

AIA Honolulu

A Chapter of The American Institute of Architects

February 3, 2009

Mr. Ted Matley
FTA Region IX
201 Mission Street, Suite 1650
San Francisco, CA 94105

Mr. Wayne Yoshioka
Department of Transportation Services
City and County of Honolulu
650 South King Street, 3rd Floor
Honolulu, Hawaii 96813

Dear Messrs. Matley and Yoshioka,

The Honolulu Chapter of the American Institute of Architects (AIA Honolulu) strongly supports the concept and implementation of a fixed guide way steel on steel rail system as an integral part of the future plans to meet the needs of our growing island community. We respectfully submit the enclosed report produced by the Honolulu High Capacity Transit Corridor Project Transit Task Force/ Honolulu Chapter/American Institute of Architects. We submit this report as a supplement to our comments and recommendations submitted to you on December 8, 2008.

We envision a versatile system, providing more service at a lower cost per mile that stimulates development and community revitalization along the entire route and built in the same time frame.

Thank you for your attention to this matter.

Sincerely,

A handwritten signature in black ink that reads "Jeffrey Y. Nishi". The signature is written in a cursive, flowing style.

Jeffrey Y. Nishi, AIA
2009 AIA Honolulu President

**American Institute of Architects/Honolulu Chapter
TASK FORCE REPORT: SUGGESTED LIGHT RAIL TRANSIT
(LRT) FOR THE HONOLULU HIGH-CAPACITY TRANSIT
CORRIDOR PROJECT**

EXECUTIVE SUMMARY

The Honolulu Chapter of the American Institute of Architects (AIA Honolulu) continues to strongly support the concept of a fixed rail transit system for Oahu. However, we also remain concerned over the appropriateness of the proposed elevated transit system particularly through the urban core of Honolulu. We therefore respectfully offer this report to assist the City administration, lawmakers, and stakeholders in strengthening community support, enhancing our neighborhoods and environment, investing taxpayer money wisely, and ensuring Federal funding for this historic project.

AIA Honolulu promotes the implementation of a flexible transit system capable of operating at, above, or below grade to accommodate the particular conditions within each community. Widely used transit technologies such as light rail transit (LRT) with overhead catenary wires allow transit planners this greater flexibility while still satisfying transit design criteria for passenger volume and frequency of service.

In light of the current economic recession, a predominantly at-grade light rail solution would offer Oahu residents a more cost effective transit system built in less time. Such a system would also be cheaper to operate and maintain, annually conserving taxpayer money. The resulting cost savings could be directed toward extending the system to UH Manoa, Waikiki, and perhaps even to Kahala Mall and Mililani/Wahiawa/Haleiwa.

At-grade systems would encourage diverse, mixed-use Transit Oriented Development (TOD) along the entire length of the transit route and help revitalize existing communities and buildings rather than concentrating new development only at station locations. Increased accessibility tends to stimulate ridership and promote inter-modal connectivity. Such systems more easily complement active streetscapes and vibrant public spaces, helping to enhance Honolulu's sense of place. Compared with elevated rail, the minimal visual and environmental impacts of at-grade systems further preserve our unique island scenery for our visitors and residents alike.

The chart on the following page summarizes the findings in the report:

PROJECT CRITERIA	ELEVATED RAIL	AT-GRADE LRT
Overall Construction Cost (20 mile system)	\$5.3 Billion+	\$2.5 Billion
Construction Cost per Mile	\$265 Million+	\$125 Million
Construction Time	9 years	Approx. 4 years
Construction Energy Consumption per Mile	170,000 MBTUs	20,000 MBTUs
Operation & Maintenance Cost (OMC)	\$63 Million per year	\$39 Million per year
Visual Impact	Moderate/High	Low
Environmental Impact	High	Low
Potential for TOD	Limited to areas near station entrances	Several major advantages for TOD
At-grade Traffic Impact	Low	Acceptable, using signal synchronization
Passenger Capacity (Passengers per Hour per Direction)	6,000	over 9,000
Current systems in North America	1 city	35 cities

+ The lack of recent all-elevated rail projects makes it difficult to verify projected costs.

SUGGESTED LIGHT RAIL TRANSIT (LRT) FOR THE HONOLULU HIGH-CAPACITY TRANSIT CORRIDOR PROJECT

AIA Honolulu continues to strongly support the concept of a fixed rail transit system for Oahu. However, we also remain concerned over the appropriateness of the proposed elevated transit system particularly through the urban core of Honolulu. AIA Honolulu promotes the implementation of a flexible transit system capable of operating at, above, or below grade to accommodate the particular conditions within each community. To assist the City administration, lawmakers, and community in strengthening community support, enhancing our neighborhoods and environment, investing taxpayer money wisely, and ensuring Federal funding for this historic project, AIA Honolulu's Transit Task Force has prepared the following comparison study of two different types of fixed rail systems:

- The elevated "hot" third rail system currently proposed in the Draft Environmental Impact Statement (DEIS) dated November 2008, and
- At-grade light rail transit (LRT) systems using an overhead "catenary" power wire

The LRT system was chosen for consideration in this study because of its flexibility; LRT guideways can be put at grade, below grade or overhead as required by planning considerations. The two rail systems are compared in terms of:

- Construction Costs
- Operating and Maintenance Costs
- Visual and Environmental Impact
- Transit-Oriented Development, and
- At-grade Traffic Impact

I. CONSTRUCTION COST

Elevated rail

The latest cost estimate for the 20-mile, 20-station elevated rail system proposed for the City & County of Honolulu is \$5.3 billion, or \$265 million per mile¹. This figure is for the initial phase from Kapolei to Ala Moana and does not include extensions to Waikiki or UH Manoa. Due to the scarcity of recently built elevated systems, it remains difficult to evaluate these projected construction costs. The only instance in which an all-elevated mass transit line was built in a major city in the United States occurred in Miami in the 1970's, which is too long ago to provide reliable cost data.

Given the large cost overruns of recent transit projects in Hawaii (H-3)² and elsewhere in the country (Boston's "Big Dig", Los Angeles subway), and the lack of construction data from elevated transit projects, we are concerned that current cost estimates and contingencies may not be adequate.

At-grade rail

Currently there are 35 at-grade rail systems operating in urban areas of North America³ (Appendix 1). These systems all use an overhead power wire and steel rails at grade (ground) level in dedicated street lanes or other existing public right-of-ways. A number of these systems

3 AIA Honolulu Task Force Report: Suggested Light Rail Transit (LRT) for the Honolulu High-Capacity Transit Corridor Project, February 2, 2009

have been built within the last 5 years and can offer a more accurate idea of projected construction costs if a 20-mile at-grade system was built in Honolulu.

The at-grade LRT systems in Charlotte, Houston, Los Angeles, Minneapolis, Phoenix, Sacramento, San Francisco and San Jose were all completed between 2003 and 2008, with the Phoenix line having just opened in December 2008. Final per-mile costs for these systems ranged from \$43 million (Houston) to \$70 million (Phoenix)⁴. Using the final cost of the Phoenix system (\$1.4 billion) and the current cost multiplier for construction costs in Hawaii (1.79 times Phoenix costs)⁵ we conservatively estimate that the total cost of a 20-mile at-grade LRT system in Honolulu would be approximately \$2.5 billion at today's prices.

The lower construction cost of at-grade rail is primarily due to the savings on materials (steel and concrete), energy and labor required to construct the elevated guideway and stations anywhere from 35 to 80 feet above ground level⁶. Secondly, there are savings on the machinery (stairs, escalators, elevators) and lighting needed at each elevated station as well as the mezzanine structures which span the street below the stations. In addition, there are substantial savings on below-grade foundation and utility realignment work needed for support of the structural columns in an elevated system.

Land Acquisition Costs: Elevated Rail

According to the latest reports from the City administration, a total of 189 properties are in the path of the proposed elevated line and will have to be acquired in part or in full⁷. The city has budgeted \$70 million to purchase the land based on current property assessments for these parcels. Our understanding is that the budget does not include a contingency for rising property assessments if and when economic conditions improve.

Although the bulk of the elevated guideway and stations will be built over public streets and right of ways, land acquisition along these areas will still be required because of the width of the guideway and of the stations. The proposed specification of "hot" third rail technology requires that the train rails be grade-separated (moved above ground level) for safety. Since the most cost-efficient way to grade-separate third rail systems is to pair two lanes of rail together on an elevated guideway, this means that the guideway is double-wide throughout its length, and any stations require additional platform space on both sides of this double-wide dimension. Land acquisition is typically required at the stations, which will be 50 feet wide by 300 feet long⁸.

Land Acquisition Costs: At-grade Rail

Although LRT systems are installed at grade, land acquisition costs are not necessarily higher than those for an elevated rail system. At-grade guideways (rails) are typically installed in existing roadways and the turning radius of at-grade LRT is normally accommodated in existing street right-of-ways. At-grade stations require only a widened sidewalk area (approximately 6 x 150 feet) on one side of the guideway. At-grade rail routes and station locations can offer planners and designers more flexibility compared with elevated rail systems which must account for large structural columns that can only be placed in the centerlines or outside of streets. At-grade rail lines can be paired on the same street or separated and put on different streets to minimize surface traffic disruption and further minimize the need for land acquisition.

Construction Time: Elevated Rail

According to the city, the estimated construction time for the first phase (20 miles) of the Honolulu system is 9 years, with construction to begin in December 2009 and full service to Ala Moana starting at the end of 2018⁹.

Construction Time: At-grade Rail

Construction time for an at-grade LRT system in Honolulu would likely be similar to the system just completed in Phoenix. The 20-mile at-grade system in that city was completed in 4 years (2004-2008)¹⁰.

Construction Energy Consumption

According to the Draft EIS for the HHCTCP, “construction of at-grade high capacity transit systems generally require 20,000 MBTUs of energy per track mile (Caltrans 1983), including track and power systems”. For an all-elevated system such as the one proposed for Honolulu, “an additional 150,000 MBTUs of energy per track mile would be required to construct the elevated structure”¹¹. Total energy required to build a mile of elevated rail line is 170,000 MBTUs, or 8.5 times the energy required for the same length of at-grade rail.

SUMMARY: CONSTRUCTION COST, TIME AND ENERGY

Comparing the latest City estimate for elevated rail (\$5.3 billion) with the uppermost estimated cost for at-grade rail (\$2.5 billion), a 20-mile at-grade LRT system would allow the City to build a transit system for one-half the cost, thereby reducing taxpayer funding. Comparing construction time of the Phoenix at-grade system (4 years) with the City’s estimated construction time for Honolulu (9 years), at-grade LRT would allow the City to build a transit system in less than one-half the time, thereby reducing necessary traffic disruptions during construction. Finally, as energy costs and consumption have come to the attention of the public in light of global warming concerns, it is important to note that the embodied (construction) energy required for a mile of elevated rail is 8.5 times that of at-grade rail.

II. OPERATING AND MAINTENANCE COSTS (OMC)

Elevated Rail

According to the City’s rail transit website, the annual operating and maintenance costs (OMC) for the proposed 20-mile elevated route will be \$63 million¹², or \$3.15 million per mile. This figure can be broken down into track-and-train OMC (which are the same whether at grade or elevated) and OMC associated with an elevated system. According to the Light Rail Industry (LRI), the typical OMC for an at-grade LRT system is \$1.5 million per mile, or \$30 million for a 20-mile system. Using a 1.3 cost multiplier to account for Honolulu’s relatively higher cost of living, we estimate that the projected OMC for tracks and trains alone in Honolulu would be \$39 million. Subtracting that figure from the City’s overall OMC figure of \$63 million leaves \$24 million, which is the OMC for elevators, escalators, lighting, painting, restrooms, and security at elevated stations.

At-grade Rail

At-grade rail typically shares existing roadway and right-of-ways resulting in significantly lower OMC than elevated rail. No stairs, escalators or elevators are required. Steel rails are recessed

into existing streets so that track and station cleaning can be done as part of normal city cleaning and maintenance programs. At-grade stations consist of widened sidewalk platforms with roof structures and ticket vending machines. Lighting and security needs at at-grade stations are minimal since they can be monitored by existing police patrols and lit by existing streetlights. The 20-mile, 28-station at-grade LRT system which opened in Phoenix in December 2008 has an annual OMC budget of \$31.6 million (\$24 million for operations + \$7.6 million for maintenance), for a unit cost of \$1.58 million per mile¹³.

SUMMARY: OPERATING AND MAINTENANCE COSTS

Compared with an elevated rail system, a 20-mile at-grade LRT system could save the City \$24 million in annual operating and maintenance costs, and thereby further maximize use of taxpayer dollars.

III. VISUAL AND ENVIRONMENTAL IMPACTS

Elevated Rail

The proposed elevated rail system will have “moderate” to “high” impact, according to the Draft EIS, on several neighborhoods through which it is proposed to run¹⁴. The guideway and stations will have two types of visual impact: blocking existing views, particularly in mauka-makai directions, and being a visual element out of scale and character with the immediate neighborhood. Mauka-makai view corridors are considered a critical part of the urban landscape of Honolulu and are protected under the City’s Primary Urban Center Development Plan of 2004. Existing mauka-makai views in the immediate vicinity along the full length of the system will be significantly impacted. Views from existing apartments near the guideway will also be impacted, particularly in units on the lower four or five floors.

There will be high visual impacts in Downtown Honolulu, where the views down Bishop Street and neighboring streets to Honolulu harbor will be partially blocked by the elevated guideway and its support columns. The Chinatown district, with its historic connection to the waterfront, will be significantly impacted by an elevated concrete structure running the full length of the district.

The proposed elevated rail system is contrary to waterfront planning in leading cities throughout the world. Cities such as San Francisco, Boston, Seattle and Sydney have in recent years removed elevated transit structures separating their neighborhoods from the urban waterfront. An elevated rail line adjacent to the waterfront in Honolulu will create a physical and visual barrier between the waterfront and the Downtown/Chinatown area, as can be seen in the following simulation from the DEIS (Figure 4-32, Page 4-80):

Simulation of guideway at Nimitz Highway/Fort Street Intersection

East of the Downtown area, Mother Waldron Park, a state Historic Site, and adjacent low-rise residential buildings will be substantially contrasted by the bulk and scale of the elevated guideway and required straddle bent structure, as seen in this simulation:

Straddle bent guideway and columns at Halekauwila Street/Cooke Street intersection

The second phase of the project (extending to UH Manoa), calls for a **double-decked guideway** between Pensacola Street and Ala Moana Center, further blocking mauka-makai views¹⁵.

Phase 2 of the City's proposed system includes a 2-mile extension to UH Manoa. The following photographs illustrate the high visual impact of an elevated system:

Existing view, intersection of King Street & University Avenue, looking mauka

Simulation of proposed guideway and station, King Street & University Avenue

The sounds from trains passing every few minutes will impact those people working or living in the immediate vicinity of the route. The noise impact will be most severe for apartment dwellers living on the 3rd to 5th floors due to proximity of the guideway. However, there will also be noise impacts on floors above the guideway because the low buffer walls which are planned to block train noise will divert the noise upward.

Construction of an elevated rail line will significantly alter the immediate environment under the entire length of the system. Construction down the center of existing divided streets will require the removal of many mature street trees. There will be a major loss of greenscape in these areas, as the street is changed from one with a center boulevard of grass and mature trees to one with a center hardscape in permanent shadow.

Construction of an elevated rail line in the urban core will create a more seriously degraded environment than in suburban areas. Urban core land underneath elevated transit structures such as highways and off-ramps tend to be paved, noisy, dusty and unpleasant for pedestrians. These environments often become favored locations for criminal activity such as drug-dealing and for the homeless.

Honolulu is a world-class tourist destination attracting millions of visitors every year who enjoy the exotic scenery and unique culture of Hawaii. An elevated rail structure in the urban core would have a detrimental effect on tourism, the primary industry in the state. The Waikiki Improvement Association has stated publicly that it has “serious concerns with a potential Waikiki spur from Kapiolani Boulevard ...to Kuhio Avenue” because of “aesthetic and physical density issues of locating the overhead track in a resort and residential area”¹⁶. As can be seen in the photographs of the King Street/University Avenue intersection, an elevated system will block existing mauka-makai views and create a visual element out of scale and character with the surrounding community.

Due to the significant visual impacts of an elevated rail system, we are concerned that proposed mitigation measures will only have a marginal effect. Aside from broad statements such as “develop design guidelines” and “coordinate with the DPP”, the only mitigation measures discussed in the DEIS are “provide new vegetation” and “shield exterior lighting”¹⁷.

At-grade Rail

In cities where subway systems are not feasible, at-grade rail has consistently been the preferred rail alternative in the last 30 years in the United States. The popularity of at-grade rail is in large part due to the low visual and environmental impact on the existing urban fabric. Grade level guideways are virtually invisible in a street except for the rails recessed into the roadway and the thin power wire overhead, as seen in the following photo of the Charlotte (NC) light rail system:

LRT street crossing in Charlotte, NC

Grade level stations are minimal in visual impact, consisting of an open platform, roof structure and ticket machines, as seen in this view of the Phoenix light rail system:

LRT street median station in Phoenix, AZ

While the Phoenix example is of a median (center-of-street) station, at-grade rail can also be located on the outer lane of existing streets, allowing existing boulevard landscaping and trees (an important feature on streets such as Kapiolani Boulevard) to remain intact. At-grade guideways can also be split into one-way streets to minimize at-grade traffic impacts. An independent transportation consultant has noted that "the requisite through-put (capacity) could be achieved in Honolulu by reserving one curb lane on each one-way street for light rail transit operations with station areas located on the sidewalk"¹⁸. This idea is consistent with a previous plan by the City to place rail transit lines on King Street.

Sound impact on neighboring apartments is substantially less than elevated rail because an at-grade guideway is 30 to 40 feet farther from (below) apartment units located on upper floors. Steel-on-steel noises are reduced with at-grade construction due to sound conduction into the surrounding soil. Most importantly, existing urban neighborhoods traversed by at-grade rail retain their existing scale, character, daylight patterns, and greenscape.

SUMMARY: VISUAL AND ENVIRONMENTAL IMPACTS

Flexible technologies such as at-grade LRT offer transit planners the ability to pose far fewer visual and environmental impacts compared with elevated rail systems. By eliminating the bulk of the environmental impacts discussed in the DEIS, community concerns can be greatly reduced and public support further expanded. The scarcity of all-elevated rail systems currently being built in the United States suggests that other municipalities have sought to avoid the frequently severe environmental impacts (and high costs) of such systems. Even with the most sensitive design guidelines and coordination, it is difficult to prevent elevated rail systems from becoming an overpowering element in any urban environment. Flexible, at-grade rail systems, on the other hand, more easily blend into the existing landscape and urban fabric.

IV. TRANSIT-ORIENTED DEVELOPMENT (TOD)

Introduction

Transit-Oriented Development (TOD) has no universal working definition throughout the country but is typically defined as compact, mixed-use development near transit facilities with a high-quality walking environment.

The potential benefits of TOD are social, environmental, and fiscal. Focusing growth around transit stations leverages public investment in transit to encourage local investment, which leads to increased business and tax revenues. TOD, proponents believe, can be an effective tool in curbing sprawl, reducing traffic congestion, and expanding housing choices. The most direct benefit of TOD is increased ridership and the associated revenue gains. Research shows residents living near stations are five to six times more likely to commute via transit than are other residents in a region. Other primary benefits include the revitalization of declining neighborhoods, financial gains for joint development opportunities, increases in the supply of affordable housing, and profits to those who own land and businesses near transit stops.

TOD's secondary benefits include congestion relief, land conservation, reduced outlays for roads, and improved safety for pedestrians and cyclists. Many of these benefits feed off of each other. TODs help create compact, walkable communities, and provide sustainable, comfortable

transportation while greatly reducing oil use. Walkable communities in turn support rail systems by providing high ridership.

Elevated Rail

Although any rail system is compatible with TOD, an elevated rail system tends to limit the full potential of TOD by separating the most important feature – the pedestrian-friendly walking environment – from the street. An elevated rail system moves all transit-related traffic and activity to 30 feet or more above the street, leaving existing businesses and buildings out of the action and creating a 30 to 50 feet wide shadow zone below that is pedestrian-unfriendly.

Although TOD can occur around the stations of an elevated system, development tends to be confined mainly around the entrances to the stations since transit riders will not be inclined to linger in the areas below the guideway and stations.

At-grade Rail

At-grade rail systems can offer transit planners and communities much greater likelihood of realizing successful transit-oriented development by encouraging the following key characteristics:

Accessibility and Safety

All riders of rail transit start and end their trips as pedestrians. A pedestrian environment in which the trip to a station is safe and easy is important for encouraging transit ridership. With at-grade rail, the route for the pedestrian between station and destination can be short and direct with a minimum of stairs and grade changes. For riders in wheelchairs, on crutches, or pushing baby carriages/strollers, getting on and off a low-floor train from a sidewalk platform is much easier than getting to a train on a platform 40 to 80 feet above the street. At-grade stations can be more frequently located than elevated stations, which means better and easier accessibility for riders, which in turn promotes higher ridership. Higher ridership leads to higher usage of adjacent businesses and increased tax revenues for the city.

Safety and security are important to transit riders. With at-grade rail, riders are able to take a variety of routes as they walk to and from stations. The random pedestrian pattern generated by at-grade rail systems leads to more overall street activity and a safer street environment. Buildings and businesses adjacent to stations and guideways provide “eyes on the street” and informal security. Conversely, the elevators required by an elevated rail system are mostly avoided at night due to security issues and have maintenance problems due to vagrants using them to sleep and urinate.

Efficiency

Successful TOD must be mixed-use, location-efficient development that balances the need for sufficient density to support convenient transit service with the scale of the adjacent community. Successful TOD projects also cater to a range of income levels of users. With at-grade rail, the potential for an upgraded pedestrian experience extends outward in all directions from the stations because pedestrians walking from at-grade stations will take the most direct route to their destination. This widespread pedestrian traffic pattern associated with at-grade rail stations raises the development potential of the entire neighborhood which encourages not only new

construction but rehabilitation of older buildings as well. The wider diversity of projects attracts a wider range of residents and neighborhood users of all income levels.

Community and Inter-modal Connectivity

At-grade rail allows planners to better utilize adjacent land uses, since no space has to be blocked out or condemned for escalators, elevators, structural columns, etc. At-grade stations can be located for easy access to the local community and interconnection with existing local businesses and services. Passengers on trains at-grade can easily connect to other modes of public transport such as buses or taxis.

Liveliness and a “Sense of Place”

At its core, transit-oriented development strives to make places work well for people. TOD aims to restore many of the features of yesteryear’s cityscapes—comfortable and enjoyable streetscapes, vibrant and interactive public spaces, and an assemblage of land uses that invite people to stroll, linger, and interact with each other. At-grade rail stations can be designed to complement existing civic spaces such as plazas, waterways, public malls or parks. There is a growing appreciation for the need to create enduring main streets and real places in American cities. Creating stations with a “sense of place” seems particularly important in Honolulu, which prides itself on being a unique destination in the United States.

SUMMARY: TRANSIT-ORIENTED DEVELOPMENT

In many ways Transit-Oriented Development seeks to reproduce the cityscapes found in American cities some 80 years ago: city streets full of pedestrians from all walks of life, sidewalks comfortable and enjoyable for a stroll and stopping to talk with fellow residents, attractive civic spaces interspersed throughout. Like the streetcar systems common in American cities in the 1920’s, at-grade rail has significant advantages for TOD in areas of accessibility, safety, efficiency, inter-modal connectivity and overall neighborhood liveliness. At grade LRT can offer transit planners and the communities they serve greater opportunities to create a successful TOD not available to planners of elevated rail.

V. AT-GRADE TRAFFIC IMPACT

Elevated Rail

With most functions raised 30 - 40 feet above street level, at-grade traffic impacts of elevated rail are primarily the result of placement of structural columns at the street level to support the guideway and stations. Where the guideway is centered on an existing street, columns will take up one traffic lane. On boulevard-type streets, guideway columns can fit within existing median strips and have little impact on traffic. Where columns are located at the sides of streets to hold up straddle-bents at stations, there will be a loss of sidewalk space.

The impact on at-grade traffic by elevated rail will be particularly severe during construction of the system. Excavation for column foundations and utility relocation will be more extensive with elevated rail than for at-grade rail, requiring larger portions of existing streets to be closed. Overall construction time for elevated rail will be twice as long as that for at-grade rail, requiring longer closure of existing streets and longer periods of impact on at-grade traffic.

At-grade Rail

At-grade traffic impacts have been cited by the City administration as a key reason for the selection of an elevated rail system. The City's engineers have set design criteria for the system at 6,000 pphpd (passengers per hour per direction) capacity, with 3 minute intervals (headway) between trains, and they have stated that it is not possible to put such a system on Honolulu streets without a major increase in traffic congestion.

However, we respectfully offer differing information for further consideration. According to independent traffic engineers, "achieving a capacity of 6,000 pphpd with 3-minute headways is easy to do with a light rail transit running on surface streets. 3 minute headways equate to 20 trains per hour, (with each train) having a capacity of 300 passengers (20 trains x 300 passengers = 6,000 pphpd)"¹⁹. Furthermore, modern light rail vehicles, such as the Siemens S70, have a capacity of 232 passengers per car. Each car is 95 feet long, meaning a 2-car train would be 190 feet long or well within the length of a typical Honolulu city block (250 – 400 feet) and out of the way of cross traffic. A system using 2-car trains of the Siemens S70 type would have a capacity of 9,280 pphpd (464 passengers x 20 trains = 9,280 pphpd), or more than 50% beyond the required 6,000 pphpd criteria.

Working examples of this type of system can be found in cities such as Charlotte, Dallas, Denver, Houston, Phoenix, Portland, Sacramento, and San Diego. Rail car manufacturer selection is not limited to Siemens; several other companies such as Alstom, Bombardier, CAF, and Kinki-Sharyo make comparable equipment such as this low-floor model used in the new Phoenix LRT system:

Phoenix LRT car manufactured by Kinki-Sharyo

According to independent traffic consultants contacted by AIA Honolulu, at-grade traffic impact is a concern with at-grade rail but is not a serious problem when combined with a signal

synchronization system and/or a traffic preempt system. A traffic preempt system alters signals at intersections to give priority to any train approaching the intersection. Successful examples of this include Portland TriMet's MAX light rail where design policy permits trains to only stop at stations to prevent traffic delays²⁰.

Pedestrian safety is also a concern when locating at-grade rail lines and stations. At-grade trains can be put in exclusive-use lanes or pedestrian malls to protect passengers from at-grade traffic as they disembark. Pedestrian barriers are also used, particularly in median (center street) stations to force pedestrians to slow down and take notice as they approach traffic lanes or intersections.

SUMMARY: AT-GRADE TRAFFIC IMPACT

At-grade LRT systems can offer transit planners a viable alternative to elevated rail while still maintaining transit system design criteria for passenger volume and train frequency. Impact on at-grade traffic can be managed through signalization systems commonly used in 35 other cities. Similarly, pedestrian and passenger safety can also be maintained via barriers and protected zones.

APPENDIX 2

AIA Public Policy on Transportation

The American Institute of Architects/Honolulu Chapter supports funding and planning to integrate all transportation modes with an emphasis on alternatives to the automobile *including* mass transit, pedestrian ways, bicycle paths, and water transit so that each region and urban area may choose the most effective and efficient combination of modes for its own needs.

Supporting Statement

We encourage the use of social, environment, and aesthetic criteria—as well as economic efficiency—in the design of routes and supporting facilities for all transit modes.

Transportation system routes and facilities should support land use objectives, including urban growth management and efficient transit mode linkages, and respect significant human, cultural and natural environments.

Furthermore, transit systems and facilities should achieve the following design objectives:

- A. Protect and enhance mauka-makai view corridors in accordance with the City & County of Honolulu's Primary Urban Center Development Plan (PUC DP) and Land Use Ordinance (LUO). Framed street views of the mountains and the shoreline are significant scenic resources that provide directional orientation to motorists, pedestrians, and visitors alike. Visual and physical access between mauka and makai should be preserved to enhance the connection between the city and the waterfront.
- B. Preserve and enhance historic and cultural districts in accordance with the City & County of Honolulu's PUC DP and LUO. The planning and design of transit systems and facilities should complement the visual context of these areas as well as their physical, historic, and cultural value. Significant vistas associated with these structures and districts should also be retained.
- C. Provide safe and healthy environments for transit passengers as well as pedestrians and neighborhood residents along the transit route. Safe and easy accessibility should also be promoted.
- D. Promote sustainable planning, design, and operation. In keeping with sustainable practices, transit systems and facilities should offer the ability to meet present needs without compromising those of future generations.

The physical and aesthetic impact of new and improved road systems should be considered by planners. Road widths and infrastructure improvements should be kept to the minimum needed to accomplish transportation and community planning objectives.

AIA Position Statement on Transit

The American Institute of Architects supports funding, planning, design and implementation to integrate all transportation modes – including mass transit, pedestrian walkways, bicycle paths and water transit – so that each region and neighborhood will be served by the most effective and efficient combination of modes to meet its own needs.

AIA encourages the use of social, environment and aesthetic criteria – as well as economic efficiency – in the design of routes and supporting facilities for all transit modes. Transportation system routes and facilities should support land use objectives – including urban growth management and efficient transit mode linkages – and respect significant human, cultural and natural environments.

AIA Honolulu (The Honolulu Chapter of The American Institute of Architects) strongly supports the concept and implementation of a fixed guideway transit system as an integral part of the future plans to meet the needs our growing island communities.

At the same time, there are serious concerns about urban design issues and visual impacts on the surrounding neighborhoods. Our greatest concerns with the City's current plan are the elevated rail along Nimitz Highway through the Downtown core and historic Chinatown that will isolate the city from Honolulu's extraordinary waterfront, as well as elevated spurs to the University of Hawaii at Manoa and Waikiki.

AIA Honolulu strongly believes that we must implement a plan that protects the mauka-makai view corridors that are outlined by the City & County of Honolulu in its own Primary Urban Center Development Plan and Land Use Ordinance.

We believe that the ultimate solution is not just about the best engineering solution, but that priority needs to be placed on the planning and design of the overall transit system to sensitively serve the needs of the residents of Oahu and its visitors, while protecting the beauty of the unique environment in which we live, work and play. Moreover, we believe that good design, combined with comprehensive urban planning, is a critical investment in our future and that of our children. By degrading our island's visual environment with an overhead system through our Downtown and historic core, we would significantly decrease Honolulu's visual appeal as a place to live. In addition, as a resort destination, an elevated rail system through the Downtown corridor and into Waikiki could negatively impact our visitor appeal for the next century.

AIA Honolulu has enjoyed greater dialogue with the City on transit issues in recent months and hopes to assume an even greater role in collaborating with the Mayor, his administration, its consultants and the Honolulu City Council to insure critical design issues are addressed as this historic project moves forward.

At this juncture, we look forward to continuing to work with the City to examine alternatives to the elevated rail through the Downtown corridor along Nimitz Highway. In particular, AIA Honolulu asks that the City consider an at-grade (street-level) or below-grade (underground) fixed guideway system, or that the alignment through Downtown be shifted so that mauka-makai view corridors are preserved for future generations.
