban Peacebuilders

Abstract ID: 1844.0.0.985.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Ashton R. Rohmer [George Mason University] arohmer@gmu.edu, presenting author

For the past century, urban planning decisions have cemented the car's dominance in our lives, whether through land use planning that has made automotive access necessary to carry out even the most mundane activities or transportation planning that has prioritized fast and efficient vehicular travel above all other modes. Beyond reshaping our built environment, the private automobile has fundamentally altered our relationships - with each other and with the natural world. Indeed, in a society where the car has become synonymous with freedom, we fail to recognize what we sacrifice in our endless pursuit of individual liberty - not only the safe movement of others but also our collective ability to fulfill an even more basic human need: to connect.

This paper tackles a set of complementary research questions: first, while we can intuit the indelible impacts of cars on our social relationships, how can we begin to detail the depth and breadth of those impacts...and what role do urban planners play in perpetuating them? Second, what would it look like for urban planners to think of themselves as urban peacebuilders...and what could we gain in the process?

To answer the first question, this paper applies Johan Galtung's (1969, 1990) triangle of violence to our transportation system using literature from a wide range of disciplines to reveal the ways in which cars have contributed to three forms of violence: direct (interpersonal behavior that causes harm), structural (processes and institutions that enable those harms or introduce new ones), and cultural (narratives and symbols that normalize the harms). In this way, it demonstrates how vehicular violence can offer a compelling framework for understanding how cars are at the center of a complex web of harms and how urban planning contributes to broader cycles of conflict.

To answer the second question, this paper adapts the philosophical approach of the ethics of care to our transportation system to illuminate how centering relationships, reciprocity, and responsibility presents a path out of car supremacy (Engster, 2009; Held, 2005). Moreover, it offers insights from community mobility initiatives that are already challenging our modal hierarchy to reimagine streets for care. In particular, this paper argues that the ethics of care presents a theoretical framework distinct from and more expansive than existing approaches. Pursuing Vision Zero, engineering a carbon-free network, and ensuring mobility justice are all admirable - and necessary - goals; however, if these become our sole guiding principles, we risk achieving them in a way that entrenches car supremacy rather than dismantling it. In fact, we can envision a world where these laudable aims have been achieved because everyone has their own emissions-free, crash-free vehicle, yet we would still be locked in a paradigm that commits the cardinal sin of cars: removing their passengers from the public realm and in turn severing our social fabric.

Amidst technical jargon and bureaucratic processes, at its core urban planning is a profession that navigates profound moral questions about who can exist where. The reinforcing dynamics of the triangle of vehicular violence makes overcoming the ethical quandaries present in our transportation system seem daunting, and our existing discourse about what the future could be only takes us so far. Ultimately, this paper posits that urban planners are not only players in a complex conflict system, but also that they can be agents of change. Indeed, given the epidemic of social isolation and its connection to parallel trends such as increasing levels of intolerance

and political polarization, this paper argues that urban planners must see themselves as urban peacebuilders and suggests a moral compass to guide the way.

Individual Paper Presentation Submission

Ziqi Liu [Worcester State University] zqliu212132@utexas.edu, presenting author

Justin Hollander [Tufts University] justin.hollander@tufts.edu

One of the biggest paradoxes in urban mobility planning is that top-down, expensive transit megaprojects often take decades to complete and fail to serve the residents who need them most. This tension reflects a broader debate in planning theory between antagonism and agonism, where the former refers to hostile and irreconcilable conflicts between groups while the latter represents a productive form of conflict recognizing each opponent as legitimate adversaries. Democracy seeks to transform antagonism into agonism, fostering structured debate rather than outright conflict. However, traditional top-down planning processes, rooted in rigid, law-based frameworks, often struggle to support agonistic approaches, limiting inclusive participation and meaningful dialogue. In transportation planning, this manifests in rigid, rational-comprehensive frameworks that exclude local voices, limiting opportunities for meaningful community engagement.

Collaborative rationality has shown its effectiveness in fostering local strategic plans. Rooted in communicative theory by Habermas, it emphasizes dialogue, consensus-building, and stakeholder participation in decision-making processes. However, most of the city or regional-level transportation plans still follow the top-down, rational-comprehensive plan-making process. Many of them ignore local voices and reinforce inequality. This study aims to provide new evidence to this mobility paradox: Can a transportation plan be formulated and implemented using a bottom-up framework guided by collaborative rationality?

The study focuses on an on-going effort of promoting BRT in Worcester to understand how a transit planning process is ground in collaborative rationality. The city of Worcester, Massachusetts, is experiencing steady population growth, placing increasing demands on its public transit system. Currently, the Worcester Regional Transit Authority (WRTA) operates a bus network serving the city and surrounding areas; however, the service is limited in frequency and coverage, challenging its ability to meet the needs of a growing urban population. Implementing a Bus Rapid Transit (BRT) system presents an opportunity to enhance mobility, reduce traffic congestion, and provide a reliable and efficient transit option to better serve residents. But there is no political will among city leaders to initiate such service, so a coalition of non-profit organizations has initiated a planning process from the bottom-up. While this group might be expected to be in antagonistic position towards city leaders, the planning thus far has taken a more agonistic quality. Something we are unpacking and understanding in this research.

This research will adopt a qualitative methodology centered around semi-structured interviews with key local stakeholders involved in the BRT initiative. These stakeholders include representatives from WRTA, neighborhood associations, local universities, local businesses, and community advocacy groups. Interviews will be conducted exploring sources of both antagonism and agonism and perceived barriers to consensus-building. Additionally, public meeting records and planning documents will be reviewed to supplement interview data and provide a comprehensive understanding of the stakeholder engagement process.

The study aims to find out the dynamic roles and the level of involvement by different stakeholders, for a BRT project in a mid-scaled Northeast city in the US. Anticipated results include identifying best practices for fostering inclusive stakeholder engagement, understanding the challenges faced in reaching consensus, and offering insights

into the role of collaboration in advancing sustainable urban transportation projects. The findings aim to inform future urban planning efforts in Worcester and other mid-sized cities pursuing similar transit initiatives, ultimately contributing to more effective and equitable transportation solutions.

Introduction. Research has examined the impact of public investments on gentrification and displacement in underserved U.S. communities. Studies have shown how new rail transit and bus rapid transit (BRT), new bike infrastructure, and new parks have contributed to gentrification and displacement. Much of this research has focused on one type of investment at a time, has used aggregate tract-level data, and has only examined whether gentrification follows public investment. To address these gaps, we seek to disentangle the impacts of different public investments on neighborhood change.

Research questions. Do new transit, bike infrastructure, and green space have a multiplying effect on gentrification and displacement? Specifically, when new transit is built in underserved communities, do concurrent investments in bike infrastructure or green space increase the risks of gentrification and displacement? And does gentrification precede public investments in new transit, bike infrastructure, and green space?

Methods. We focused on four metropolitan areas in the Western U.S. (Denver, Utah's Wasatch Front, Portland, and Seattle) that have seen significant investment in new rail/BRT, bike infrastructure, and parks. We built a longitudinal dataset with household-level data from Data Axle between 2006 and 2023 in the four regions. Data for public investments was collected from transit agencies (rail and BRT), metropolitan planning organizations and cities (bike infrastructure), and the Trust for Public Land (parks). We classified households in gentrification-eligible block groups as treatment if within a half-mile of new public investment (e.g., new rail transit) and as control if otherwise, considering multiple combinations of proximity to several types of public investments (e.g., proximity to new rail transit and park vs. proximity to park only). We then built mixed-effect models to track residential mobility in and out of areas near new transit but without new park investment and bike infrastructure investments, and compare such residential mobility with new transit areas that do have new parks and/or new bike infrastructure. To do so, models included interaction terms between the various treatments (e.g., transit treatment and park treatment). Thanks to this household-level dataset, we tracked the low-income renter households who moved out of various treatment areas, which enabled us to model potential displacement processes. These models controlled for household characteristics, neighborhood demographics, housing characteristics, and other features affecting gentrification and displacement.

Results. Preliminary regression results for Utah's Wasatch Front suggest that displacement is more likely to occur in the years preceding the opening of new transit stations than after they open. In other words, low-income renter households are more likely to move away from areas that are about to receive new transit than from similar control areas that will not receive transit investments. These results suggest that the announcement of new transit investment might affect displacement, as the real estate market might respond to such an announcement. The concomitant presence of bike infrastructure or new parks in areas with new transit investment does not seem to

create added displacement risk. Analyses of gentrification and of the three other regions will be completed before the ACSP conference.

Implications. Evidence from this study can help define gentrification and displacement risk factors associated with new public investments in sustainable infrastructure. These risk factors can inform the planning of equitable transit-oriented developments by providing planners with information about the potential impacts of other public investments alongside transit. Because displacement might occur before transit stations open, cities and nonprofits should implement affordable housing policies and investments well in advance of transit investments.

No School Bus, No Problem? How Students Get to School Without Bus Service

Abstract ID: 1844.0.0.247.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Seung Jae Lieu [Georgia Institute of Technology] slieu3@gatech.edu, presenting author

Gulsah Akar [Georgia Institute of Technology] gulsah.akar@design.gatech.edu

School commute times coincide with peak hours for child-involved crashes, highlighting the high safety stakes of school trips (Wheeler-Martin et al., 2020). Among available transportation modes, school buses are the second most widely used and the safest in the United States. (NHTSA, 2025; FHWA, 2019). However, Georgia state policy stipulates that students residing within 1.5 miles of school are ineligible for state-funded school bus service (Speroni, 2023; Georgia Code § 20-2-188). This exclusion of a safe, reliable transportation option raises equity concerns, particularly for children in non-walkable neighborhoods, those near the upper limit of this distance, or households with limited vehicle access. By constraining mobility options, such policies may force children to use less safe modes, reinforcing car dependency and exacerbating transportation and health disparities. To examine policy gaps in states where school bus service is mandated beyond certain distances including Georgia and to identify the need for more inclusive transportation policies, this study asks: What transportation modes do children living close to their schools choose when school bus access is unavailable, and how are these choices shaped by the built environment and household attributes as well as parental and individual characteristics? We pay particular attention to eye-level streetscape features, including sky visibility, and incorporate the Social Vulnerability Index, developed by CDC (2018), as an equity measure. Our findings show correlations between built environment factors and travel choices among students living close to their schools. We present how these outcomes vary across different neighborhoods and socioeconomic groups, with a focus on the impact of lacking bus service. Our results inform built environment and policy improvements that promote safe, equitable school travel options, while critically examining Georgia's school bus policy.

This study analyzed school transportation mode choice among K–12 students in Georgia using the 2017 National Household Travel Survey Add-on dataset. We first identified school trips where the origin was within 1.5 miles of the school and confirmed that the corresponding school district did not provide bus service, yielding a sample of trips made by walking, biking, or automobile. Built environment features were measured at both the neighborhood and street levels, including streetscape elements extracted via computer vision from street view imagery. These factors were combined with individual, household, and parental attributes in a discrete choice analysis. Automobile use served as the reference category; while walking and biking are grouped together as the non-auto alternative.

The results suggest that children from households with fewer vehicles and those who walk frequently are more likely to choose non-auto modes. Built environment features also influence mode choice: greater POI accessibility and higher building-to-street ratios are associated with increased likelihood of using non-auto modes, while higher intersection density, employment density, and greater sky visibility are linked to reduced use. While some findings align with prior walkability research, the negative impacts of intersection density may suggest safety issues for children. Parental factors (e.g., commute mode, perceptions of neighborhood safety) also play a key role. The relationship between the SVI and non-auto travel suggests that children in more vulnerable communities tend to rely more on walking or biking. The lack of bus service may pose greater challenges for these children, exacerbating transportation inequities. These findings highlight the need to improve walkable environments to support safe and equitable school travel for children. They also call into question the policy of not providing bus service to students within 1.5 miles of school, particularly in areas where walking and biking are unsafe.

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Samuel Speroni [UCLA Institute of Transportation Studies] ssperoni@ucla.edu, presenting author

The emotional effects of commuting to work are clear: the commute adds stress and reduces happiness, and nearly all other types of trips are associated with higher levels of life satisfaction. But one other type of trip functions more like a commute trip, in that it fits a set schedule and recurs nearly daily: the school trip for children. Scholars have paid less attention to any similar effects from the school commute; specifically, research has yet to uncover the stress burden that chauffeuring and/or escorting children to and from school places on parents/guardians. While scholars have investigated the myriad reasons parents drive their children to school, the literature has not yet explored how that responsibility may affect parents/guardians. Would providing school transportation (such as a school bus or ridehail trip) reduce parental stress?

This study examines the potential relationship between stress and school transportation through a pilot randomized control trial of school-provided transportation service at the UCLA Lab School, a private elementary school owned and operated by UCLA and intentionally engaged in research partnership with university researchers. Like many private schools nationally (and many public schools in California), the UCLA Lab School does not provide school-sponsored transportation to its students and families. This study proceeds in three phases: a survey, a pilot program, and a follow-up survey.

First, in February 2025 Lab School leaders distributed a survey to the school's 299 families that asked about families' regular scheduled travel behaviors for work and school for all members of their household, including other children not attending the Lab School. The survey asked about which adults in the household bore the responsibility of school chauffeuring, about the stress that the responding parent feels about transportation generally, about how easy to difficult they find transporting their child to the Lab School, and whether their family would be interested in school-sponsored transportation if it were provided. I linked these data to school administrative data to include analysis about the students' residential location, family income, and race/ethnicity. I also used the 2017 National Household Travel Survey California Add-On to contextualize the Lab School's students and transportation patterns with those of private school students in California generally. Approximately 95 percent of students at the Lab School are driven to school, slightly above the 90 percent of all private school students in California.

Second, the school's research partnership team and I identified 101 families who responded to the transportation survey and who indicated interest in receiving school-sponsored transportation. Of these, a portion will be selected for a pilot program that will provide shared ridehail trips via HopSkipDrive, a ridehailing company that specializes in this type of service. The pilot will run for the final six weeks of the 2024-2025 school year.

Third, upon completion of this pilot, families in both the treatment group (those who received HopSkipDrive rides) and the control group (those who did not) will receive a second survey that asks about changes in family travel behavior and their stress levels related to transportation, and for feedback about the pilot program. I will use findings from this second survey to assess how the pilot program may or may not have affected parents' stress levels, compared with the control group and controlling for family income, race/ethnicity, and the size of the family's activity space.

Findings from this study can be used by both planners and educators to understand the role that providing transportation or not can have on families, particularly the parents of students. While transportation is a sizable budget item for school districts, reducing stress and freeing up time for parents can be an indirect benefit of these programs.

This paper compares changes in urban public transport (PT) demand and supply before, during, and after COVID-19 in five countries: Great Britain and Germany in Europe, the USA and Canada in North America, and Australia. We also examine a range of PT system and government policies that were implemented during and since the COVID-19 pandemic to improve safety, adjust service levels, and encourage PT ridership.

PT ridership fell sharply in all five countries during 2020 and 2021, when COVID-19 rates were highest. As a percentage of 2019 levels, the lowest annual ridership for each country was 31% for Great Britain, 42% for Canada, 46% for the USA, 48% for Australia, and 64% in Germany--but with considerable month-by-month variation due to various waves of COVID. The latest full year of available data (2023) indicates that Germany (91%) and Great Britain (86%) recovered the highest percentages of 2019 ridership levels compared to 80% in Canada, 76% in Australia, and 72% in the USA. Bus ridership declined less than rail ridership, and bus ridership recovered more fully. That is especially the case in the USA, Canada, and Australia. Our analysis of PT in five large cities finds that recovery rates were generally higher on weekends than on weekdays, both for bus and rail.

The most important government policy for PT has been a massive increase in funding, especially from central governments, to offset the large operating budget deficits resulting from lost passenger revenue. That funding enabled PT systems to maintain or reduce fares while avoiding large reductions in supply. Dependable government subsidies will be necessary in the coming years to make PT financially sustainable and to enable long-term planning for infrastructure modernization and improved service. PT's wide range of economic, social, and environmental benefits are often cited as justification for PT subsidies.

Redefining Transit Deserts: A Data-Driven Framework for Identifying Transit Inequities

Abstract ID: 1844.0.0.883.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Bumsoo Lee [University of Illinois] bumsoo@illinois.edu, presenting author

Lindsay Braun [University of Illinois] lmbraun@illinois.edu

Srirang Sohoni [University of Illinois] ssohon3@illinois.edu

Public transit plays a crucial role in providing transit-dependent individuals with access to employment opportunities and essential services. However, transit access is unevenly distributed across urban areas, resulting in service gaps and transportation insecurity, particularly for low-income households and people of color (Barajas and Brown 2021). Identifying these gaps and addressing transportation poverty has led to the increasing use of the “transit desert” concept. However, most transit desert studies compare transit supply and demand using normalized scales such as z-scores (Jiao, Conrad, and Azimian 2021; Currie 2010), which often leads to false identification of transit deserts. Further, relying on relative measures, these studies do not establish normative thresholds of transit service necessary to ensure basic mobility for transit-dependent populations. While several recent studies have attempted to define accessibility insufficiency—specifically the thresholds of accessibility poverty—the complicated accessibility framework, which combines both transportation and land use, provides little practical guidance for transit planners (Klumpenhower and Karner 2025; Martens and Cohen-Zada 2022).

This study addresses this research gap by developing and testing an alternative method for identifying transit deserts, using the Chicago metropolitan region as a case study. Our proposed approach is grounded in the travel behavior of transit riders, is easily replicable with publicly available data, and offers practical policy guidance for transit planners by focusing transit service. The primary data sources include the 2019 My Daily Travel Survey by the Chicago Metropolitan Agency for Planning (CMAP), the American Community Survey (ACS), and General Transit Feed Specification (GTFS) data from regional transit agencies. Drawing on the United States Department of Agriculture’s (USDA’s) established methodology for identifying food deserts—low-income census tracts where a significant number or share of residents have limited access to a grocery store—we define transit-dependent block groups (BGs) where a significant number or proportion of residents lack access to adequate transit service as transit deserts. This approach involves the following analysis steps.

First, we define transit-dependent individuals and identify transit-dependent BGs where more than a threshold proportion of residents are transit dependent. This process includes three steps: i) Define transit-dependent groups through a typology of transit riders using latent profile analysis (LPA), with travel behavior and vehicle access variables as input. ii) Conduct a multinomial logit (MNL) analysis to examine how demographic and socioeconomic variables influence the probability of being transit dependent. iii) Use the estimated MNL coefficients and BG-level ACS data to predict the probability of transit dependency across subpopulations with different characteristics, estimating the number of transit-dependent residents in all BGs in the Chicago region.

Second, we identify transit-dependent BGs where a significant proportion or number of residents live beyond the reach of adequate transit service. This involves: i) Defining minimum threshold transit service levels required to meet the basic mobility needs of transit-dependent populations. These thresholds will be determined based on a review of relevant literature and an empirical analysis of transit use behavior in the region. ii) Estimating the number of residents living outside the defined adequate transit service area—a

Half-mile from rail transit and a quarter-mile from bus stops offering adequate service. We will test a range of threshold proportions and absolute numbers of residents to identify the most relevant criteria.

Finally, we will compare the results obtained from our proposed method with those derived from existing approaches for identifying transit deserts and transit poverty.

Relative Accessibility as the Potential for Car Independence

Abstract ID: 1844.0.0.429.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Carole Voulgaris [Harvard University] cvoulgaris@gsd.harvard.edu, presenting author

Transportation accessibility metrics, operationalized as a travel-time-weighted sum of destinations that can be reached by a given mode, have become increasingly common tools to evaluate how well the combination of land-use patterns and transportation infrastructure facilitates activity and interaction within an urban area (Levin 2020; Siddiq and Taylor 2021). A debate has emerged on the topic of whether accessibility is itself a goal (Walker 2018) or if it is mostly useful as a proxy or determinant of travel behavior (Karner 2022), and this tension may reflect the difficulty of predicting travel choices based on accessibility metrics that describe the usefulness of a single mode. The current edition of the Transit Capacity and Quality of Service Manual (Transportation Research Board 2013) incorporates the concept of evaluating the ratio of transit travel times to travel times by car as a transit system performance metric. Similarly, evaluating the ratio of car-based accessibility to the accessibility available to those without a car may be a useful measure of the freedom travelers have to meet their daily needs without relying on a private vehicle.

I propose the ratio of average car-free accessibility to average accessibility by car as a measure of the potential for car independence (PCI). I have calculated this metric for each of 917 core-based statistical areas (CBSAs) (including both metropolitan and micropolitan areas) in the United States and for each of the 81,144 census tracts contained within those areas. I validate this as a measure of car independence by calculating its Pearson's correlation with each of five travel-behavior variables from the 2019-2023 5-year sample of the American Community Survey: The share of workers that commute to work by each of four modes (car, transit, walking, and cycling) and the share of households that does not own a vehicle. Finally, I estimate a set of regression models to evaluate the degree to which several built environment characteristics predict the PCI indicator at both the regional (CBSA) level and the neighborhood (census tract) level.

I find that, at a 95-percent confidence level, the region-level PCI indicator has a significant correlation in the expected direction with the percentage of workers who walk to work, the percentage of workers who bike to work, and with the percentage of households without vehicle access. A higher PCI index is associated with a greater share of workers who walk or bike to work and a greater share of households without vehicle access. The region-level PCI indicator has a correlation in the opposite to the expected direction for the percentage of households who drive to work (90 percent confidence) or commute to work by public transit (95 percent confidence). The tract-level PCI indicator has a significant (99-percent confidence) correlation with all five travel behavior outcomes in the expected direction.

A linear regression model predicting the tract-level PCI indicator based on the total area of the region, the population density of the region, and the population density of the tract predicts about nine percent of the variation in the tract-level PCI indicator. The results of that regression suggest that higher PCI indicators are associated with regions that have a smaller total land area, a lower population density at the regional level, and a higher population density at the tract level. In other words, a tract with the greatest potential for car-independence would be a relatively high-density neighborhood within a small, low-density micropolitan area. Interestingly, these are areas that generally do not have extensive public transit systems. The potential for greater car independence in those types of places is largely driven by shorter proximities than by greater mobility by non-car modes.

Rethinking Transport for Equitable Park Access: A Multi-Modal Planning Perspective

Abstract ID: 1844.0.0.436.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Yiyang Wang [University of British Columbia] yiyang99@student.ubc.ca, presenting author

Keunhyun Park [The University of British Columbia] keun.park@ubc.ca

Kai Hei Mau [The University of British Columbia] khmau@student.ubc.ca

Central Theme and Research Questions: Access to large parks offers critical health and social benefits, yet many residents face challenges due to limited mobility and car-centric transportation system. In urban areas dominated by car-centric infrastructure, individuals who could benefit most from nature—such as lower-income groups — often face the greatest barriers to reaching parks (Rigolon, 2016; Park et al., 2021). While existing studies explore park access through walking or driving, less is known about access variations across multiple transport modes, including shared mobility options (Fang et al., 2025; Huang et al., 2024). This study investigates the spatial and socioeconomic patterns of multi-modal access to parks (M2P) in Metro Vancouver, BC, Canada. Specifically, it asks: (1) What are the spatial inequalities and socioeconomic inequities in multi-modal access to large parks across Metro Vancouver? (2) Which neighbourhoods face the greatest access challenges, and what targeted interventions could improve M2P accessibility?

Approach and Methodology: For the first question, we calculated M2P measures for 3,590 neighborhoods (census dissemination areas) and 58 large parks (>30 hectares) using spatial network modeling of five trip chain scenarios (driving, transit, biking, bikeshare, and carshare). Accessibility was measured using three methods—minimum distance, cumulative opportunities, and gravity models. We assessed spatial equality with Lorenz curves and Gini coefficients, and income-based equity using the Concentration Index (Karner et al., 2024).

To answer the second question, we first identified target neighbourhoods by overlaying composite M2P accessibility scores with socio-demographic indicators as proxies for low mobility. Based on consultations with municipal transportation planners to develop feasible intervention scenarios, we simulated M2P measures and evaluated different scenarios' impacts on access and equity.

Key Findings: Our results show that driving offers the most evenly distributed park access, while shared mobility modes are least equitable and tend to favor higher-income neighbourhoods. Among the three models, the gravity model, which considers multiple parks and their quality, revealed greater disparities in M2P access. We identified key underserved areas with low mobility but low multi-modal accessibility: Surrey, White Rock, Richmond, City of Langley, and Maple Ridge. These areas are less urbanized, heavily car-dependent, and put less priority on transit and shared mobility infrastructure development. Consultations with municipal planners yielded several feasible interventions, including expanding protected bike lanes, rerouting transit lines to park entrances, and expanding carshare home zones and bikeshare stations. Simulation results demonstrate that these targeted strategies can improve M2P access and narrow equity gaps.

Relevance and Implications: These results highlight the need for transportation planning that prioritizes equity, reduces car dependency, and expands affordable alternatives for underserved communities. This study advances park accessibility research by integrating multi-modal methods and shared mobility into equity analysis. It offers practical insights for planners to identify underserved areas and implement targeted interventions. By aligning with local planning priorities, the research supports more inclusive access to green spaces and promotes equitable infrastructure development.

Rethinking Travel Time: When Minutes Become a Matter of Well-being

Abstract ID: 1844.0.0.717.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Jones Adu-Mensah [University of Michigan] jadumens@umich.edu, presenting author

Urban planners have long perpetuated systemic transportation inequities by prioritizing the travel experiences of higher-income individuals and their communities through metrics that undervalue the time and needs of their low-income counterparts. Current planning practices rely on the value of travel time savings, a narrow economic metric that assigns a monetary value to reduced travel time based on individuals' willingness to pay (Small 2012), sometimes approximated as a proportion of the median wage rate (White 2016). This approach, rooted in exchange value, reduces time savings to commodified resources and obscures broader societal impacts. By prioritizing monetary valuations, planners inadvertently engage in "commodity fetishism" and design transportation systems that disadvantage low-income individuals who are unable to "purchase" travel time savings (Martens and Di Ciommo 2017).

This research challenges the exchange value of travel time savings paradigm by proposing a shift to use value—the actual utility of travel time savings in improving daily life. Drawing on the capabilities framework (Robeyns 2005) —, which evaluates how resources enable individuals to pursue activities essential to their well-being, this research investigates how travel time constraints deprive low-income communities of time for well-being activities. The analysis specifically contrasts high- and low-income groups due to their starkly divergent access to time-saving resources: high-income individuals benefit from subsidized infrastructure (e.g., express lanes, private car usage) and can substitute lost time with paid services, whereas low-income populations face systemic underinvestment in public transit, compounding time poverty (Giurge, Whillans, and West 2020). This disparity compounds time poverty, making travel time constraints uniquely detrimental to low-income well-being.

I focus on the United States, a country characterized by a two-tiered transportation system and decades of detailed time-use data collection through the American Time Use Survey (ATUS). Using this time-use survey, I employ a two-stage comparison to analyze how travel time savings increase time spent on well-being activities. First, within-income-group comparisons identify how travel time savings (limitations) increase (reduce) time spent on well-being activities, revealing the "use value" of time in specific socioeconomic contexts. Second, a between-income-group comparison quantifies disparities in how travel time impacts well-being across income brackets.

Centering on lived experiences rather than monetary abstractions exposes systemic biases associated with the exchange value of travel time. The findings indicate that high-income individuals benefiting from travel time savings are increasing their time spent on well-being activities at rates higher than their low-income counterparts. These findings advocate for reorienting planning practices toward equity-oriented metrics that prioritize time as a resource for enhancing capabilities, not merely a cost to be optimized. This research contributes methodologically—by operationalizing the capabilities framework in transportation equity analysis—and practically, offering policymakers tools to design transit systems that redress the long perpetuation of systemic transportation inequities.

Right Turn on Red: Energy-Saving Measure or Unsafe Maneuver?

Abstract ID: 1844.0.0.841.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Bruce Appleyard [San Diego State University] appleyard1@gmail.com, presenting author

There is a growing interest in prohibiting right turn on red (RTOR) policies in the name of pedestrian and bicycle safety but there is not enough research on the subject to help agencies make informed decisions. When Congress passed the Energy Policy and Conservation Act of 1975, they included a provision requiring states to permit right turns on red lights as an energy-saving measure to receive federal assistance for mandated conservation programs. Since 1980, all states have permitted right turns on red as a general rule. More research is needed to help guide state policies that can support jurisdictions in making more informed and context-sensitive decisions. This research examines the infrastructure design and built environment-related factors associated with RTOR collisions - particularly those involving pedestrians and bicyclists. We also looked at emissions issues for RTOR maneuvers. Our findings reveal that RTOR movements are generally unsafe for pedestrians, bicyclists, and drivers, while only marginally useful in lowering emissions and only under certain contexts. Those marginal benefits may further decline with increased electric vehicle (EV) adoption. Despite RTOR crashes being a small portion of collisions and fatalities at signalized intersections, they tend to be more severe for vulnerable road users (e.g., bicyclists and pedestrians). Additionally, given the rise of SUVs/pickups in the U.S. personal automobile fleet - which tend to cause more severe collisions - RTOR prohibition is a proactive safety strategy consistent with the internationally recognized and USDOT-adopted Safe Systems approach. We recommend that state policy should make it easier for California communities to prohibit RTOR movements. We also recognize that banning or permitting RTOR movements should acknowledge the specific contexts of the communities (their place types), which could unduly burden cities that want to allow or prohibit RTOR at a vast number of their intersections in terms of signage. Informed decisions about RTOR policies can improve road safety for all.

Roundabouts are for Rich People: Who Gets Traffic Control Devices and Why It Matters

Abstract ID: 1844.0.0.824.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Matthew Bhagat-Conway [University of North Carolina at Chapel Hill] mwbc@unc.edu, presenting author

Matthew Palm [University of North Carolina Chapel Hill] palmmatt@unc.edu

Ashley Hernandez [UNC Chapel Hill] ashleych@unc.edu

Tabitha Combs [University of North Carolina at Chapel Hill] tacombs@live.unc.edu

Questions: Almost every intersection around the world has some form of traffic control device—from the simplest two-way stop up to complex traffic signal systems. This arose remarkably quickly after advent of the automobile. In 1914, the first traffic lights and stops signs were installed, and by the late 1920's, modern, automated traffic lights were widespread (McShane, 1999). The development of roundabouts took longer; modern roundabouts didn't arrive in the US until 1990 (Waddell, 1997).

In this article, we investigate how disparities in the provision of traffic signals, roundabouts, and stop signs vary across neighborhood sociodemographics, using a dataset of all North Carolina intersections.

Methods: We estimate multinomial logit models predicting provision of traffic control devices at each intersection. The “outcomes” model evaluates the relationship between poverty or race and traffic control devices. The “intrinsic” model adds controls for traffic volumes and population density. The final “mechanisms” model adds controls for state ownership and when the area around the intersection was developed. We estimate separate models for racial composition and poverty level.

Findings: Intersections are more likely to be signalized (vs. stop-controlled) in impoverished areas (all models) or in areas with large populations of Black (all models), Asian (outcomes and mechanisms models), Hispanic, or multiracial communities (outcomes model).

For roundabouts, we find a different story. Across all models, intersections in impoverished areas are significantly less likely to have roundabouts, while results by race are varied. We also identified a mechanism that contributes to these disparities: lower-income neighborhoods tend to be older, and roundabouts in the US are rare in neighborhoods built before 2000.

Roundabouts have safety benefits relative to both signalized and stop-controlled intersections (Maji & Ghosh, 2025). Thus, differential provision of roundabouts is an equity concern, particularly as roads in lower-income neighborhoods are more dangerous to begin with (Dumbaugh et al., 2022).

Our findings suggest that municipalities and DOTs should focus more on safety investments such as roundabouts, and less on traffic flow investments such as signals, in lower income neighborhoods. Traffic signals have a “warrant” process to guide engineers when a signal is appropriate, which may explain increased prevalence in communities with less political capital to oppose engineering guidance. Furthermore, traffic signals are primarily a traffic flow device, not a safety device, and the needs of motorists have been prioritized in disadvantaged neighborhoods since the dawn of motordom (McShane, 1999).

Roundabouts have no such “warrant” process, which may lead to them being underutilized, as separate engineering studies are required to justify each roundabout (Federal Highway Administration, 2000). Developing

clear guidance for roundabout installation, with a focus on safety above traffic flow, may help ameliorate the disparities. Equitable provision of roundabouts will also require retrofitting existing neighborhoods.

Rural Health Provider Insights on Transportation Barriers to Substance Use Disorder Care

Abstract ID: 1844.0.0.887.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Anita Borlak [University of Nebraska–Lincoln] aborlak2@huskers.unl.edu, presenting author

Abigail Cochran [University of Nebraska–Lincoln] acochran@unl.edu

Ciara Nelson-Forcade [University of Nebraska–Lincoln] cnelson69@huskers.unl.edu

Across the United States, an estimated 48.5 million Americans live with a substance use disorder (SUD). Despite this high prevalence, nearly four in five individuals do not receive treatment, often due to multiple overlapping barriers—including stigma, inadequate provider training, a shortage of addiction specialists, and lack of transportation to treatment facilities (Madras et al., 2020). Transportation barriers are particularly acute and include limited or no access to public transit, suspension or lack of a driver’s license, long travel distances, and high transportation costs (Harwerth et al., 2023). These challenges are especially severe in rural areas, where public transportation is minimal and often reliant on non-emergency medical transportation (NEMT) services (Kiang et al., 2021).

In Nebraska, 88 of the state’s 93 counties are federally designated Mental Health Professional Shortage Areas. The long distances between communities and treatment facilities significantly hinder access to care, particularly for individuals with limited mobility or resources. Research consistently shows that the farther a treatment facility is located, the less likely a person is to pursue or maintain care. While telehealth services have expanded since the COVID-19 pandemic, these modalities do not fully eliminate transportation challenges—especially for rural residents lacking digital literacy or stable internet access (Vinella-Brusher et al., 2022).

This study investigates how transportation barriers affect access to SUD treatment in rural Nebraska by centering the perspectives of providers and care coordinators. Through in-depth, semi-structured interviews with clinicians, care coordinators, and community health workers, we explore three key themes: how transportation barriers shape access to SUD care; how providers are adapting to evolving modalities such as telehealth; and how they are envisioning or implementing solutions to overcome transportation-related obstacles. Participants are being recruited from “care deserts” identified through prior geospatial analysis, where geographic isolation and lack of transit options most acutely impact access.

Findings will offer new insights into how providers perceive and respond to transportation barriers in their practice. Providers report that transportation is one of the most consistent determinants of whether a patient can initiate or continue treatment. While telehealth is an important tool for expanding reach, its effectiveness is tempered by infrastructure gaps and the need for in-person services for many treatment types. In response, providers are leveraging creative solutions, such as flexible scheduling, coordination with local transportation providers, and the use of mobile clinics and peer-based support systems to fill access gaps.

This research makes a unique contribution by capturing how transportation barriers to SUD treatment are understood and navigated from the provider perspective—an area that remains underexamined in rural health and transportation planning literature (Nelson-Forcade et al., 2025). The findings will inform actionable strategies for reducing access inequities and improving transportation safety and service delivery for rural communities facing the dual challenges of substance use and geographic isolation.

Accurately measuring public-right-of-way dimensions is essential to evaluating how street design affects both travel behavior and safety. However, gathering city-scale information with precision is difficult given the number of and complexity within urban intersections. To address this challenge in the context of pedestrian crossings – a crucial component of a city’s walkability – we introduce a highly scalable and accurate analysis pipeline for automatically measuring crosswalk distance applied to America’s 100 largest cities (covering millions of crossings). First, OpenStreetMap intersection coordinates were used to target satellite-imagery tile retrieval. Then Meta’s Segment Anything Model was trained on high-entropy intersection images to differentiate drivable from non-drivable surfaces (i.e. roads vs. sidewalks). A small number of post-processing steps were then developed to optimize intersection measurement accuracy, including to ensure that refuge islands are segmented as non-drivable space, and to prune extraneous segments that overlap with known drivable road space. Next, all available crosswalk edges from OpenStreetMap were extracted, and we augmented this query by generating edges from centerline points (boosting the number of intersections for which crossing distance can be measured). Finally, those crosswalk edges are overlaid on the segmented intersection images and a grow-cut algorithm is applied, which connects each edge to its adjacent sidewalk and measures crosswalk distance with high accuracy. Overall, this analysis pipeline measures crosswalks with a median absolute error of 4 feet, 9 inches (89% accuracy), when compared to manually-verified crosswalk datasets, and can compute crossing distances for entire American cities in roughly one hour. This level of precision allows for visualizing the variance in crossing distance at multiple geographic scales (neighborhoods, entire cities, and nationally), which empowers planners to prioritize streetscape investments to enhance the pedestrian experience.

School Escorting Effects on Parental Commuting Routes and Household Travel Carbon Emissions

Abstract ID: 1844.0.0.328.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Dawei Wang [Southeast University] wdw@seu.edu.cn, presenting author

Wenzhu Zhou [Southeast University] zhouwenzhu@seu.edu.cn

School escorting has become an integral component of urban household travel, particularly reshaping commuting patterns in dual-earner families. Parents must modify work commute routes to accommodate escorting tasks, potentially increasing detour distances and travel time while altering transport modes - collectively influencing household travel carbon emissions. However, existing evidence predominantly examines individual-level effects while overlooking intra-household interactions. We argue that such interactions manifest in three dimensions: joint decisions on residential, workplace, and school locations; allocation of escorting tasks and transportation modes; and behavioral interdependencies between parents' travel patterns. Using survey data from 442 dual-earner couples with schoolchildren in Nanjing, China (collected May 2024), we employed multinomial logit models to examine how parents optimize escorting routes and schedules, allocate transportation resources, and subsequently affect household travel carbon emissions, accounting for their interdependencies. The results demonstrate that school escorting significantly alters household travel patterns and parental commuting routes. Notably, gendered disparities emerge: when route adjustments are minimal, mothers predominantly assume escorting responsibilities and retain priority in transport mode selection. As detours increase, higher vehicle ownership correlates with reduced maternal driving for school trips (from 68% to 42%) and increased paternal involvement (from 32% to 58%), elevating household emissions by 12-18%. Furthermore, we identify interactive effects in task allocation between parents, which indirectly influence family travel carbon footprints through behavioral spillovers. These findings suggest that policy interventions aimed at optimizing school escorting routes, reducing commuting time, and reducing emissions in urban China must integrate intra-household dynamics and cultural norms in task and resource allocation.

Shared Mobility as a Safety Solution: Evidence from Post-Secondary Students in the GTHA

Abstract ID: 1844.0.0.1125.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Seyedmohsen Alavi [York University] alavim@yorku.ca, presenting author

Justin Podur [York University] jpodur@yorku.ca

Urban transportation systems are undergoing a transformative shift, with shared mobility being explored as a potential strategy to enhance safety and accessibility. Safety concerns significantly influence modal choices, particularly among vulnerable groups within the post-secondary student population, such as women, non-binary and LGBTQ+ individuals, and students with specific mobility needs. Building on existing literature on gender gaps in urban mobility and the role of shared mobility, this study investigates the impact of shared mobility modes, such as ride-hailing, bikesharing and microtransit, on the safety perceptions and travel behaviors of post-secondary students in the Greater Toronto and Hamilton Area (GTHA).

Research Question: How do shared mobility options influence the safety perceptions and travel behaviors of post-secondary students in the GTHA, with a focus on vulnerable subgroups such as women, non-binary and LGBTQ+ individuals, and those with mobility needs?

Approach and Methodology: This study employs a mixed-methods approach, integrating quantitative data from a structured survey (n=257) distributed among post-secondary students across several GTHA universities and qualitative insights from in-depth interviews. The survey assesses factors influencing mode choice, including safety, accessibility, and frequency of shared mobility use, while interviews provide a deeper understanding of safety concerns and experiences.

Meaningful and New Findings: Results indicate gender disparities in safety perceptions, with non-male students, such as women, non-binary, and LGBTQ+ individuals, reporting higher safety concerns. Approximately 82% of respondents now prefer shared mobility over public transit, citing safety as a primary reason, with qualitative data highlighting its role in alleviating safety-related anxiety for these vulnerable groups during first-mile/last-mile transit segments. Most non-male respondents cited safety as a key factor in choosing their travel mode, specifically shared mobility, either as their primary mode or as a first mile/last-mile connection, with regression analysis confirming statistically significant differences.

Relevance and Implications: These findings highlight the critical need to develop multimodal transportation systems integrating shared mobility to effectively address safety and equity concerns, especially for vulnerable student populations. Urban planners and policymakers should prioritize shared mobility as a central component of inclusive transportation strategies, ensuring safer, more accessible, and equitable transit options for diverse student populations.

Shifting Attitudes Toward Reduced Car Dependence: A Multidimensional Scaling Experiment in Singapore

Abstract ID: 1844.0.0.374.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Evan Iacobucci [Missouri State University] eiacobucci@missouristate.edu, presenting author

Joseph Woelfel [State University of New York at Buffalo] jwoelfel@msn.com

Kenton Anderson [Singapore Institute of Management] kba2@buffalo.edu

Views of transportation planners diverge from the public, especially in the US. This divergence centers on the role of cars, with planners seeing less car dependence as essential to a sustainable future, while the public reflexively bristles at policies that might inhibit driving (e.g., congestion pricing). A main obstacle to such policies is public acceptability. Design of public messaging is a crucial component in garnering acceptability, which could benefit from precise understanding of what messages would be most effective.

We conducted a randomized control trial (RCT) experiment in Singapore, which has long enforced policies that restrict car ownership and increase the cost of driving. In this experiment we a) measure attitudes toward predominating transportation policies in Singapore, and b) assess the impact of messaging associating these policies with the desirable effect of reduced traffic congestion. To address these goals, we introduce Galileo theory and method—a specialized multidimensional scaling methodology used in sociology and communication studies—to the field of planning.

Our method differs from traditional tools by 1) Measuring attitudes as paired comparisons between relevant concepts, capturing relationships between all concepts in the measured set, as opposed to a simple binary (e.g., favorable / unfavorable), 2) Using ratio scales to capture these relationships with precision, and 3) Construction of a high-dimensional cognitive space wherein we can track the “movement” of concepts in response to messaging, representing changes in attitudes. The key advantages of this method are a) ability to capture attitudes and relationships with higher precision, and b) the ability to mathematically determine effective messaging to shift attitudes based on these measurements.

We developed a questionnaire that measured attitudes toward traffic reduction policies, transportation modes, and relevant attributes. Questionnaires were distributed to a diverse group of undergraduate students, which, though not representative, serves as proof-of-concept for the methodology. We captured demographic and travel behavior information, ensuring uniformity between the control (n=66) and treatment (n=78) groups. Because we had no existing measurements from which to generate an ideal message, our treatment message was designed simply to associate the key traffic policies with their goal of reducing congestion.

We hypothesized that in Singapore, where automobile-reduction policies are the norm, participants would not have strong perceptions of these policies, and they would be possible to shift. We expected the same would not be true of the effects of these policies, e.g., perceptions of travel modes, attributes, etc. The results of our experiment corroborate these expectations: Perceptions of key travel modes were nearly identical between control and treatment. The policy concepts and traffic congestion, however, converged toward one another, which also had the effect of participants viewing them as more convenient, practical, and necessary. This interpretation (and effectiveness of the message) is corroborated by the distances the concepts moved in cognitive space, with the policy and congestion concepts moving vastly more than the mode or attribute concepts.

These findings should be of interest to scholars interested in advancing sustainable transport policy. We were able to measure transportation-related attitudes precisely and reliably, facilitating accurate prediction of messaging effects through spatial projection. Results suggest habituation to reduced-car policies may lead not only to acceptance, but indifference. We suggest that durable changes in attitudes require continuous messaging over time, that messaging strategies should be tested before deployment to maximize effectiveness and avoid unintended effects, and that detailed understanding of the dynamics of policy support requires precise measurement of attitudes.

Shifting Spaces: Land Use and Zoning Adaptations in the Autonomous and Shared Mobility Era

Abstract ID: 1844.0.0.1104.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Robert Binder [University of Oregon] rbinder@uoregon.edu, presenting author

Nico Larco [University of Oregon] nlarco@uoregon.edu

Zoning is not only a technical mechanism for organizing land—it is a powerful tool for shaping spatial equity, environmental resilience, and mobility access. As autonomous vehicles (AVs) and shared mobility systems begin to alter travel patterns, there is a need to reconsider how our built environment is shaped, reshaped, and governed in metropolitan areas. While the impacts of AVs remain uncertain, scholars have begun to analyze likely shifts. Soteropoulos et al. (2019) highlight that travel behavior and land use outcomes are highly sensitive to assumptions about vehicle ownership models, value of time, and the role of public transit. Pimenta et al. (2023) found that shared AVs may reduce parking needs and support higher densities, while private AVs may encourage sprawl and dispersed development. Montoya (2024) calls attention to the zoning systems themselves, which remain largely unprepared for a transformation in urban land uses and demands, and advocates for proactive, equity-centered adaptation. Together, these early studies of the inevitable emergence of AVs show that AVs and shared mobility could reconfigure urban form—but will only achieve planning goals if institutions act with foresight.

In this research, we explored how AVs and shared mobility are likely to affect land use and zoning requirements in large U.S. cities and regions, and what implications this has for local governments and Metropolitan Planning Organizations (MPOs). Following a structured review of existing literature and modeling, we completed stakeholder interviews designed to engage planners, transportation officials, developers, and public agency staff, and to understand how jurisdictions are approaching (or avoiding) questions of land use change related to AVs. With these insights, we then developed a GIS-based spatial analysis of parcel-level land uses in Los Angeles. In selecting Los Angeles as our case study, we sought to engage a city with vast and varied built environment typologies—from a transit-rich downtown to automobile-dependent neighborhoods—offered a meaningful landscape for examining potential AV-induced adaptations and transformations.

We spatially analyze parcel-level data to identify auto-serving land uses that may be made obsolete, as well as parcels with potential for repurposing or infrastructure retrofits. We overlaid these with current zoning designations to model future scenarios across different parts of the Los Angeles region. Attention was paid to typological diversity—how the built environment (including the spatiality of structures and the road network) varied across dense cores, arterial corridors, and single-family residential fabrics. We modeled under two distinct modules: one reflecting current travel behaviors, and another representing an increased transit use environment. Within these modules, we adjusted assumptions about vehicle ownership structures (fleet/shared vehicles vs. privately owned vehicles) and the geographies of AV deployment (region-wide vs. city center-focused). In each scenario, we modeled potential land use changes (increases, reductions, or stable) related to parking demand, e-commerce activity, brick-and-mortar retail activity, fuel station transformations, and density of the built environment.

In the final paper, we will present the spatial outputs of this work, including maps of land use change potential and zoning mismatch across Los Angeles County. We will also describe findings from our stakeholder interviews, including planning frictions and governance dynamics related to emerging transportation technologies. While this research does not predict the full shape of an AV-driven urban future, it offers a grounded framework for understanding what is at stake—and what tools planners may need—in adapting land uses and zoning to meet

evolving needs. We contribute both conceptual scaffolding and applied techniques to help cities navigate this uncertain, but consequential, terrain.

Slower Roads, Cleaner Skies? Causal Effects of Speed Limit Reduction on Urban Air Quality

Abstract ID: 1844.0.0.168.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Wookjae Yang [Incheon National University] wookjae.yang@inu.ac.kr, presenting author

Byungkuk Kang [Incheon National University] quddnr2233@inu.ac.kr

Background: Vehicle speed limit reduction policies have been widely studied for their impact on traffic safety, but their potential effects on air quality remain less understood. In 2021, South Korea implemented the "Safe Speed 5030" policy to lower speed limits to 50 km/h on urban roads and 30 km/h in residential zones. After implementations, even though several studies have confirmed improvements in safety outcomes, such as reducing crash frequency and severity (Woo et al., 2023; Son et al., 2019), yet little has been paid to the effects on air quality that may have been affected by increased traffic volumes induced by speed reductions. Traffic conditions, shaped by speed limitations, can substantially impact pollutant emissions, including particulate matter (PM_{2.5} and PM₁₀) (Baldasano et al., 2010; Bel & Rosell, 2013; Casanova & Fonseca, 2012; Dijkema et al., 2008; Rossi et al., 2020).

Objective: This study aims to assess the causal effects of the 5030 speed limit reduction policy on air quality, explicitly targeting particulate matter (PM₁₀), carbon monoxide (CO), nitrogen oxides (NO_x), volatile organic compounds (VOCs), and carbon dioxide (CO₂). By employing a quasi-experimental study design, this research addresses gaps in existing studies by investigating the causal impacts of speed limit reduction on air quality across different urban contexts, controlling for confounding variables.

Data & Methods: The study utilizes a quasi-experimental research design combining propensity score matching (PSM) and spatial difference-in-differences (SDID) regression. First, PSM was used to minimize confounding effects of the built environment and socioeconomic status by matching comparable groups of treatment and control traffic analysis zones (TAZs). "Safe Speed 5030" was implemented in 2021. The baseline data collected in 2020 – one year before 5030 – was used for PSM analysis. Following PSM, spatial difference-in-differences regressions, including spatial lag DID and spatial error DID, are applied to estimate the treatment effects of speed limit reductions on air quality.

Results: The PSM result indicates that after matching, the mean differences between the treatment and control groups were substantially reduced, indicating that matching was effective in balancing covariates. The matched sample shows that none of the covariates exhibit statistically significant differences, suggesting that the matching process effectively minimized potential confounding effects. The results of three different models (linear regression DID, spatial error DID, and spatial lag DID) were applied to five air pollutants: CO₂, CO, NO_x, VOCs, and PM₁₀. The "Time * Treatment" interaction is positive and highly statistically significant across all pollutants. This confirms that the speed limit reduction policy increased volume and thereby increased emissions, worsening the air quality. The effect sizes vary by pollutant, but the general pattern became worse (increases in air pollution levels) after the intervention in the treatment group.

Implications: The results of this study highlight a critical gap in the effectiveness of the Safety 5030 policy regarding achieving comprehensive sustainability goals. Although the policy successfully contributes to the United Nations' Sustainable Development Goals (SDGs) by significantly reducing crashes and enhancing road safety, it fails to achieve another key aspect of sustainability—improving air quality. Policymakers should recognize that solely focusing on speed limit reductions may not be sufficient to mitigate urban air pollution. Therefore, comprehensive strategies are required to achieve sustainable urban environments.

Social Normalization of Fare Evasion in Public Transit

Abstract ID: 1844.0.0.307.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Duco Zhao [Newton North High School] ducozhao2008@gmail.com, presenting author

Haris Koutsopoulos [Northeastern University] h.koutsopoulos@northeastern.edu

Fare evasion is a serious issue in public transportation, costing transit agencies millions of dollars in revenue that could be redirected into infrastructure and service improvements. Although public transportation is vital in providing affordable and sustainable mobility, chronic fare evasion undermines these goals by eroding public trust, straining resources, and diminishing ride quality. Though fare evasion has been significantly studied, traditional regulatory approaches have emphasized external enforcement, deterrence, and pricing mechanisms. However, compliance with fare payment relies largely on the social norm that passengers will pay their fares voluntarily. Where this norm collapses, fare evasion is not so much a question of resisting policy as it is a question of overcoming a physical barrier.

This study investigates when and under what circumstances fare evasion becomes socially normalized and analyzes the underlying factors that contribute to its normalization. Moreover, it will investigate whether social norms related to fare evasion vary across sociodemographic characteristics, such as income, occupation, race, gender, student status, and past experiences with the MBTA. Finally, this study will evaluate how social norms of fare payment evolve and transform with time, using the launch of a new commuter rail line on March 24, 2025, as a natural point of observation.

To address these questions, the research will use semi-structured interviews and surveys with transit riders, enforcement officials, and staff in the Massachusetts Bay Transportation Authority (MBTA), the primary public transportation service in the greater Boston area. The study on the commuter rail will include multiple waves of interviews at various time points at the opening of the new commuter rail line and various time points following to examine whether and how social norms evolve across time.

Preliminary expectations are that fare evasion becomes a social norm when there is widespread perceived unfairness in the fare system, distrust of the transit agency, low levels of enforcement, and a lack of social pressure to abide by fare rules. Among younger riders, fare evasion may also be influenced by peer pressure, with some viewing it as a rebellious act or even a fun challenge. These norms spread as individuals observe and internalize the behavior of others, especially in environments where nonpayment is common and goes unpunished. Understanding whether fare evasion has been normalized, and how, can inform MBTA policy initiatives to stem the practice is important. The findings of this research will contribute to current knowledge on the social and psychological factors of fare evasion, enabling transit agencies to develop more effective and equitable enforcement policies. The findings will also provide valuable insight into the ways social norms of fare payment establish themselves in new transit environments, guiding policy for future expansions and ridership changes.

Spatial Patterns of Electric Vehicle Miles Traveled (EVMT) as a Proportion of Total Mobility

Abstract ID: 1844.0.0.325.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Shiqi Ding [University of Washington] shiqidi@uw.edu, presenting author

Lingzi Wu [University of Washington] lingwu@uw.edu

Electric vehicles (EVs) are widely promoted as a low-emission transportation option. Although EV adoption rates have been extensively studied, adoption alone does not reflect how much total travel becomes electrified. In urban transportation systems with multiple travel modes, EV represents just one option among many. Accurately forecasting energy demand by personal EVs and, thus, emission reductions, requires metrics that reflect real-world usage patterns beyond merely the adoption rate (Jia & Chen, 2022). Some studies assumed that EVs directly replace conventional vehicles with identical usage patterns when predicting energy demand (Ellingsen et al., 2016; Xing et al., 2021), disregarding the distinct EV travel behaviors influenced by range considerations and charging availability (Zhang et al., 2025). While other studies acknowledged behavioral differences, they primarily examined the different patterns of EV usage among vehicle models (Zhao et al., 2023). Importantly, understanding spatial patterns of EV usage as a proportion of total miles traveled remains unexplored.

To address this gap, we propose a new metric—the percentage of electric vehicle miles traveled (EVMT)—which quantifies the percentage of total travel miles that are electrified within a given area. This metric allows for understanding how personal EVs integrate into broader travel patterns. Our study addresses two questions: how does the EVMT proportion vary spatially, and how does its spatial heterogeneity correlate with socio-spatial characteristics? We estimated EVMT proportion at the census tract level across the Seattle metropolitan area, using the public and representative household travel survey data of 2023 provided by Puget Sound Regional Council. Our approach had two key steps: first, we employed a Bayesian hierarchical Fay-Herriot model for small area estimation (SAE); second, we applied linear regression and geographically weighted regression (GWR) to quantify the relationships with key factors. Specifically, to overcome the inherent challenges of sparse and small sample sizes in survey data, our SAE model incorporated 10 auxiliary variables, including household socioeconomic, public charging infrastructure, and built environment factors. While leveraging spatial smoothing for precision, we calibrated estimates to preserve evidence of near-zero EV usage in certain tracts based on their EV registration records.

Our results reveal substantial spatial heterogeneity in EVMT proportion across census tracts (range: 0-0.97, median: 0.064, mean: 0.13). Thus, while some neighborhoods already have remarkably high electrification, most areas have modest EV usage. Regression analysis demonstrates EVMT is positively associated with homeownership rates and public Level 2 chargers, but negatively with public fast chargers. This could be explained by misalignments between current fast charger locations and residential EV charging needs. Surprisingly, EV ownership does not significantly correlate with actual EV usage. This further confirms that adoption alone fails to reflect actual usage. In addition, our GWR model reveals spatial variations in these relationships. For instance, multi-worker households (2+) are negatively associated with EVMT, with this effect being twice as strong in rural areas compared to core urban neighborhoods. This indicates potential barriers to EV usage in households with complex travel needs in rural areas.

Our findings challenge prior assumptions that higher EV adoption equates to higher EV usage, and that EVs are a direct replacement of conventional vehicles. Planners should implement context-specific charging infrastructure strategies and targeted interventions to optimize the climate and social outcomes. In summary, understanding the

spatial patterns of EVMT proportion provides a more realistic metric to forecast the dynamic urban mobility energy demand and emission reductions from electrification.

Spatiotemporal Trends in EV Ownership and Their Relationship to Sociodemographics and Infrastructure

Abstract ID: 1844.0.0.991.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Ouafa Benkraouda [University of Illinois] ouafab2@illinois.edu, presenting author

Arnab Chakraborty [University of Utah] a.chakraborty@utah.edu

As electric vehicle (EV) adoption grows, it is increasingly leveraged as a proxy for gauging readiness for connected and automated vehicle (CAV) deployment. However, relying on EV ownership alone as a measure of readiness may overlook critical equity considerations. This study investigates the spatiotemporal patterns of EV ownership in Chicago and Greater Peoria, Illinois, from 2018 to 2023, to evaluate the extent to which EV adoption reflects equitable transportation readiness. Using longitudinal EV registration data mapped to census tracts, alongside sociodemographic and infrastructural indicators, the analysis employs KNN clustering and ordered logit regression to explore the influence of demographic, socioeconomic, and infrastructural variables on EV growth.

Findings show a pronounced correlation between higher EV ownership and higher median income, educational attainment, and the proportion of foreign-born residents, with disparities more evident in larger urban contexts such as Chicago. In both cities, tracts in the lowest EV adoption clusters exhibit greater transportation disadvantage, higher Area Deprivation Index (ADI) scores, and lower public infrastructure availability. Notably, a significant positive correlation is found between EV ownership and the foreign-born population, suggesting that immigrant communities, often overlooked in adoption models, may play a key role in early technology uptake—potentially due to cultural, social, or behavioral factors (Holland et al., 2019; Tian et al., 2020).

Contrary to expectations, greater density of EV charging stations is negatively associated with high-growth adoption tracts in Chicago, raising questions about the effectiveness of current infrastructure deployment strategies. This echoes findings by Hsu and Fingerman (2021), who showed that charging access disparities persist even when controlling for population density. The association between EV ownership and housing type also challenges traditional assumptions. While prior research suggests single-family homes facilitate EV adoption due to private charging availability, this study, in alignment with Sinton et al. (2024), finds that areas with higher proportions of multi-unit dwellings are more likely to be high-growth EV tracts, possibly due to proximity to shared infrastructure and shorter commute times.

These patterns reveal the limitations of using EV ownership as a singular readiness metric for CAV deployment. Spatial autocorrelation analyses confirm strong clustering of EV adoption by socioeconomic and demographic characteristics, reinforcing that infrastructure and policy interventions must be targeted and context-aware. As Caulfield et al. (2022) argue, failing to account for structural inequities in mobility technology rollouts risks perpetuating disparities in access and outcomes.

This study underscores the need for a multi-dimensional framework that incorporates equity-focused indicators such as ADI, transportation disadvantage, housing form, and education level. Policymakers must move beyond simplistic adoption metrics and consider the broader structural and spatial factors that influence readiness for CAVs. Strategic deployment of infrastructure, targeted engagement with immigrant communities, and equity-first planning approaches are necessary to ensure inclusive and just mobility futures.

Strategies, Opportunities, and Challenges of Integrating Transit and Shared Micromobility

Abstract ID: 1844.0.0.87.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Anne Brown [University of Oregon] abrown33@uoregon.edu, presenting author

Niels van Oort [Delft University of Technology] n.vanoort@tudelft.nl

Many cities are keen to integrate public transit and shared micromobility (e.g., bikeshare and shared e-scooters) to expand mobility options, overcome first/last mile barriers to public transit, and shift more people out of cars. While previous research and pilot evaluations have documented individual case studies or elements of integration (e.g., integrated trip planning and fare payment, governance structures, vehicle co-location), best practices for successful and long-term sustainable integration remain unclear. To fill this gap, this research asks and answers three questions. First, how do different cities and shared micromobility operators approach and frame the transit-shared micromobility integration? Second, what integration strategies have been implemented to date? And third, what are the opportunities or challenges of each strategy, and which are critical to sustained success? This research synthesizes existing literature alongside interviews with over 25 professionals representing cities, public transport agencies, and shared micromobility operators from across North America and Europe. Together, findings present a typology of transit-shared micromobility integration and key lessons for how cities should prioritize resources and efforts to integrate shared micromobility and public transit to achieve broad city goals. Findings reveal that how shared micromobility is framed—particularly if it is viewed and regulated as part of the broader public transportation system—underpins many of the regulatory and policy approaches governing integration. While technological integrations such as trip planning and mobility as a service have received keen attention in both research and practice, practical barriers including data and privacy, and back-end technology integration present barriers to adoption and scale. Interviewed professionals highlight infrastructure, governance, and subsidy as core elements needed to foster and sustain a public transport system that includes shared micromobility.

Street-level and Building Features' Nonlinear Impacts on Mode Share around Transit Stations

Abstract ID: 1844.0.0.388.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

SeyedSajjad Abdollahpour [Johns Hopkins University] sabdoll2@jh.edu, presenting author

Shima Hamidi [Johns Hopkins University] shamidi2@jhu.edu

Ebrahim Azimi [Johns Hopkins University] eazimi2@jh.edu

Few studies at the national level have examined the impact of fine-scale built environment features on travel behavior (Angel et al., 2024; Choi and Ewing 2021; Liu et al., 2023, Xu et al., 2023; Wang et al., 2023), particularly in the U.S. using a nonlinear approach. This study investigates the influence of street-level built environment features, street network characteristics, and building attributes on commuting mode share around public transit stations across the country. Specifically, it addresses the following questions: (i) To what extent do micro-scale, street level features contribute to commute mode share compared to meso-scale, neighborhood level variables such as population and employment density? (ii) Are there effective ranges for these features in influencing commuting mode share? (iii) Do interactions exist between street-level features—such as greenery, street patterns, and enclosure—and neighborhood-level variables like land use mix, population and employment density?

To explore these questions, we leveraged Google Street View (GSV) imagery to extract street-level built environment features, including greenery, enclosure, sidewalks, and roadways. Additionally, we incorporated street network characteristics such as intersection density, link-node ratio, average geodesic distance, and block size, as well as building-related attributes (e.g., number and average area of buildings) from the Microsoft Building Footprint dataset. A series of XGBoost models and Shapley Additive Explanations (SHAP) plots were used to detect threshold effects and assess the relative importance of various predictors in influencing commuting mode share across more than 2,890 rail and BRT stations nationwide.

The results indicate that street-level built environment and building features collectively contribute approximately 25 percent to the predictive power of commuting mode shares around public transit stations. Furthermore, their effects are nonlinear, with distinct effective ranges. For instance, enclosure positively influences active commuting modes when within the range of 0.2 to 1.2, beyond which the effect diminishes. Additionally, interaction effects are observed between street-level features (e.g., greenness, intersection density), building features (e.g., number and area of buildings), and neighborhood level, census-tract variables (e.g., population density) in shaping commuting mode shares.

These findings underscore the importance of considering micro-scale urban design elements in transportation planning to promote sustainable mobility and reduce automobile dependence. By integrating these insights into transit-oriented development and land-use planning strategies, cities can design more walkable, and transit-supportive environments.

A Complete Street is a road designed to safely accommodate everyone—drivers, cyclists, transit users, and pedestrians of all ages and abilities—by integrating inclusive planning and design. To initiate complete street policies, it is necessary to evaluate the current street conditions and how well they meet completeness, including transit accessibility. However, current approaches often assess transit accessibility at the transit stop or area level, overlooking transit accessibility at different locations along the streets. In addition, current methods often fail to capture certain aspects of public transit users' needs, such as the comfort and availability of informational amenities at the bus stop infrastructure. In response, our research proposes a new framework for evaluating transit accessibility at the street level, emphasizing the localized conditions that transit users encounter on the streets and at bus stops.

Our methodology includes two steps. First, each bus stop is evaluated by two variables: bus operational service and bus stop quality. We employed the Atlanta region's General Transit Feed Specification (GTFS) data with an algorithm that computed various bus operational service status variables from this data. For bus stop quality, an object detection algorithm trained on street view imagery assessed the status of the bus stop's detailed amenities, such as shelters and schedule boards. These metrics are then combined into a service index.

Second, we integrate this service index into a comprehensive street-level transit accessibility estimation using an interpolated point-based approach. Our method applies network buffers around walkable areas of transit stops and calculates transit accessibility for each interpolated point along the street. The average score of these points becomes the representative transit accessibility index for that street segment, ensuring that transit accessibility at specific locations where transit users stand is captured.

Applying this street-level index in the Atlanta region, we analyzed its statistical significance to overall street scores along with other components such as sidewalk widths and the existence of bicycle lanes. The result demonstrates that our measure of transit accessibility, which incorporates localized conditions affecting transit users, significantly impacts street completeness compared to conventional approaches.

These findings suggest two implications for complete street initiative planning: First, it is essential to reflect detailed transit accessibility on streets, and the quality of transit stops is essential. Second, the appropriate observation scale is critical for developing complete street designs. Our approach provides a more comprehensive understanding of how transit accessibility contributes to creating complete streets by integrating a fine-grained assessment that emphasizes bus stop conditions and the specific locations where transit users are positioned.

Super Commuting and the COVID-19 Pandemic: Insights from California

Abstract ID: 1844.0.0.495.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Evelyn Blumenberg [University of California, Los Angeles] eblumenb@ucla.edu, presenting author

Fariba Siddiq [UCLA Institute of Transportation Studies] fsiddiq@ucla.edu

Brian Taylor [UCLA] btaylor@ucla.edu

Super commuting—typically defined as one-way journeys to work of 90+ minutes—has long captured the attention of the general public, planners, elected officials, and researchers. High housing costs in large urban areas may be one important factor motivating outward moves to outer suburban and exurban communities with lower housing costs, which may result in very long commutes. This pattern may be exacerbated by discrimination in both the housing and the labor markets, which can restrict opportunities and increase super commutes among lower-income and non-white workers (Allen et al., 2022; Islam & Saphores, 2022).

Prior to the COVID-19 pandemic, the average one-way commute duration in the U.S. had increased to a new high: 27.6 minutes (Burd et al., 2021). Evidence suggests that the pandemic accelerated outward residential moves due to increased working from home, which both increased demand for more residential space for work, and decreased the frequency of commuting, making very long commutes more tolerable. For example, Ramani et al. (2024) find that three-fifths of households that left big city centers during this crisis moved to the suburbs of the same city. As a result, on average workers now live further from their workplaces than they did prior to the pandemic (Akan et al., 2024).

In this paper, we examine the impact of the pandemic on super commuting. We draw on data from the 2019 and 2023 one-year American Community Survey Public Use Microdata Samples (PUMS) for California, the most populous U.S. state. We predict the likelihood of commuting among workers — in other words, not working from home — and the likelihood of super commuting 90 minutes or more one-way.

Relative to non-super commuters, super commuters are more likely to ride public transit to work, have less formal education, avoid peak hours for arriving at their worksites, be male, and married; they are less likely to live in dense urban areas. Contrary to our hypothesis, however, controlling for other characteristics, the models show that super commuting is less common among workers in 2023 compared to 2019. This finding may be due to an increased share of workers who would otherwise have super-commutes working from home post-pandemic. Indeed, the data show that in 2023 workers were less likely to commute to their workplaces compared to the pre-pandemic period. However, these findings must be interpreted with caution, as the U.S. Census Bureau identifies remote workers as workers who work at home a majority of work days, therefore excluding what could be many super commutes among hybrid workers who go into the office, say, two days per week.

Super commutes can take a toll on the lives of workers and their families, as long periods spent commuting is time away from sleeping, parenting, socializing, and exercising. Very long public transit trips may entail multiple transfers, long periods of standing, and waiting outside in inclement weather. Super commutes in automobiles contribute to traffic congestion, air pollution, and climate change.

Despite the popular attention paid to super commuting, our analysis finds that extreme commuters are a small—and potentially declining—percentage of the workforce, suggesting that researchers ought to focus more broadly on increasing commute durations, and less on the “super” aspects of the journey to work. Further, the continued shift in the percentage of households living in outlying areas likely means longer trips for all forms of travel, and not

just commuting, which warrants more investigation as well. Finally, our analysis highlights the importance of improving travel data to better understand the evolving relationship between workplace flexibility and the commute.

Testing the Principles of the '15-Minute City' in Socialist-Era Housing Estates in Kraków,

Abstract ID: 1844.0.0.116.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Daniel Hess [University at Buffalo, State University of New York] dbhess@buffalo.edu, presenting author

Rita Łabuz [Kraków University of Technology, Poland] rita.labuz@pk.edu.pl

Recent enthusiasm for planning local pedestrian access to nearby services and neighborhood assets are reflected in the '15-minute city' strategy that envisions dense urban places that take advantage of connectivity, proximity, mixed-use development, and human-scale design. The '15-minute city' approach is aimed at improving the quality of life in neighborhoods by de-centering the automobile while nurturing mixed-use neighborhoods, facilitating walkability, and supporting urban sustainability.

Urban scholars have noted that the principles of the '15-minute city' concept are closely aligned with neighborhood planning innovations developed throughout the late 19th and 20th centuries, including Ebenezer Howard's Garden City and Clarence Perry's neighborhood unit for planned developments (Hall 2014). Scholars have not yet, however, fully recognized the consistency of the '15-minute city' with modernist urbanism as reflected in the plans for post-World War II housing estates in Central and Eastern Europe (during state socialism in the decades following World War II).

We select Kraków, Poland, which is home to 24 housing estates dating from the era of state socialism. For this study, we include all housing developments constructed in Kraków between 1949 and 1989 and which reflect various eras of town planning concepts during state socialism. We use publicly-available spatial data to assess how socialist-era housing estates meet today's aims for the '15-minute city'. We take inspiration from the urban code—in effect during state socialism in Poland from the 1970s until 1989—which encouraged proximity of services from planned residential districts.

The objective of this research is to explore the extent to which the built form of large housing estates satisfy the aims of the '15-minute city'. We measure walkability using the QGIS plug-in in ArcGIS as a means of assessing buffered pedestrian access to parks and greenspace and retail, commercial, and community services. By overlaying our spatial analysis of population density with measure of access for pedestrians, bicyclists, and public transport users we produce a composite assessment of the principles of the '15-minute city'. This method allows us to develop a comprehensive understand of the interplay between density, proximity, access, and mobility within the large housing estates of Kraków and assess how residential districts and their surrounding environments dating from various eras of development align with the principles of the 15 minute city.

The results of this analysis will help clarify the degree to which socialist-era principles are aligned with contemporary concern for access and mobility reflected in the '15-minute city'. This will help isolate potential aspects of large housing estates that need attention in future redevelopment schemes and help city planners promote (to residents and potential residents) the ecological and sustainability-related aspects of living in large housing estates. Our results will be useful to people engaged in the renovation of apartment buildings and the built environment and public spaces within these residential districts.

The Association Between Active Transportation Plans and Built Environment Transformation

Abstract ID: 1844.0.0.272.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Meiqing Li [University of Central Florida] meiqing@ucf.edu, presenting author

Plans, as a primary outcome of planning, play a critical role in shaping the built environment and human behavior. Over the past few decades, active transportation plans, or pedestrian and bicycle plans have become a common type of plans by counties, cities, and other jurisdictions in the U.S., which aim to promote sustainable means of transportation. Previous studies have described spatial and temporal patterns of pedestrian and bicycle plans (Aytur et al., 2013), behavioral effects in terms of walking and cycling activities (Duncan, 2023), as well as their impact on traffic safety (Kerr et al., 2013). A wider range of literatures study the relationship between built environment, travel behavior and safety. Nevertheless, few studies have yet investigated the causal pathway of plan implementation (Burby, 2003; Lyles et al., 2016). In this study, I examine the association between plans and the built environment changes that occur, plausibly through plan implementation. I aim to answer one general research question: do active transportation plans affect the built environment over time? Specifically, 1) Is the presence of active transportation plans associated with lead to an increase in safety countermeasures (marked crosswalks) in priority areas (rail stations)? Does the mention of specific treatment (e.g., marked crosswalk) in the plan make a difference in the outcome of plan implementation? 2) How is the time since adoption of the initial plan associated with changes in implementation? I hypothesize that the pedestrian environment enhancements are likely to happen with concrete and specific recommendations in the plans; and that the longer since the initial proposal, the more likely pedestrian environment improves.

The study uses a mixed method approach to investigate the trends and implementation pathways of pedestrian infrastructure enhancements around BART and Caltrain stations in the San Francisco Bay Area. It utilizes several novel datasets generated by AI from unstructured data (e.g., Google Street View, planning documents) with statistical modeling, to systematically examine the built environment changes and their association with plans at a high spatial-temporal resolution. Findings from this study suggest the potential role of plans in making effective changes in marked crosswalks at station area intersections, as well as the interactive effects contributed by a variety of station area characteristics. The upgrading and addition of high-visibility crosswalks exhibit an overall improvement of pedestrian environment. While previous studies shows no significant relationship between plan implementation and the increase of walking (Duncan, 2023), this study does show that the presence of plan can have some intermediary effect on the positive change to the built environment in terms of pedestrian safety enhancement that can lead to more pleasant pedestrian experience. However, the statistical models present weak or no statistically significant associations between most indicators of plan implementation (i.e., presence of the plan, updates, and age of initial plan) and pedestrian infrastructure improvements. The results imply little relevance of the question whether a local jurisdiction should put down specific recommendations to pedestrian or active transportation master plans. Indeed, pedestrian environment enhancements could take place through other street enhancement programs such as Safe Route to Schools, Vision Zero, and Complete Streets. Many other unobserved factors could also influence the effectiveness of plan implementation, for example, targeted funding support for active transportation infrastructure, advocacies and community support. This finding, to some extent, corroborates with those studies on other types of plans suggesting little causal impacts of plans the codify policies that are likely to happen regardless of the plans.

The Expenditure Burdens of Super-Commuting: An Analysis of California

Abstract ID: 1844.0.0.553.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Brian Taylor [UCLA] btaylor@ucla.edu, presenting author

Hao Ding [UCLA] haoding@ucla.edu

Evelyn Blumenberg [University of California, Los Angeles] eblumenb@ucla.edu

In recent years, the phenomenon of very long commutes, or “super-commutes,” has drawn the attention of the general public, planners, elected officials, and researchers. In the US, researchers have defined super-commuting as one-way commutes that exceed 50 miles in distance or 90 minutes in duration. Recent news coverage of workers who wake before dawn and spend hours on freeways or public transit to travel from their more affordable homes in Stockton (or Riverside) to their workplaces in San Francisco (or Los Angeles) has helped make super-commuting a hot topic. Policy makers are concerned about both the phenomenon broadly and whether super-commuting burdens fall disproportionately on particular, less advantaged segments of the workforce. Super-commuting likely exacts significant physical and psychological tolls on workers and their families, in terms of less sleep, exercise, socializing, parenting, and more, as well as economic burden – the search for more affordable housing in the urban periphery may be traded off with much higher transportation expenditures, which may increase overall expenditure burdens.

In this paper, we examine the housing and transportation (H+T) expenditures and expenditure burdens of super-commuter households (i.e. households with at least one super-commuter) in California. Our analysis seeks to answer three questions: 1) how H+T expenditures and expenditure burdens vary for super-commuter households across income levels, 2) whether super-commuter households have higher H+T expenditures and expenditure burdens than otherwise similar households, and if they do, 3) how commute mode choice, remote working, and residential locations mediate the association between supercommuting and H+T expenditures and expenditure burdens.

We first use the California add-on to the 2017 National Household Travel Survey and the Public Use Microdata Sample of the 2019 5-year American Community Survey data to calculate households’ H+T expenditures and expenditure burdens. We descriptively analyse these data to examine the distributions of H+T expenditures and expenditure burdens of super-commuter households across income levels. We then test the associations between super-commuting and H+T expenditures and expenditure burdens using regression analysis, controlling for socioeconomic and built environment factors. We also use interaction terms between super-commuting and commute mode, remote working, and residential location to examine how these factors mediate the relationship between super-commuting and H+T expenditures and expenditure burdens.

We find that H+T expenditures increase, but expenditure burdens decline as income increases for super-commuter households. Controlling for socioeconomic and built environment factors, super-commuter households have higher H+T expenditures and expenditure burdens than non-super-commuter households across all income levels. Further, commute mode choice and residential location, but not remote working, mediate the association between super-commuting and H+T expenditures, while all three factors mediate the association between super-commuting and H+T expenditure burdens.

Our results suggest that households’ welfare gains from affordable housing in peripheral urban areas are eroded, and may be negated, by the increased expenditures and expenditure burdens from super-commuting. These

expenditure burdens endured by super-commuting households, while consequential, do not even consider the time and stress burdens imposed by very long commutes. Policies to address these burdens are broadly two-fold: (1) increase housing supply and affordability in more central, job-rich parts of metropolitan areas to decrease the motivation to move far out in search of affordable housing and begin super-commuting, and (2) consider encouraging remote work options, at least part-time, to reduce the frequency (if not the length) of super-commuting.

The Use of a Natural Experiment to Identify Comprehensive Impacts of Free Fare Transit Policy

Abstract ID: 1844.0.0.37.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Bogdan Kapatsila [University of Iowa] bogdan-kapatsila@uiowa.edu, presenting author

This study investigates the effects of the transit free fare policy in Iowa City Metropolitan Statistical Area, IA, by capitalizing on the natural experiment setting that the historical differences in fare policies between the three transit agencies that serve the region offer. Numerous US transit agencies use some form of reduced or free fare policy to increase ridership, save operational costs, or advance community development goals, with many temporary free fare programs introduced during the COVID-19 pandemic due to the federal financial support through the Coronavirus Aid, Relief, and Economic Security (CARES) Act, the Coronavirus Response and Relief Supplemental Appropriations (CRRSA) Act, and the American Rescue Plan (ARP) Act (Kirschen and Pettine, 2022). Nevertheless, the empirical evidence of the impacts of established systems is scarce, while analysis of temporary programs implemented during the pandemic is confounded by the reduced amount of travel due to work from home policies, stay-at-home orders, and concerns for personal health at that time (Qi et al., 2023). Many existing free fare programs in the US apply to only some services, like three bus routes in Boston, MA (Office of Boston City Councilor Michelle Wu, 2021), or are limited to certain population group, like youth under the age of 18 in many communities the State of Washington (Public Transportation Division, 2024) complicating the ability to reliably estimate the effects. In this regard, Iowa City offers a unique opportunity to gain insights into the effects of the free fare policy by having three different transit providers serving the same region, where one, the University of Iowa's CAMBUS, has been historically free, another, Iowa City's Transit, started the free fare program in August 2023, and the third, Coralville Transit, kept the cost of \$1 per ride. While Iowa City is not the only US college town that offers free-fare transit service (e.g. Corvallis, OR, Chapel Hill, NC, among the others) the three-agency setting allows to establish the causal effect through the evaluation of changes in the same region. The underlying hypothesis is that Iowa City Transit routes received the 'treatment' (fares were reduced to 0), while nothing changed for CAMBUS and Coralville transit. Looking at the 2022-2024 ridership trends, the study confirms that even though some ridership growth can be attributed to the increase in the level of service (Pearson correlation $r(36)=0.58$, $p=0.0002$), it can likely be associated with the free fare policy as well, as ridership growth on Iowa City transit outpaced the expansion of service, and ridership change for the other two providers. The effects can be traced beyond fixed transit routes since paratransit services originating in Iowa City are also included in the free fare policy, and they saw an increase in demand greater than in the neighboring Coralville since August 2023. We also identified the route-level and time-specific factors, like demographic characteristics of the service area, quality of the built environment, and the weather that influenced transit ridership in the region between 2022 and 2024 using a multilevel regression modeling framework. Lastly, no significant changes to riders' perceptions of trip quality, safety, and crowdedness were detected when 2022-2024 responses from a survey collected from a sample of random users of smartphone transit trip planning application Transit was analyzed. Many US transit agencies are interested in the implementation of fare free programs (Saphores et al., 2020), and this study responds to that demand by providing empirical evidence on the impacts of such policy for operators, riders, and the community.

Toward Sufficient Access: Measuring Accessibility Poverty Through Perceived Accessibility

Abstract ID: 1844.0.0.1154.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Md Hamidur Rahman [The University of Texas at Austin] hamidur.rahman@utexas.edu, presenting author

Alex Karner [The University of Texas at Austin] alex.karner@utexas.edu

Access to essential destinations is a key determinant of well-being, yet current transportation planning and equity assessments continue to prioritize objective measures such as travel time or distance (Pot et al., 2021). These measures, while useful, often fail to capture the lived realities and subjective experiences of marginalized populations, including low-income, older, disabled, immigrant, and carless individuals. Recent literature has emphasized the need to center perceived accessibility as a means of identifying what constitutes sufficient access in specific contexts (Lättman et al., 2024; Pot et al., 2024). However, the link between perceived access, travel behavior, activity participation, travel satisfaction, and well-being remain underexplored, particularly in the U.S. context.

To address this gap, we have developed a national survey instrument that will be distributed to a planned sample of 400–500 participants using Qualtrics. The instrument targets transport-disadvantaged populations and explores perceived access to jobs, healthcare, groceries, social, and recreational destinations. Survey items include Likert-scale measures of perceived access, travel barriers, transport insecurity, attitude as well as travel adaptations and unmet activity needs. Drawing from the Capability Approach and theories of transport-related social exclusion this framework integrates both subjective and objective indicators. Data analysis will involve confirmatory factor analysis (CFA) to develop latent constructs of perceived accessibility, followed by structural equation modeling (SEM) to examine the links between perceived access, activity participation, travel satisfaction, and subjective well-being.

Although data collection has not yet commenced, the study anticipates identifying a set of meaningful associations between perceived accessibility and travel behavior outcomes. We expect findings to demonstrate that individuals who report low perceived access also experience reduced activity participation and lower life satisfaction—despite similar objective accessibility levels—thereby reinforcing the argument for context-specific, person-based thresholds for what counts as “sufficient access.”

This research has both theoretical and policy implications. It advances scholarly debates by proposing a refined, perception-based framework for evaluating accessibility poverty and transportation adequacy. In practical terms, it offers a new lens for identifying where and for whom transportation investments may be falling short.

Transit Agencies, Cities, and the Impact of Extreme Weather on Transportation Systems

Abstract ID: 1844.0.0.519.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Mahtot Gebresselassie [York University] mahtote@yorku.ca, presenting author

Dwayne Baker [Queens College, City University of New York] dwayne.baker@qc.cuny.edu

Climate-change induced extreme weather is catching cities and their public transit unprepared as the recent flooding in Toronto and super storms in New York City have demonstrated. Along with these storms, current research (e.g., Miao, et al., 2018) has shown transit system's vulnerability to extreme weather events. Thus, the need to have more adaptability and mitigation measures to combat extreme weather is imperative. Existing studies have found that perceived vulnerability, political ideology, and institutional capacity encourage transit agencies to plan for extreme weather change (Miao, et al., 2018) yet agencies largely focus on adaptation rather than mitigation (Giordono, et al., 2021). In either case, research suggests that policies are generally presented after extreme weather events. Our research thus asks: How are transit agencies and cities prepared to respond to the impact of extreme weather on transportation systems? We conducted a content analysis where we selected 100 North American cities and investigated whether their transit agencies or municipal governments have severe-weather related policies currently in-place and the extent of these policies as they relate to public transit. Preliminary findings in our qualitative research show that only roughly half of the transit agencies (and their host cities) have published plans addressing climate-change induced extreme weather. However, these plans vary greatly, with a focus on four dominant themes: 1) adaptation or resiliency – short-term or immediate responses to extreme weather (Dzyuban et al., 2022); 2) mitigation of climate change through proactive strategies; 3) adaptation, resiliency, and mitigation strategies combined in the document (Dzyuban et al., 2018); and 4) risk assessment (Jaroszweski et al., 2010) plans to develop plans in the future. We also found that transit agencies of larger cities tend to have plans that combine short-term and long-term strategies. As climate-change induced severe weather continues to impact cities and their public transportation systems, having such policies will be important for cities and transportation agencies. This research is relevant for cities, transportation agencies, planners, policymakers, and researchers.

Transportation Barriers and Residential Transitions to Assisted Living Among Older Adults

Abstract ID: 1844.0.0.680.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

SangO Kim [Lewis Center for Regional Policy Studies, UCLA] sangokim@ucla.edu, presenting author

Understanding the factors that influence the residential choices of older adults is critical as the United States is witnessing a significant demographic shift. By 2035, 21 percent of the US population will be 65 years and older. While most older adults strongly prefer age-in-place within their familiar community setting, they may increasingly encounter transportation barriers that limit their ability to engage in essential activities such as grocery shopping, receiving healthcare, and maintaining social connections. Additionally, age-related risks such as falls and accidents can further reduce their willingness to travel. In this context, moving to assisted living facilities can offer older adults a way to maintain independent mobility—through age-friendly design and on-site transportation services—while also reducing the need to travel for everyday necessities.

From this end, the study investigated whether experiencing transportation barriers influence older adults' decision to relocate to more transportation-supportive assisted living environments (e.g., residential care homes, lifespan communities, nursing homes, etc.), rather than continuing to age in place. Given the growing challenge of meeting the residential needs of older adults, a better understanding of how transportation—alongside other drivers of residential transition such as health status, financial resources, or housing quality—influences these decisions will provide valuable insights for policymakers and community planners.

This study draws on data from the National Health and Aging Trends Study (NHATS), a nationally representative longitudinal survey of Medicare beneficiaries aged 65 and older in the United States. NHATS's panel design enables the analysis of within-person changes over time while accounting for individual fixed effects. To assess the causal impact of transportation barriers on residential transitions, the study employed propensity score matching—a statistical technique that reduces selection bias by balancing observed covariates across treatment and control groups. Two subsamples were constructed: one consisting of older adults who transitioned into assisted living facilities, and another of those who continued aging in place. Using regression-based propensity scores, individuals in the two groups were matched on key social, demographic, and economic characteristics. The average treatment effect on the treated (ATT) was then estimated to determine whether past experiences of transportation barriers that limited participation in out-of-home activities significantly increased the likelihood of transitioning to an assisted living environment.

The findings show that prior experiences of transportation barriers significantly influence older adult's decision to move into assisted living environments. Additionally, variables such as gender, household structure (e.g., widowhood), and personal mobility limitations (e.g., reliance on a wheelchair) also play a role in moderating this relationship. Notably, older adults who experienced transportation barriers were more likely to relocate to facilities that offer more onsite services, such as shuttle services, accessible walking areas, or recreational amenities.

These findings offer practical implications for both public and private stakeholders. By evaluating community age-friendliness through a transportation lens, stakeholders can better anticipate future demand for assisted living. Moreover, the results can inform the development of targeted transportation interventions that not only support aging in place but also help address broader housing and care challenges in an aging society.

Travel Needs of South Asian Older Adult Women in Mid Size Canadian Cities

Abstract ID: 1844.0.0.911.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Bhavya Bogra [Queen's University] bhavya.bogra@queensu.ca, presenting author

The 2021 Canadian census reports that 2.5 million South Asian immigrants, from Bangladesh, India, Pakistan, Sri Lanka, and Nepal, make up 7.1% of Canada's total population. Of this group, women represent 48.5%, and the population continues to grow (Statistics Canada, 2021). This growth warrants developing clear understanding of South Asian immigrant population's settlement needs and its policy implications, particularly transportation challenges they face in reaching locations of their desired activities. The travel behavior of South Asian immigrants is influenced by traditional norms and gendered roles that often assign driving responsibilities to men, thereby limiting women's mobility (Shafi et al., 2023). Older women aged 65 and above face significant mobility barriers due to poor health, low income, and limited technological skills (Ozbilen et al., 2022). Therefore, this study investigates the local transportation needs of South Asian older adult women in Canada and the challenges they face in meeting those needs.

The research focuses on mid-sized cities, which are experiencing the most rapid growth of older adult population (Hartt & Biglieri, 2018). Kingston, Ontario, with a total population of 132,485 in 2021, is indeed midsized and has a considerable proportion of older adult women, making upto 12.0% of its total population, alongside a large significant South Asian population (Statistics Canada, 2021).

The paper uses primary qualitative data gathered from semi-structured interviews, where participants shared insights into their daily activity patterns, transportation needs, difficulties in organizing trips, unmet transportation needs, and the underlying factors contributing to these challenges. The interview data was thematically coded and analyzed using NVivo software. Initial findings from the interviews suggest that older adult women who immigrated to Canada in recent years experience greater transportation challenges. These difficulties are primarily due to their unfamiliarity with local transportation systems and more significant language barriers, in contrast to those who arrived earlier and have since adapted to the car-dependent culture.

Giovanni Circella [Ghent University] gcircella@ucdavis.edu

The COVID-19 pandemic significantly disrupted daily routines by altering commuting patterns, social interactions, access to public spaces, and physical mobility outside the home. Vulnerable populations, such as older adults, individuals with disabilities, and those from low-income households, faced disproportionate constraints on their mobility and activity participation, particularly during the early stages of the pandemic (Batur et al., 2023; Hasson et al., 2022). These challenges were further exacerbated by disparities in access to digital infrastructure, as reliable internet connectivity became essential for maintaining many aspects of daily life. Given that certain groups encountered substantial barriers to engaging in both essential and non-essential activities due to geographic and digital limitations, it is critical to reassess post-pandemic activity participation patterns using the most recent data. To that end, the current study addresses this gap by investigating how individuals engage in daily activities using data from the 2023 wave of the California Mobility Panel, a comprehensive survey capturing travel behavior, mobility preferences, and transportation barriers, across diverse California households (for more detailed information about the survey, please see Ozbilen et al., 2024). We examine how socio-demographic factors, mobility limitations, psychological attitudes, online activity participation, and neighborhood characteristics affect engagement in discretionary activities (e.g., attending concerts, meeting friends, or exercising outside) and utilitarian activities (e.g., running errands, attending regular non-work meetings such as church or social club gatherings) in the post-pandemic context.

We employ Latent Class Cluster Analysis (LCCA), a method widely applied in prior travel behavior studies (Liu et al., 2021; Rafiq & McNally, 2021), to identify four distinct activity participation groups: Moderately Active, Low-key Engaged, Physically Active, and Socially Engaged. The Moderately Active group represents individuals with average levels of engagement in both discretionary and utilitarian activities, reflecting a balanced activity pattern. The Low-key Engaged group, which includes a large share of older adults, is characterized by high levels of mobility limitations, financial hardship, and negative attitudes toward both driving and active travel, and has the lowest levels of activity participation. In contrast, the Physically Active group also includes many older adults but is defined by positive attitudes toward active lifestyles and frequent participation in physical activities, despite less engagement in social events. Both the Low-key Engaged and Physically Active groups predominantly reside in suburban areas, though the latter tend to live in neighborhoods with higher walkability scores, which may reflect broader differences in built environment and infrastructure quality. The Socially Engaged group, who are typically younger, higher-income, and urban residents, exhibited the highest frequency of social activities. Online activity participation also varied across clusters, with those who were more socially and physically active also reporting higher levels of online engagement, suggesting that digital participation may complement out-of-home activities rather than replace them.

This study contributes to planning scholarship by integrating travel behavior, mobility challenges, and activity participation frameworks to examine persistent post-pandemic disparities in California. Our analysis shows that individuals with mobility limitations and financial hardship are less engaged in out-of-home activities, highlighting how both physical and economic barriers contribute to reduced participation in daily life. These constraints are more pronounced for those in low-density, car-dependent neighborhoods with limited pedestrian infrastructure. Additionally, attitudinal factors, such as being pro-environment or pro-active, are associated with greater activity participation. The findings offer an important post-pandemic baseline for understanding persistent disparities in activity participation and identifying priorities for inclusive transportation and land use strategies. For planning practice, this calls for coordinated interventions: improving walkability in suburban neighborhoods, enhancing affordable travel options to reduce financial barriers, and supporting access to both digital and physical forms of participation in daily life.

Understanding Driverless Taxi Adoption and its Impacts on Travel Behavior

Abstract ID: 1844.0.0.357.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Seung Eun Choi [Georgia Institute of Technology] schoi473@gatech.edu, presenting author

Patricia Mokhtarian [Georgia Institute of Technology] patmokh@gatech.edu

The advent of driverless taxi services, such as Waymo, is beginning to mark a transformative shift in urban transportation. These services promise cleaner air, reduced traffic congestion, enhanced safety, connection to public transit and progress toward climate goals by delivering fully autonomous electric vehicle trips (<https://waymo.com/sustainability/>). Despite the benefits, integrating driverless taxi services into existing urban environments also poses considerable challenges. These include adapting urban infrastructure, establishing regulatory frameworks to address liability, safety standards, and data privacy, and promoting sustainable urban design (Wann, 2024; Orieno et al., 2024). Considering both the potential benefits and these integration challenges provides strong motivation to more deeply investigate the behaviors and intentions of driverless taxi users and non-users.

While some individuals have embraced these services, others remain hesitant due to safety concerns, unfamiliarity, or the novelty of the technology. Studies have shown that prior exposure to partial automation features, such as adaptive cruise control or automated parking, is positively associated with trust and favorable attitudes toward fully automated systems. However, negative experiences, such as drops in automated steering support, can lead to decreased trust and lower perceptions of system performance (Haus et al., 2023). Given that most recent-vintage vehicles now include some level of advanced driver assistance systems (ADAS), it is useful to capture attitudes toward fully automated vehicles in the context of these partial automation experiences.

Accordingly, this research seeks to address these significant questions by investigating the adoption and non-adoption of driverless taxis, with a particular focus on workers in Phoenix, San Francisco, and Los Angeles. Employing an extensive survey of approximately 1,700 workers, the study targets both users and non-users, gathering considerable data on actual and hypothetical behaviors, socio-economic and demographic profiles, job characteristics, travel patterns, and attitudes toward driverless taxis. The analysis will apply descriptive and inferential statistics to identify adoption profiles, behavior patterns, and regional variations.

This study's wide-ranging analysis of explanatory and outcome variables, alongside cross-regional comparisons, offers valuable insights into the factors shaping driverless taxi adoption. The results will help urban planners, policymakers, and transit authorities make better-informed decisions about the continuous growth and extension of driverless taxi services, ensuring such innovations' sustainability, accessibility, and efficiency within urban transportation systems. Furthermore, insights into adoption barriers will guide targeted infrastructure and service improvements, fostering equitable, efficient, and resilient urban mobility.

Unequal Access: Analyzing Transit Deserts and Mobility Challenges in Oklahoma City

Abstract ID: 1844.0.0.369.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Tahsin Tabassum [University of Oklahoma (Norman, OK)] tahsin.tabassum-1@ou.edu, presenting author

Ladan Mozaffarian [University of Oklahoma (Norman, OK)] ladan.mozaffarian@ou.edu

Junfeng Jiao [University of Texas at Austin] jjiao@austin.utexas.edu

Urban public transportation systems are crucial for ensuring equitable access to employment, education, and healthcare. However, many fast-growing cities, face gaps in transit infrastructure that disproportionately affect low-income communities, older adults, youth, and people without reliable access to automobiles (Jiao & Dillivan, 2013; Lubitow et al., 2017). These inequities often manifest as “transit deserts,” where demand for public transportation exceeds supply, impeding personal mobility for transit-dependent groups (Jiao, 2017). Compounding the issue is the Oklahoma city’s historically car-centric development, which has led to service gaps and inefficiencies within its public transit network. The consequences are particularly significant in a sprawling urban environment like Oklahoma City, whose limited transit coverage exacerbates socioeconomic and racial disparities (Census Bureau, 2022; OKDOT, 2023). Building on the city’s existing transportation challenges, this study’s overarching aim is to quantify and address transit deserts in Oklahoma City. Specifically, its primary objective is to evaluate the degree to which public transportation supply aligns with the needs of residents at the block group level. To guide this evaluation, we aim to address two primary research questions: 1) Which neighborhoods in Oklahoma City exhibit the largest discrepancies between transit demand and supply? And 2) How effectively does current transit infrastructure respond to the needs of transit-dependent populations, particularly in socioeconomically disadvantaged areas?

This study employed geospatial techniques. First, publicly available datasets such as the U.S. Census for demographic and socioeconomic indicators, General Transit Feed Specification (GTFS) files for transit routes and stops, and OpenStreetMap for street network data were collected and merged. Transit demand was quantified by calculating the number of transit-dependent individuals, defined as those lacking access to private vehicles, younger than 18, older than 65, or living below the poverty line. Transit supply was assessed using multiple metrics, including the density of transit stops, routes, intersection density, sidewalk coverage, bike lanes, road speed limits, and weekday service frequency. Each metric was standardized (z-score) and aggregated to produce a composite supply index, which was then subtracted from the composite demand index to reveal transit gaps across 725 block groups in Oklahoma City.

The findings indicate that approximately 13.24% of Oklahoma City’s total population, about 91,989 residents are transit-dependent. While downtown areas exhibit relatively robust transit coverage, over 70% of block groups experience higher demand than available transit services, creating pronounced “transit deserts” outside the urban core. These gaps overwhelmingly coincide with lower-income, racially diverse neighborhoods, underscoring persistent transit inequities.

Policy recommendations emerging from this study emphasize equity-driven interventions. Specifically, expanding transit routes to underserved regions, reevaluating suburban land use to incorporate transit-focused planning, and revisiting funding mechanisms that currently favor higher-income or more centrally located neighborhoods could substantially improve access. Community engagement is also essential: consulting residents can guide decisions on practical needs like wheelchair-accessible stops and extended service hours.

Overall, the spatial mismatch between transit supply and demand in Oklahoma City underlines the urgency of more inclusive mobility strategies. By pinpointing areas with the most severe service gaps, this research offers a roadmap for policymakers to direct investments, reduce socioeconomic divides, and strengthen urban sustainability. Such measures not only support vulnerable populations but also contribute to broader goals of economic vitality and community well-being.

Unlocking the Future of Curbs with Autonomous Vehicles? Exploring Incentives for Smarter Use.

Abstract ID: 1844.0.0.920.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

William Riggs [University of San Francisco] wriggs@usfca.edu, presenting author

As cities grow, the curb has emerged as one of the most contested and underutilized urban assets. Traditionally dedicated to long-term vehicle parking, curb space is now in high demand from many sources. This study explores how policy reform, technology integration, and incentive-based strategies can be employed to reimagine and reallocate curb space in ways that promote efficiency, equity, and sustainability. Drawing on over 20 expert interviews and in-depth analysis of curb management policies from leading global cities—including San Francisco, Seattle, Lisbon, Amsterdam, and Barcelona—the study identifies key themes shaping the transition toward more dynamic and high-value curb use.

Findings indicate that cities making the greatest progress in curb optimization deploy demand-responsive pricing, digital permitting systems, and real-time data collection to better match curb use with actual demand. However, implementation challenges persist due to political resistance, fragmented interagency governance, limited enforcement capabilities, and an overemphasis on private vehicle storage. A central contribution of the study is the reexamination of demand-based parking pricing models, building on the foundational economic theories that have historically guided curb policy.

While these models advocate for efficient parking turnover through market-based pricing, the study finds that such frameworks often conflict with contemporary curb needs—particularly the high frequency and short-duration demands of passenger pick-ups and drop-offs (PUDO), freight deliveries, and micromobility activity. These tensions call for a hybrid curb strategy, incorporating time-based curb reallocation, short-term access pricing, and digital reservation tools that prioritize turnover and multimodal accessibility over static parking. Quantitative modeling in the study illustrates the potential for cities to generate greater revenue and improve service quality by transitioning away from fixed parking fees to dynamic curb access charges. Cities like Washington, D.C. and Lyon have piloted innovative programs—such as geofenced loading zones and weight-based curb pricing—that have demonstrate the feasibility of aligning economic incentives with sustainable curb use.

The role of data standardization is also addressed in detail. Tools like the Curb Data Specification (CDS) and General Transit Feed Specification (GTFS) offer cities a foundation for integrating enforcement, pricing, and curbside coordination across multiple transportation modes. However, the study cautions against relying solely on data as a proxy for action. Experts interviewed repeatedly emphasized that while real-time, high-granularity curb data is essential, cities often become mired in perpetual data collection without implementing the policy changes that data is meant to inform. Instead, the study advocates for a balanced approach—leveraging data to support decision-making.

In sum, recommendations from the study fall under three core domains: policy, technology, and behavioral change. Policy reforms include shifting curb space from vehicle storage toward high-turnover uses that promote economic activity, safety, and shared mobility. Technological solutions include AI-enabled enforcement, digital permitting, and dynamic pricing platforms. Behavioral change strategies involve public education campaigns and re-framing the curb as a public asset for access and movement rather than static parking. Ultimately, the study concludes that the curb represents one of the most valuable and under-managed resources in the urban mobility ecosystem. And

unlocking its full potential will require cities to embrace a multimodal framework that reflects modern transportation needs.

Unpacking the Micro-Politics of Everyday Neurodivergent Mobility Practices for Inclusive Transport

Abstract ID: 1844.0.0.1108.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Samantha Leger [University of Waterloo] sjleger@uwaterloo.ca, presenting author

Jennifer Dean [University of Waterloo] jennifer.dean@uwaterloo.ca

Ensuring equitable and inclusive built environments is one of the central pressures for modern urban planning. Across planning disciplines, historically unjust practices are being interrogated and reimagined to acknowledge and address systemic racism, sexism, genderism, and ableism. Yet, how planners can do so is an inherently reflective process, as we continue to learn and unlearn what is both helpful and harmful to historically marginalized groups. For example, some historic accommodation measures for people with disabilities would minimize or negate their dis/abilities, which led to enduring ableism even in well-intentioned efforts. However, more recent advancements in disability planning instead center dis/abled needs and voices in how we plan, electing to value difference rather than minimizing it (Stafford et al., 2022).

Despite these ongoing advancements in the societal understanding of disability, there has remained a gap in how urban planning has wrestled with ableism, especially in transportation planning practices. Too often, transportation planning will elect a 'one size fits all' approach to disability planning, which fails to engage with the nuanced and embodied experiences of getting around with dis/ability (Levine & Karner, 2023).

To respond to this gap, this session discusses the sensorial and affective experiences of neurodivergent adults navigating and negotiating everyday mobility practices. As a form of cognitive difference, neurodivergence is known as an 'invisible disability'; one which is not immediately seen by those who do not live it. Invisible dis/abilities challenge the often-expected binary of ability which expects bodies and minds to either be 'abled' or 'disabled'. Neurodivergence (and other invisible dis/abilities) accentuate the constantly fluid and relational spectrum of dis/ability and uncover the 'hiddenness' of navigating space when differently abled, but not visibly disabled (Toronyi, 2019).

Fundamentally, this work sits at the intersection of critical dis/abilities and the politics of mobility, utilizing a framework of mobility representation and practice (De Certeau, 1984; Cresswell, 2010) to understand 1) what are the embodied and affective experiences of neurodivergent mobility practices and 2) how do such practices (re)form experiences of the self, of landscape, and the act of getting around.

This study was conducted through a grounded-theory analysis of 30 qualitative and semi-structured interviews with neurodivergent adults (those who identify as either Autistic or with Attention Deficit and Hyperactivity Disorder (ADHD), or both) who actively travel in their everyday lives and live in Ontario, Canada. Our findings revealed a diverse set of commuting and travel behaviours and preferences, but despite this heterogeneity across mode preferences for everyday mobility practices, the in-depth sensorial and affective analysis revealed parallels within the micro-politics of decision-making that were intrinsically tied to navigating and negotiating space whilst neurodivergent. Specifically, we found that people who are neurodivergent seek out commuting and everyday travel practices that allow them to construct a sense of predictability, agency, and interest. Such insights allow us to form recommendations about how to more meaningfully accommodate pluralistic perspectives of dis/ability in inclusive transportation strategies. We conclude with a call for transportation planning efforts to acknowledge the relational and affective experiences of dis/ability and move away from blanketing interventions which fail to

acknowledge the diversity and plurality of the differently and dis/abled populations, including those who think, feel, and process information differently.

Urban Mobility and Time Poverty in the Lives of Bronx Home Care Workers

Abstract ID: 1844.0.0.753.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Soojung Han [Cornell University] sh935@cornell.edu, presenting author

Every day, home health aides in the Bronx navigate unreliable and fragmented public transportation to reach their clients across New York City. These workers, predominantly low-income women of color and immigrants, play a vital role in sustaining the well-being of Medicaid recipients in the Bronx, enabling them to stay in their community, travel to medical appointments, and maintain independence. Despite the critical role they play, home health aides endure significant transportation inequities that compound their precarious working conditions, characterized by unpredictable work schedules, unreliable transit, and the physical and emotional strain of lengthy commutes.

This project is conducted in collaboration with two organizations at the forefront of advocating for home care workers' labor rights, Cooperative Home Care Associates (CHCA) and 1199SEIU. The research draws on two complementary qualitative methods. First, I conducted ethnographic fieldwork with 30 home health aides living and working in the Bronx, focusing on their experiences navigating transit and managing care responsibilities. Second, I carried out 15 go-along interviews with a subset of these aides, accompanying them during their commutes to capture real-time observations of how transportation access shapes their daily schedules, mobility patterns, and time management strategies.

My findings show that public transit fails to accommodate the home health aides' nonstandard commutes and travel to spatially dispersed residential locations. Health aides often navigate long wait times, multi-modal transfers, and "trip-chaining" routines that incorporate caregiving duties at work and at home—further extending their workday and heightening their temporal precarity. Many aides report building their lives around transit inefficiencies, such as leaving hours earlier or accepting fewer shifts to avoid impossible commutes.

By foregrounding the lived experiences of mobile home care workers, my research contributes to a growing literature on mobility justice, gendered commutes, and the spatial politics of care work. I argue that planning discourses must extend beyond metrics of accessibility or ridership to consider how transportation systems support or undermine the conditions of care as an essential service in the city. This study calls for planning approaches that center care infrastructure and integrate the needs of feminized, racialized and classed labor force into urban mobility systems.

Urbanization, Electric Vehicles, and the Environmental Kuznets Curve

Abstract ID: 1844.0.0.567.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Ji Soo Kim [Korea Advanced Institute of Science & Technology] jk1577@kaist.ac.kr, presenting author

The Environmental Kuznets Curve posits an inverted U-shaped relationship between economic development and environmental degradation, where emissions rise in the early stages of growth but decline as economies mature. Urbanization has often been viewed as a juxtaposition to this trajectory, as densely populated cities tend to experience sustained emissions growth. This study, however, challenges that view by investigating how electric vehicle adoption, charging infrastructure expansion, and economic growth in U.S. cities contribute to the Environmental Kuznets Curve. Using zip code-level data across the U.S. spanning two decades, spatial logistic regression analyses reveal that while the early introduction of charging infrastructure—concentrated in urban areas—initially correlates with higher emissions, the widespread adoption of electric vehicles leads to a substantial reduction in on-road carbon emissions over time. These findings challenge prior assumptions that urbanization hinders the Environmental Kuznets Curve, suggesting instead that well-planned electric mobility solutions may accelerate the transition to the environmental improvement phase of the curve. Based on these results, the study offers a framework for how cities can leverage electric vehicle adoption to drive both environmental improvement and economic growth. These insights contribute to the broader discourse on how cities can reshape their environmental trajectories and transition toward more sustainable development pathways.

User Perspectives on Fare-Free Transit: Rider Experience and Factors Influencing Continued Use

Abstract ID: 1844.0.0.722.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Joel Mendez [University of Kansas] jmendez2@ku.edu, presenting author

Fare-free transit policies have garnered significant attention in the United States, with many major transit service providers considering their adoption. The elimination of fares is viewed as a way to eliminate barriers towards use and increase patronage. However, some argue that service improvements—such as increased frequency, expanded service areas, and enhanced reliability—may have a greater impact on attracting and retaining riders. This raises important questions about the most effective approach transit providers should take to achieve sustained ridership growth. Should agencies prioritize fare elimination, or would investments in service quality yield greater long-term benefits?

This study explores the experiences of bus riders in the Kansas City metropolitan area following the implementation of a fare-free transit policy. By examining the perspectives of transit users, this research seeks to answer two key questions: (1) What has the experience of riders been since the implementation of fare-free transit? and (2) What factors are most influential in contributing towards continued use of transit for transit users? How experiences vary based on socio-demographic characteristics is explored. Through the administration of surveys with bus users, the study investigates both the benefits and challenges of fare-free transit, including accessibility, service reliability, safety, and rider satisfaction. While the removal of fares has reduced financial barriers towards use, findings suggest that other factors play a crucial role in determining whether passengers continue to use transit. Understanding these influences is essential for transit agencies aiming to sustain and grow ridership.

Central Theme: This study investigates whether small-scale enhancements to public transportation infrastructure can influence people's travel behaviors. While urban governments have extensively evaluated the impacts of large-scale investments—such as new metro lines, expressways, cycling and pedestrian paths, and provisions of shared bikes or e-scooters—less attention has been paid to minimal yet potentially impactful interventions at the peripheries of transit journeys. Singapore has substantially invested in the public transit infrastructure. A notable initiative to improve first- and last-mile connectivity in Singapore is the sheltered walkway system, providing overhead shelters along pedestrian walkways connecting public transit hubs (such as bus interchanges and train stations) to many surrounding residences and facilities for public use. The primary objectives of setting up the system are to enhance walking convenience and encourage more walking trips to transit hubs rather than relying on other transport modes to finish such short trips. In this context, the main research question in this study is whether sheltered walkway connections increase the share of walking in urban residents' first- and last-mile trips to and from transit hubs.

Methodology: We employ a Difference-in-differences (DID) model for a stepwise analysis. First, using bus stop-level traffic data (tap-in and tap-out counts from farecards) from September 2022 and 2023, we examine whether the introduction of sheltered walkways affects transit usage at bus stops located several stops away from major transit hubs. Second, using the 2012 and 2016 waves of the Singapore Household Travel Survey (HTS), we explore changes in local travel behavior—specifically, whether residents walk more and use other transport modes less after gaining access to the sheltered walkway network.

Findings: Preliminary analysis of bus stop-level data suggests that sheltered walkways reduce short-distance bus trips, with an average decrease of 2.7% in tap-ins and 3.4% in tap-outs in bus stops within five stops from public transit hub stations. This effect is most pronounced at bus stops two to three stops from nearby hub stations—within typical walking distance (0.8 to 1.7 km)—and fades beyond this range. HTS data further indicate that the availability of sheltered walkways leads to increased walking, both as the primary mode of travel (increases by 4.4%) and as the first-mile mode (increases by 3.7%), particularly during off-peak and evening peak hours. More substantial effects are observed among individuals living within 1.6 km of a transit hub.

Implications for planning practice: These findings contribute to the literature by providing empirical evidence on the effectiveness of small-scale transit infrastructure improvements in shaping travel behavior and enhancing public transit efficiency. Practically, the results offer valuable insights for future expansions of Singapore's sheltered walkway network and suggest that similar initiatives could be beneficial in other high-density urban contexts worldwide—supporting active mobility, improving public transit performance, and fostering healthier cities.

What Do Workers Do on Remote-Only Workdays with Time Saved from Not Commuting?

Abstract ID: 1844.0.0.886.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Yongsung Lee [University of California, Davis] yshlee@ucdavis.edu, presenting author

This study examines a crucial yet underexplored factor influencing post-pandemic teleworking: the differences in activities and travel patterns between remote-only and in-person workdays for the same individuals. By analyzing how workers allocate their time and trips across these two work settings, we can uncover underlying motivations for sustained telework. These insights can inform planning and policy efforts to promote sustainable transportation.

Key questions include:

1. How much time do hybrid workers save on remote-only workdays by not commuting?
2. Do hybrid workers make more non-work-related trips on remote-only workdays than on in-person workdays to handle personal responsibilities or due to cabin fever? If so, who are they in terms of personal, household, attitudinal, and built-environment attributes?
3. Do hybrid workers make fewer non-work-related trips on remote-only workdays by chaining such trips with their work-related trips on in-person workdays? If so, who are they in terms of personal, household, attitudinal, and built-environment attributes?
4. How do these strategies influence travel behavior, particularly the use of private vehicles and alternative travel options? To what extent do various factors (e.g., built-environment attributes at home and workplace) explain these travel outcomes?

This study leverages the latest wave of the California Mobility Panel, a series of transportation surveys conducted in a consistent structure since 2018. This panel has been instrumental in tracking and analyzing evolving travel behavior trends, focusing on California residents. The most recent survey wave (N=6,469) was administered from August 2023 to January 2024 and collected comprehensive data on various factors influencing travel behavior. Key variables in this study include differences in time use for the same individuals between a typical remote-only workday and an in-person workday. The survey first estimates the maximum amount of time saved from not commuting (including two-way travel and personal grooming time) and then asks respondents whether they engage more or less in a set of out-of-home activities and associated trips on a remote-only workday, inspired by the American Time Use Survey. To examine heterogeneity in remote-work-facilitated differences in activity and travel patterns, we employ latent-class cluster analysis (LCCA) on a sample of hybrid workers (N=854) who typically commuted to work and worked remotely at least once a week for both.

Preliminary results identify four latent classes, each exhibiting unique behaviors on remote-only days compared to in-person workdays. Older adults are more likely to fall into the About the same category (30.8%), while lower-income individuals are overrepresented in the Less on most activities category (12.3%), likely indicating that they consolidate activities on commute days to reduce travel costs. Those living with children are more likely to be in the More on most activities category (30.6%), suggesting they use remote days to balance work and personal responsibilities. Interestingly, individuals who prefer cycling, lead physically active lifestyles, and favor urban

environments are likely to fall into the More on three activities category (26.4%), indicating a lifestyle-driven choice to engage in more out-of-home activities on remote days.

In sum, this study identifies distinct ways in which teleworking influences activities and non-commuting trips, shedding light on the ways workers utilize time saved on remote-only workdays. These findings provide in-depth insights into the motivations for teleworking and its implications for local and regional travel patterns.

What Drives Online Food Delivery? Evidence from Mobile App Engagement Data

Abstract ID: 1844.0.0.1080.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Jaehyun Ha [University of Southern California] jaehyunh@usc.edu, presenting author

The rapid growth of online food delivery platforms is reshaping how people access prepared meals in U.S. cities, with wide-ranging implications for food access, land use, and transportation systems. As delivery demand increasingly influences urban traffic patterns, curb space competition, and last-mile logistics, understanding the behavioral and spatial drivers of this shift has become critical for transportation planning and policy. Yet, despite the expanding role of delivery services in everyday life, we know relatively little about who uses these platforms and under what conditions—particularly with respect to neighborhood context and equity. This study addresses that gap by identifying demographic and spatial disparities in online food delivery app usage.

To measure engagement with online food delivery, I construct a behavioral proxy using mobile app activity data from Global Wireless Solutions, which captures interactions from over 40,000 individuals across the United States. Although direct, disaggregated measures of food delivery demand are unavailable, this dataset offers an indirect but meaningful approximation through daily app access patterns. I track individual-level usage of leading delivery platforms—Uber Eats, DoorDash, Grubhub, and Postmates—by counting the number of distinct days on which each user accessed one or more of these apps. This approach captures variation in delivery-related behavior and reflects repeated interactions throughout the ordering and delivery process.

The explanatory framework incorporates a broad set of individual, temporal, environmental, and spatial variables. Individual-level controls include demographic attributes (e.g., age, gender) and indicators of general daily activity. Temporal controls account for day-of-week variation, while environmental conditions are captured via a weather-based indicator of unbenign travel conditions. To reflect physical food access, I include measures of accessibility to restaurants by walking 15 minutes. At the neighborhood level, I account for population density, income, and racial composition to assess how socioeconomic context influences delivery behavior. Finally, I control for relative location by measuring the distance to the nearest subcenter.

The analysis proceeds in two stages. First, I conduct a descriptive analysis to examine patterns in delivery app usage across individuals, geographic regions, time (days and months), and platforms. This includes identifying dominant app providers across space. Second, I estimate regression models using a high-resolution panel dataset in which each observation represents a user-day in 2023. These models assess how online food delivery engagement varies with demographic, spatial, and environmental factors.

The results show that younger and more mobile individuals are significantly more likely to engage with delivery apps, particularly on weekdays and during inclement weather. App usage is highest in dense, high-income neighborhoods, while lower-income and majority-minority neighborhoods exhibit lower levels of engagement—even after accounting for physical restaurant accessibility. Distance from employment subcenters is positively associated with usage, pointing to more delivery demands in peripheral locations. As certain populations reduce their physical travel and increasingly rely on online access to food, equitable access to digital infrastructure becomes a critical dimension of food accessibility. Recognizing who depends on these services—and under what conditions—can help planners address emerging disparities in the evolving urban food landscape.

What is a “Successful” System for Funding Transportation? Lessons from Ontario, Canada

Abstract ID: 1844.0.0.418.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Matthias Sweet [Toronto Metropolitan University (formerly Ryerson)] matthiassweet@torontomu.ca, presenting author

Murtaza Haider [Toronto Metropolitan University (formerly Ryerson)] murtaza.haider@torontomu.ca

Victor Copetti [Toronto Metropolitan University (formerly Ryerson)] vcopetti@torontomu.ca

Few transportation professionals are excited about the prospects of spending their careers producing plans for infrastructure which will never be built. Understanding the conditions under which plans can become reality is therefore of central interest to transportation planners. Understanding transportation funding policy is critical not only to transform “good” projects into reality, but also as a gatekeeping process to limit “bad” projects. Moreover, historic transportation funding sources are becoming less reliable, considering dramatic geopolitical policy uncertainty and increasingly fuel-efficient vehicles and changing technologies (Hajiamiri and Wachs, 2010). Understanding both current systemic funding forces’ influences on transportation investments and structural changes is critical towards transportation planners to shape how programs become realities.

By focusing on a case study of Ontario, Canada, which is in the process of a generational investment in transit infrastructure (Mok et al., 2025), this study illustrates opportunities for addressing these challenges. Ontario’s policy shift was spurred by the increased provincial role in transit capital funding and supportive policies, but its success depends on future provincial governments continuing to prioritize transportation investments. With a slowly increasing Canadian federal role, there are also new funding opportunities. Looking forwards, municipalities lack transportation funding options and instead rely on the funding priorities of the provincial political process (Kitchen, Slack, and Hachard, 2019).

This case study uses a policy assessment lens which builds upon Patton et al. (2016) and explores the dimensions of efficiency, equity, efficacy/feasibility, and environmental sustainability. The novel empirical contributions of the case study relate to answering two questions: 1) what is a “success” in the space of designing transportation funding policy? and 2) what action may be taken towards better “success” in Ontario’s system of transportation funding?

This study adopts a qualitative research approach involving experts in transportation policy and funding in Ontario. First, as part of a broader research initiative (since fall 2023), key planners and policymakers embark upon a process of co-education, through which presentations are delivered by different group members related to organization-specific transportation funding considerations. Organizations include federal, provincial, municipal, and non-profit organizations representing transportation and urban fiscal policy interests. Second, expert interviews are conducted (between January and March 2025) with 23 individuals representing these organizations as well as others, including select private sector consultants. Interview questions focus on areas related to experts’ roles and knowledge of transportation funding, policy formulation and assessment, technical and political feasibility, and key guidance for policy success. Findings are distilled and circulated to interviewees through a co-learning process. Third, a series of three focus groups (in April 2025) are conducted, where lessons from the interviews are shared with participants. A menu of policy options is identified before the focus group engagement is used to prioritize elements of past and potential future success in how Ontario funds transportation infrastructure. Findings are presented based on broad thematic analysis and based on coding using both inductive and deductive approaches. Ontario, Canada represents a unique policy context in that it is currently undergoing a

generational shift in public transit investment and broader sustainability-oriented policy priorities. Nevertheless, findings from this empirical case study provide guidance for other policy contexts on how to design transportation funding in a way which better serves broader planning and policy goals.

When Do Workers Hit the Road? Exploring Post-Pandemic Travel Timing in the U.S.

Abstract ID: 1844.0.0.867.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Fariba Siddiq [UCLA Institute of Transportation Studies] fsiddiq@ucla.edu, presenting author

The COVID-19 pandemic profoundly altered the landscape of work, leading to the widespread adoption of remote and hybrid work arrangements. The significant shift to remote and hybrid work may offer potential benefits such as reduced peak-period travel, lower levels of traffic congestion, and greater flexibility in the timing of travel. Indeed, pre-pandemic research shows a tendency to avoid peak periods among workers with flexible work arrangements (Lachapelle et al., 2018; Stiles & Smart, 2021). However, the share of people with flexible work arrangements was quite small before the pandemic (5.7%). This figure tripled by 2021, and remained significantly higher (15.2%) in 2022 than pre-pandemic levels (Burrows & Burd, 2024).

With such a substantial increase in remote and hybrid workers, there is evidence that peak-hour congestion has changed in many places (Speroni et al., 2024). Given that congestion is a non-linear phenomenon, the effect of even modest changes in commuting can have outsized effects on traffic delays. However, reduced delays can have their own rebound effect, whereby the new lower time cost of peak travel can attract more travelers onto newly decongested roads (Downs, 2005). This effect may be particularly true for workers in jobs with flexible work arrangements, who are less spatially and temporally bound by their work than traditional commuters. On the one hand, workers with flexible work arrangements can choose to avoid peak hours, either by shifting their daily commutes out of peak periods or/and by scheduling non-work-related trips during off-peak times (Lachapelle et al., 2018). On the other hand, they may choose to schedule their non-work-related trips during peak periods because of their flexible work schedules and reduced (real or perceived) peak period congestion.

Which one of these scenarios holds sway over the other? Do workers with flexible work arrangements have similar trip-making patterns as traditional commuters during different times of the day in the post-pandemic era, or do they travel less during peak periods than traditional commuters as the pre-pandemic research suggests? To answer these questions, I examine the timing of travel of U.S. workers using data from the 2022 National Household Travel Survey. I analyze the share of trips made during the morning peak (6 AM – 9 AM), midday (9 AM – 4 PM), the afternoon peak (4 PM – 8 PM), and evening and overnight (8 PM – 6 AM) by workers in various work arrangements descriptively. I also estimate four Poisson models for each time period to predict the count of trips taken during the respective time periods with the total number of trips taken during the travel day as the offset.

I find that controlling for other factors associated with the timing of travel, remote and hybrid workers make a smaller share of their trips during peak periods compared to traditional commuters and a larger share of their trips during the middle of the day in the post-pandemic era. On average, traditional commuters make the highest number of trips during the afternoon peak period, whereas hybrid workers and fully remote workers make their highest number of trips during the middle of the day.

With the surge of remote and hybrid workers coming out of the pandemic, planning and policy efforts must focus on adjusting road management policies (such as the timing of peak periods, and curb-adjacent travel lanes) and public transit schedules to reflect new patterns in the timing of travel demand.

When the Wheels Stop Turning: Impacts of School Bus Service Unreliability on Children and Families

Abstract ID: 1844.0.0.919.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Tabitha Combs [University of North Carolina at Chapel Hill] tacombs@live.unc.edu, presenting author

Matthew Palm [University of North Carolina Chapel Hill] palmmatt@unc.edu

In January, 2024, the Durham (North Carolina) Public School system (DPS) experienced significant disruptions in school bus services for a period of two weeks due to a pay dispute among school bus mechanics. These disruptions resulted in children arriving multiple hours late for school, waiting multiple hours after school for a ride home, and in many cases, missing school altogether. A small but growing body of literature suggests that reliable school bus services enhance educational outcomes in the US, particularly in non-rural areas (Hopson et al., 2022), and significantly reduce chronic absenteeism among students, with the greatest effects among students from economically disadvantaged backgrounds (Edwards, 2023).

This paper presents the findings from a survey of 525 DPS families, seeking to examine the impact of household resources and infrastructure availability on families' ability to adapt to the unexpected changes and uncertainty around school transportation and attendance. The survey, which was adapted from the National Center for Safe Routes to Schools parent survey, also documented immediate impacts on children's school attendance, activity participation, and access to school-based and on parents' work schedules and financial stability. The survey also included sociodemographic questions, allowing us to identify differential impacts of the bus service disruptions by race and income. The survey was introduced at the end of January, 2024—just as the bus service disruptions were resolving—allowing us to capture data on the disruptions' impacts on families while the events were still fresh in their minds.

We analyze quantitative survey data using R, while qualitative open-ended responses are thematically coded using a grounded theory approach. Our preliminary findings suggest that non-white students and students from low-income households were significantly more likely to miss instructional time and meals due to the disruptions. Over two-thirds of students who rode the bus regularly before the disruption decreased their reliance on the bus; with the majority of students switching to a family vehicle as their primary mode to school; open-ended questions indicate this switch increased financial burdens on families and decreased safety in school drop-off zones. Additional analyses will explore the extent to which built environments and infrastructure availability in respondents' neighborhoods and students' school zones affects student impacts and family coping strategies.

This paper addresses critical gaps in understanding the intersection of school transportation disruptions and educational inequities in a mid-size city (Bierbaum et al., 2021). Even before the pandemic, school districts across the country have struggled to provide reliable bus service (Martinez et al, 2023). Yet, to date, there is very little research on the impacts of the loss of reliable bus service on families and children. The exceptional case of Durham, where the pay dispute took place within an overall context of diminishing school transportation services—a crisis within a crisis—provides a unique opportunity to understand the immediate impacts and long-term coping strategies families face when they no longer have certainty over whether and how their children will get to school. For planners, these findings highlight the critical role that safe, uninterrupted walking and bicycling infrastructure can play in ameliorating the impacts of school transportation disruptions.

Why They Ride (or Don't): Unpacking Student Perceptions of Public Transit Use

Abstract ID: 1844.0.0.204.2025

Track 14: Transportation and Infrastructure Planning

Individual Paper Presentation Submission

Ladan Mozaffarian [University of Oklahoma (Norman, OK)] ladan.mozaffarian@ou.edu, presenting author

Tahsin Tabassum [University of Oklahoma (Norman, OK)] tahsin.tabassum-1@ou.edu

Taylor Fleming [University of Oklahoma (Norman, OK)] tfleming@ou.edu

Public transportation offers affordability, sustainability, and accessibility—qualities particularly important to university students who often lack private vehicles and rely on transit systems to meet their mobility needs. While traditional models of transit ridership emphasize measurable factors like time, cost, and distance, a growing body of research suggests that subjective perceptions, such as perceived safety, comfort, environmental consciousness, and convenience, play a pivotal role in determining whether individuals use public transit (Bagdatli & Ipek, 2022; Meixell & Norbis, 2008). University students are a critical demographic in this conversation: not only are they frequent users of public transportation, but their preferences and habits could shape long-term transit behaviors. However, recent shifts, such as increased car ownership and post-pandemic health concerns, have diminished transit reliance among students. Negative safety perceptions—especially among women and marginalized groups—are often cited as deterrents (Ceccato et al., 2021), while environmental values may motivate interest in transit use but not consistently translate into action (Whitley et al., 2018). This study investigates these dynamics through two guiding research questions: (1) What are the key perception-based factors that influence university students' decisions to use or avoid public transit? (2) How do these perceptions correlate with actual ridership behavior?

The study employs a mixed-methods case study framework focused on the University of Oklahoma's Campus. Through a two-stage research design, first, a campus-wide survey gathers data on student perceptions of public transit, including both users and non-users, to ensure a comprehensive view of barriers and motivators. The key variables in our survey include perceptions of safety, service quality, affordability, reliability, and environmental benefits. The qualitative phase involves content analysis using NVivo software to identify and code emerging themes. In the second phase, quantitative techniques—Structural Equation Modeling (SEM)—will be used to assess how these perception-based factors relate to actual transit ridership, using survey results and ridership data obtained from local transit providers.

The study anticipates identifying specific psychological and experiential factors—beyond logistics—that affect transit mode choice. Prior research shows that even when transit is affordable and accessible, negative perceptions regarding personal safety, service reliability, and nighttime travel often prevent students from using it (Shaaban & Kim, 2016). Moreover, students' self-identified environmental values, while strong in survey responses, frequently fail to result in increased transit use—revealing an attitude-behavior gap (Whitley et al., 2018). By quantifying these relationships, this study will produce empirically grounded insights on university students' transit behavior and ridership. The findings will help transit planners and university administrators develop more targeted, perception-sensitive interventions to increase ridership among student populations.

This research contributes to urban and transportation planning by integrating social and psychological dimensions into conventional transportation analysis. It enhances understanding of how identity, emotion, and perception shape public service usage, reinforcing the importance of user-centered planning. The findings will provide transit agencies and campus planners with data-driven recommendations to align service design with the values and concerns of student users. From a scholarly perspective, the study introduces a replicable framework for

perception-based transit analysis in campus settings. It also advances educational practices in planning by demonstrating the importance of mixed-methods research in capturing complex behavioral dynamics.

A Tree is a Tree is a Tree: State Policy Interpretations of Federal Roadside Vegetation Guidance

Abstract ID: 1842.0.0.415.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Ellen Oettinger White [State University of New York College of Environmental Science and Forestry at Syracuse]
eowhite@esf.edu, presenting author

In this study, we will document and analyze the content of roadside vegetation management policies at state departments of transportation (DOTs). We will compare results to tree crash trends over time, using a dataset of tree crash fatalities by state between 1985-2022, assembled from the NHTSA Fatality Analysis Reporting System. Findings are expected to reveal insights into transportation policy variation across states, bolster current research into the power of state DOTs, and illustrate the complexity of an issue like roadside tree management, which encapsulates a tension between technoscientific epistemologies and those of the planning and environmental professions.

Dialogue about balancing the needs of traffic safety with roadside forests is accelerating between engineering and urban design, planning, and landscape architecture practitioners. In fact, last year, the NCHRP issued an RFP to investigate the relationship between roadside trees and traffic safety across contexts, maintenance regimes, tree species and morphology, and crash characteristics. Existing state DOT guidelines for roadside trees run the gamut from outdated to nuanced to aggressively anti-tree. For instance, Ohio's Roadside Safety Landscape Guidelines states, "Trees are proven killers when placed by the roadside." By contrast, Wisconsin's Facilities Development Manual offers several considerations for using vegetation to improve roadside safety: "Multi-stemmed shrubby plants may be used as supplemental impact attenuators in conjunction with other systems," and "Plants can often be used to delineate changes in the horizontal alignment of highways. They are typically used on the outside of curves where the combination of vertical and horizontal alignments combine and may confuse the driver as to where the road goes." (Planting and Aesthetic Design Section 20, pp. 7-8).

Practice today, as suggested by the Ohio manual language, is governed by the clear zone guideline, keeping a roadside free of fixed objects such as trees. Like many engineering guidelines, the clear zone began as a flexible concept that could be adapted to sites and leave decisions up to "engineering judgment" (Turner, 1987, p. 89). In particular, "Trees must be regarded as fixed objects, but they also deserve consideration beyond that given to other objects." (Turner, 1987, p. 89). In the 21st century, however, this nuanced approach to roadside trees has been lost in both practice and research. Wolf and Bratton (2006) note that the accepted rule is for any tree of four inch diameter or greater to be 30 or more feet from the road edge. "Alternative findings are rarely considered." (Wolf and Bratton, 2006, p. 171).

While some NCHRP documents have reviewed state-by-state DOT practices, the resulting surveys often capture individual staff responses and rarely span a full 50-state dataset. State manuals shape practice, though we recognize that practice deviates from written guidance to varying degrees by jurisdiction (White, 2023). We first gather DOT roadside vegetation guidance by state. Electronic guidance documents are typically online. In the absence of online documentation, we rely on professional contacts and direct outreach to planning or landscape architecture units within each DOT. Second, we devise a list of codes to structure deductive coding, in which the

codes are predetermined. Third, we perform content analysis using an open source code-and-retrieve software such as Taguette, and synthesize findings according to theme. Finally, we group the states into thematic categories and compare results to tree crash fatality trends over time. Depending on the results, we will structure a follow-on study linking tree crash fatality trends over time to state policies over time. Findings are expected to expand and deepen conversations at the professional boundary between engineering and the allied design professions.

Access without Automobiles for Urban Arterials

Abstract ID: 1842.0.0.909.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

David King [Arizona State University] david.a.king@asu.edu, presenting author

Kevin Krizek [University of Colorado-Boulder] kjkkrizek@gmail.com

Urban arterial roads in the US are a challenge for planners. These roads are historically designed for high volumes of traffic, and over decades rules of these roads have been codified into law in ways that guarantee ease of auto travel while harming all other ways of getting around. The conundrum is that these roads are both valuable as conduits of vehicular travel while being damaging to local communities. The reason these roads are damaging is that, because of their design, they become barriers. Barriers to active travel modes because vehicular traffic is too dangerous, barriers to better transit service as the roads are clogged with drivers, barriers to walking because of their width and auto-centric design, and barriers to permeable districts because they make it nearly impossible to travel without a car. Urban arterials are increasingly considered for redesign and rebuilding to alleviate these problems.

This research examines a selection of arterial road redesigns in US cities. In all selected cases, conventional auto-centric arterial design was replaced by multi-modal street design. The questions explored here include 1) how accessibility by non-auto modes changed, 2) what was the change in the total amount of space devoted to automobile traffic and non-auto modes, and 3) to what degree automobile traffic was deprioritized. The data used for these analyses includes site measurements, traffic counts, engineering standards, and planning documents.

We do not expect that these studies of road redesigns will result in clean and generalizable findings. However, we expect that we will be able to assess the relative value of access by non-automobile modes through the deprioritization of automobile traffic. The amount of space devoted to each mode will be measured, changes in lane width, changes to the windshield view of drivers, changes to speed limits, and other changes to the pedestrian environment will be studied. In some cases, we expect to find that non-auto modes remain subordinate to automobile traffic, inhibiting accessibility gains. Examples of automobile traffic priority after a redesign includes things such as higher or unchanged speed limits, a lack of natural elements that provide shade and pleasant walking experiences, pedestrian crossings that are not safe for people aged eight to eighty, and wide road lanes designed for freeway speeds.

The contributions of this research are to local efforts to rebuild streets to support multi-modal transport goals, boost local economic vibrancy, and help develop new performance metrics for planning and engineering. Arterial redesign with accessibility by non-auto modes in mind promotes multiple planning goals, yet getting beyond the motornormative mindset remains a major challenge.

Barriers to Adopting Machine Learning in Metropolitan Planning Organizations' Travel Demand Modeling

Abstract ID: 1842.0.0.76.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Hannaneh Abdollahzadeh Kalantari [University of Utah] hannah.kalantari@utah.edu, presenting author

Reid Ewing [University of Utah] ewing@arch.utah.edu

Metropolitan Planning Organizations (MPOs) play a critical role in regional transportation planning by forecasting travel demand to inform infrastructure investment and policy decisions. Traditionally, travel demand models (TDMs) have relied on trip-based or activity-based frameworks (Okrah et al., 2016), yet recent advancements in machine learning (ML) have demonstrated significant potential for improving predictive accuracy in capturing complex travel behaviors (Cheng et al., 2019; Liu et al., 2024). Despite these advantages, ML-based models have not seen widespread adoption among MPOs. This study seeks to answer two key research questions: (1) What are the primary barriers preventing MPOs from adopting ML in travel demand modeling? (2) How can ML facilitate the incorporation of non-motorized modes into regional models?

To address these questions, we built the foundation of this study on our previous research (Kalantari et al., 2025), which demonstrated the superior predictive accuracy of ML models in mode choice prediction compared to traditional modeling approaches such as nested logit and multinomial logit models. While our prior study employed a quantitative approach to validate the effectiveness of ML, this study shifts towards a qualitative inquiry to gain deeper insights into the barriers and opportunities surrounding ML adoption. Specifically, we employ a mixed-methods approach, integrating expert input and a nationwide survey targeting travel demand modelers both in MPOs and the private sector. The survey, designed based on expert feedback, gathers insights on awareness, perceived benefits, and barriers related to ML adoption, including technical expertise, financial constraints, data availability, organizational resistance, and policy considerations. Additionally, it explores the extent to which MPOs model non-motorized modes and whether ML is perceived as a viable tool to enhance active transportation forecasting. This approach allows us to move beyond purely statistical validation and develop a more nuanced understanding of the institutional, technical, and policy-related challenges that influence ML adoption in practice. By triangulating findings from both quantitative and qualitative perspectives, we aim to establish a more comprehensive evidence base to inform strategies for bridging the gap between academic advancements in ML and their real-world implementation in transportation planning.

Preliminary findings suggest that while ML is recognized for its potential in improving model accuracy, major obstacles hinder its adoption, including a lack of technical expertise within MPOs, concerns over model transparency and interpretability, and the financial investment required for capacity building. Many MPOs also face challenges in collecting and integrating active mode data, limiting their ability to model walking and biking effectively. However, respondents indicate that access to training programs, successful case studies, and collaboration with academic institutions could facilitate ML adoption.

This study contributes to planning scholarship and practice by providing empirical insights into the barriers and opportunities for ML adoption in MPOs, filling a critical knowledge gap in transportation planning research. The findings have direct implications for policymakers, practitioners, and researchers seeking to improve travel demand modeling and promote the integration of non-motorized modes in regional planning. By identifying key challenges and potential solutions, this work informs strategies for bridging the gap between ML advancements and real-world transportation planning applications.

Beyond Feasibility: Telework, Commuting, and Equity in Post-Pandemic Maryland

Abstract ID: 1842.0.0.514.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Alibi Shokputov [University of Maryland College Park] ashokput@umd.edu, presenting author

Chester Harvey [University of Maryland] cwharvey@umd.edu

The COVID-19 pandemic led to a rapid expansion of telework, reshaping commuting patterns and highlighting inequities in access to telework and control over work schedules. As the boom in early 2020s telecommuting subsides, we can now better determine who benefited from remote work over the medium to long term. Drawing on labor market segmentation theory, this study connects research on commuting, telework equity, and segmented labor markets in the context of pandemic recovery. While Dingel and Neiman (2020) estimated that 37% of U.S. jobs were telework-feasible, mainly higher-wage roles, less is known about how that potential has translated into actual commuting outcomes, given varying levels of scheduling autonomy, workplace flexibility, and geographic constraints.

This study asks: To what extent do jobs deemed remote-feasible actually result in reduced commuting, reflect reported work arrangements, and align with workers' preferences or perceptions of telework potential? Using data from three waves of the annual Maryland Commuter Survey (2022–2024), we explore how telework plays out across different occupational and demographic groups. The survey provides rich information on travel behavior, employment characteristics, demographics, ZIP-code–level residential and workplace locations, and self-reported telecommuting activity, preferences, and perceived feasibility. Maryland's diverse economy, proximity to Washington, D.C., and substantial cross-border commuting flows make it a valuable case for studying evolving telework practices. Recognizing that definitions of remote work vary across studies (Buckman et al., 2025), we compare respondents' actual telecommuting frequency in the prior work week with their reported remote work arrangements. This approach reveals how telework operates in practice, beyond static classifications or nominal labels.

To approximate longitudinal trends and capture variation within groups, we use a synthetic cohort approach to construct repeated cross-sectional profiles of occupational and demographic subgroups. Our analysis focuses on four key areas: changes in commuting behavior over time, disparities across worker cohorts, alignment between workers' preferences and actual flexibility, and the distinct challenges faced by those with multiple or mobile worksites (MMW). Importantly, 17% of respondents reported working fully in person but across multiple locations rather than at a single, fixed site. Because the survey explicitly distinguishes MMW employees from traditional on-site workers, we are able to identify them as a substantial segment of Maryland's workforce. These workers exhibit unique commuting patterns that are often overlooked in broader discussions of telework, highlighting the need to account for spatial and organizational complexity in evaluating remote work trends.

Preliminary findings show that while many jobs remain theoretically compatible with telework, actual adoption has declined and is stabilizing near pre-pandemic levels. The share of hybrid or remote workers in Maryland dropped from 64% in 2022 to 34% in 2023, and further to 27% in 2024, approaching the pre-pandemic baseline of 33%. At the same time, more than half of fully in-person workers report wanting some form of remote work and believe their roles could accommodate it. Yet remote and hybrid arrangements remain disproportionately concentrated in office-based occupations, which account for 39% of the workforce. As a result, many workers in telework-feasible roles continue commuting daily, especially those with limited control over their schedules.

Post-pandemic telework trends may reinforce existing inequities in workplace flexibility, with broader implications for commuting, job access, and mobility. By examining how hybrid and remote work unfold across workforce segments, our analysis supports more equitable, integrated transportation, land use, and labor policies.

Beyond the Average: Improving Summaries of Accessibility for Transportation Performance Measurement

Abstract ID: 1842.0.0.723.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Chester Harvey [University of Maryland] cwharvey@umd.edu, presenting author

Behnam Tahmasbi [University of Maryland] behnamt@umd.edu

Researchers and policymakers agree that measures of access to opportunity are more robust indicators of transportation system performance than measures of mobility (e.g., miles traveled) and infrastructure (e.g., facility miles) that have long dominated performance reporting at state departments of transportation (DOTs) (Gibson et al., 2021, Karner et al., 2022; Litman, 2024). Accessibility measures can be used to examine transportation equity, such as whether residents across socioeconomic strata have comparable access to jobs. They can also reveal how small changes, such as closing network gaps, may substantially increase the destinations users can feasibly reach. Because accessibility is a characteristic of a particular place, or even a particular user, it is spatially precise by default, often calculated for representative points within census blocks, grid cells, or other small units of analysis. This allows areas with anomalously low or high access to be easily identified. It also poses challenges, however, for inserting accessibility into performance frameworks that require statewide summaries. One approach has been to average accessibility across a state or region, sometimes weighting by population (Owen et al., 2024). While straightforward, this reveals little about how accessibility is distributed geographically or socially. Averages are also insensitive to localized improvements that may pose substantial benefits to particular locations or groups. The difficulty of effectively summarizing accessibility at a statewide level has likely impeded its adoption in DOT performance reporting systems.

This project, in partnership with the Maryland Department of Transportation (MDOT), investigates approaches for summarizing accessibility to contribute to the agency's Attainment Reporting (AR) system (MDOT, 2024). The AR currently includes eight measures that report on infrastructure quantity rather than opportunities afforded by that infrastructure, or measure access to infrastructure rather than opportunities at destinations. The current measure of statewide miles of low-stress bikeways, for example, could be exchanged for a measure of access by bicycle to key destinations, reflecting how short bikeways that connect to destinations may offer greater benefit than long ones with fewer connections. Another existing measure, population within a half mile of a transit station, could be updated to reflect the access transit provides to key destinations. Simply averaging bicycle or transit accessibility across the entire state, however, would poorly represent the value of these systems in the areas they serve.

Our work uses data developed by the Accessibility Observatory, through a pool-funded study of which MDOT is a part, that measures cumulative opportunities to key destination types—jobs, shopping, education, etc—from each census block throughout Maryland (Accessibility Observatory, 2025). These data form map surfaces showing how access by different transportation modes—auto, transit, bike, and walk—varies across the state and from year to year. Our project investigates how these data can be distilled into statewide summaries that fit into MDOT's AR framework to track progress over time. One approach might be to set a minimum standard for access and summarize the proportion of areas meeting this standard. Alternatively, inequality in access could be measured through a Gini coefficient or a ratio between access levels at the top and bottom of the distribution. Equitability could be examined by comparing distributions of access across socioeconomic groups. Operationalizing these summaries raises questions about how standards can be reasonably defined and whether they ought to be differentiated between urban, suburban, and rural contexts or considered universal. Our study addresses both the mechanical and ethical dimensions of developing such measures.

Coordinated Decision-Making and EV Adoption Within Complex Public Fleets

Abstract ID: 1842.0.0.406.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Michael Montilla [University of California, Berkeley] michaelmontilla@berkeley.edu, presenting author

Research into commercial adoption of electric vehicles (EVs) is longstanding, and EV studies looking at government owned fleets has grown considerably since 2015. But this latter line of research often concentrates on transit fleets, or considers government fleets alongside commercial fleets or non-fleet vehicles. On the whole, there is a lack of academic literature focused on non-transit, public fleets despite the relative ubiquity of such fleets across regions and levels of government. For the current project, I address this research gap by examining the decision-making processes of public fleet EV adoption through a mixed-methods case-study of the California Department of Transportation (Caltrans).

Previous research into fleet decision-making has identified numerous complexities limiting adoption of EVs. Some of these complexities are organizational. Public fleets typically rely on a highly formalized but decentralized style of decision-making with a multitude of actors shaping EV purchasing decisions (Nesbit and Sperling, 2001). This decision-making style is slow, and can result in uncoordinated actions. For example, the actors empowered to make EV purchasing decisions, are often not the same people making charger installation decisions despite evidence that charger installation enables EV adoption (Khan and Maoh, 2021).

Other complexities restricting fleet EV adoption are infrastructural. Public fleet facilities are typically decades old, and they were not designed with EV charging in mind. The same is true for electricity generation, and distribution systems. Given increasing demand for electricity at a societal level, large-scale charger installation at fleet depots may not be possible without upgrades to the electrical grid (Yu et al., 2016). Fleet operators express worry regarding grid reliability and capacity, especially as they begin to adopt medium- and heavy-duty EVs which consume much more electricity per mile than light-duty vehicles (Sugihara et al., 2023; Powell et al., 2024).

For these reasons, fleet operators have begun coordinating with energy providers, but such efforts broaden EV decision-making complexity. Utility companies sit outside fleet bureaucracies, and while fleet-owning governments can motivate infrastructural upgrades near fleet facilities, utility companies hold the lion's share of influence regarding grid improvements.

With these issues in mind, I ask: Which strategies are public fleet operators following to coordinate internally towards vehicle electrification, and externally with local utility companies towards infrastructural upgrades? And which coordination strategies and facility characteristics lead to faster fleet decarbonization?

To inform these questions, I have partnered with Caltrans to perform an in-depth investigation of their decision-making practices, facilities, and operational patterns using semi-structured interviews, site observations, and statistical analyses of decision-making records, facility characteristics, and telematics data. Caltrans is a great case-study for this topic. It owns a large, and complex fleet with a mix of vehicle types operating over a wide range of environmental contexts, and across the territories of multiple energy providers. It exhibits a highly formalized but decentralized style of decision-making common to most public fleets, and it is bound by California law to decarbonize their road vehicles by 2035. As such, it has replaced or scheduled replacement of nearly 900 motor vehicles with EVs, including a few medium-duty trucks, but exactly which vehicles are identified for EV replacement varies across facilities, vehicle characteristics, and coordination strategies. Through this study, I will ascertain how such variations affect EV purchasing decisions while evaluating coordination strategies that accelerate EV adoption.

Effect of shared micromobility on public transit ridership: Complementary or substitutionary?

Abstract ID: 1842.0.0.930.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Innovative practices, concepts, and ideas for pedagogy

Kwangyul Choi [Inha University] kwangyul@inha.ac.kr, presenting author

John Park [University of Maryland] jpark5@umd.edu

Shared micromobility collectively refers to any small, human- or electric-powered travel mode used by multiple users as a shared resource. The most frequently used forms of shared micromobility are regular/electric bikes and electric scooters. This emerging transportation option has become popular worldwide, and as a result, its ridership has dramatically risen in recent years. In the United States, the number of trips via bike share (both regular and electric) and scooter share reached 35 million in 2017 and had quadrupled by 2019. During the pandemic, the ridership plummeted, but it quickly returned to pre-pandemic levels around 2022. As these new mobility options have been widely used, their impact on travel has become significant, particularly for urban residents.

Regarding the impact on public transportation, shared micromobility is expected to increase transit ridership by dealing with the first-/last-mile problems by complementing the local or regional transit system (Böcker et al., 2020; Zhang & Zhang, 2018). However, empirical findings are rather mixed. Some studies suggest that shared micromobility is more likely to substitute local public transit services (Campbell & Brakewood, 2017; Luo et al., 2021). In contrast, other studies demonstrate that it has both competing and complementary effects on public transit ridership (Yan et al., 2021). These inconsistent findings in practice may result from variations in regional characteristics and the service provided, but a large number of existing studies focused on a single city, mostly large metros such as New York City, Chicago, and Washington, D.C., or on a single type of shared micromobility (e.g., bike share or scooter share).

Hence, the current study attempts to examine the role of shared micromobility in public transit ridership in 146 urbanized areas (populations between 200,000 and 1.5 million) across the United States with a focus on three types of shared micromobility service (i.e., regular bikes, e-bikes, and e-scooters). To this end, we adopt the difference-in-differences (DID) approach and quantify the changes in transit ridership per capita in urbanized areas before and after the adoption of shared micromobility while controlling other likely drivers of public transit ridership change. Thus, we shed light on the impact of the options of shared micromobility service on public transit ridership at the regional level and suggest relevant planning strategies or policies to integrate shared micromobility and public transit service in the region. By doing this, we make a valuable contribution to the literature regarding the impact of shared micromobility on public transit trips.

Effects of Built Environment Factors on Injury Severity of Motor Vehicle Accidents

Abstract ID: 1842.0.0.1014.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Hiroyuki Iseki [University of Maryland, College Park] hiseki@umd.edu, presenting author

Kartik Kaushik [University of Maryland School of Medicine] kkaushik@som.umaryland.edu

Joshua H. Davis [University of Maryland, College Park] jhdavis@umd.edu

Traffic safety is an essential component of healthy communities and neighborhoods. Many studies have investigated the potential influences of built environment factors on traffic accidents. Dumbaugh and his colleagues examined the impacts of locational factors, including the built environment and land use, on traffic safety (Dumbaugh & Rae, 2009; Ewing & Dumbaugh, 2009; Merlin et al., 2020; Saha et al., 2020). Ewing and Dumbaugh (2009) also presented a conceptual framework in which built environment factors (development patterns and roadway designs) affect the outcome variables (crash frequency and crash severity) through the mediating factors (traffic volumes, traffic conflicts, and traffic speeds). The higher the traffic volume, the more frequency of vehicle accidents. Traffic speed affects the time a driver takes to react to unexpected events or objects, resulting in a stronger force of impact in a crash, increasing the frequency and injury severity. Despite the large volume of studies on traffic accidents, scant studies have examined the effects that built environment factors may have on the severity of injuries, partly because of quality data on injuries.

This study examines the under-studies effects of built environment factors on injury severity in traffic accidents, taking advantage of the injury-diagnosed data at hospitals. The primary data in our study are the admission data between 2016 and 2021 obtained from the R Adams Cowley Shock Trauma Center at the University of Maryland Medical Center in Baltimore. The admission data provide details about the patient and injuries, including the Injury Severity Score (ISS) obtained from the global consensus-derived Abbreviated Injury Scale based on medical diagnostics by trained physicians. These records were linked at the person level with the vehicle crash data in Maryland to obtain the accident locations and whether the admitted person was a vehicle driver, passenger, or pedestrian/cyclist in the accident. The study also incorporates two data sets that contain built environment factors: the Environmental Protection Agency's (EPA) 2021 Smart Location Database (SLD) and Maryland Generalized (Land Use) Zoning (GLUZ) data. The SLD includes a variety of location attribute variables related to 3Ds (density, diversity, and design), accessibility, and transit service at the census block group level. We use a spatial join to link accident records to the SLD and MD GLUZ data and, so far, apply the Categorical and Regression Trees (CART) model with five levels, a non-parametric machine learning technique for logistic regression.

Within 6,732 individual patients, 23%, 26%, 24%, 14%, and 12% had injuries at the minor, moderate, serious, severe, and critical/fatal level, respectively. We found in the preliminary analysis that increasing housing or commercial density, which are defined as dwelling units per acre (du/ac) and jobs per acre (jobs/ac), respectively, greatly impacts injury severity as the most critical variable. The most common density level of single-family zoning in Maryland is around 6.5 du/ac. We also found that accidents in the areas of about 10 du/ac or above are unlikely to result in the ISS serious or above for patients. Similarly, it is unlikely that accidents in the areas with job densities of about 8 jobs/ac or crashes higher results in the ISS serious or above. In short, denser areas are less likely to produce worse injury outcomes, although the densities required to improve motorist crash injury severities are about half those for VRU: 5 du/ac and 4 jobs/ac. These results hold across age and sex of patients.

This study is the first step in understanding the effects of built environment factors on injury severity so that decisions on land use, zoning, and other built environments can be guided to improve roadway safety rather than unintentionally compromising it.

Examining the Spatial Relationship between Shared Mobility and Public Transit in the U.S. μ SAs

Abstract ID: 1842.0.0.361.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Critique related to a hot topic in planning research

Aisharya Bhattacharjee [The University of Texas at Arlington] aisharya.bhattacharjee@uta.edu, presenting author

Jianling Li [University of Texas at Arlington] jjli@uta.edu

Qisheng Pan [University of Texas at Arlington] qisheng.pan@uta.edu

The interplay between public transit and emerging mobility paradigms as app-based shared mobility services (ride-hailing, bike-sharing) hold significant implications for sustainable and integrated mobility, especially outside traditional metropolitan cores (Shen et al., 2021). Shared mobility sometimes complements and sometimes compete with public transit (Luo et al., 2023). Understanding how shared mobility interacts with transit within Micropolitan Statistical Areas (μ SAs) – regions characterized by smaller urban cores surrounded by rural areas, while controlling socio-economic and built environment factors is essential to integrate these services and optimize their role in commuting (Zuniga-Garcia et al., 2022).

Existing literature has explored socio-economic determinants of public transit ridership within metropolitan areas (Taylor & Fink, 2013; Alam, et. al, 2015), but micropolitan areas characterized by low transit access and high car dependency remain relatively underexamined. Further, traditional regression approaches assume these relationships are constant across geographical locations. Consequently, there remains limited knowledge of how shared mobility influences public transit ridership in μ SAs. With focus on 538 μ SAs, this study addresses these gaps by assessing spatial heterogeneity in shared mobility's influence on transit ridership, identifying transit-supportive/deficient areas, and highlight integration opportunities.

This study posits that determinants of public transit ridership in μ SAs vary spatially and distinct spatial clusters exist where shared mobility services either complement transit ridership or substitute for it. Key research questions are:

1. What are the relative influences of shared mobility options on public transit ridership across μ SAs, controlling for socio-economic and built environment characteristics?
2. How do these influences exhibit spatial variation, and what types of spatial clusters emerge indicating transit-supportive or transit-deficient areas?
3. How do bike sharing station locations and ride-hailing service areas align with these clusters, and what implications can this offer for integrating shared mobility with public transit to enhance commuting accessibility?

The analysis uses data from ACS 2023, U.S. EPA Smart Location and USDOT BTS. To capture integration potential between public transit and shared mobility, Ordinary Least Squares (OLS) regression is employed with public transit ridership as DV. Two key IVs are considered: (1) density of bike-sharing stations, and (2) availability of ride-hailing services within μ SAs, with positive coefficients indicating complementary dynamics and negative coefficients suggesting substitution effects. Guided by previous research, the model incorporates socio-economic (age, race, gender, education, income, housing tenure status, household size, car ownership) and built environment (jobs per housing unit, population density, employment density, road network density, intersection density, transit service density) attributes as control variables. Geographically Weighted Regression (GWR) is employed for local-level assessment of how availability of shared mobility services influences public transit ridership across μ SAs. Spatial clustering is applied to GWR outputs to locate typologies of transit-supportive/deficient areas. These clusters are

interpreted to identify potential shared mobility “hotspots” i.e., areas where transit-supportive conditions exist but usage is low (opportunity), or areas where shared mobility may be drawing away from transit use (competition).

Findings suggest spatially heterogeneous relationships between shared mobility availability and transit ridership across μ SAs. Distinct spatial clusters indicate areas where shared mobility complements transit, highlighting the importance of localized planning approaches and identifying areas where shared mobility could enhance transit access or address service gaps.

Exploring Public Opinion About E-Scooters, Issues with Their Use, and Potential Policy Interventions

Abstract ID: 1842.0.0.1015.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Kevin Fang [Sonoma State University] fangk@sonoma.edu, presenting author

Asha W. Agrawal [San Jose State University] asha.weinstein.agrawal@sjsu.edu

Hilary Nixon [San Jose State University] hilary.nixon@sjsu.edu

The emergence of e-scooters over the last several years has yielded varying responses from members of the public. On one hand, e-scooters have been sufficiently popular to sustain shared scooter systems in hundreds of cities worldwide. However, e-scooters have not been without their complaints, with media articles expressing concern about various aspects of scooter use and some examples of politicians running on anti-scooter platforms. While concerns about e-scooters certainly exist, such negative opinions may or may not be held by the public at large. For example, in San Diego, California, authorities received around 10,000 e-scooter complaints in 2018/19. However, 74 percent of these complaints came from just the same 10 people.

To explore broad public opinion about e-scooters, we performed a demographically representative survey of 2,500 US adults. Respondents were asked their general feelings about the presence of e-scooter travel in their communities, potential problems associated with their use, and support or opposition to several potential policy interventions.

Overall, most respondents viewed the existence of e-scooters as a net positive for their communities. 84 percent said scooters were very/somewhat good for their communities versus 16 percent who said they were very/somewhat bad. This is actually somewhat higher support for e-scooters than a survey conducted by transportation analytics firm Populus in the early days of shared scooter systems back in 2018.

Two commonly cited concerns with e-scooters are safety and parking management. In terms of safety, less than half of respondents (39 percent) said e-scooters were a danger to pedestrians, while 18 percent felt they were a danger to their riders. Regarding parking, 28 percent felt that parked e-scooters frequently blocked pedestrians, while 14 percent thought parked e-scooters on sidewalks are ugly.

When asked about potential policies addressing scooter-related issues, most respondents (87 percent) supported a minimum age for e-scooter ridership, with a plurality (31 percent) selecting a preferred minimum age of 16 years old. Majorities also supported requiring use of lights at night (67 percent) and apply DUI rules to scooter riders (62 percent).

Respondents were less supportive of some other potential restrictions. Only 28 percent supported a ban on scooter riding on sidewalks, although a majority were in favor of some restrictions on sidewalk riding. Additionally, only 26 percent of respondents supported a ban on scooter riding at night. Such bans have been enacted in some cities, including Atlanta, Georgia, and Bloomington, Indiana.

Integrating calculated and achieved access: uncovering unmet travel needs in Detroit

Abstract ID: 1842.0.0.905.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Amy Zhang Fong [University of Michigan - Ann Arbor] amyzfong@umich.edu, presenting author

Atiyya Shaw [University of Michigan - Ann Arbor] atiyya@umich.edu

Limited disaggregate data has traditionally limited systematic analysis of travel needs to place-based and/or normative generalizations (i.e., calculated accessibility measures) (Karner, Pereira, and Farber 2024,). However, individuals' particular mobility resources, preferences, and circumstances also matter. Aggregate and individual conditions jointly influence achieved access, here defined as the degree to which someone can realize opportunities for social participation vis-à-vis the transport-land use system (Vecchio and Martens, 2021). What nuances emerge from integrating aggregate measures with insights gained from directly asking people about their travel experiences?

This work uses personal survey data from an address-based probability sample collected under the Detroit Metro Area Communities Study (DMACS) in 2023. We use latent class cluster analysis to identify distinct classes of achieved access based on individuals' responses to questions about transportation and housing affordability, security, and satisfaction. We examine how achieved access varies within and across levels of neighborhood and regional accessibility, mobility patterns, and sociodemographic characteristics. For example, preliminary analysis indicates that among center city residents, frequent bus riders, younger- and middle-aged adults, single parents, and those without cars were more likely to have unmet travel needs. Despite having highest residential transit access to jobs in the city, these individuals experienced cost burdens, suppressed travel and activity participation, and strained social relationships from lack of reliable transportation (Murphy et al., 2022). This focuses attention on travel needs that calculated accessibility measures, even once combined with aggregate neighborhood sociodemographic characteristics, may overlook.

This work uses original survey data to introduce evidence towards conceptual debates on measuring accessibility and its relations to travel behavior and well-being (Negm et al., 2025; Vecchio and Martens, 2021). In doing so, it illustrates how combined calculated and achieved access measures can shed light on the distribution, nature, and consequences of unmet travel needs in a city or region.

Mapping Risk from the Perspective of Cyclists

Abstract ID: 1842.0.0.647.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Sean Qian [Carnegie Mellon University] seanqian@cmu.edu, presenting author

Ruoxi Ma [Carnegie Mellon University] ruoxim@andrew.cmu.edu

Clark Haynes [Velo.ai] gch@velo.ai

Tao Tao [Carnegie Mellon University] taot@andrew.cmu.edu

Cycling has become an increasingly popular mode of transportation in recent years due to its environmental benefits, affordability, and contributions to public health. However, despite its advantages, safety concerns remain a major barrier to widespread adoption. Bicyclists are among the most vulnerable road users, with a high risk of severe injuries or fatalities when involved in traffic crashes. Traditionally, research on bicyclist safety has focused on measurable risk factors such as traffic volume, vehicle speeds, road design, and cyclist behavior (Monsere et al., 2015; Tao et al., 2021). While these factors are valuable for crash risk estimation, they often overlook near-miss incidents—close encounters that do not result in crashes but indicate unsafe interactions between cyclists and vehicles. Data on near-miss incidents—such as vehicle overtakes, passing distances, and prevailing traffic speeds—provide critical insights from the cyclists' perspective (Lindsey et al., 2021; Powell et al., 2024). Compared to traditional risk factors like traffic volume and speed, near-miss data may offer a more direct reflection of the risks cyclists face. Unfortunately, such datasets are scarce, leading to their underutilization in existing research.

To address this gap, our study introduces a novel approach by leveraging a near-miss dataset collected by the company Velo.ai in Pittsburgh. Velo.ai utilizes sensor-equipped devices installed on both personal and shared bicycles to autonomously detect and record detailed data on near-miss events with advanced computer vision algorithms. These include metrics such as passing distances, proximity to vehicles, and traffic conditions at the time of the incident. The dataset comprises over 62 hours of cycling trips covering more than 476 miles in Pittsburgh's Strip District, offering a rich and granular view of cyclist experiences in urban settings. In addition, datasets of weather data, vehicle travel speed, police traffic stop report, network of bicycle facilities, built environment attributes, socio-demographic patterns, Waze traffic events will be applied.

Using these inputs, we will develop and compare multiple predictive models to estimate bicycle crash risk at the street segment level across Pittsburgh. Each model will be evaluated based on its prediction accuracy and computational complexity. The model with the best performance will be selected for generating a comprehensive risk map, which will visually depict areas of high and low crash risk throughout the city. Furthermore, we will compare the predicted crash risk map with historical crash data to assess how well the model captures actual safety outcomes. This comparison aims to highlight the added value of near-miss data in identifying hidden patterns of cyclist risk that traditional data sources might overlook.

Ultimately, this research aims to deepen our understanding of urban cycling safety by focusing on the cyclist's perspective. By incorporating near-miss data into crash risk prediction, our study seeks to inform more responsive infrastructure planning, targeted safety interventions, and policy decisions that prioritize cyclist well-being in the evolving urban mobility landscape.

Refining LTS for Inclusion and Accuracy: A Cross-Disciplinary, International Delphi Approach

Abstract ID: 1842.0.0.972.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Susan Loftus [Loftus Planning and Design] skloftus@mac.com, presenting author

Ahoura Zandiatashbar [San Jose State University] ahoura.zandiatashbar@sjsu.edu

Level of Traffic Stress (LTS) methodologies are key tools for evaluating the comfort and safety of bicycling environments. While widely adopted in the U.S., current LTS frameworks were developed primarily through theoretical models with limited expert input and often fail to capture the needs of low-stress-tolerant users—such as children, older adults, and many women. As artificial intelligence increasingly incorporates LTS data to optimize bike networks the lack of a validated, inclusive methodology threatens the effectiveness and equity of future investments.

This study advances a revised LTS methodology using a modified Delphi consensus-building process, engaging a 25-member international panel of experts from the fields of urban planning, civil engineering, psychology, and human-centered design, with an emphasis on selecting those with expertise or research relevant to low stress cycling. The panel reflects a wide range of academic and professional backgrounds, spanning the U.S., Canada, the Netherlands, the U.K., Norway, Sweden, and Australia. To better reflect the demographics of low-stress-tolerant cyclists, intentional efforts were made to ensure a panel composition with more women than men. With interdisciplinary diversity and geographic breadth, the group offers a rich foundation for evaluating LTS frameworks through both technical and social lenses.

The study focuses on refining three core components of the LTS framework: rubrics for LTS 1 and 2 (including user group definitions, behavioral descriptors and estimated proportions of the population each level is intended to serve), the set of environmental and facility factors to be considered, and the classification of stress thresholds. The three-round Delphi process consists of open-ended prompts and structured questionnaires. This consensus-building technique facilitates refinement of responses based on insights shared by other panelists. The project also evaluates alignment between U.S., Canadian, and Dutch standards, offering critical insights for both domestic and global application.

We hypothesize that (1) U.S. LTS systems differ significantly from evaluative standards in Canada and the Netherlands (2) variables used to define lower-stress tolerances are more complex than those required to define higher-stress tolerances, and (3) the speed threshold for LTS 1 classification should be set at or below 20 mph except in cases where a physically protected bike lane is present, aligning with emerging behavioral and safety research. These hypotheses directly address current methodological gaps in the literature and practice.

By integrating cross-disciplinary and international perspectives, the resulting methodology supports more inclusive, behaviorally informed, and globally applicable LTS tool. This refined and validated methodology also serves as a critical building block for the development of advanced AI supported network planning tools. Our presentation will share the consensus-building process and highlight early findings from this expert-driven framework redesign.

Revisiting Transit-Induced Displacement Hypothesis with Consumer Data: Insights from Minneapolis

Abstract ID: 1842.0.0.854.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Manuel Santana Palacios [The Ohio State University] santanapalacios.1@osu.edu, presenting author

Over the past two decades, more than 200 new mass transit infrastructure projects have been introduced worldwide, with over one-third inaugurated in the U.S. within the past seven years. Many of these projects have been funded through a new wave of federal programs aimed at promoting equity. While transportation planners, funding agencies, and policymakers champion public transit investments, concerns persist among local communities, housing advocates, and urban scholars about the potential displacement of lower-income households—the very populations these projects aim to serve. This concern is encapsulated in the transit-induced displacement hypothesis (Chapple & Loukaitou-Sideris, 2019). This paper examines three key questions: (1) How do large public transit investments affect residential sorting? (2) How do household relocation patterns vary by socioeconomic status? (3) Do these patterns suggest displacement of lower-income groups from transit-rich neighborhoods?

Urban economic theory provides a framework for understanding how transportation investments might influence displacement. Transit investments generate accessibility benefits, primarily through travel time savings. Properties near transit stations gain a competitive advantage in accessibility. Given the finite supply of well-located properties, households may be willing to pay a premium for proximity to transit. These accessibility benefits become capitalized into property values, potentially pricing out lower-income households. Despite this theoretical foundation, empirical evidence remains elusive. Research suggests that transit's effects on neighborhood change are marginal or difficult to quantify (Delmelle, 2021). Understanding whether transit induced displacement is challenging due to significant data limitations, particularly the lack of disaggregated panel datasets that capture regional residential sorting patterns and provide a representative picture of in- and out-migration (Bardaka, 2023). Rodnyansky et al. (2022) used tax records to study whether LRT investments in Los Angeles County contribute to the displacement of lower-income residents. Consistent with much of the literature, their findings reveal a complex picture with no clear evidence supporting the hypothesis.

This research contributes to the ongoing debate by testing the transit-induced displacement hypothesis using a large-scale longitudinal consumer dataset from Data Axle, along with transit project data from the Transit Explorer Database (Freeman & Vance, 2024) and the American Community Survey. The analysis focuses on the relocation patterns of about 670,000 households in the Minneapolis-St. Paul metro area between 2009 and 2019, which saw the introduction of two major transit lines: the Green Line LRT (2014) and the Red Line BRT (2013). While the Green Line primarily serves lower-income census tracts, the Red Line covers a wider range of areas. Early findings show that nearly 25% of households relocated within the metro area, with around 3,700 households living in or near the project station areas at some point. The data reveals notable in- and out-migration patterns around the transit stations. I anticipate the controlled discrete choice models will reveal some evidence supporting the transit-induced displacement hypothesis, that will be included in my presentation.

Shrinking Cities, Shrinking Transit, and Disaccumulation: A Case Study of a Small Midwestern City

Abstract ID: 1842.0.0.945.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Dwayne Baker [Queens College, City University of New York] dwayne.baker@qc.cuny.edu, presenting author

This study connects the concept of disaccumulation with transit service reductions in the small-sized, Midwestern city of Decatur, Illinois. That is, I use the concept of disaccumulation as a framework for understanding how reductions in transit service impact transit dependent areas and why this reduction occurs. As noted, disaccumulation is an inherent part of capitalist structures where capitalist systems need to get rid of or sell all goods produced in order to make a profit (Gilmore, 2007; Wolff, 1984). It also helps maintain accumulation processes as well as stave off crises within capitalist systems (Gilmore, 2007). In this regard, disaccumulation is essentially the act of “getting rid of” components to allow for accumulation or stability. I thus argue that “getting rid of” or removing transit routes in the face of crises (i.e., shrinking cities and accompanying diminishing ridership) is an example of disaccumulation and is an inherent part of changes within the capitalist structures of American cities.

I focus on Decatur, Illinois as a case study site. Decatur is unique in its intensity of population decline. Decatur’s population declined by roughly 9% between 2010 and 2023 – from approximately 76,000 persons to 69,000 persons and is often listed as one of the U.S.’s fastest shrinking cities and one crippled from deindustrialization (Biles, 2021; Smith, 2020). This decline has been steady since its peak in 1980 of just of 94,000 people. Yet, it is also reflective of similar shrinking (and especially rust-belt) cities – whether small-, medium-, or large-sized. That is, population decline in core cities driven by deindustrialization, but an increase in the suburban cities of these core spaces.

More importantly, the city of Decatur recently proposed to reduce its bus service from 16 to 10 fixed routes in the coming years (Moore, 2014). This is due to a renewed focus on the city center, declining bus ridership, and a push to increase micro-transit. However, I question where and who these reductions will most affect and whether this “disaccumulation” in transit service also coincides with a “disaccumulation” of different areas of the city – namely those spaces with more transit dependent riders. Thus, I use ACS 2023, 5-year estimates data at the block group level to conduct spatial analyses along with descriptive statistics to address where and who are impacted by the proposed disaccumulation of transit service. Preliminary results reveal that transit dependent neighborhoods (namely, those with lower-income levels and higher poverty rates) are more likely to receive route removals when focusing solely on the city of Decatur. However, when expanded to the county level, transit dependent block groups are not more or less likely to receive route removals. Yet, suburban block groups examined have higher rates of car ownership.

Focusing on small-sized city such as Decatur is important largely due to the overwhelming focus in transit equity research on mid- and larger-sized cities with multi-modal systems. While transportation systems in larger cities indeed move larger populations, changes in transit service for small cities may have far more detrimental impacts. Indeed, removing a single bus route within a larger city with a multi-modal mass transit system may cause transit frustration where a rider may have to change modes or have a longer commute. Removing a single route in a smaller city may mean that a transit dependent rider does not travel at all. This study, therefore, presents a framework for understanding transit service reductions in shrinking, small-sized U.S. cities.

Towards a Better Framework for Assessing Perceived Accessibility

Abstract ID: 1842.0.0.1163.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Andong Chen [Texas A&M University] andongch@tamu.edu, presenting author

While accessibility measures have been increasingly adopted in transportation and land use planning at both local and regional scales, there is still an ongoing debate on the use of calculated or perceived accessibility measures and how they would inform policy makers by revealing the determinants of accessibility. This paper focuses on the perceived accessibility measures, particularly how the design of perceived accessibility measures influences the relationship between travel behavior and perceived accessibility at a regional scale. To investigate this question, we first examined the existing instruments for evaluating the perception of accessibility such as the Perceived Accessibility Scale (PAC) as well as other individual survey designs. We analyzed how each index defined and operationalized perceived accessibility and categorized these indexes to create a synthesized survey instrument that investigated the determinants of perceived accessibility and the relationship between perceived accessibility and travel behavior. The demographic information and the neighborhood characteristics near participant's residence will also be collected for further analysis. The survey instrument is distributed through Amazon Mechanical Turk to maximize the geographical coverage and reach participants with a variety of demographic background. This data from this survey will be analyzed using Generalized Linear Mixed Model as individual characteristics are expected to influence the perceived accessibility based on the evidence from previous literature. The result will contribute to the field by creating a better index for assessing perceived accessibility and shed light on how this framework can help transportation planners make informed decisions.

U.S. Road Diets Turn 10: What Do We Know about their Distribution and Impacts?

Abstract ID: 1842.0.0.1111.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Lindsay Braun [University of Illinois] lmbraun@illinois.edu, presenting author

Kyuhyun Lee [University of Illinois, Urbana Champaign] klee181@illinois.edu

In 2014, the Federal Highway Administration (FHWA) released its first official guidance on the design and implementation of “road diets,” a street redesign strategy that involves reducing the number and/or width of vehicle travel lanes to improve multimodal safety. While this concept was not new, the FHWA guidance led to growing recognition and use of this approach in U.S. transportation planning practice.

Evidence on the impacts of road diets on travel speeds and crash rates is limited primarily to before-and-after studies of individual projects. While this evidence suggests a variety of safety benefits, there has not been a widespread, systematic analysis of road diet impacts across projects and cities. Additionally, limited work has considered the distribution of road diets: which types of neighborhoods have received these interventions, and thus, to whom have the benefits accrued? This question is important from an equity perspective, given other evidence that marginalized groups have disproportionately high pedestrian and bicycle crash rates and low access to multimodal infrastructure.

The safety impacts of road diets could take time to appear in the data, since crashes are relatively sparse over time and across space. Thus, the approximately ten-year anniversary of the FHWA guidance represents ideal timing to analyze the impacts of road diets on a broad scale. A critical barrier to this type of analysis, however, is a lack of data: there is no centralized inventory of road diet projects, and it can be difficult to collect consistent and complete data on projects even within an individual city.

In work currently underway, we address this gap using Chicago as a test case for assembling road diet data and addressing two research questions:

1. Where have road diets been implemented?
2. What impacts have they had on multimodal safety?

We apply a social equity lens to both questions, considering (1) whether road diets have been built disproportionately in privileged neighborhoods and (2) whether their safety impacts have varied across sociodemographic contexts.

We are currently preparing an inventory of road diet projects implemented in Chicago from 2010 onward. This process involves triangulating between Capital Improvement Programs, longitudinal Google Street View, and other local sources (e.g., planning documents, news articles, conversations with planners). The result will be a comprehensive database of road diets and their key attributes, including approval/implementation dates, location, length, configuration, and funding. We will then join this database with longitudinal data on traffic crashes and area-level sociodemographic characteristics from the American Community Survey.

Although this work is in progress, it stems directly from a related analysis on disparities in the street-scale attributes of “walkable” environments in Chicago. Specifically, we used a pedestrian audit tool and Google Street View imagery to examine the characteristics of streets in matched pairs of block groups, which had similar overall built environment characteristics (e.g., population and employment density, distance from downtown, objectively

measured walkability) but different income levels. One key finding was that, among 14 matched pairs of streets with the same functional classification, road diets had been implemented on six of the high-income streets (43%) but none of the low-income streets.

This finding motivated our current “Research in Motion,” suggesting potential disparities in the distribution of road diets and illustrating the broader importance of collecting systematic data on road diets in U.S. cities. Through this Chicago-based test case, we will develop a data-collection protocol that can be applied to other cities for a broad geographic analysis of road diet impacts, as well as a better understanding of how this critical safety intervention can support reductions in crash disparities.

Understanding the Spatial Distribution of Parent-Taught Driver Education Participation in Iowa

Abstract ID: 1842.0.0.691.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Shariha Boshra Diya [Iowa State University] sbdiya@iastate.edu, presenting author

Robert Pfaff [Iowa State University] robpfaff@iastate.edu

Monica Haddad [Iowa State University] haddad@iastate.edu

Teen driving is a longstanding cultural norm in the United States, offering mobility and independence to young individuals. However, access to traditional driver education programs, especially in rural areas, has declined, which is limiting opportunities for many teens (Pezoldt et al., 2007). To address this, the State of Iowa has implemented the Parent-Taught Driver Education (PTDE) program as a lower-cost, more convenient alternative to school-based training. While the program aims to enhance teen driver safety and has grown rapidly, from 400 participants in 2021 to 15,000 in 2025 (Iowa DOT), but little is known about who participates and where they live. Prior research indicates that attitudes toward PTDE vary by geography, minority status, and income level (Hartos & Huff, 2008) and how limited geographic access to driver education opportunities can disproportionately affect low-income and minority communities (Ryerson et al., 2022).

Given that rural areas often have limited access to traditional driver education, we hypothesize that PTDE may serve as a critical alternative for families in rural regions. The research question guiding this study is: What is the spatial distribution of participants in Iowa's PTDE program (2021-2024)? What are the socio-economic characteristics of the areas where they live in? Spatial disparities in PTDE adoption remain largely unexamined, especially in states like Iowa where rural geography comprises majority of the landscape. While prior research has explored safety outcomes of PTDE in other states, its accessibility remains understudied. This study addresses that gap by analyzing spatial disparities in PTDE participation in Iowa. Guided by the advocacy planning theory, it examines how social and geographic factors influence uneven patterns of engagement.

This study examines the spatial distribution of PTDE participation in Iowa to assess whether enrollment patterns show spatial dependency or spatial randomness. Using data from the Iowa DOT-funded project "Safety Impacts of Parent-Taught Driver Education" (Grant No. SPR-4003), we apply geospatial analysis with ArcGIS Pro and GeoDA at the census tract level. Global spatial analysis and Local Indicators of Spatial Association (LISA) will identify spatial patterns in participation. We also conduct regression analysis to explore how socio-demographic and geographic factors relate to PTDE enrollment, using the percentage of participants as the dependent variable. Variables include address data, income, age distribution, racial composition (ACS Data), and accessibility. The study also compares trends across urban and rural areas, factoring in proximity to commercial driver education, road networks, and local socioeconomic conditions. Results will guide policies to improve PTDE access and promote effective driver education for Iowa's teen population.

Whose street is it anyway? Uncovering the role of car-centric biases in bikelash controversies

Abstract ID: 1842.0.0.1018.2025

Track 14: Transportation and Infrastructure Planning

Research-in-Motion Presentation Submission, Research currently in process

Hayley Wiers [Arizona State University] hwiers@asu.edu, presenting author

Bikelash, or community opposition to bicycle infrastructure, frequently disrupts the already slow and bureaucratic process of building safe and connected bicycle infrastructure along city streets. From existing bikelash literature, we know that bikelash is especially likely to occur when proposed bicycle infrastructure is perceived to negatively impact automobility (e.g., slowing car traffic and/or removing car parking/travel lanes) (Wilson and Mitra 2020), and that the arguments made against bicycle infrastructure often project objectivity, using technical language to promote car-centric planning (Egan and Caulfield 2024). Existing case studies of bikelash reveal symptoms of bikelash (e.g., strong political opposition against bike lane projects; removal of bicycle infrastructure after it is built) as well as strategies some planning practitioners have used to ‘treat’ the symptoms (e.g., identifying political champions for bike projects; funding bicycle infrastructure through external sources) (Wilson and Mitra 2020). However, building bicycle infrastructure by these means does not keep pace with broader, time-sensitive planning goals such as reducing traffic deaths, mitigating climate change, and reducing car dependency. Achieving these goals hinges upon planners’ ability to overcome—and even prevent—bikelash by targeting its root cause(s).

One potential driver of bikelash is what some researchers have dubbed ‘motonormativity’, a bias that favors cars and their drivers due to the massive sociocultural impact of automobility (Walker, Tapp, and Davis 2022). Arguments against bicycle infrastructure very often coalesce into a debate about who and what is entitled to public street space, making bikelash appear to be at least as much about cars as it is about bikes (Egan and Caulfield 2024; Wilson and Mitra 2020). Studies of other types of bicycle controversies reveal deep tensions between drivers and cyclists, which are disproportionately harmful to cyclists (Delbosc et al. 2019; Ralph et al. 2019). Mounting evidence suggests that these tensions play out politically through opposition to building public bicycle infrastructure.

Using Phoenix, Arizona as a case study, my dissertation research answers the overarching research question: How do people’s feelings about cars relate to bicycle controversies? I approach the topic through social media analysis, interviews, and grounded theory methods. To investigate the feelings and ideas underlying bikelash, I analyzed social media responses to crashes between cyclists and drivers. I collected and thematically coded a sample of approximately 2,000 individual Facebook comments on posts by local news outlets reporting crashes between cyclists and drivers in the Phoenix area. This analysis aims to reveal people’s feelings about bicyclists as street users and about bicycling infrastructure, as well as the implications of these feelings on bicyclists’ right to the street. These feelings are more clearly revealed in comments on posts about bicyclist-involved crashes than within bikelash discourse, where people have vested interests in the outcome and tend to use their words more judiciously.

To further investigate the mechanisms underlying bikelash, I conducted a series of in-depth interviews with bikelash participants, including local planners, engineers, elected officials, bicycling advocates, business owners, opponents of bicycle infrastructure, and members of the press and thematically analyzed the interview data. This analysis aims to identify the ways bikelash discourse centers around cars (and people’s feelings about cars) as well as how different groups’ views about who and what has a right to the street affect [mis]communication between opposing groups. Based on the results of both analyses, I use grounded theory methods to expand upon the construct of motonormativity and consider its depth, expressions, and implications for transportation planning.

Track 15 Roundtables

Emerging Trends and Ongoing Challenges with Urban Design Pedagogy

Abstract ID: 1843.0.0.695.2025

Track 15: Urban Design

Roundtable Submission, Topical Discussions

Kelly Gregg [University at Buffalo] kgregg@buffalo.edu, organizer

Brent Ryan [MIT] bdr@mit.edu

Danillo Palazzo [University of Cincinnati] palazzdo@ucmail.uc.edu

Ryun Jung Lee [University of Texas at San Antonio] ryunjung.lee@utsa.edu

Lohren Deeg [Ball State University] lohren.deeg@gmail.com

The dynamic nature of urban environments will continue to require forward-thinking approaches to urban design practice and education. Furthermore, urban planning students continue to be interested in learning how urban design methods can address these complex challenges. This topical discussion roundtable aims to explore the emerging trends, recent innovations, and ongoing challenges in urban design education especially within the context of an urban planning department.

Our panelists and participants will engage in discussions regarding the scope of an urban design curriculum within an urban planning department including but not limited to discussions about: the role of studio-based learning as a cornerstone of urban design education, how to foster critical thinking, creativity and real-world problem-solving skills through site based projects. Additionally, the conversation will explore the incorporation of artificial intelligence (AI) and other emerging technologies in urban design processes, assessing their impact on both pedagogical approaches and professional practice. With the rise of remote learning, the session will also address challenges and opportunities associated with virtual studio environments, hybrid learning models, and digital collaboration tools.

Objectives:

- To discuss key innovations transforming urban design education especially within urban planning departments.
- To identify major challenges and barriers to progress in integrating new methodologies and technologies into studio and urban design education.
- To explore interdisciplinary approaches and collaboration opportunities across architecture, planning, real-estate and related fields.
- To engage with the audience in a meaningful Q&A session to gather diverse perspectives on the future of urban design education.

Jota Samper [University of Colorado] jota@colorado.edu

This session convenes a diverse group for a facilitated debate about whether (and how) neighborhood design in heterogeneous places can promote higher levels of inclusion and belonging for all. To get at this, the roundtable focuses on a seemingly modest concept: the signaling of inclusion.

The session opens with comments from roundtable participants, serving as the departure point for additional audience discussion that seeks to advance thinking around the following questions:

1. What constitutes a “signal of inclusion”?
2. What sensory and media mechanisms are deployed to convey welcome and/or exclusion?
3. Why and to what extent should urban designers address signals of inclusion?

Avoid the Quicksand: Navigating VR/XR and Emerging Technologies in Urban Design Education

Abstract ID: 1841.0.0.994.2025

Track 15: Urban Design

Professional Development Workshop Submission

Fu Li [Clemson University] lifu93@hotmail.com, organizer

Junyan Ye [Peking University] yejunyan@pku.edu.cn

Yuan Shuai [The Hong Kong Polytechnic University] shuai.yuan@polyu.edu.hk

Liyan Xu [Peking University] xuliyan@pku.edu.cn

Evidence-based design is becoming a fundamental research pillar in environmental studies, urban design, landscape architecture, and related disciplines, with Extended Reality (XR) and other cutting-edge technologies advancing these fields in recent years. This workshop will share our experiences organizing design courses over the past five years and engage participants in discussions about relevant issues. We will introduce how to design a seminar/studio syllabus incorporating evidence-based research theories, providing students with a platform to prepare content related to design themes and research, building their critical research and data analysis skills, and feeding research results back into the design process, and methods for promoting research findings and enhancing communication skills. The workshop will explore semester progress check mechanisms, iteration strategies, and class organizing practices. We will share multiple cases integrating emerging technology with design courses, including technology pipeline selection, preparation from the instructor's team, common challenges and solutions, and hardware-software integration experiences. We will discuss organizing an interdisciplinary teaching team that provides the necessary support, collaborates with primary design instructors, and manages student grouping. Building on the discussion with the audiences, we will summarize key success factors, limitations, and lessons from challenging cases, reflect on constructing such courses better, and envision the future development of XR technologies in educational applications. This workshop aims to share practical experience, helping audiences evaluate and effectively apply emerging technologies in their teaching practices, providing a future .

Workshop Objectives

1. Explore how evidence-based design methods and cutting-edge technologies like XR can effectively integrate to improve urban design teaching quality
2. Share experiences and strategies for building interdisciplinary teaching teams and addressing challenges in integrating technology with design education
3. Provide a practical framework to help educators incorporate XR technology into their course design
4. Showcase multiple successful and failed cases, analyzing key success factors and common pitfalls
5. Create a platform for participants to share their experiences using cutting-edge technologies in urban design education

Workshop Schedule

1. Introduction and Background (10 minutes): Potential of evidence-based design methods and VR technology in urban design education
2. Case Analysis (20 minutes): Presentation of multiple course implementation cases, analyzing successful experiences and lessons from failures
3. Practical Framework (10 minutes): Providing practical frameworks for course design, team building, and technology selection for participants to reflect on.
4. Interactive Discussion (40 minutes): Participants share their experiences, discuss common challenges and solutions
5. Quick Summary (10 minutes): Addressing critical questions from participants and summarizing key points

What will the audience learn from your workshop: Participants will learn practical strategies for integrating VR/XR and other technologies into design process, building interdisciplinary teams and creating evidence-based design frameworks. We will provide practitioners with actionable insights, helping them evaluate technologies and actions.

Reminders for attendees: Participants DO NOT need to bring a VR Headset, XR device, or other equipment. We encourage all types of audiences in different roles, from instructors, researchers, and students, to share with us your experience and build a meaningful dialogue.

A Study on the Impact of Agent-Based Greenspace Access on Mental Health

Abstract ID: 1844.0.0.1055.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Yu-Hyun Kim [Pusan National University] youhuen907@pusan.ac.kr, presenting author

[Research Backgrounds, Objectives] There is a growing interest in exploring the relationship between mental health and the urban environments. In particular, the increasing concentration of population in cities, with two-thirds of the world's population expected to live in cities by 2050, is expected to increase the number of people with mental health problems. Also, the urban environment itself has been identified as a risk factor for mental health (Peen et al., 2010). Since greenspace has been reported to have a positive relationship with mental health, various efforts are being made to promote mental health at the urban level, such as spatial planning and park creation programs, mainly in developed countries such as the United States and the United Kingdom, where urban populations are densely concentrated (Hillsdon et al., 2006). While the importance of urban green space for positive mental health is discussed in terms of area, location, distance, number, and frequency, the accessibility of urban green space remains the key determinant.. The concept of accessibility can be described in terms of availability and proximity (Guagliardo, 2004), but existing studies have focused on the concept of availability, which refers to the amount of services that can be provided, and have failed to consider the changes that occur during the process of using green space (Park et al., 2022). Therefore, this study aims to identify the impact of greenspace accessibility on mental health by using agent-based modeling(ABM) to consider the attributes and behavioral rules of individual actors.

[Data and Method] This study builds an ABM to understand the impact of access to greenspace on mental health from an actor perspective in Roanoke, Virginia, USA. The main purpose of the model is to simulate the interaction of multiple actors to access a green space, and it represents a series of processes such as actors' movement, decision, and utilization. Through the built model, simulations were conducted by considering the pattern of movement of greenspace users to access greenspace, obstacles and determinants to access greenspace, and the number of greenspaces. The results of the simulation provided data on the probability of accessing greenspace and the time it takes according to the spatial distribution of users, which was later used to identify factors affecting mental health. The mental health data, was obtained from the US CDC's annual survey data by census tract.

[Expected Outcomes] To determine the average number of greenspaces visited and the time it takes to access and use a greenspace from an individual actor's residence, we will run the model 100 times, randomizing each actor's residence. After cumulatively reconstructing the results, we found that the actor who visited the most greenspaces needed to visit three greenspaces to access them, and the actor who took the longest time to access a greenspace spent about 78.19 minutes. The highest number of actors visited one greenspace, and the highest number of actors spent an average of 10 to 20 minutes in each greenspace. To explore the effect of actor-based greenspace access on mental health, we conducted a multiple regression analysis of the effect of greenspace access on mental health by census tract. Among the general characteristics of individuals, age and income level had statistically significant effects on mental health. Among the physical environment of the community, safety and comfort were found to have an impact. The younger the age and lower the household income level, the lower the effect of access

to greenspace on mental health, and the higher the safety and comfort of the physical environment, the stronger the positive effect of access to greenspace on mental health.

Collective Comfort as Civic Infrastructure: An Urban Code for Heat Resilience

Abstract ID: 1844.0.0.1100.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Dalia Munenzon [University of Houston] dmunenzo@central.uh.edu, presenting author

As extreme heat events intensify due to climate change, urban cooling strategies must evolve beyond emergency interventions toward systemic, long-term transformations—especially in U.S. southern cities. Unlike floods or hurricanes, heat remains an invisible threat despite being the deadliest climate-related hazard. This risk disproportionately affects historically disinvested communities, where spatial inequities in shade access, infrastructure investment, and energy affordability deepen thermal vulnerability.

This paper presents An Urban Code for Heat Resilience as a core outcome of the ongoing Collective Comfort research initiative, which reimagines the cooling center as a hybrid civic and educational hub. Rather than treating cooling as a temporary emergency response, Collective Comfort advances a vision of thermal equity through durable, multifunctional spatial interventions—what we call collective comfort: a public right to safety, agency, and well-being in a warming world. This framework positions cooling infrastructure as essential civic infrastructure—embedding it within the codes, land use strategies, and social infrastructure of the city.

The Urban Code builds from research and design collaborations with interdisciplinary teams and community-based organizations, particularly in Phoenix, Arizona, and Houston, Texas—two cities with extreme but distinct climatic conditions (arid vs. humid). In both contexts, we analyze spatial vulnerabilities in single-family residential areas, mobile home parks, and under-shaded public domains. The proposed Urban Code introduces policy tools and spatial typologies—such as shading corridors, thermal commons, and neighborhood-scale resilience hubs—that adapt to local morphology while re-centering thermal relief around equity and public life.

Crucially, these interventions are not only design gestures but part of a broader shift toward social infrastructure—flexible spaces that foster health, connection, and civic learning year-round. We explore three scalable typologies (adaptive reuse, plug-in, and ground-up) emerging from the Collective Comfort project, and how they inform an urban design logic of hybridity: combining passive cooling, microgrid-supported energy resilience, and place-based programming. This spatial logic reorients the urban environment around both climate preparedness and everyday livability.

Through case studies like the Wesley United Methodist Church and the Palo Verde Library in Phoenix, alongside emerging Houston-based efforts responding to compound climate and energy vulnerabilities, we demonstrate how this code can guide both grassroots innovation and institutional planning.

By linking zoning, urban form, and the right to collective comfort, this work contributes to planning and urban design by embedding climate adaptation directly into civic life. It offers a replicable framework for cities to confront the era of heat with dignity, care, and spatial justice.

Demystifying Mystery in Urban Environment : Operationalizing Pedestrian Preference

Abstract ID: 1844.0.0.984.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Yejun Lee [Yonsei University] lyjun0214@yonsei.ac.kr, presenting author

Jae Min Lee [Yonsei University] jaemin.lee@yonsei.ac.kr

Understanding how urban environments influence pedestrians' preferences is crucial to understanding walking in urban design. This study aims to measure pedestrians' preferences with an index based on spatial data from urban environments.

Many urban design researchers attempt to understand the relationships between preferences and urban landscapes. First, Kaplan (1975) categorized landscape preference into two dimensions. One dimension is the tense of information, whether information is provided in the present or the future. The other dimension is the quantity of information, whether the amount of information is large or small. Using these two dimensions, landscape preferences are classified into coherence, identifiability, complexity, and mystery. Among the four factors of landscape preference, Kaplan & Kaplan (1989) found that "mystery" is a key predictor of landscape preferences. "Mystery" involves the future promised information and moderate information that draws pedestrians to enter and venture forth. To evaluate mystery, measurement methods using various physical properties and environmental cues have been proposed. First, Gimblett et al. (1985) discovered five factors that influence mystery: screening (i.e., anything that can be used to partially obstruct or obscure the view of the larger landscape), enclosure (i.e., the degree to which landscape elements surround the observer), physical accessibility (i.e., an apparent means of moving through or into the landscape), distance of view, and illumination. Additionally, Herzog (1988) and Nasar & Cubukcu (2011) found that curving pathways are considered a key factor for predicting mystery. Moreover, Jacobs (1993) explained that several great city patterns have curved streets, which make orientation difficult and provide mystery. Though mystery is important to pedestrians' preferences, these approaches did not operationalize mystery to be used in practical urban design. Also, these approaches lack precise measures to support these statements since the associated research was qualitative in nature. Therefore, this research will address the gap by creating a preference index using spatial data of urban environments, so that mystery can be evaluated in practical urban design.

Our research seeks to operationalize mystery in urban settings so that we're developing a pedestrian preference index. The pedestrian preference index is classified into two categories according to two dimensions of landscape preference. To examine the tense of information, we used street curvature (Nasar & Cubukcu, 2011; Herzog, 1988), the number of junctions (Scotland. Scottish Government, 2010), and the distance to the nearest landmark (Lynch, 1960). To examine the quantity of information, we used land use of nearby buildings (Tong & Bode, 2022), and vegetation density (Bjerke et al., 2006). After creating the index scores based on the defined index focusing on the central area of London, we compared them to three dependent variables representing pedestrians' preference. First, we used camera location data (pedestrian viewpoint) from 'Geograph' to examine viewpoint density, which represents areas that are preferred. Second, we used local integration R3 in Space Syntax because it is used to predict pedestrians' preferred route choices (Ericson et al., 2020). Lastly, we used Visibility Graph Analysis (VGA) to predict preferred gathering spaces (Jumpei Ueno et al., 2012). As a result, we expect that if the index score is higher, the viewpoint density, the R3 value, and VGA value will also be greater.

Our research provides insight into which urban settings impact pedestrians' preferences by comparing the pedestrian preference index and current preferred area for pedestrians. Furthermore, our results lay the

groundwork for providing perceptual urban design with spatial analysis and giving practical insights for urban planners to create more engaging and walkable cities.

Double Standards: Regulating Street Connectivity in Public & Private Communities in the U.S

Abstract ID: 1844.0.0.250.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Zhan Guo [New York University] zg11@nyu.edu, presenting author

Tim Guangyu Wu [New York University] gw923@nyu.edu

Urban street networks play a pivotal role in shaping mobility, land use patterns, and broader planning outcomes. Yet, their long-term evolution and the influence of regulatory frameworks remain underexplored. This study investigates how street connectivity has changed over time across the continental United States and examines the role of regulatory differences between public and private residential streets in shaping these patterns.

We develop a high-resolution spatiotemporal dataset by integrating OpenStreetMap (OSM) with the Historical Settlement Data Compilation (HISDAC), offering intersection connectivity measures at a 250-meter resolution spanning two centuries. Our methodology enhances spatial accuracy, filters network artifacts, and leverages Google Street View data to refine private street identification, increasing detection rates by one-third beyond standard OSM attributes. Our data encompasses over 10 million intersections and dead-ends, including more than 600,000 private street nodes. From this dataset, we further identified approximately 3,000 private communities larger than one square kilometer and identified nearby public street communities for comparative analysis. Connectivity is primarily measured using nodal degree—the number of streets meeting at an intersection—and complemented with additional network attributes such as circuitry, land use mix, and urban form indicators to account for confounding factors.

Our preliminary findings reveal a distinct historical trajectory of street connectivity. Connectivity peaked in pre-automobile urban forms, declined throughout much of the 20th century, and began rebounding in the 1990s. This resurgence reflects a shift in street design rules and principles, emphasizing accessibility and multimodal mobility. Private residential streets have consistently exhibited lower connectivity than public streets, highlighting the role of regulatory oversight in shaping urban networks. Notably, as overall connectivity has increased, the gap between public and private residential streets has narrowed. Regional analysis shows consistent trends across U.S. regions, with some variation in the pace and magnitude of change.

By linking our dataset with the Wharton Residential Land Use Regulation Index (WRLURI), we find that stricter land use regulations are associated with lower connectivity in public residential streets. In contrast, private gated communities, often designed with greater flexibility, show no significant regulatory impact. These findings provide critical insights into the effects of regulatory frameworks on street network evolution.

This study offers valuable contributions to ongoing debates on urban regulation, land use policy, and sustainable development. Understanding how connectivity evolves and how regulations shape street networks is essential for informing policies that promote accessibility, walkability, and efficient land use. With the recent trend toward deregulation and decentralized planning at municipal and state levels—such as the removal of minimum parking requirements—our findings offer timely, evidence-based insights for policymakers seeking to balance regulatory flexibility with sustainable urban design.

Fostering Social Resilience through Built Form: Evidence

Abstract ID: 1844.0.0.392.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Szymon Nogalski [University of Cincinnati] szymon.nogalski@gmail.com, presenting author

The key to continuous existence of a city lies in its sustained capacity to repair, adapt, and regenerate itself. Scholarship on resilience within built environment disciplines has primarily centred on three scales: buildings, landscapes, and cities. Architects have explored energy-efficient and sustainable solutions through advancements in building technologies and systems. Landscape architects and environmental scientists have addressed site-specific and systemic challenges, such as water and air quality management. Meanwhile, city planners have focused on urban resilience to natural events and the social and economic aspects of sustainability. Together, these scales encompass much of what is required for a sustainable and resilient built environment.

However, resilience as a distinct focus in urban design is a relatively new area of study. In line with other disciplines, resilience in urban design is often framed as risk management or a subset of sustainability. The term "resilient cities" often skews heavily toward disaster recovery and biophilia, leaving a detailed understanding of urban form underexplored, particularly in the context of the social and economic dimensions of resilience.

Social and economic capacity to adapt and evolve is primarily manifest in social infrastructure, i.e. a network of places that play an important role for social cohesion and public life. Places like schools, libraries, 'third places', businesses, but also parks and plazas provide conditions and opportunities for formation and cultivation of social relations – from weak ties to strong and formative personal relationships. These social infrastructures have been often viewed as important for the sense of community, well-being and quality of life; but they also play a role in providing e.g. informal support networks, economic opportunities and access to recourses. The provision and vitality of social infrastructure are therefore related to response and adaptation mechanisms within communities and thus a component of their resilience.

This understanding of social infrastructure must therefore extend beyond the formal spaces of social encounter to include all places that provide affordances for social interactions; increasing resilience of cities therefore involves creation and cultivation of built environment that includes such affordances. The parochial realm in a predominantly residential neighbourhood – a territory where people share a sense of commonality and involvement – in this context forms an arena of intervention, with its combination of private, common and public spaces and interfaces between them.

This contribution introduces form-related characteristics of built environment that support social infrastructure in its resilience-building dimension. Four scales of urban design interventions are therefore considered, reflecting primary conditions of interest and influence for urban design practice: the public-private interface, the street, the neighbourhood and the wider district. Using Boston predominantly neighbourhoods as a case study, characteristics of built form that provide affordances contributing to social interaction and formation of social relations are identified at each scale, supported by empirical evidence that includes typo-morphological mapping data (parcellation, form of public-private interfaces, characteristics of street network and common and public spaces, location and form of non-residential uses) and observation (physical traces, activity and personalisation of spaces, use of formal social infrastructure).

From Fixity to Flow: A Scoping Review of Place Attachment Research in South Korea

Abstract ID: 1844.0.0.982.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Heewan Kim [Seoul National University] heewan0608@snu.ac.kr, presenting author

In Kwon Park [Seoul National University] parkik@snu.ac.kr

Research on place attachment has steadily increased in South Korea since the 2000s, yet it remains narrowly concentrated on specific topics while lacking sufficient exploration of its essential dimension—everyday life. Place attachment is a phenomenological concept that deals with "everyday rootedness" through emotional bonds between people and places, emphasizing the importance of "everyday practice" in familiar places. This study aims to conduct a scoping review to examine these research trends and analyze how existing literature conceptualizes and approaches the everyday dimension of place attachment.

Our analysis examined the titles and keywords of all Korean Citation Index (KCI) registered papers in social sciences addressing place attachment (n=285). The results show that 66% of studies (n=187/285) focused on tourism and development (tourist sites=145, festivals/events=26, development projects=16), while 8% (n=22/285) examined commercial and consumer spaces (cafes/restaurants=13, department stores/discount stores/malls=6, others such as campsites=3). Through the People-Place-Process (PPP) framework of place attachment, these studies focused primarily on specific target groups (tourists/visitors, residents of development areas, residents of event-hosting areas, and consumers), non-everyday places (tourist destinations, large-scale facilities, development project areas, and consumer spaces) and goal-oriented processes (satisfaction factors including revisit intention, willingness to pay, and customer loyalty, development support, and pro-environmental behaviors).

Recent discussions of "everyday rootedness" through place attachment emphasize its fluidity. Following the mobility turn in social sciences since the 2000s, scholars increasingly recognize the need to move beyond sedentary assumptions and understand place attachment as a dynamic, fluid process that continuously evolves. To examine how existing literature conceptualizes and analyzes the everyday dimension of place attachment, this study focuses on 76 papers addressing this aspect. The study investigates their specific themes and subjects, employing the "Fixity-Flow Framework" (Di Masso et al., 2019) to identify key domains for analyzing fluidity. By moving beyond the sedentary dichotomy of "everyday vs. non-everyday places," this research highlights fluid place experiences in its comprehensive literature review.

Our analysis of the literature using the Fixity-Flow Framework reveals that place attachment is shaped by mobility patterns that vary across socio-economic groups. South Korea serves as a compelling case due to its rapid urbanization and increasing mobility, making it a unique context for exploring the interplay between fixity and flow. By examining South Korean studies, this research sheds light on how place attachment evolves in a highly mobile society and provides insights applicable to other rapidly urbanizing and globalizing contexts. This review contributes to the broader discourse on place attachment by demonstrating how mobility influences place experiences beyond Western-centric perspectives. It offers a foundation for comparative studies, fostering discussions on the universality and context-specificity of place attachment dynamics in an era of increasing mobility.

Lohren Deeg [Ball State University] lohren.deeg@gmail.com, presenting author

Reflecting on the levels of citizen participation and engagement first outlined in Sherry Arnstein's 1968 article A ladder of citizen participation, it may be argued that Arnstein's ladder can and should be reexamined in the current digital and social media contexts. To stimulate creativity, dialogue, and visual understanding in the urban design and planning processes, it has become increasingly necessary to become disruptive in the dialogue and communication of urban futures. This need for disruption provides food for thought regarding both pedagogy and public participation methods in the post Covid-19 era. It is argued that the interactive qualities of new tools such as digital review boards yield many possibilities for the future of work and the future of learning in the design and planning disciplines. Digital review boards provide wider access and different forms of dialogue to both digital natives and interested citizens that otherwise would not be reached. The author designed and tested such an activity with a digital review board during social distancing measures. Following the lifting of those restrictions, and observing the negative effects of excessive screen time, the author revived a series of haptic lessons that could facilitate student learning and community outreach. Crafting urban land use and massing models with simple, everyday materials such as cleaning sponges and plastic building blocks stimulated visualization and discussion for infill development in several scenarios and with a variety of demographics. Student reflections and feedback, as well as observed behaviors served as evidence and metrics for these studies. Reflection on these new tools and processes considering Arnstein's ladder have become necessary to help communities continue to recover from the upheaval of the pandemic, repair broken cycles of community dialogue, react to changing forces in the economy, consider the challenges of climate change, and adapt to the demand for more diverse typologies in real estate and the urban form.

This study proposes a novel workflow for applying text-to-image generative AI in conceptual open space design. Traditional methods of conceptual design—such as hand sketching and manual rendering—are often time-consuming, resource-intensive, and limited by the individual designer’s experience. To address these challenges, we develop an AI-assisted design workflow that integrates Stable Diffusion with ControlNet and Low-Rank Adaptation (LoRA), enabling rapid generation of spatially coherent design images from simple text prompts and sketches. Three common types—natural parks, city plazas, and courtyard gardens—serve as case studies.

The proposed method involves training LoRA models on extremely small datasets (fewer than 10 images per design type), significantly reducing data collection and training time. With just 20 minutes of training on a personal computer, the fine-tuned models produce diverse, detailed, and structurally consistent open space designs. We compare outputs from fine-tuned and non-fine-tuned models using both quantitative metrics—PSNR, SSIM, and LPIPS—and qualitative evaluation criteria based on layout, function, and visual aesthetics. Our results show that the fine-tuned models consistently outperform baseline models across all evaluation dimensions, producing designs with improved clarity, spatial organization, scale control, and fidelity to input prompts.

This research makes two primary contributions. First, it introduces an efficient and replicable AI-assisted workflow that covers the entire conceptual open space design process—from sketching and dataset curation to model training and design evaluation—thereby enhancing early-stage design productivity. Second, it demonstrates that high-quality conceptual design is achievable with minimal resources and training data, which is particularly valuable for rapid ideation and iterative feedback cycles in professional or academic design settings.

By bridging computational design tools with urban design, this study contributes to the growing body of research on AI in the built environment. It also offers practical guidance on how designers—especially those without programming expertise—can integrate generative AI tools into their creative processes.

Green Growth and Sustainability Transitions: Evolution of Planning in an Arctic City, Luleå (Sweden)

Abstract ID: 1844.0.0.590.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Aleksandra Durova [University of Virginia] adurova@virginia.edu, presenting author

Matthew Jull [University of Virginia] mj5kh@virginia.edu

As the green transition becomes a priority across the European Union, Nordic countries are leading efforts to expand investment in green industries and promote climate neutrality. With increasing investments in green industrial production, cities face the challenge of planning for growth and reshaping urban landscapes. However, how cities adapt spatial planning and the built environment to meet these goals remains uncertain. This paper examines how the sustainability and green agendas influence urban development in Luleå, Northern Sweden — a city emerging as a key player in the green transition through efforts to establish a fossil-free steel industry and a regional green value chain. These developments introduce new planning challenges related to rapid growth, environmental pressures, and socio-economic impacts. A historical parallel can be drawn with the growth period in the 1960s and 70s, when large-scale housing and infrastructure investments were made in anticipation of the Stålverk 80 steel plant—later canceled—leaving parts of the city underutilized. Today's industrial expansion, framed by climate and sustainability imperatives, raises similar questions about planning for growth and its long-term consequences. Luleå's commitment to sustainability suggests that current planning may shape a city fundamentally different from the one resulting from the mid-20th century technocratic planning. The study uses spatial analysis, historical planning records, and contemporary documents to examine how residential development and design strategies have evolved across multiple neighborhoods. Using orthophotos and satellite imagery, we characterize the scale and direction of urban change since the mid-20th century. Five city areas are analyzed, representing various residential typologies and their close relation to neighborhoods from the previous growth period. Findings reveal a transformation in urban form, marked by human-scale design, flexible layouts, and greater integration of natural landscapes compared to the modernist planning of the earlier growth period. While contemporary planning promotes denser and more diverse residential patterns, it still reflects some of the enduring legacies of welfare-state planning. However, unlike earlier periods shaped by substantial public investment, today's sustainability planning operates within a market-oriented logic that may sideline social equity. The paper concludes by situating Luleå's trajectory within broader debates on the shift from welfare to sustainable city models, highlighting concerns about rising inequality as a challenge linked to green urban development.

How Does Urban Informality Durability? : A Case Study of Street Vendors in Yeongdo, Busan

Abstract ID: 1844.0.0.320.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Si-Hyun Ban [Pusan National University] qkstlgus11@naver.com, presenting author

Ji-Hyun Kim [Pusan National University] jikim@pusan.ac.kr

The concept of informality has evolved across various fields, including urban planning and design, stemming from discussions on informal sectors led by economists in the 1970s. Initially perceived as separate from formal structures and primarily linked to the Third World and urban poor, informality has since been reinterpreted through various critical perspectives. Rather than a purely illegal phenomenon, urban informality is now understood as an ongoing process present in all urban spaces, not just declining areas. It is also viewed through the lens of temporary and tactical urbanism, which activates urban spaces as part of urbanization.

This study examines urban informality in this context, raising the question: “How does the durability of urban informality manifest across different social and spatial contexts?” Building on Roy’s (2005) framework, it analyzes how informality persists over time. The case of Yeongdo street vendors illustrates the interplay between formality and informality, where social-spatial positioning and stakeholder interactions shape informal practices.

The research employs qualitative methods, including analysis of reports, media sources, and local government data, along with semi-structured interviews and field surveys involving merchants and government officials.

Findings reveal three key aspects. First, the government strategically legalizes or outlaws street vendors, blurring boundaries between formality and informality. Second, shifting social perceptions—amplified by social media—have expanded informality’s presence and durability, reframing it as a tool for local tourism rather than solely a regulatory concern. Nonetheless, the Yeongdo-gu Office continues to perceive it ambiguously, balancing its benefits and challenges. Third, public officials remain passive toward informal actors, recognizing their role in revitalizing urban spaces outside formal planning systems.

Ultimately, this study highlights how informal activities, operating beyond conventional planning structures, contribute to urban regeneration. Moving beyond a rigid formality-informality dichotomy, it emphasizes the dynamic interaction between informal practices and formal planning. As traditional planning systems struggle to accommodate society’s evolving needs, modern urban design must embrace greater flexibility, allowing for the organic development of informal activities within cities.

Integrating Stormwater Management and Active Transportation: Case Studies in Street Design

Abstract ID: 1844.0.0.145.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Alan Vlakancic [University at Buffalo] ahv2@buffalo.edu, presenting author

Kelly Gregg [University at Buffalo] kgregg@buffalo.edu

Omar Suri [University at Buffalo] omarsuri@buffalo.edu

Using a series of representative case studies, this research explores stormwater management and street design, specifically questioning how cities incorporate pedestrian and cyclist amenities when undertaking construction for sewer and stormwater management projects. Stormwater management is a well-articulated aspect of street design within landscape architecture practice and civil engineering. Similarly, the National Association of Transportation Officials (NACTO), the Complete Streets initiative, and the Vision Zero movement are leading transportation planning toward streets that safely accommodate pedestrians and cyclists (Congressional Research Service, 2024; Gregg & Hess, 2019; NACTO, 2025). However, the expectation that streets will incorporate both stormwater management and pedestrian/cyclist improvements is less clearly conceptualized.

Many cities across the United States have aging infrastructure that will need to be upgraded in the coming years (Zaleski, 2021). Sewer reconstruction and stormwater projects present significant opportunities to integrate new street designs alongside other major infrastructure investments. Linking sewer and stormwater projects with pedestrian and cyclist improvements can offer multiple benefits for climate change adaptation and mitigation, promoting safety and accessibility for non-motorized users (FHWA & US DOT, 2022; FHWA, 2022).

One such example is the recently completed Niagara Street Cycle Track in Buffalo, NY, which combined sewer upgrades, stormwater retention, and alternative transportation goals, resulting in a holistic redesign of the street. In building Niagara Street, Buffalo's Sewer Authority leveraged funding available for stormwater projects due to the city's status under the Environmental Protection Agency (EPA) Clean Water Act Consent Decree. With 91 cities under EPA Consent Decrees, we selected our case studies from this cohort, assuming they would be more likely to make investments aimed at reducing stormwater runoff (Bluefield Research, 2018; EPA, 2025).

We developed the case studies through reviews of municipal documents and semi-structured expert interviews with professionals from planning, transportation, and sewer authority agencies involved in these projects. Our initial research suggests that there are numerous challenges in realizing these potential benefits of combining above and below ground project goals, one of which is the barrier posed by municipal silos and ineffective intergovernmental coordination (Scott, 2020; Scott & Gong, 2021). Often, sewer and stormwater projects are managed by different departments or agencies, separate from transportation and public works projects that shape street design. As a result, we observed a disconnect between managing the street right-of-way at the surface and below the surface. Many sewer projects are only required to replace the street to its original condition, missing the opportunity to coordinate efforts and rethink the overall street right-of-way.

Interdisciplinary Service-Learning: Urban & Landscape Design for Climate Adaptation

Abstract ID: 1844.0.0.879.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Qiong Wang [University of Georgia] qiong.wang@uga.edu, presenting author

Yao Wang [Louisiana State University] yaowang@lsu.edu

Planning education is increasingly called to integrate interdisciplinary and experiential learning to prepare future professionals for the complex challenges of climate change and urban resilience. While planning and landscape architecture share overlapping concerns, such as place-making, sustainability, and community engagement, they often remain siloed in pedagogical practice. Drawing from recent calls in the literature for constructivist and collaborative studio models, this study explores how interdisciplinary service-learning studios can bridge these disciplinary divides to enhance student learning and address real-world challenges.

Research Questions-The research questions include: 1) How does an interdisciplinary, service-learning studio experience shape students' understanding of urban and landscape design principles? and 2) What are the pedagogical outcomes of such collaboration for climate adaptation planning?

Methods-In Fall 2024, an interdisciplinary collaboration was launched between the PLAN 6520 Urban Design Studio at the University of Georgia (UGA) and the LA 3001 Site Planning and Design Studio at Louisiana State University (LSU). A total of 25 students—11 graduate students from the Master of Urban Planning and Design program at UGA and 14 undergraduate students from the Bachelor of Landscape Architecture program at LSU—collaborated on the design of a mixed-use, climate-resilient development for a 367-acre site in Savannah, Georgia. Partnering with the Savannah Planning, Zoning, and Urban Design Department, students engaged in site visits, stakeholder meetings, and public presentations. Data for this study were collected through post-course surveys and written reflections. Survey questions assessed student perceptions of interdisciplinary collaboration, design outcomes, and the influence of service learning on their understanding of design principles.

Results-Findings show that students found the interdisciplinary format highly beneficial to their educational experience. The majority reported that their understanding of both urban and landscape design principles was “significantly” enhanced through interdisciplinary collaboration. Over 90% of respondents rated the quality of design outcomes as “good” or “excellent.” Additionally, almost all students expressed strong interest in participating in future service-learning projects, highlighting the project's success in engaging students and fostering enthusiasm for practical, collaborative learning opportunities. Students appreciated the opportunity to address real-world planning and design issues, including ecological sensitivity, housing needs, and community engagement in a historically and environmentally rich context like Savannah.

Conclusions-This case study demonstrates the value of interdisciplinary, service-learning studios in advancing planning pedagogy and sustainability education. The integration of landscape architecture and urban planning perspectives fostered richer, context-sensitive designs and deepened students' understanding of climate adaptation strategies. The project underscores the importance of cross-institutional and cross-disciplinary collaboration to foster critical thinking, peer learning, and professional preparedness in planning education. These findings support broader efforts to embed sustainability literacy and interdisciplinary methods into planning curricula and practice.

Investigating Planning Process and Actual Usage of Privately Owned Indoor Public Spaces in Seoul

Abstract ID: 1844.0.0.1072.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Seongkyung Yoo [Yonsei University] yoosk@yonsei.ac.kr, presenting author

Jae Min Lee [Yonsei University] jaemin.lee@yonsei.ac.kr

Outdoor public space (e.g., public plazas and parks) creation in urban cores is limited due to the cost of land and management. As an alternative, indoor public spaces in Seoul, which serve as weatherproof social centers, are increasing. Interestingly, the private sector did not receive any incentives for creating these spaces. What is the developers' motivation?

The perspective on indoor public spaces has varied since the late 20th century. In the concept of 'adjacent attraction,' the decontextualized elements, such as museums, libraries, and landscapes in malls, are just parts of the marketplace to make commodities and shopping experiences desirable (Crawford, 1992). On the other hand, in the concept of 'collective spaces,' privately owned public spaces play a crucial role in urban life as not being strictly public nor private, but being both (De Solà-Morales, 1992, as cited in Poot, 2015). This supports the private sectors' assertion that their motive is to contribute to public well-being. However, contemporary examples in Seoul are hard to demonstrate in such a simple dichotomy.

Seoul citizens are increasingly using the new spaces as extensions of the urban landscape, benefiting from easy access to public transportation and well-maintained conditions. Amorepacific, a cosmetic company, opened its new headquarters building's atrium and underground concourses for the public since 2017. Citizens use this space as a covered pedestrian area to sit at tables and enjoy lunch breaks from tenant restaurants. Coex Mall, located at the center of Gangnam, has been providing Starfield Library since 2017. Users not only read but have coffee, enjoy literature events, and meet their acquaintances, serving the atrium-styled library as a landmark. The Hyundai Seoul, established in 2021 within the Yeouido business district, has implemented innovative spatial design including indoor landscapes to distinguish itself from conventional Korean department stores, even removing the term "department store" from its original name, "Hyundai Department Store" (An, 2024). The basement floor is populated with businesspeople during the workday lunch hours, while weekend visitors enjoy strolling around the trees under the air conditioner. These spaces are extending their services beyond their immediate customers. Why did these corporations undertake such experiments?

This research investigates the planning process and usage of indoor public spaces in Seoul. The study will examine the true motivations and expectations of various stakeholders in each process through a series of interviews, along with the designer's expectations. Actual usage will be analyzed through field studies utilizing eye observations, interviews, and Light Detection and Ranging (LIDAR). LIDAR has been frequently used to analyze human behavior over long periods in wide areas (Koide, Miura, & Menegatti, 2019). For this study, the technology will identify spatial morphology and facilities that promote public use.

The findings can improve the Seoul Metropolitan Government's building code, which lately included indoor public spaces to be eligible for floor area ratio incentives. As citizens of various cities with similar sizes behave similarly in urban centers (Whyte, 1988), the behavior findings can be expanded to other cities worldwide.

Investigating the Influence of Previous Living Environments on Soundscape Preferences

Abstract ID: 1844.0.0.528.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Hanbing Liang [University of Wisconsin - Madison] hliang8@wisc.edu, presenting author

This study explores the relationship between students' previous living environments and their current soundscape preferences when studying in outdoor spaces. Existing research highlights the role of soundscapes in shaping experiences and well-being, particularly in educational environments (Indrani et al., 2023; Visentin et al., 2023). Natural sounds, such as birdsong and rustling leaves, are often associated with increased focus and reduced stress, promoting restorative environments conducive to learning (Visentin et al., 2023). However, preferences for specific soundscapes can vary significantly based on personal exposure and adaptation over time (Farina, 2014).

Socio-cultural background, auditory health, and previous environmental exposure are key factors influencing soundscape preferences (Kang et al., 2016). For instance, students from rural areas often gravitate toward natural soundscapes, while those raised in urban environments may find comfort in mechanical sounds like traffic noise, which they associate with familiarity and nostalgia. Moreover, research indicates that soundscapes not only impact emotional and psychological states but also affect cognitive processes such as attention, memory, and learning outcomes (Clark & Paunovic, 2018).

This study employs an interactive sound mixing module that allows participants to customize their ideal outdoor study soundscapes by selecting and adjusting the levels of natural, human, and mechanical sounds. Preferences are evaluated in relation to reading, writing and routine tasks. The module also incorporates survey questions to gather data on participants' socio-cultural backgrounds and previous soundscape exposure. The study uses statistical and spatial analysis to explore relationships among demographic factors, hearing health, neurodiversity, prior exposure, and soundscape preferences. The findings will provide insights into how individuals' past auditory experiences shape their soundscape preferences for learning activities.

This research builds on existing literature by examining how soundscapes influence productivity, well-being, and overall learning experiences in outdoor settings. It also explores the potential long-term effects of environmental exposure on the development of soundscape preferences, emphasizing how urban planning and design shape auditory preferences over time. By uncovering these gradual influences and the nuanced differences across individuals and contexts, the study contributes to ongoing debates about how to design urban spaces and outdoor study environments that not only accommodate diverse auditory needs but also foster inclusivity and well-being for individuals from varied backgrounds.

Mapping Where and What People See: Comparing Public and Expert based Scenic Urban Views in London

Abstract ID: 1844.0.0.1025.2025

Track 15: Urban Design

Individual Paper Presentation Submission

In Jung [Dept. of Urban Planning & Engineering, Yonsei University] jungin0605@yonsei.ac.kr, presenting author
Jae Min Lee [Yonsei University] jaemin.lee@yonsei.ac.kr

There has been extensive debate over how to incorporate public perception into the selection and management of scenic urban views. This discourse has primarily revolved around two contrasting approaches: expert-based and user-based methods (Dunkel, 2016; Daniel, 2001). Expert-based approaches have dominated the designation and management of urban scenic views, whereas user-based approaches remain understudied and insufficiently integrated into planning practices (Dunkel, 2016; Wei et al., 2022; Batool et al., 2021).

The expert-based approach typically relies on professional evaluations to designate viewpoints for protection, often through formal urban view management policies (Zacharias, 1999). Notable examples include the London View Management Framework (LVMF) (London Plan, 2012), Vancouver's View Cone Assessment (Zacharias, 1999), and Seoul's Han River Management Plan (Park & Kim, 2011). However, such approaches have been criticized for excluding public input from the selection process (Zacharias, 1999; Dunkel, 2016; Daniel, 2001). Also, expert-designated viewpoints and viewing objects are rarely revised, often overlooking changes in locations and content.

In contrast, the user-based approach emphasizes the importance of incorporating public preferences to preserve aesthetic and cultural landscape values (Schirpke et al., 2013; Wei et al., 2022; Dunkel, 2016). Methods include GIS-based modeling using public surveys (Schirpke et al., 2013), deep learning with Google Street View imagery (Wei et al., 2022), and analysis of crowdsourced geotagged photographs (Dunkel, 2016). However, most studies focus either on the location or visual content of viewing objects and tend to treat viewpoints and viewing objects separately rather than through a comprehensive framework.

This study compares user-based and expert-designated scenic viewpoints and viewing objects, addressing three key questions from a user-centered perspective: where people go to experience scenic urban views, what they prefer to view, and how user-based viewpoints and viewing objects change over time. It further examines whether user-based viewpoints and viewing objects align spatially and visually with expert-designated counterparts.

To address these questions, this study used geotagged photographic data from Geograph, a platform where users upload images tagged with coordinates for camera locations (viewpoints) and photographed objects (viewing objects). Previous researchers have used photographs as proxies for public visual preferences and perceived scenic quality (Dunkel, 2016; Calcagni et al., 2022).

Focusing on central London, the data were collected via Geograph API and analyzed using GIS. We examined the spatial distribution of camera and object coordinates and applied Hot Spot Analysis to identify user-based scenic viewpoints and viewing objects. Viewing objects were defined as locations photographed most frequently, and viewpoints as clusters of highest camera density. We identified 44 user-based scenic viewpoints and 47 user-based viewing objects and compared their spatial alignment with the 44 viewpoints and 47 viewing objects designated by LVMF. To assess alignment, Nearest Neighbor Analysis (Whallon, 1974) evaluated point-to-point proximity within a 30-meter radius. Additionally, Bivariate Point Pattern Analysis (Illian et al., 2008) was applied to statistically examine overall spatial overlap and clustering between user-based and expert-designated locations.

This study demonstrates that user-based scenic viewpoints and viewing objects exhibit significant temporal changes, highlighting the evolving nature of public preferences. While some user-based locations spatially align with those designated by LVMF, others show considerable spatial divergence. These findings emphasize the importance of incorporating user perspectives into urban scenic view management to support the development of adaptive strategies that better reflect changing public preferences.

Claire Nelischer [University of California, Los Angeles] cnelischer@ucla.edu, presenting author

Parks and green spaces, like other urban infrastructures, are illustrative sites in which political, economic, and cultural power struggles are made visible. In recent decades, as sustainability and greening goals gain ground in urban policy discourses and growth agendas, cities increasingly turn to partnerships with private and nonprofit actors to fund and govern urban green spaces (Loughran, 2022). As a result, philanthropic donors have become important partners in urban park production; in Canadian cities, in particular, there has been notable growth in the scale and profile of donor-led park projects in recent years. Philanthropic partnerships can offer much-needed capital funding and open avenues for participation in park planning and programming. But these partnerships also raise critical questions about how private power shapes urban public environments, and implications for equity in planning processes and in realized green spaces.

Considering justice in both planning processes and in material public spaces, this study investigates how private interests are embedded in the governance and design of the public realm through philanthropic giving, and probes implications for park justice. I examine the political economic drivers, planning processes, and justice-based implications of philanthropic engagement in the development and management of urban parks and green spaces. With a focus on recent projects in Toronto, Canada, I ask: what is the role of philanthropy in the development and governance of urban green space, and what are the implications for park justice?

My study centers on three cases in Toronto, Canada, each of which are illustrative examples of high-profile, philanthropy-led urban park projects, linked to infrastructure reuse efforts: The Bentway, The Meadoway, and The Art Trail. To analyze and compare the cases, I triangulate several qualitative methods, including policy and planning document analysis, semi-structured interviews with project stakeholders and advocates, site observations and urban design analysis of planned and realized parks, and critical discourse analysis of newspaper coverage of the three projects. My analysis draws from urban political ecology frameworks that integrate political-economic theories of urban environmental governance (Kaika et al. 2023) and social theories of the cultural construction of urban nature (Angelo, 2021), with a focus on urban design discourses and practices (Goh, 2021). Extending from processes to outcomes, I use frameworks of urban justice (Low and Iveson, 2016) to evaluate the implications of this form of green space governance on distributive, procedural, and recognitional dimensions of justice in parks.

My findings indicate that philanthropy-led park projects reshape both urban imaginaries and material urban landscapes. I find that global policy discourses on urban sustainability, urban service delivery, and urban design have been adapted to the Toronto context, serving to naturalize the value of both urban greening projects and of philanthropic participation and to neutralize community dissent. As power for park development is consolidated amongst select donors and elected officials, elite interests are enacted in the public realm. This produces a particular aesthetic representation of nature in the city that, while generating public benefit, exacerbates unevenness in green space access and compounds procedural and recognitional injustices in parks.

Theoretically, these findings illuminate how Toronto's unique sociopolitical conditions intersect with broader structural forces to shape local urban environmental governance, thereby advancing understanding of power relations in the production of urban green space. Practically, the findings may inform local policy and planning

efforts to open avenues for participation in park governance and self-determination in public space, with an eye to ongoing inequities in power and in park access.

With modern urbanization accelerates, the spatial stress of high-rise buildings and narrow streets in high-density urban environments could substantially impact urban residents' health and well-being. As a long-standing focus area in urban design, street section profiles and urban canyon effects have generated extensive discourse among researchers and practitioners. Recent empirical studies have shown that urban residents face significantly higher risks of developing stress-related mental disorders compared to rural populations, with the psychological stress from urban street environments being a non-negligible factor. Understanding these effects across different cultural contexts is essential for creating healthier, more psychologically supportive urban spaces that accommodate diverse populations and their varied perceptual responses.

This multisite pilot study employs virtual reality to facilitate vivid, 3-dimensional urban street environments with varying spatial densities to explore differences in perceived spatial pressure. The 20 different environmental conditions consist of values of street road weight (2 levels), side building height/aspect ratio of the section view (5 levels), and with/without sidewalk trees (2 levels). The participant was required to randomly experience one of the conditions for 1 minute. Then, they would finish an in-headset survey of the State-Trait Anxiety Scale-6 items version (STAI) and 7 items Semantic Differential Scale (SD) for that condition. Each participant experienced 10 conditions in total. We recorded the corresponding psychological indicator of heart rate and skin conductance level (EDA) via a biomarker wristband. We recruited participants in China (n=110) and the United States (n=60).

The results show that while physiological indicators (heart rate, EDA) did not differ significantly between and within cultural groups, mixed-linear analysis of STAI and SD items revealed some differences across multiple dimensions. There are notable perceptual differences between environmental conditions and cultural groups, particularly in openness, perceived spatial freedom, stress, comfort, and satisfaction. Additionally, we found various interaction effects between cultural background and street composition elements (aspect ratio, greenery, and street width), indicating that different populations may have different psychological responses to various street characteristics. Interestingly, the presence of plants significantly alleviated perceived stress and enhanced the sense of spatial freedom.

The findings could provide a cross-cultural perspective for urban design and public space planning, suggesting that cultural background factors need to be considered in urban design. The study also offers a replicable research paradigm sample, providing consistent research exposure and data collection methods across different cultures through experimental design.

Individual Paper Presentation Submission

Suzanne Moomaw [University of Virginia School of Architecture, Department of Urban and Environmental Planning] swm2x@virginia.edu, presenting author

This paper reimagines design studio pedagogy and practice in urban planning. It explores new opportunities for the planning studio that incorporates planning theory and practice, confronts inequity in existing community design, and applies sustainability principles to generational climate challenges. It builds the research and practice objectives of planning design studios in three distinct areas: first, a developed matrix of planning studio learning outcomes; second, the community engagement practice and research skills that studio projects should generate; and third, clarity on how planning studios differ from either urban design or architecture studios. Judith Grant Long (2012) makes the distinction between planning and architecture studios arguing that it is often about the concept and territories of design. This confusion has been a challenge in the pedagogy as planning has attempted to make studios a version of the design disciplines. This discussion examines learning objectives of planning studios, delivery systems, and pedagogical advances focusing on the “concepts and territories of design” in the planning. This discussion explores the continuing challenge of urban planning studios that includes the weighting of competing goals and learning objectives such as data and design visualization, problem definition, and research-driven suites of solutions, which can be in contest with design products. Using the Ukraine Green Recovery Lab and Studio as the case study, this paper illustrates a divergent and experimental approach to designing a studio that bridges disciplines and incorporates a multidisciplinary and solutions-based approach. In collaboration with the U.S. Department of State’s Office of Global Partnerships Diplomacy Lab initiative, the Department of Urban and Environmental Planning at the University of Virginia School of Architecture created a design-focused a multi-disciplinary approach to rebuilding the City of Izium. The strategy included the collaboration of undergraduate and graduate students from architecture, architectural history, landscape architecture, urban and environmental planning, and urban design to develop a phased design and action plan for rebuilding that is affordable, sustainable, equitable, and accessible providing a replicable template for planning studios. This paper includes a review of past and current literature on the planning studio and is supplemented by quantitative and qualitative data that includes learning outcomes, scale of work projects, skills and competencies needed, and final products expected. The proposed paper is intended as both a roadmap about what planning students need to know, how they know it, and the professional applications of studio pedagogy to learning outcomes for planners.

Right-of-Way Adaptations and Resilience: Pandemic Streateries and Social Interactions in Seattle

Abstract ID: 1844.0.0.474.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Katherine Idziorek [University of North Carolina at Charlotte] kidziorek@charlotte.edu, presenting author
Daniel B. Abramson [University of Washington Department of Urban Design and Planning] abramson@uw.edu
Brian Kirk [University of Washington Department of Urban Design and Planning] brnkrk35@gmail.com
Branden Born [University of Washington] bborn@uw.edu

During the COVID-19 pandemic, cities around the world were faced with a sudden loss of access to indoor spaces for in-person public interaction. Distancing and mask mandates especially affected places where people consumed food and drink and gathered to socialize. Restaurants that could afford to do so expanded into the public right-of-way (ROW) by building temporary outdoor dining structures (“street eateries,” or “streateries”) on sidewalks and in curbside parking spaces. ROW re-design during the pandemic was in some cases completely ad hoc and unanticipated, while in other cases drew on previously envisioned experiments that were adapted for pandemic conditions. Such re-designs also varied in the degree to which city governments promoted them as part of larger-scale, longer-term planning visions, or took a more passive role as regulators of largely uncoordinated, temporary “tactical” interventions.

Adaptive interventions in public space are often relatively low cost and flexible, taking advantage of underutilized spaces and allowing for rapid deployment and removal when they are no longer needed (Brand and Nicholson, 2016). However, even temporary adaptations that are intended to perform a particular function often develop new functions and persist over time, creating new opportunities for social connection and activating previously unexploited potential for social and economic benefits that endure beyond the disaster itself (Anderson, 1978).

In Seattle, pandemic streatory construction was primarily initiated by businesses and regulated through the ad hoc Safe Start pandemic permitting program. The program was informed by and encouraged as consistent with a city-wide pilot program, pre-dating the pandemic, to increase the social capacity and vibrancy of the public realm while simultaneously allowing businesses to expand their operations without needing to expand permanent private spaces. The pandemic presented SDOT with an opportunity to experiment more rapidly and extensively with different types of uses in the ROW, including parklets, sidewalk cafes, and dining patios, as elements of a broader program to “steward vibrant public spaces” and “encourage social activity, help local businesses thrive, and create safer, more attractive streets” (Brody et al., 2024; Seattle Department of Transportation, 2023). As pandemic restrictions lifted and demand for outdoor dining spaces dropped, streateries and similar adaptive uses have persisted, with many streateries being developed into more permanent structures. This is happening in the context of debates in local communities about allowing streateries to continue versus returning street configurations to pre pandemic conditions – in most cases, to fixed designs that favor automobile over pedestrian traffic and movement in general over more stationary activities.

Our study presents an approach to assessing the value and impacts of streateries, and potentially other features of street spaces, in the context of Seattle’s broader policy aims to promote public space vibrancy, which is often equated with “staying” activities in the context of streets as settings for social life (Mehta & Bosson, 2021). Of particular interest, but also especially challenging to implement, is the possibility of accounting for spontaneous, opportunistic, chance encounters as aspects of public life. By modifying and supplementing Seattle’s Public Life Study protocol to observe and analyze streatory and sidewalk use, we find that besides supporting business continuity in a major disruption, streateries and parklets increased low-intensity social interactions, chance

encounters, and diversity of activities in the ROW – outcomes that correlate with increased social resilience. Findings also provide practical guidance for “tactical” placemaking, including the design of streateries and other ROW interventions.

Street Design Adaptations for Autonomous Bus Transit: Rethinking Complete Streets in the U.S.

Abstract ID: 1844.0.0.1058.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Yanghe Liu [University of Florida] liuyanghe@ufl.edu, presenting author

Kaifa Lu [University of Florida] kaifa.lu@ufl.edu

Zhong-Ren Peng [University of Florida] zpeng@ufl.edu

Autonomous vehicle (AV) technology has introduced new possibilities for the future of public transit in the United States. According to the FTA (2024), over half of U.S. states have tested autonomous shuttles (AS)—driverless minibuses or vans—through pilot programs. However, a pressing challenge emerges: are current street designs, shaped by decades of car-centric development, ready for AV-based transit? While the “complete streets” concept has long aimed to create multimodal, inclusive road systems, little research has systematically assessed how these principles align with the operational needs of transit bus automation (Tengilimoglu et al., 2024; Manivasakan et al., 2021). Therefore, this study examines which existing street design elements need to be adapted to ensure the safe and efficient deployment of autonomous buses in car-dependent American communities.

Specifically, this study draws on a national expert survey targeting two groups: attendants from all AS pilot programs in the U.S. and AV engineers and researchers. These experts evaluated 25 street design elements, selected from guides and blueprints published by the National Association of City Transportation Officials (NACTO, 2020; 2014) on complete streets and autonomous urbanism, across five domains:

1. Vehicular way: 1) Dedicated AS lane, 2) multiple lanes, 3) widened lanes, 4) markings and signs quality, and 5) road surface quality.
2. Intersection and sidewalk: 1) Lane consistency, 2) intersection visibility, 3) speed calming facilities, 4) courtesy cutouts, and 5) dedicated sidewalks.
3. Cycling infrastructure: 1) Dedicated bikeways, 2) widened bikeways, 3) physical protection, 4) raised curbs, and 5) buffers.
4. Bus transit infrastructure: 1) Rapid transit lane, 2) in-lane bus stops, 3) pull-out bus stops, 4) bus bulb stops, and 5) bus shelters.
5. External features: 1) Street trees, 2) street plants, 3) lighting conditions, 4) weather impacts, and 5) internet coverage.

Each expert provided two recommendation ratings per element—one for improving operational safety (e.g., collision avoidance, navigation reliability) and one for improving operational efficiency (e.g., reduced traffic disruption, smoother operation)—using a 5-point Likert scale. To analyze the relationship between individual element scores and experts’ overall assessments of domain-level importance, an ordered logit model is applied. The model can help identify the most essential design elements to prioritize.

Currently, data have been collected from 14 active AS pilot sites representing diverse contexts, including urban, suburban, and institutional campus environments. Example sites include VIVA Shuttle (Palo Alto, CA), Move Nona (Orlando, FL), TIM (Port St. Lucie, FL), and Navy Yard AV (Philadelphia, PA). These real-world programs provide valuable context for understanding how road infrastructure and design strategies, such as implementing dedicated

AS lanes, managing vegetation for camera and LiDAR visibility, or reconfiguring intersections, influence AV transit performance.

Expected results include: (1) descriptive statistics identifying the most strongly recommended street design elements for AS operation; (2) ordered logit model findings that determine which elements significantly influence experts' perceptions of importance; (3) real-world illustrations of infrastructure gaps and redesign needs observed in AS pilot sites; and (4) revised, actionable recommendations for street design guidelines to better integrate autonomous bus transit into the complete streets framework. In short, this study offers timely insights to help urban planners and policymakers prepare American streets for the future of autonomous transit, ultimately mitigating car dependency through innovative mobility solutions.

Street-Level Urban Vibrancy for the Elderly: Temporal and Spatial Insights

Abstract ID: 1844.0.0.663.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Sujin Lee [Georgia Institute of Technology] sjlee15@gmail.com, presenting author

Seung Jae Lieu [Georgia Institute of Technology] slieu3@gatech.edu

Haeryung Lee [Seoul National University] starthr@snu.ac.kr

Subhrajit Guhathakurta [Georgia Institute of Technology] subhro.guha@design.gatech.edu

Understanding urban vibrancy is crucial for promoting human activities and interactions in public spaces (Huang et al., 2020) yet creating vibrant environments for aging populations presents a significant challenge. Elderly individuals encounter distinct constraints, such as limited mobility, heightened sensitivity to urban heat and environmental conditions, and less opportunities for social engagement (Loukaitou-Sideris et al., 2014; Zhang, et al., 2017). While existing literature has extensively explored built environmental, morphological, and functional determinants of urban vibrancy, there remains a critical gap in understanding how these factors specifically influence elderly urban vibrancy at a fine-grained street level (Jang et al., 2024; Jiang et al., 2022). This study addresses this gap by investigating the impact of comprehensive spatial context variables on elderly individuals' street-level urban vibrancy compared with young adults. Specifically, the research examines how neighborhood and street-level built-environment characteristics, street morphology and function, and thermal comfort increase elderly urban vibrancy. Recognizing the temporal variations in elderly mobility and environmental sensitivity, the study also explores how these relationships differ across various times of the day.

We employed a Geographically Weighted Gradient Boosting Decision Tree approach to examine how spatial features influence elderly urban vibrancy in Seoul, South Korea. This method used foot traffic data as a proxy for urban vibrancy, utilizing mobile phone signal-based tracking data to estimate population movement across road segments in 2022. Among spatial features, the built environment characteristics encompassed neighborhood and street-level features, which include visual streetscape features extracted through computer vision analysis of street-view imagery. By incorporating geographically weighted kernels, our approach enabled to explore how relationships dynamically differ across Seoul's diverse urban landscape and throughout distinct periods of the day.

The results reveal that street segments characterized by higher levels of greenery, improved pedestrian infrastructure, and proximity to amenities such as parks and community center attract significantly more elderly individuals, particularly during morning and early afternoon periods. In contrast, urban heat exposure negatively impacts elderly vibrancy, with elderly foot traffic declining during midday hours. We also found that several explanatory variables have varying effects on elderly urban activity at different times of day. This research integrates temporal dynamics and comprehensive spatial features to provide insights that can inform and guide age-friendly urban design strategies.

The Impact of Spatial Elements in Chinese Cultural Creative Districts on Creatives' identity

Abstract ID: 1844.0.0.574.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Zimu Fan [University of Leeds] cnzf@leeds.ac.uk, presenting author

Cultural and Creative Districts (CCDs) have become important spaces in contemporary cities for fostering innovation, creativity, and knowledge-based industries. These districts play a vital role in stimulating local economic growth, supporting talent development, and promoting cultural exchange (Florida, 2002; Bianchini & Montgomery, 2020). Their functions extend across various sectors, including culture, arts, innovation, and technology, with contributions to tourism, talent cultivation, and cultural export. In China, CCDs are often developed through the adaptive reuse of industrial heritage sites, typically located on the peripheries or in marginal corners of urban centers. However, when redevelopment and design processes are carried out inappropriately—neglecting the cultural authenticity of the architectural space and the actual experiences of users—these spaces risk losing their appeal (Zhao & Chan, 2021). This weakens spatial identity, drives away creative professionals, and undermines the sustainability of urban regeneration efforts. It also leads to inefficient land use and poses risks to talent retention, resulting in unsustainable urban growth.

Many scholars studying the development of creative industries and cultural districts have emphasized that place identity plays a central role in forming emotional and functional bonds between users and their environments (Sepe, 2018). In cultural spaces, such identity is not only derived from symbolic meaning and memory but is also significantly shaped by interior design elements—such as lighting, color, materiality, spatial layout, privacy, and cultural symbolism (Ponzini & Rossi, 2010). Based on this, the core research question of this study is: Which interior environmental design elements affect creative professionals' sense of place identity in the Greater Bay Area's CCDs?

This research was conducted through fieldwork in several cultural and creative districts across the Greater Bay Area, employing semi-structured interviews and photographic documentation as primary data collection methods. Through initial coding of the data, the study found that many CCDs in the region suffer from design voids and lack spatial features that support creative workers' sense of place identity. Some spaces fail to create a sense of belonging or attachment, thereby lacking the spatial "stickiness" necessary to retain creative talent. However, a number of case studies also demonstrated that well-designed environments can evoke comfort, belonging, and identity among users. During the interviews, specific spatial features were repeatedly mentioned by respondents as impactful. Based on respondents' varying professional backgrounds and value systems, the key interior design elements identified were grouped into three main categories: (1) spatial physical form, (2) sensory atmosphere, and (3) cultural expression. These factors were found to play essential roles in shaping spatial perception and fostering place attachment.

This study highlights the importance of user-centered spatial design in post-industrial cultural sites. Top-down planning often overlooks the real needs of creative communities, resulting in decontextualized and uninspiring environments that fail to attract or retain talent. Therefore, designers and planners should adopt adaptive and inclusive design strategies that prioritize emotional engagement and cultural identity. By transforming recognized environmental elements through thoughtful spatial design, CCDs can enhance their cultural distinctiveness and spatial cohesion from a sustainability perspective. As such, this study offers practical implications for urban planning in cities facing similar challenges and provides a micro-scale lens for understanding the complex

relationship between people and urban space. It contributes both empirical evidence and theoretical grounding for future spatial interventions in the context of creative urban regeneration.

Jaehyun Ha [University of Southern California] jaehyunh@usc.edu

Donghwan Ki [The Ohio State University] ki.17@osu.edu

Falls are a significant and growing health challenge, especially for aging populations worldwide. As the global population ages, with over 10% now classified as older adults (65+), the risk of falls has emerged as a pressing concern. Falls are the second leading cause of unintentional injury deaths globally, with over 600,000 fatalities reported annually according to the World Health Organization.

This study investigates the association between built environment features and outdoor fall risks among older adults using data from 6,302 emergency dispatch cases in Jeonbuk Province, South Korea. While extensive research has explored biological and behavioral factors contributing to falls, the role of environmental factors, especially in outdoor settings, remains understudied. This research addresses this gap by leveraging deep learning-based computer vision analysis of half a million street view images to identify micro-scale streetscape features associated with outdoor fall incidents.

The study employed a zero-inflated Poisson model to analyze fall incidents at a granular level using 100m x 100m grid cells across six cities in Jeonbuk Province. This region faces significant challenges with both an aging population and declining resident numbers, making it an ideal setting for examining environmental factors related to falls among older adults.

The findings reveal that older adults are more likely to experience falls in areas with high population density ($\beta = 0.223$, $p < 0.01$) and mixed-use land ($\beta = 0.257$, $p < 0.01$). These densely populated, mixed-use environments may pose increased risks due to higher foot traffic and more complex navigation requirements. However, the research also identifies protective environmental features. Specifically, certain streetscape features like curbs ($\beta = -0.134$, $p < 0.01$) and brick surfaces ($\beta = -0.024$, $p < 0.1$) can mitigate fall risks, while asphalt ($\beta = 0.045$, $p < 0.05$) and concrete surfaces ($\beta = 0.026$, $p < 0.1$) may exacerbate them.

Additionally, the presence of crosswalks was negatively associated with fall incidents, suggesting they provide safer spaces for pedestrian crossing. Conversely, steep slopes, pedestrian barriers (such as poles, junction boxes, and parked vehicles), transit stops, and areas with high pedestrian accident rates were positively associated with fall counts.

The research highlights an important paradox: while high-density, mixed-use developments are typically promoted for encouraging walkability and physical activity, they may simultaneously present increased fall risks for older adults. This finding underscores the need for a dual approach in urban design—promoting compact, walkable environments while simultaneously mitigating potential hazards through targeted streetscape interventions.

The study suggests that specific design interventions in micro-scale urban features, such as curb designs and surface materials, could help create safer environments for older adults. These targeted interventions could complement individual-based strategies, such as strength training and education, to comprehensively address fall risks among older adults.

This research provides valuable insights for urban planners, designers, and policymakers working to create safer, age-friendly streetscapes that accommodate the aging population. As populations continue to age globally, understanding and addressing environmental factors contributing to outdoor falls will become increasingly important for building sustainable, healthy, and inclusive communities.

Towards Open-air Markets for People: Integrating Shopping, Transport, and Urban Transformation

Abstract ID: 1844.0.0.134.2025

Track 15: Urban Design

Pre-Organized Paper Presentation

Fujie Rao [Shanghai Jiao Tong University] raofujie@gmail.com, presenting author

Yijun Kong [Shanghai Jiao Tong University] kongyijunjack@sjtu.edu.cn

Yingnan Zhang [Zhejiang University] zhangyingnan@zju.edu.cn

Urban transport is fundamental to the shaping of shopping space. Various types of shopping spaces have emerged to accommodate different flows of people while turning encounters between people and goods/services into transactions (Rao et al., 2018): for example, markets and main streets cater to pedestrian movements, malls and big-box stores prioritise vehicular access, and online shopping websites/apps follow data flow. People's passion for walking, cycling, and living-locally was reignited during the Covid-19 pandemic, especially as they endured travel restrictions and physical distance requirements (Florida et al., 2023). Temporary open-air markets, where people walk/cycle to shop and socialise with a lower risk of catching respiratory diseases than indoor shopping premises, mushroomed in cities. Establishing or revitalising local shopping areas – e.g., open-air markets – has been considered a key strategy for promoting Covid/post-Covid sustainable urban transitions (Moreno et al., 2021; Rao, Kong, et al., 2024), however, the spatial-temporal forms of open-air markets and their relationships to urban transport have received little research attention (Rao, Zhao, et al., 2024). In what ways can the spatial forms of open-air markets contribute to urban public life? To what degree are the temporal provisions of such markets mediated by active transport?

We conducted a case study of Paris, a leading city advocating for and implementing the transition to a 15-minute city (Moreno et al., 2021). Paris is renowned for an advanced network of open-air markets, with 76 such markets widely distributed throughout the city. Paris publishes fine-grained geographically-referenced datasets of open-air markets – the only dataset of its kind accessible online according to our knowledge – and urban transport on the open data portal Paris Data. Through the 'mapping' of 500 m walking catchments of public/private interfaces from the centre of each open-air market and a 'morphological typology' of all markets, we explored the capacities of such markets for sustaining urban transformations at the scale of a 15-minute walkable neighbourhood. Using 'correlation and regression analysis', we measured how various metrics of urban forms concerning walking, cycling, and rapid transit mediate the number of opening days of open-air markets.

Our morphological study presents a robust capacity of open-air markets for creating local walkable urban public space. Nearly half of Paris's public space is serviced by local open-air markets, as the 15-minute walking catchments of open-air markets cover 48% of all public/private interfaces citywide. The street market, nucleated market, and synergies between them activate sidewalks, laneways, and plazas, while transforming car-based transport infrastructures – e.g., traffic islands, roundabouts, and parking grounds – to public spaces for people. Our statistical analysis reveals nuanced morphological features of active transport that can stimulate a more permanent open-air market: roughly equal car and pedestrian spaces, fewer designated bicycle routes, and more transit station entrances. Therefore, keeping a strong adaptive capacity of the space in-between buildings could be more important than pedestrianising the road or establishing separate bike lanes. Human-scale urban design for transit station areas is crucial, as the number of station entrances, rather than that of stations, matters more for the vitality of open-air markets.

Understanding Intergroup Contact Through Park Design: Observational Study of Four Houston Parks

Abstract ID: 1844.0.0.223.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Haoyue Yang [Texas A&M University] momoyizan@tamu.edu, presenting author

Chanam Lee [Texas A&M University] chanam@tamu.edu

Xuemei Zhu [Texas A&M University] xuemeizhu@tamu.edu

Recent trends highlight a concerning decline in social engagement among Americans, with reductions in time spent socializing and growing levels of isolation. The U.S. Surgeon General's 2023 advisory, *Our Epidemic of Loneliness and Isolation*, underscores the urgent need to enhance social infrastructure to rebuild community connection. Urban parks are widely recognized as important public spaces for facilitating social interaction and promoting inclusion (Oldenburg, 1999; Jacobs, 1961; Gehl, 1987), yet limited research examines how specific design features influence intergroup contact.

This study applies intergroup contact theory to urban parks, focusing on how design can support interaction across racial/ethnic and age groups. Built upon a prior study that analyzed mobile big data and social network patterns to assess visitor diversity and park popularity in Houston, TX, this study uses direct on-site observation to examine social behavior in four highly visited parks—two paired neighborhood parks and two community parks—selected for their variation in visitor diversity.

By documenting the spatial and temporal patterns of intergroup contact, this research identifies environmental features that support or inhibit diverse interactions. The findings contribute to a broader understanding of how landscape design can promote social inclusion, extending prior research on park use preferences by race and age (Payne, Mowen, & Orsega-Smith, 2002; Vaughan, Cohen, & Han, 2018), and landscape participation patterns (Elmendorf, Willits, & Sasidharan, 2005). It also considers how residential segregation (Bischoff & Reardon, 2014) continues to shape park use and exposure to diversity. By positioning parks as active agents in reducing social fragmentation and fostering contact among diverse populations, this study offers practical design strategies for urban planners, landscape architects, and community stakeholders committed to building inclusive and socially sustainable public spaces.

Unpacking Walking Disparities: How Neighborhood Deprivation Shapes the Built Environment Effects

Abstract ID: 1844.0.0.1041.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Yunjeong Song [The Ohio State University] yunjjsong@gmail.com, presenting author

Dong-ah Choi [Hanyang University] dachoi@hanyang.ac.kr

Andy Hong [University of Utah] a.hong@utah.edu

Contemporary research in urban planning and public health consistently demonstrates the built environment's strong influence on walking behavior and associated health outcomes. Walkable neighborhoods—characterized by high residential density, mixed land use, connected street networks, and accessible destinations—are linked to increased physical activity and reduced chronic disease risk. However, recent scholarship has highlighted the importance of equity in walkability outcomes, as socioeconomically disadvantaged communities often face infrastructure gaps, safety concerns, and contextual barriers that can limit the benefits of walkable environments.

Although supportive built environments are generally associated with higher levels of physical activity, the extent to which this relationship holds in socioeconomically disadvantaged communities remains contested. While some studies report stronger effects for more advantaged groups, others find either no difference or even greater effects in disadvantaged areas. To gain a deeper understanding of this ongoing debate, this study incorporates a composite Neighborhood Deprivation Index that captures multiple dimensions of socioeconomic disadvantage. We analyze how neighborhood context moderates the relationship between built environment features and walking behavior, providing empirical evidence from Korean cities.

Drawing on data from 229 administrative districts (Si-Gun-Gu) and over 229,000 individuals from the 2021 Korea Community Health Survey, we assess daily walking time as a function of built environment and neighborhood-level deprivation. Built environment features are operationalized using a Principal Component Analysis–derived Walkability Index based on seven indicators aligned with the 5Ds framework (density, diversity, design, destination accessibility, and distance to transit). Neighborhood deprivation is measured through another PCA-based index using nine indicators, including education level, housing quality, aging population, and household structure. A multi-level zero-inflated negative binomial (ZINB) model is employed to account for excess zero-walking responses and the nested structure of individuals within districts.

Our findings reveal that the built environment has a positive and significant effect on average daily walking time. Individuals living in areas with higher population and job density, greater land use mix, better transit access, and pedestrian-oriented design features walk more on average. Importantly, this effect is significantly moderated by neighborhood deprivation: improvements in walkability are more strongly associated with increases in walking time in socioeconomically deprived areas. In contrast, the effect is weaker in less deprived districts. These results challenge the dominant view that walkability primarily benefits more advantaged populations and suggest that walkability improvements may be especially effective in addressing physical inactivity in disadvantaged communities. Additionally, the model highlights that individuals with limited physical capacity are substantially more likely to report no walking activity, emphasizing the need for targeted support beyond infrastructure improvements.

This study contributes to the literature by providing large-scale, empirical evidence on how built environment interventions interact with social disadvantage in shaping transportation-related walking behavior. Our findings underscore the importance of equity-driven planning: walkability improvements can serve not only as a public

health strategy but also as a tool to reduce spatial and health disparities. By integrating physical and social dimensions into urban design, policymakers can better allocate resources and create healthier, more inclusive communities.

Urban Design and UHI Effects of TOD Types in the Seoul Metropolitan Area

Abstract ID: 1844.0.0.1078.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Jung Kyun Ha [Urban Planning and Engineering, Yonsei University] kyun0912@yonsei.ac.kr, presenting author
Jae Min Lee [Yonsei University] jaemin.lee@yonsei.ac.kr

Transit-Oriented Development (TOD) is widely regarded as a sustainable urban strategy that promotes compact, mixed-use development around public transportation (Calthorpe, 1993; Cervero & Kockelman, 1997). Its benefits related to mobility, land value, and urban form have been extensively explored (Ewing & Cervero, 2010). Meanwhile, Urban Heat Island (UHI) effects—driven by impervious surfaces, dense built environments, and limited vegetation—have emerged as a critical urban climate challenge, intensifying surface temperatures, energy use, and public health risks (Zhou et al., 2011).

Despite the prominence of both TOD and UHI in urban research and policy, few studies have addressed their intersection or potential trade-offs. The compactness and density that make TOD efficient may also amplify thermal stress in urban environments. While UHI has been widely studied through physical and spatial indicators, most analyses remain at macro or meso scales. Localized, design-focused research—particularly on TOD's thermal impacts—remains scarce. Moreover, remote sensing approaches that integrate land surface temperature (LST) with urban form and socio-environmental features are underutilized (Kim & Brown, 2021), and cross-typology or metropolitan-scale comparisons are especially rare.

This study addresses these gaps through three research questions:

- (1) To what extent does TOD, as a compact development model, contribute to or mitigate urban heat in metropolitan contexts?
- (2) Which TOD-related urban form and environmental variables influence LST, and how might they be optimized to reduce UHI effects?
- (3) How do different types of TOD—urban, suburban, and non-TOD—differ in their associated UHI impacts?

The study focuses on the Seoul Metropolitan Area, encompassing all major subway stations and their surrounding 800-meter buffer zones. The temporal scope spans the summer season of 2024 (June 1 to August 31), capturing the peak period of urban heat conditions (Zhou et al., 2016). Using Google Earth Engine (GEE), land surface temperature (LST) is derived from satellite imagery and processed for spatial analysis (Voogt & Oke, 2003).

Independent variables include satellite-based environmental indicators such as the Normalized Difference Vegetation Index (NDVI) and Impervious Surface Area (ISA); demographic and transit usage features, including residential population, employment population, and daily subway ridership; urban morphological characteristics such as Building Coverage Ratio (BCR), Floor Area Ratio (FAR), building height, and exterior materials; and land use diversity, measured using Shannon's entropy index (Buyantuyev & Wu, 2010; Xiao-Ling Chen et al., 2005). TOD classification is conducted using K-means clustering, based on transit usage and land use diversity variables. This results in three categories: urban TOD, suburban TOD, and non-TOD areas. A multiple linear regression model is then applied to assess the relationship between LST and the selected explanatory variables, both across and within each TOD category (Kamruzzaman et al., 2018).

Preliminary findings are expected to reveal distinct UHI patterns between TOD types. Urban TOD areas may exhibit higher LST due to increased impervious surfaces and development intensity, whereas suburban TODs may offer relative mitigation effects through more extensive vegetation and lower density. This analysis will shed light on the role of urban form, transit intensity, and land use diversity in shaping urban thermal conditions.

The results of this study offer actionable insights for urban planners and policymakers. By empirically evaluating how TOD design characteristics influence local heat dynamics, the research contributes to climate-responsive planning, particularly in rapidly urbanizing metropolitan regions. The findings also support the integration of environmental metrics into TOD guidelines and promote more resilient urban design practices.

Where Do Encampments Form? Predicting the Geography of Homelessness

Abstract ID: 1844.0.0.983.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Sneha Tallavajjula [University of Colorado Denver] nagasneha.tallavajjula@ucdenver.edu, presenting author

Homelessness is a growing challenge in U.S. cities, with encampments increasingly impacting public spaces. While research has focused on structural factors like housing affordability and service accessibility, there is limited understanding of how the spatial implications of urban form, including street networks, transit infrastructure, public space design, and land-use patterns, shape encampment dynamics. This study integrates spatial econometrics and urban design to provide a predictive framework for planners and policymakers to identify areas at higher risk for encampment formation, enabling them to allocate resources proactively.

This study draws on three interrelated theoretical perspectives: spatial dependence, urban mobility, and territoriality, which collectively inform an emergent framework that examines the physical boundaries of urban space and accessibility. Spatial dependence theory (Anselin, 1995) suggests that spatial patterns emerge due to proximity effects and the influence of land-use decisions. Urban mobility theory (Sheller, 2018; Martens, 2017) examines how transit access and mobility constraints shape spatial opportunities. Meanwhile, territoriality and negotiation of space (Mitchell, 2003) explore how certain groups and spatial practices are contested and regulated within urban landscapes. Together, these theories shift planning from static models of urban space to dynamic ones that prioritize justice, accessibility, and the lived experiences of unhoused individuals. This study examines how urban boundaries, including street layouts, public space configurations, zoning laws, and transit accessibility affect encampment dynamics. Two core research questions guiding this study are: (1) What spatial factors and urban design characteristics affect the formation, distribution, and persistence of homeless encampments? (2) How do spatial dependencies and governance structures interact to influence encampment dynamics across different urban contexts?

The methodology combines spatial econometrics with urban design analysis. First, Moran's I and Lagrange Multiplier (LM) tests will assess spatial autocorrelation in encampment locations. Based on these results, Spatial Autoregressive (SAR) models will be used to quantify clustering effects while controlling for demographic, land-use, and transit infrastructure factors. If spatial heterogeneity is detected, Geographically Weighted Regression (GWR) will allow for local variations in spatial dependencies to be examined. This integrated approach will provide a spatially explicit model of how urban form and physical infrastructure shape encampment dynamics.

A comparative analysis across Denver, Austin, and Minneapolis will assess the consistency of spatial predictors across distinct policy and governance landscapes. These cities were selected for their similar demographic and socioeconomic characteristics but distinct, yet comparable, approaches to homelessness policy. Denver prioritizes permanent housing solutions, Austin focuses on rapid rehousing and increasing shelter capacity, and Minneapolis coordinates housing and social services through county-level partnerships. By examining how these policy environments interact with spatial dynamics, this study will provide insights into how various spatial and governance factors influence encampment dynamics. If similar spatial determinants emerge across all three cities, the study will strengthen the validity of this predictive framework as an adaptive planning tool.

This research advances planning scholarship by shifting the focus from efficiency-based models to those centered on accessibility. By utilizing a spatially explicit modeling approach, this study provides empirically grounded insights

into how urban form interacts with various structures to shape homelessness outcomes. These findings can help cities address homelessness and spatial inequalities more efficiently and effectively.

Youth-Centred Place Knowing and Placemaking in Aotearoa New Zealand's Public Housing

Abstract ID: 1844.0.0.586.2025

Track 15: Urban Design

Individual Paper Presentation Submission

Crystal Victoria Olin [Victoria University of Wellington - School of Architecture] crystal.olin@vuw.ac.nz, presenting author

Carly Owen [Victoria University of Wellington - School of Architecture] carly.owen@vuw.ac.nz

Amber Haussmann [Victoria University of Wellington - School of Architecture] amber.haussmann@vuw.ac.nz

How can placemaking processes be reimagined to centre lived experiences and spatial aspirations of young people living in public housing? This research investigates how participatory, culturally grounded placemaking can be used to engage youth in shaping design outcomes and longer-term development strategies for public housing and other collective urban environments (Olin et al., 2022). The project addresses the underrepresentation of youth in planning and design processes that affect their everyday lives (Derr et al., 2018). It asks: What does placemaking look like when driven by the experiences and imaginations of youth? And how can their contributions inform both temporary interventions and permanent upgrades in public housing?

To answer these questions, we conducted a collaborative research project with young people aged 7–24 living in a Wellington housing site managed by Te Toi Mahana, a community housing provider. The study used site-based workshops, creative mapping, drawing, and facilitated discussion to surface youth experiences and place ideas. Methods were informed by kaupapa Māori research ethics and Pacific principles of talanoa (open conversation), with activities held in shared spaces at the housing site and supported by whānau (families), the housing provider and community events.

The project unfolded in three phases: (1) an initial phase of place knowing; (2) a co-design phase where participants imagined their future environment; and (3) a temporary installation that prototyped some of these ideas on-site and gave back to the community. Youth input was synthesized into recommendations for design and engagement processes, and for permanent upgrades to the site, as well as to inform future development across the provider's portfolio.

Findings reveal several recurring themes: the need for enhanced safety and security through lighting and clearer accessways; the desire for age-appropriate, flexible spaces that support autonomy and social connection; the importance of recreational infrastructure, including courts, play areas, and gathering spaces; and concerns around maintenance, rubbish, and environmental care. These themes resonate with international literature on placemaking in public housing, such as the importance of access to well-maintained and safe shared spaces, community activities, and everyday routines in building a sense of place and supporting wellbeing among tenants (Chisholm et al., 2023). They also go beyond highlighting youth priorities for their built environment to reveal a strong collective ethos: most design ideas were oriented toward community benefit rather than individual gain.

This research contributes to urban design and planning scholarship by offering a replicable model for youth-centred engagement in low-income housing contexts. It challenges tokenistic consultation practices and demonstrates how youth participation, when well-supported and culturally attuned, can shape both design outcomes and broader conversations. For practitioners, it offers strategies for engaging young people as design contributors, and for housing providers, it provides evidence of the value of site-specific co-design processes. The project also raises implications for urban design and planning education by demonstrating the critical role of ethics, cultural literacy, and process design in participatory work.

We conclude with a set of recommendations for housing providers, designers, and planning professionals on embedding youth-centred placemaking into future housing and urban development projects. These include not only design and engagement strategies but also structural shifts needed to resource, support, and scale such approaches within system constraints. These recommendations are especially relevant as housing providers in Aotearoa New Zealand face ongoing trade-offs between investing in wellbeing, maintaining infrastructure, and meeting housing demand (Witten et al., 2025).

Anyplace Architecture: Measuring Placelessness and Place Value in Podium & Wrap Apartments

Abstract ID: 1842.0.0.1097.2025

Track 15: Urban Design

Research-in-Motion Presentation Submission, Research currently in process

Liz Falletta [USC Price School of Public Policy] falletta@usc.edu, presenting author

The proliferation of two distinct, yet related, apartment types across the United States over the past decade has been praised for providing much needed housing, but also criticized as monotonous, placeless, and formulaic. “Podium” buildings, which stack apartments over a concrete base, and “wrap” buildings, which wrap units around a concrete core, can be found on urban infill to exurban greenfield sites in cities of all sizes across the U.S. Both are working to alleviate the housing crisis in high-growth cities like Nashville, Austin and Phoenix. Public conversations about these buildings, however, discount the important role podiums and wraps are playing in housing production and question the future of cities with a concentration of these building types. In these venues, podium and wrap apartments are “blandmarks,” which are everywhere, but look like they could be anywhere.

While the inherent density of the podium and wrap typologies ensures the delivery of 200 to 500 apartment units for each building produced, their architectural and urban design characteristics and resulting place quality, does vary significantly. The design of most podiums and wraps is the result of a contradictory process where the sameness intrinsic in their repetitive program, load bearing wall construction and fire exiting requirements is at odds with the differentiation often required by planning regulation, which can specify or restrict materials, colors, and styles, require changes of plane and adjustment of roof height after a certain length of façade, and subject buildings to design review boards. Well-designed and constructed examples that adjust building volumes to their surrounding contexts, use high-quality materials in well-composed facades, and express local identity with thoughtful urban design, definitely exist. But many are characterized by haphazard construction, boxy massing, over-long street walls, generic and repetitive facades, cheap materials and an absence of urban design, which are often described as boring, chaotic, or simply ugly.

Geographer Edward Relph has defined placelessness as “a weakening of the identity of place to the point where they not only look alike but feel alike and offer the same bland possibilities for experience” (Freestone & Liu 2016, 2). To what degree are the podium and wrap buildings developed across the U.S. “placeless” and, if these buildings are indeed not delivering place quality, are they at least helping cities achieve other urban policy goals around housing affordability, climate change adaptation and health and wellbeing? To answer these questions, the proposed research reviews the concepts of “non-place” and “placelessness” in the planning literature, as theorized by Relph, and uses it to develop a measure of relative placelessness (Arefi 1999, Freestone & Liu 2016, Relph 1976). This measure will be applied to examples of podium and wrap apartment buildings in the diverse geographical contexts of Nashville, TN; Austin, TX and Phoenix, AZ. Once a hierarchy of more to less placeless is established, these buildings’ “place value” will be evaluated, as theorized by architect and urban designer Matthew Carmona, examining whether and how these buildings address economic, environmental and social goals beyond their image and identity (Carmona 2019).
