Results: Amongst adults, 10 goals were endorsed by a majority of participants, with reducing dangerous behaviors receiving the highest mean rating (5.4/6) and percentage of endorsement (96%). A high percentage (>90%) endorsed improving communication skills, improving quality of life, and reducing self-injurious behaviors as good intervention goals. Reducing motor stimming and reducing fixations received the lowest mean scores (1.7/6) and overall endorsements (11.9% and 9% respectively). EGA revealed three communities, which we interpreted as “Uncontroversial Goals”, “Controversial Goals”, and “Social Goals”. In terms of demographics, the only relationship that exceeded the threshold for practical significance was gender. Specifically, individuals who identified as non-binary/other gender were less likely to endorse Controversial (OR=0.189, CrI95% [0.060, 0.625], Pd=0.995, BFROPE=22.9) and Social (OR=0.247, CrI95% [0.065, 1.057], Pd=0.965, BFROPE=4.94) goals compared to males.

Conclusions: Initial analyses of the perspectives of autistic adults shed some light on which intervention goals should be addressed with autistic children. It is critical that these goals continue to be evaluated by younger populations, including adolescents, to determine if these are also the opinions of those who are more likely to be currently receiving these interventions.

434.206 (Poster) Piloting a Culturally Adapted Community-Based Parent Psychoeducational Intervention for Chinese Immigrant Families of Children with ASD
Y. Xu, F. Chen, M. Mirza and S. Magana, (1)Department of Health Sciences Education, University of Illinois College of Medicine, Rockford, IL, (2)University of Illinois at Chicago, Chicago, IL, (3)Occupational Therapy, University of Illinois at Chicago, Chicago, IL, (4)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX

Background:
Asian Americans are the fastest growing racial minority in US, and Chinese Americans are the largest ethnic group among them (US Census Bureau, 2017). Meanwhile, there is a steady growth of children diagnosed with autism spectrum disorder (ASD). However, Asian children with ASD are under-diagnosed and underserved compared to White children (Baio et al., 2018; Christensen et al., 2016; Son, Parish & Igdalsky, 2017). When accessing services, Chinese American families, especially newer immigrants, often face language barriers, lack of culturally appropriate services, and unfamiliarity with the complex healthcare systems (Lo, 2008; Son et al., 2017). There is a critical need for culturally appropriate interventions addressing these health disparities.

Objectives: The current study aims to present the pilot results of a culturally adapted intervention, “Parents Taking Action” (PTA. Magaña et al., 2020), for low-income Chinese immigrant families of young children with ASD in the US.

Methods:
We recruited 27 Chinese immigrant mothers of children with ASD between 2 and 10 years old to participate in the culturally adapted version of PTA, a psychoeducational intervention originally designed for Latino families of children with ASD (Xu et al., 2022). The majority (70.4%) of them live in low-income households and do not speak English well (66.7%). The majority (59.3%) of the children with ASD had severe symptoms (categorized using CARS-2). The average age of children in the sample was 5.4 years and most of them were born in the US. Four trained community health workers who are themselves Chinese mothers of children with ASD delivered the intervention online via zoom during the COVID-19 pandemic.

We collected pre and post intervention data on family and child outcomes, social validity, and attendance rate. In addition, we conducted focus groups post intervention to obtain participant feedbacks. For family outcomes, we collected family empowerment using the Family
Outcome Survey-Revised (Bailey et al., 2011), parental stress (PSI-SF, Abidin, 1990), parental self-efficacy and frequency in using evidence-based strategies (covering play skills, communication, social skills, and addressing challenging behaviors with naturalistic strategies) taught in the intervention (Magaña et al., 2020). For child outcomes, we collected child’s frequency and severity of challenging behaviors (SIB-R, Bruininks et al., 1996), social communication skills (SCQ, Rutter et al., 2007), and the number of services received. Paired-sample t-tests were performed to compare the pre and post intervention differences.

Results:

Parents reported significantly increased family empowerment (Cohen’s d=.74), increased confidence (d=1.23) and frequency (d=1.03) in using evidence-based strategies. The number of services children received also increased significantly after parents’ completion of the intervention (d=.49). Participants in the post intervention focus group reported that the intervention is feasible and acceptable.

Conclusions:

To our knowledge, this is the first culturally adapted intervention targeting low-income Chinese immigrant families of children with ASD. The pilot intervention showed promising preliminary effects in both family and child outcomes. Despite the difference in intervention modes of delivery compared to the original PTA, the intervention still showed significant increase in similar outcomes found in the original PTA RCT study (Magaña et al., 2020).

---

434.207  (Poster) Positive Developmental Trajectories of Children with Autism Spectrum Disorder and Severe Intellectual Disability Following Exchange and Development Therapy

R. Blanc¹, M. Latinus¹, M. Guidotti¹, J. L. Adrien¹, S. Roux¹, P. Dansart¹, C. Barthélémy¹, F. Bonnet-Brilhaut¹ and J. Malvy⁹, (1)1. Exac-T, Centre Universitaire de Pédiatrie, CHRU de Tours, Tours, France, (2)Université Paris Cité, Laboratoire de Psychopathologie et Processus de Santé, Boulon-Billancourt, France, (3)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (4)Exac-t, Excellence Center in Autism and neurodevelopmental disorders, Tours, France, (5)Université Paris Cité, Boulon-Billancourt, France, (6)UMR 1253, iBrain, Université de Tours, Inserm, TOURS, France, (7)UMR 1253, iBrain, Université de Tours, INSERM, Tours, France, (8)UMR iBrain 1253, Inserm, University of Tours, TOURS, France, (9)CHRU Tours, Tours, France

Background: Early intervention programs positively affect key behaviours for children with Autism Spectrum Disorder. Yet, most of these programs do not target children with severe autistic symptomatology associated with intellectual disability.

Objectives:

The aim of this study was to investigate psychological and clinical outcomes of children with severe autism and intellectual disability enrolled in the Early Phase of the Tailored and Inclusive Program for Autism - Tours (TIPA-T). The TIPA-T includes in addition to individual and collective speech and psychomotor therapies and school time, the Exchange and Development Therapy (EDT). The EDT is an individual neurofunctional intervention, consisting on one-to-one exchange between a child and a therapist taking place in a pared-down environment to facilitate exchanges. It aims to rehabilitate psychophysiological abilities at the roots of social communication, through structured sequences of “social play”.

Methods:

32 children (26 males; 45 months) with ASD and with mild-to-moderate intellectual deficiency were enrolled in the TIPA-T, which comprises, weekly, 20 hours of group-based and 2 hours of one-to-one therapies including EDT during the school year. Cognitive and socio-emotional skills and general development were evaluated with the Social Cognitive Evaluation Battery (SCEB) scale and the Brunet-Lézine scale-Revised, respectively, before and after 9 months of intervention. Autistic symptomatology was evaluated with the Revised Behavior Summarized Evaluation (BSE-R) scale at 5 time points in a subset of 14 children, both in individual and group settings.

Results:

Cognitive and socio-emotional skills before therapy had average levels of 2.44 and 1.94 on a 4 -point scale, respectively. Statistically significant post-intervention improvements were found in cognitive and socio-emotional skills, with average level reaching 2.97 and 2.53, respectively. All but one child showed improvements in at least one social domain, and 78% of children gained one-level in at least 4 social domains. 29 children improved in cognitive domains with 66% of children improving in at least 3 cognitive domains. Autistic symptomatology evaluated in one-to-one settings significantly decreased with therapy (interaction deficits: -0.92; modulation deficits: -0.88), this reduction was observed in more than 85% of children. In group setting, autistic symptomatology also decreased in more than 60% of children. Global developmental age significantly increased by 3.8 months.

Conclusions:
EDT improves cognitive and social skills of most children with ASD but also core symptoms of autism, yet, with heterogeneous outcomes profiles, in line with the strong heterogeneity of profiles observed in ASD. At the group level, this study highlights the benefits of the EDT within the TIPA-T for children with ASD for severe autism associated with intellectual disability. The EDT allowed a general improvement for both cognitive and socio-emotional domains as well as a reduction in the severity of autistic symptomatology. In addition, assessment of autistic core symptoms with the BSE-R showed an improvement of social interaction, both in one-to-one and group evaluation, demonstrating the generalizability of the skills learned during the EDT.

434.208 (Poster) Predictors of Response to Early Start Denver Model: Systematic Review of the Literature and Experimental Study in 32 Young Children with Autism Spectrum Disorder.

A. M. Persico, L. Asta, T. Di Bella, F. La Fauci Belponera, M. Bruschetta, S. Martines, E. Basile, M. Boncoddo, F. Bellomo, F. Cucinotta, A. Ricciardello, L. Turriziani and C. Colombi, (1)Child & Adolescent Neuropsychiatry, Dept. of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, (2)Dept. of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, (3)Interdepartmental Program "Autism 0-90", "G. Martino" University Hospital, University of Messina, Messina, Italy, (4)IRCCS Centro Neurolesi "Bonino-Pulejo", Messina, Italy, (5)Costanza Colombi, Pisa, MI, Italy

Background: The effectiveness of early intensive interventions in young children diagnosed with ASD is now well established, but there continues to be great interindividual variability in treatment response. Furthermore, there is a need for parameters able to predict response to naturalistic developmental treatments, like the Early Start Denver Model (ESDM), as compared to more structured and therapist-driven Early Intensive Behavioral Interventions (EIBI).

Objectives: The purpose of this study is twofold: (a) we performed a systematic review and meta-analysis of all published Literature to identify putative predictors of response to ESDM and EIBI; (b) we experimentally sought predictors of response in a sample of 32 children treated with ESDM for nine months after receiving an ASD diagnosis.

Methods: (a) four databases (EmBase, PubMed, Scopus and WebOfScience) were systematically searched and quantitative, empirical studies published in peer-reviewed journals were included if ESDM or EIBI treatment were started between the ages of 12 and 48 months. Data were meta-analyzed combining p-values according to Fisher’s method; (b) 32 children received 9 months of ESDM treatment each by a team of three certified therapists, four 90-min sessions/wk for nine months. A panel of tests was administered at the beginning (T0), after 4 months (T1) and at the end (T2) of 9 months of treatment.

Results: (a) our search yielded 1,601 articles, including 475 in WOS, 212 in PubMed, 666 in Scopus, and 248 in Embase. After study selection and the addition of eight studies found in the reference lists of selected articles, a total thirteen articles on EIBI and eleven articles on ESDM met the inclusion criteria. A set of socio-communication skills including intention to communicate, receptive and expressive language, and attention to faces, most consistently predicts response to ESDM (combined P=1.12E-11), while higher IQ/DQ at intake represents the strongest predictor of positive response to EIBI (P=8.24E-10). (b) Four children (13%) were full responders, 8 children (26%) were partial responders and 20 children (61%) were low responders to ESDM. Strongest predictors of full response are the GMDS-ER Personal-Social Scale (P=0.007) and the PEP-3 Cognitive Verbal and Preverbal scale (P=0.003). PEP-3 Receptive Language (P=0.02) and Visuo-Motor Imitation (P=0.03) are significant predictor of partial/full response.

Conclusions: Our systematic review and meta-analysis indicates that predictors of response to ESDM in very young children newly diagnosed with ASD tend to fall into the socio-communication and language domain, whereas response to EIBI seems to be better predicted by cognitive development. In line with this conceptual framework, our experimental study confirms that response to ESDM is associated with better socio-communication and receptive language skills at treatment onset. Larger samples will be necessary to reach definitive conclusions, but this systematic review and our experimental findings begin to shed some light on patient characteristics predictive of preferential response to ESDM and to EIBI, and may provide clinically useful information to begin personalizing treatment in very young children newly diagnosed with ASD.

B. Schirmer, L. Morgan, L. A. Edwards, Q. O. Wedderburn and M. Siller, (1) Marcus Autism Center, Atlanta, GA, (2) Emory University, Marcus Autism Center, Atlanta, GA, (3) The University of South Carolina, Atlanta, GA, (4) Emory University School of Medicine, Atlanta, GA

Background: Children with autism spectrum disorder (ASD) show characteristic deficits in social attention and interaction (Bauminger-Zviely & Shefer, 2021; Sigman et al., 1986). Preschool classrooms provide unique opportunities for scaffolding social attention and engagement (Feuerstein & Landa, 2020). Moments of social attention to peers or teachers may emerge because of generalized behavioral tendencies of the child (Constantino et al., 2017), because of classroom interventions/supports implemented by the teacher, or both.

Objectives: To investigate whether observational classroom measures of social attention are predicted by (1) eye-tracking measures of social-visual engagement (SVE), (2) parent ratings of children’s social disability, and (3) observational measures of teacher-implemented classroom supports.
Methods: Participants were children 20 to 64 months who were enrolled in three classrooms of an inclusive preschool program serving children with and without autism. ASD: n=14, Mage(SD)=43(13) months; TD: n= 18, Mage(SD)=48(10) months. Eye-tracking measures of SVE were collected while children viewed videos of naturalistic scenes of social interaction, and quantified in terms of percent gaze allocation to the faces in these scenes. Classroom videos were recorded once per week, for five weeks. For each child and recording day, a 5-minute segment of center time (i.e., indoor free-play) was selected randomly for observational coding. Social attention was coded minute-by-minute using two rating scales capturing children’s visual attention to the faces and actions of peers and teachers (Morgan et al., 2018). Classroom supports were coded using two rating scales of the Classroom Assessment Scoring System (Piattas et al., 2008) capturing the teachers’ active facilitation and supportive language use. Finally, parents completed the Social Responsiveness Scale (SRS; Constantino & Gruber, 2005), a quantitative measure of social disability.

Results: To accommodate the five repeated observational measures, data were analyzed using mixed models for longitudinal data (SAS Proc Mixed). Social attention was specified as the outcome. Predictors included (1) SVA, (2) parent-rated social disability, (3) ASD diagnostic classifications, (4) classroom supports, and (5) demographic characteristics (child age, gender, race/ethnicity). Single predictor models were specified, and hierarchically integrated as appropriate. Detailed results are presented in Table 1. Results from the final multi-predictor model show that children’s classroom social attention was independently predicted by (1) SVA, F(1,85) = 13.2, p < .001, and (2) the interaction between social disability and classroom supports, F(1,85) = 8.9, p < .01. Visual analyses of the interaction term (Figure 1) indicate that the association between classroom supports and classroom social attention was stronger in children with higher levels of social disability, compared to children with lower levels of social disability.

Conclusions: Objective, automated measures of SVE predict classroom social attention in children across a range of social disability. Future research should investigate whether SVE changes in response to intervention and/or over the course of a school year. Independently, results from this research illustrate how children’s social disability impacts the relation between classroom supports and classroom social attention. This finding suggests that teachers allocate their attention and supports to children who need them most, and the supports that they offer impact different children in different ways.

434.210 (Poster) Promoting Emotional and Behavioral Interventions in ASD Treatment: Evidence from Epigram, a Naturalistic Prospective and Longitudinal Study
C. Bettencourt1, N. Garret-Gloanec1, H. Pellerin1, D. Cohen2, G. Bertamini1 and F. Roos-Weil1, (1)Groupe Hospitalo-Universitaire Pitié-Salpêtrière, APHP, SU, Paris, France., (2)Institut des Systèmes Intelligents et Robotiques, Sorbonne Université, Paris, France, (3)Centre Nantais de Parentalité, Nantes, France, (4)Department of Child and Adolescent Psychiatry, Hôpital Universitaire Pitié-Salpêtrière, Sorbonne University, Paris, France, (5)Institut des Systèmes Intelligents et de Robotiques, CNRS UMR 7222, Sorbonne University, Paris, France, (6)Department of Psychology and Cognitive Science, Laboratory of Observation, Diagnosis, and Education (ODFLab) - University of Trento, Rovereto (TN), France, (7)Centre Médico-Psychologique, Paris, France

Background: Integrative care practices (ICP) in the management of autism spectrum disorders (ASD) do not currently benefit from sufficiently rigorous evaluations. In addition, they lack formalization despite their important place in clinical practice, particularly in France, where they are implemented in day hospital structures. Additionally prognostic factors from naturalistic treatment studies of children with ASD remain largely unknown.

Objectives: We aimed to identify baseline and treatment-related prognostic predictors at 1-year follow-up after Integrative Care Practices (ICP).

Methods: Eighty-nine children (3-6 years) with severe ASD were given ICP combining nine therapeutic workshops based on children’s needs. Participants were assessed at baseline and during 12 months follow-up with the Psycho-educational Profile-3-R, Children Autism Rating Scale, Parental global impression (PGI), and the Autistic Behaviors Scale. We assessed prognostic predictors using multivariable regression models and explored treatment ingredients influencing outcome using Classification and Regression Trees (CART).

Results: Multivariable models showed that being a child from first generation immigrant parents predicted worse maladaptive behaviors, whereas play activities had an opposite effect; severity of ASD and impaired cognitive functions predicted worse autism severity; and lower play activities predicted worse PGI. Regarding treatment effects, more emotion/behavioral interventions predicted better outcomes and more communication interventions predicted lower autism severity, whereas more education and cognitive interventions had an opposite effect. CART confirmed that more interventions in the emotion/behavior domain helped classifying cases with better outcomes. More parental support was associated with decreased maladaptive behaviors. Sensorimotor and education interventions also significantly contributed to classify cases according to outcomes but defined subgroups with opposite prognosis.

Conclusions: Children who exhibited the best prognosis following ICPs had less autism severity, better cognition at baseline and non-migrant parents. Emotion/behavior interventions appeared key across all outcomes and should be promoted.

434.211 (Poster) Structured Psycho-Education Intervention for Ameliorating Sleep Problems in Children with ASD
Background:

According to parent reports, the prevalence of sleep disturbances in children with autism is twice as high as that reported in typically developing children or children with other developmental delays. Previous studies have suggested that improving sleep hygiene and reducing parental involvement at bedtime may lead to improved sleep in ASD children. Here, we report initial findings from an ongoing behavioral intervention study using a structured parent psycho-education protocol.

Objectives: To examine the effectiveness of a group behavioral sleep-intervention protocol utilizing the “camping out” technique for younger children with ASD.

Methods:

To date, 56 families of 2.5-5.5-year-old children with ASD were recruited at the Azrieli National Centre for Autism and Neurodevelopment Research (ANCAN). Thirty-three families completed the intervention, 14 families dropped out and 9 families are in the final stages of the intervention. Current analyses were conducted with 24 participants. The intervention includes 2 workshops in which parents receive information about sleep disturbances and learn techniques for ameliorating sleep problems in the context of ASD. This includes ways of improving sleep hygiene and the implementation of the “camping out” technique, where parents gradually reduce their involvement in sleep onset. In addition, parents receive two phone calls per week for a period of 6 weeks with encouragement to continue applying the techniques and an opportunity to ask clarification questions. Study outcome measures are collected before the intervention and 8 weeks after the end of the intervention. Measures include: (1) Child Sleep Habit Questionnaire (CSHQ); (2) Family Inventory of Sleep Habits (FISH) (3) 5-day sleep dairy in parallel with sleep tracking device (FITBIT Charge3).

Results:

Total sleep disturbance scores on the CSHQ decreased significantly from 50.9 to 47.3 following the intervention (t(23)=2.64, p<0.01). FISH scores, increased significantly from 45.3 to 50.3 following the intervention (t(23)=5.29, p<0.01). However, there were no significant changes in sleep latency or duration according to sleep diary records (t(23)=0.05, p=0.96), (t(23)=0.47, p=0.64, respectively).

Conclusions:

These initial findings suggest that the implemented psycho-educational intervention may have improved parental perception of sleep disturbances as reported in parental questionnaires but did not reduce sleep latency or increase sleep duration as reported in sleep diaries.

434.212 (Poster) Supporting Early Social Communication Development within Family Routines – Where Do Families Need More Support?

A. J. Schwichtenberg1, A. M. Kellerman2, C. Masters2 and A. Janis3, (1)Human Development and Family Studies, Purdue University, West Lafayette, IN, (2)Purdue University, West Lafayette, IN, (3)Purdue developmental studies lab, West Lafayette, IN

Background: Parent-mediated interventions (PMIs) are common intervention models; especially, when supporting children with early elevated autism risks or an early autism diagnosis. PMIs often encourage caregivers to incorporate social communication bids, responses, and scaffolding within naturalistic family routines like play or feeding. However, routines are often treated equally without consideration for which routines may warrant additional support for caregivers.

Objectives: Within a parent-mediated intervention model, identify family routines wherein additional caregiver support for social communication scaffolding is warranted.

Methods: Forty-two families with social communication concerns for their young children (aged 8 months to 5 years) participated in an ongoing family routines-based PMI. Children within this study had a confirmed autism spectrum disorder diagnosis or were awaiting diagnostic confirmation and presented with clear language and/or social concerns. Baseline data for the present study includes detailed behavioral codes of in-home recordings from four family routines (play, feeding, clothing/diaper change, and bedtime routines). All data for the present study were collected before the start of their PMI training. Data includes codes for caregiver and child communicative bids, responses, and modality (e.g., vocalization, giving, showing, deictic communication, conventional gestures). Caregiver education, and child age, sex, and developmental quotient were explored as covariates across all correlational and general linear models.
Results: Caregiver communication patterns were not correlated across the four routines (all \( p > .05 \)) and caregivers used significantly more communication bids, responses, and scaffolding during meal and bedtime routines (when compared to parent-child play and diaper/clothing change; Figure 1a). These patterns were distinctly different for children. They displayed significantly more communication during play than in the other routines (Figure 2a). For both caregivers and children gesture use was the most common during play (Figures 1b, 2b). Several additional social communication differences were present and will be further elucidated in the full presentation.

Conclusions: Within parent-mediated interventions, play interactions are often a target area for caregiver support. The present study highlights how play interactions follow a notably different pattern than other (arguably more common) routines. In particular, diaper/clothing changes had lower levels of communication for both caregivers and children making it a clear target routine for additional support. Similarly, gesture use was most common during play and additional programing/training to incorporate gestures into other family routines is supported by the present data. Future PMIs can build on this work by acknowledging multiple family routines in their targets and by structuring support to fit noted relative weaknesses.

434.213 (Poster) Supporting Teachers of Autistic Children to Promote Inclusive Education: A Feasibility Study

S. Van der Paelt, C. Bontinck, J. Maljaars, I. Noens, and H. Roeyers, (1)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Liga Autisme Vlaanderen, Melle, Belgium, (3)Parenting and Special Education Research Unit, KU Leuven, Leuven, Belgium, (4)Parenting and Special Education Research Unit, Faculty of Educational Sciences, KU Leuven, Leuven, Belgium

Background: Research on support programmes for autistic children is typically conducted in an academic setting. Implementing these programmes in practice can pose difficulties. With support of the Flemish government, the Academic Collaborative Centre for Autism was founded. Its aim is to further develop, evaluate and disseminate support programmes for autistic individuals, which are used in practice settings. The current study focusses on a programme aimed at supporting teachers of autistic children to help the child participate in an inclusive classroom. Research has shown that including an autistic child in a classroom with typically developing peers can be challenging for the teacher, who is often in need for support to promote participation of the autistic child in the classroom.

Objectives: The aim of this study was to assess the feasibility of this programme, taking into account the perspective of teacher and counsellor.

Methods: Participants were counsellors of 84 children (64 boys) with a confirmed or preliminary diagnosis of autism. For 64 children, also teachers took part in the study. The children were between 2.5 and 7 years old \((M = 5.17; SD = 1.15)\). The individualized programme consisted of 10 sessions of 3 hours in the classroom. Depending on the goals for the child the programme consisted of psycho-education for the teacher, adapting the environment to the child, promoting communication and interaction, dealing with challenging behaviour and emotional difficulties, teaching adaptive skills, task performance, play, learning how to fill in free time and/or supporting the child during school transitions. After the last session counsellors and teachers received an online questionnaire of 26 items on the practical organization, class factors, effect on child, effect on teacher and collaboration with the teacher. The questionnaire for the teacher did not include this last category. The questions were rated on a scale of 1 to 7.

Results: Counsellors \((M = 5.35; SD = 0.80)\) and teachers \((M = 5.47; SD = 1.40)\) were on average satisfied with the practical organization of the support. The effect on the child was also rated positively by both counsellors \((M = 5.30; SD = 1.29)\) and teachers \((M = 5.61; SD = 1.37)\). This was also true for the effect on the teacher \((M = 5.39; SD = 1.28\) for counsellors and \(M = 5.07; SD = 0.99\) for teachers). Counsellors rated the feasibility to use the programme in the classroom with other children between “not sure” and “slightly agree” \((M = 4.55; SD = 1.32)\), while teachers rated these class factors more positively \((M = 5.46; SD = 1.40)\). The collaboration with the teacher was rated positively by the counsellors \((M = 5.45; SD = 1.27)\).

Conclusions: Teachers and counsellors were satisfied with the effect of the support programme on teacher and child. In most cases the practical organization did not pose many difficulties. Offering support in a classroom with a group of typically developing peers can be somewhat challenging, according to the counsellors. However, teachers saw this as less of an obstacle.

434.214 (Poster) Teacher-Implemented Early Achievements Intervention Shows Efficacy for Improving Autistic Preschoolers’ Social Communication Outcomes

R. Landa, A. M. Engelstad and C. B. Holingue, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Center for Autism and Related Disorders, Boston Children’s Hospital and Harvard University, Baltimore, MD

Background:

Early social and communication skills are major predictors of adult outcomes for those with autism. Early intervention (Early Achievements [EA]) implemented in a clinical setting targeting such skills improved short-term and longer-term outcomes. Few evidence-
based teacher-implemented early interventions for autistic preschoolers have demonstrated efficacy. Furthermore, research is needed to elucidate whether inclusive classrooms confer advantage relative to non-inclusive classrooms to early acquisition of social communication skills.

Objectives:

Determine whether: (1) teachers randomized to EA-focused workshops and coaching demonstrate superior EA implementation fidelity and sustainment compared to workshops only (WO) group; (2) relative to preschoolers in the WO group, EA preschoolers demonstrate superior social-communication outcomes; and (3) children in inclusive EA classrooms demonstrate superior social communication outcomes relative to non-inclusive EA classrooms.

Methods:

Teachers were randomized to the EA professional development (PD) (n=33) or WO (n=36) group. EA PD consisted of five workshops and 20 job-embedded coaching sessions. WO teachers attended five workshops unrelated to EA. EA teachers were trained to embed high-dosage instruction targeting language, imitation, joint attention, and peer-to-peer engagement in classroom group interaction contexts using naturalistic developmental behavioral intervention strategies (Schreibman et al., 2015). Participants’ baseline demographic data are presented in Table 1.

Teachers’ implementation fidelity was assessed monthly, pre-through post-PD; EA teachers’ sustainment was measured the following school year, six months post-PD. Children’s classroom-based social communication behavior was video-recorded pre- and post-PD and coded by researchers blinded to group and data acquisition timing. Distal social and language measures were administered at pre- and post-PD. 3-level hierarchical linear models accounting for clustering at the individual, classroom, and school levels assessed growth patterns. T-tests compared baseline autism symptomatology (ADOS CSS-Total) and nonverbal cognition (Mullen Scales of Early Learning Visual Reception age equivalency) for EA inclusive versus non-inclusive classrooms. Linear regression models compared child social communication outcomes in inclusive versus non-inclusive EA classrooms, controlling for baseline age and nonverbal cognition (Mullen Scales of Early Learning Visual Reception age equivalency).

Results:

At pre-PD, no group differences were detected in teacher fidelity (WO mean=32.8%, EA=29.6%). EA teachers demonstrated significantly greater gains in fidelity than WO teachers (β=0.12, p <.001). At post-PD, mean EA and WO teacher fidelity was 87.9% and 32.2%, respectively. EA teachers sustained fidelity (X ̅=81.1%).

Compared to children in the WO group, the EA group made greater pre-post gains on proximal measures of joint attention, initiation of peer engagement, and motor imitation. The EA group generalized imitation learning per their superior outcomes compared to the WO group on the distal imitation measure. See Table 2 for more results. Children in inclusive EA classrooms had higher nonverbal cognitive functioning (mean=31.28 months) compared to those in non-inclusive EA classrooms (mean=23.11 months). No significant differences were detected in social communication treatment effects in inclusive compared to non-inclusive EA classrooms.

Conclusions:

EA demonstrated efficacy for improving social communication outcomes for minimally verbal autistic preschoolers with high levels of autism symptomatology, regardless of classroom inclusion status. Findings indicate promise of scalability of teacher-implemented EA intervention for autistic 3- to 5-year-olds.

434.215 (Poster) Teacher-Implemented Social Emotional Engagement-Knowledge and Skills (SEE-KS) Intervention: Feasibility and Preliminary Efficacy in Early Childhood Classrooms

L. Morgan1, M. Siller2, S. Fuhrmeister3, B. Schirmer4 and Q. O. Wedderburn5, (1)Emory University, Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Children’s Healthcare of Atlanta, Atlanta, GA, (4)Marcus Autism Center, Atlanta, GA, (5)The University of South Carolina, Atlanta, GA

Background: With increasing numbers of children with or at high likelihood for autism being served in inclusive early childhood education (ECE) settings, educators are challenged to meet diverse student needs. The complexity and specificity of many professional development (PD) interventions for autism, however, creates barriers to adoption and implementation. Thus, it is critical that PD interventions be developed and tested so that teachers of children with autism and social communication challenges may effectively learn to implement the intervention with high fidelity in ECE settings.
Background: As the need for accessible interventions for autism spectrum disorder (ASD) grows, telehealth intervention become an important strategy to facilitate parent’s teaching skills. With the COVID-19 public health crisis, in-person interventions have become largely infeasible during 2020-2022; therefore, it is crucial to develop an evidence-based telehealth parent-mediated intervention for young children with autism spectrum disorder with cultural adaptation. Growing studies have been explored the topic in the West. However, few studies focus on the issue in Asia area, especially in Taiwan.

Objectives: The purpose of the study was to develop a therapist-directed telehealth parent-mediated intervention for young children with autism spectrum disorder. The current report was to report initial findings of an RCT study.

Methods: Thirty-three children with ASD ages 18-48 months and their parents were randomized into the therapist-directed or self-directed groups. All of the children were diagnosed with DSM-5 and also used ADOS or ADI-R by a research team including psychiatrist, psychologist or trained graduate students in clinical psychology program. Parents in the therapist-assisted group received the website lessons and 13 weekly 1-hour coaching sessions, while parents in the self-directed group only received the website lessons. The 13 website lessons combined the rationales and teaching strategies from P-ESDM (Parent implementing Early Start Denver Model, Rogers, et al, 2012) and Project ImPACT (Improving Parents as Communication Teacher, Ingersoll & Dvorcsak, 2019). Both program manuals were translated into Traditional Chinese version and published in local publishers before the study. The first author is PI and have gotten certified ESDM therapist and ImPACT coach. The initial parental outcome measures including intervention knowledge, intervention fidelity mainly referred ESDM mode, parental stress, parenting efficacy and quality of life after intervention.

Results: Before the intervention, two groups were no difference on the above parental outcome measures. After intervention, the initial results showed (1) In terms of the primary outcomes, the parents in both groups improved significantly in intervention knowledge and implementation fidelity. Parents in therapist-assisted group have greater gains in the implementation fidelity (p < .003). (2) Regarding the secondary outcomes, there were no significant changes in parental stress, parenting efficacy and quality of life after intervention.

Conclusions: Overall, our preliminary findings revealed that telehealth parent-mediated program can increase the intervention knowledge and implementation fidelity in both groups. Additionally, therapist-assisted mode could provide more benefit for the implementation fidelity. Further studies are needed to recruit more participants and follow up the two groups to understand the intervention stability.
Background: Challenges in communication are common in autistic individuals. Though there is growing literature supporting the efficacy of naturalistic developmental behavioral interventions (NDBIs), such as Pivotal Response Treatment (PRT), for targeting communication skills, disparities in access to intervention remain a serious barrier to treatment. Advancements in technology can be used to bridge the gap in treatment accessibility for families who cannot access NDBIs. This pilot study aims to evaluate a telehealth model of PRT parent training to see if parents are able to implement PRT with fidelity after receiving virtual training and if children show improvements in functional communication skills and find the intervention acceptable.

Objectives: To evaluate a telehealth model of PRT parent training.

Methods: Twenty-one autistic children (2-6 years) with severe expressive language delays and their parents participated in this uncontrolled trial. Parents attended 12 weekly telehealth parent education sessions with a PRT-trained therapist and submitted 10-minute home videos of PRT practice before and after the study. Standardized measures such as Vineland Adaptive Behavior Scale (VABS), the MacArthur-Bates Communicative Development Inventory (CDI) Words & Gestures and the Family Empowerment Scale (FES) were used to assess child and parent outcomes. Home videos were coded to assess change in parent fidelity of implementation and child utterances. Child positive and negative affect during videos was coded as proxy for child treatment acceptability.

Results: Parent-reported communication scores on the VABS significantly increased post-intervention (t(15) = 2.80, p = 0.014), while socialization scores did not change (t(16) = 1.62, p = 0.126). On the CDI, parents reported their children were able to express more distinct words out of a list of 396 words after intervention (t(19) = 2.39, p = 0.028), and a trend toward significance was observed on receptive abilities (words understood; t(19) = 1.76, p = .094). Analysis of home videos indicated that children made significantly more utterances per minute in response to parents’ non-verbal prompts in post-intervention videos than before intervention, (t(20) = 2.72, p = .013). Though all other types of utterances (unintelligible, imitative, verbally-prompted) increased, the changes were not statistically significant. 20 of 21 parents achieved at least 80% fidelity of overall PRT implementation and most parents (16/21) implemented all six PRT principles with fidelity. Parents reported feeling greater family empowerment after intervention (t(17) = 2.19, p = .043). Children’s positive (t(20) = -.288) and negative (t(20) = .838) affect were not significantly different from pre- to post-treatment (p values > .05).

Conclusions: This study is one of the first to demonstrate the efficacy of PRT parent training via telehealth in improving child communication skills as well as parent fidelity. This study is also one of the first to look at acceptability of PRT from the child’s perspective through affect ratings. Evidence that affect did not significantly change at the group level following treatment suggests preliminary acceptability of parent implemented PRT. More rigorous research, like randomized controlled trials, are needed to better understand the impact of telehealth PRT parent training as a tool for overcoming intervention accessibility barriers.

434.218 (Poster) Telehealth Pivotal Response Treatment Parent Training: A Randomized Controlled Pilot Trial
K. Paszek1, M. E. Millan1, T. Lark2, J. Shkel1, A. Y. Hardan1 and G. W. Gengoux1, (1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Palo Alto University, Palo Alto, CA

Background: Challenges in communication are commonly observed in children with Autism Spectrum Disorder (ASD). As literature grows supporting the efficacy of Pivotal Response Treatment (PRT) for improving social communication skills in children with ASD, access to intervention continues to be a barrier for many families. Determining the efficacy of utilizing telehealth methods to provide treatment to families is critical in improving access to care.

Objectives: The aim of this study was to conduct a randomized controlled pilot trial to examine the effects of training parents in PRT via telehealth (PRT-T) and investigate whether parents can learn via telehealth to deliver PRT in the home setting and whether their children will show greater improvement in communication skills compared to children in a waitlist control group (WL).

Methods: Recruitment for this trial is ongoing. Participants to date include 28 children with ASD, aged 2-5:11 years (M=4.09 ± 1.08 years) with significant expressive language delays and their parents. Children were randomly assigned to WL (N=14) or PRT-T (N=15). During PRT-T parents and children participated in 12 weekly 60-minute parent education sessions via secure video conference with a PRT-trained therapist. Parents completed the MacArthur-Bates Communicative Development Inventory (CDI) at baseline and week 12 and an expert clinician naïve to treatment assignment completed the Clinical Global Impression Improvement rating (CGI-I) at week 12. In addition, home videos were collected at baseline and week 12 to assess PRT implementation and change in frequency of child utterances in the home setting.

Results: Preliminary analyses reveal that children enrolled in PRT-T showed significantly greater improvement on the CDI – Words Produced Total Score between baseline (M = 129.7 ± 92.1) and week 12 (M = 192.4 ± 111.7), compared to the WL (BL: M = 45.08 ± 55.693; Wk 12: M = 48.08 ± 66.274; F = 4.306; p = 0.048). Furthermore, CGI-I ratings indicated that the PRT-T group showed more overall improvement in communication skills compared to controls (X2 (3, N=28) = 11.44; p = 0.010). Specifically, 1 child was rated as...
“very much improved” (0 in WL), 8 children rated as “much improved” (1 in WL), 6 children as “minimally improved” (7 in WL), and none rated as “no change” (5 in WL). Analysis of parent fidelity and child utterances from the home videos is in progress.

Conclusions: These preliminary data suggest that delivery of PRT parent training via telehealth is effective for improving child communication skills and may be a promising method for increasing access to evidence-based treatment for young children with ASD and their families.

434.219 (Poster) The Acceptability and Effectiveness of Caregivers Skills Training in Vietnam  
H. S. Vu, H. Hoang, T. Quach and C. Q. Tran, (1)Center for Creative Initiatives in Health and Population, Hanoi, Viet Nam, (2)Center for Creative Initiatives in Health and Population, hanoi, Viet Nam

Background:

The Caregives Skills Training (CST) Programs was developed by the World Health Organization (WHO) to target caregivers of children between 2-9 years with developmental disorders or delays. The program aims to provide caregivers with strategies to support their children’s development by engaging children in everyday activities and applying strategies to support the development of the child’s communication skills and reduce challenging behavior. Since 2019, with financial support from USAID, the Center for Creative Initiatives in Health and Population (CCHIP) has been piloting and implementing in three central provinces in Vietnam.

Objectives:

Assessing the acceptability and effectiveness of the CST program (Vietnamese version) through investigating parent’s feedbacks and measuring changes in caregivers’ knowledge and confidence, and children’s improvement.

Methods:

The study used mix-methods. WHODAS child was used to measure changes in children’s improvement and pre and post self-administered questionnaires to measure changes in caregiver’s knowledge and confidence level. A total of 179 parent-child dyad (children Mean age = 44.8, SD: 18.9 month) were enrolled in the intervention program and completed pre- and post-intervention assessment. Some care-givers were interviewed at the end of the training courses for their feedbacks on the acceptability.

Results:

After nine weeks of intervention, there were improvement in both caregiver and children’s outcomes. There were statistically significant changes in caregiver’s knowledge (17.64 score in pre vs 19.30 score at post tests), and in caregiver’s confidence (4.85 score in pre vs 8.6 score at post tests). There were significant reduction in WHODAS scores (suggesting less difficulties/improvement) on all seven domains, from 5.18 score to 14.05 score. Interviewed care-givers also reported several advantages of the program, and expressed their high acceptability to the program.

Conclusions:

There is evidence of the effects of the CST program on improving child’s outcomes in terms of communication, self-care, getting along, participation and life activities overall. Future research might explore further factors that influences the effectiveness, feasibility and acceptance of the implementing CST program at larger scale.

434.220 (Poster) The Effect of “Resilience Intervention with Parents of Children with ASD” on Parental Resilience and Well-Being and on Children’s Behavior and Emotion Regulation  
T. Gev, D. Hamiel, N. Gershon, N. Cohen-Aronson, D. Diamant and N. Laor, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, ISRAEL, (2)Cohen-Harris Resilience Center, Autism treatment and research center-association for children at risk, Giv'at Shemuel, Israel, (3)Psychology, Reichman University, Herzliya, Israel, (4)Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background:

Parents of children with ASD deal with various challenges stemming from their child’s course of development. They experience increased levels of stress, anxiety and depression as compared to parents of children with typical development (Bitsika et al. 2013). These experiences challenge their psychological resilience and well-being. Research on parent-specific interventions aimed at improving psychological resilience and well-being is scarce (Kuhlthau et al., 2020; Schwartzman et al., 2021). Furthermore, the possible impact of parental improved resilience and well-being on these children’s behavior and emotional regulation has rarely been studied. The Resilience
Intervention with Parents of Children with ASD (RIPCA) is a 17-weeks group-based program, designed to teach parents evidence-based resilience strategies, emotion regulation techniques, and child behavior management strategies. RIPCA was based on an educational resilience intervention program, that showed significant improvements in children’s stress and mood 3 months after termination of the intervention (Wolmer et al., 2011).

Objectives:
To examine the immediate and delayed effect of RIPCA on (1) parental resilience and well-being, and (2) child behavior, anxiety and emotion regulation.

Methods:
A case comparison design was conducted. Two groups of parents of preschool children with ASD (3-6 years old) were recruited. Participants assigned to either RIPCA (n=49) or Treatment as Usual (TAU) group (n=56). Both groups received individual parent training by mental health professionals working at the preschool, while the RIPCA participants also received the group intervention. Participants completed questionnaires evaluating parental resilience and well-being, and child’s anxiety, behavior, and emotion regulation. Assessments were conducted pre intervention (T1), post intervention (T2), and at follow up, 8-10 weeks after the intervention (T3).

Results:
Post intervention (T2), no significant changes were found in both groups on either parent or child measures. Interestingly, at the follow-up assessment (T3), results indicated that the RIPCA group significantly reduced parental negative relationships, an aspect of parental resilience. Parents also reported a significant decrease in children’s maladaptive behaviors (agitation and crying) and children's separation anxiety. In addition, findings in the intervention group, trending toward significance levels, were improved general parental resilience, decreased parental depressive symptoms, and decreased children's reactivity, an aspect of emotion regulation. No such changes, or any other significant changes, were found in the TAU group.

Conclusions:
results support the effectiveness overtime of RIPCA in (1) improving parental resilience and well-being among parents of young children with ASD, (2) decreasing children's maladaptive behaviors (agitation and crying), anxiety symptoms, and emotion dysregulation. These results are encouraging, as they show direct improvement in the parent as a caregiver and an indirect improvement for the child. Significant changes reported only at T3 might indicate that parents attending the RIPCA program undergo a relatively gradual internalization and implementation process of resilience tools. Further exploration of the internalization process and the differential contribution of both parental resilience and child behavior management techniques to child behavior and emotion regulation is needed.

434.221 (Poster) The Effect of Parental Involvement on the Efficacy of the PEERS for Preschoolers (P4P) Social Skills Intervention: Preliminary Results of an Israeli Randomized Controlled Trial

L. Oliver-Aronson1, T. Gev2,3, E. A. Laugeson4, and O. Golan2,3, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (3)Association for Children at Risk, Givat-Shmuel, Israel, (4)UCLA Semel Institute for Neuroscience and Human Behavior, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA

Background: Many research-supported interventions for children with ASD rely on parents as key support figures, since parents are perceived as facilitators of social learning opportunities, and maintenance and generalizability of treatment gains (Siller et al.,2018). Indeed, social-skills training groups involving parents are considered the most effective treatment mode for children with ASD (DeRosier et al., 2011). The Program for the Education and Enrichment of Relational Skills (PEERS; Laugeson & Frankel, 2010) is an evidence-based parent-assisted social-skills training program for children with ASD, which has a preschooler version - PEERS for preschoolers (P4P). In the program, parents attend their own group, parallel to their children's, in which they are taught how to support the practicing of learned skills during everyday interactions with their child and to facilitate social interactions with peers for their children (Park et al., 2022). Previous studies revealed concurrent improvements in social and caregiving skills, with subsequent changes in family functioning, following the intervention (Factor et.al, 2022) which maintained at follow-up (Antezana et al, 2022). Whereas these findings add to previous reports of the effectiveness of parental involvement in children's social-skills programs, they have not directly examined the role of parental involvement in intervention-related outcomes, have not been tested through a randomized controlled trial, and have not examined generalization of gains to other social settings.

Objectives: This study aims to conduct a randomized controlled trial comparing the effects of the parent-supported P4P program to those of a P4P program with minimal parent involvement (P4P-mpi) on intervention related gains in child social-skills and generalization to school settings.
**Background:** Executive function (EF) is a series of cognitive abilities and processes for performing goal-directed behaviors. EF comprises three core EFs, namely, inhibitory control (IC), working memory (WM), and cognitive flexibility (CF), which are the foundation of higher-order EF, such as planning, problem solving, and reasoning. Children with autism spectrum disorder (ASD) experience difficulties in EF that impact their school and family lives. Given the importance of the core EFs, EF intervention may be beneficial to and necessary for children with ASD. However, few EF intervention programs have been designed to directly target the core EFs in children with ASD. Therefore, the efficacy of a core EFs-based intervention program for children with ASD needs to be examined.

**Objectives:** The aim of the study was to investigate the efficacy of an executive function intervention program (EFIP) in children with ASD aged 4 to 7.

**Methods:** Thirty-six participants (5 females) aged 4-7 (M=5.29, SD=0.98), who were diagnosed with ASD without an intellectual disability were randomly assigned to one of two conditions: P4P intervention (n=18), or a P4P intervention with minimal parental involvement (P4P-MPI; n=18), in which parents did not attend their own group, but rather received parent handouts highlighting didactic lessons. Each intervention group included up to 10 children. Conditions were comparable on age, sex, cognitive abilities and ADOS-2 scores. Participants were evaluated prior to and following the 16-week group intervention. Outcomes were assessed using parent and teacher questionnaires: Social-skills Improvement System (SSIS; Gresham & Elliott, 2008) and Social Responsiveness Scale, 2nd ed. (SRS-2; Constantino & Gruber, 2012).

**Results:** Parent reports have shown significantly improved social-skills of children on the SSIS (Fig. 1a) and increased social motivation on the SRS-2 for the P4P condition but not the P4P-MPI condition (Fig 1b).

Similarly, teacher reports have shown significantly improved social-skills on the SSIS (Fig. 1c) and improvements on the social communication index of the SRS-2 (Fig. 1d) for the P4P condition, but not for the P4P-MPI condition.

**Conclusions:** Results highlight the importance of parental involvement in child-focused social-skills interventions for children with ASD. These results also demonstrate improved generalization of learned skills to school settings when parents are involved in treatment. Lastly, these results offer preliminary support for cross-cultural effectiveness of P4P, and the first evidence for its efficacy in a randomized controlled trial.
Background: Parents of autistic children often report the absence or delay of social developmental milestones related to social skills (Martínez-Pedraza & Carter, 2009). The PEERS® for Preschoolers (P4P) Program is an evidence-based social skills intervention for preschool-aged autistic children and children with other social challenges (Park et al., 2022). Historically, P4P has been conducted in-person, which allowed clinicians to give real-time performance feedback to parents as they provided in-vivo social coaching to their children (Factor et al., 2022). However, in the wake of the COVID-19 pandemic, P4P transitioned to a parent-only telehealth delivery, requiring performance feedback to be given retrospectively during homework review of video self-modeling assignments. While telehealth outcomes for remote delivery of P4P have been promising (Factor et al., 2022), little is known about the influence of video self-modeling homework completion on treatment outcome.

Objectives: The current study aims to assess the impact of video self-modeling homework assignments of parent-child social coaching interactions on social skills treatment gains following P4P.

Methods: Participants included 30 parents and one grandparent of children between 4 and 6 years who completed the telehealth adaptation of P4P (Mchild age=4.93, SD=.83). Preschoolers presented with social difficulties and 19 had received historical diagnoses of autism (63.3%). As part of the adapted telehealth intervention, parents were required to complete weekly video self-modeling homework assignments focused on parent social coaching of targeted play skills. Parents then received performance feedback from the treatment team during homework review. Treatment outcome was assessed using the Quality of Play Questionnaire (QPQ; Frankel et al., 2010), Social Responsiveness Scale–Second Edition (SRS-2; Constantino & Gruber, 2012), Social Skills Improvement System social skills subdomain (SSIS-SS; Gresham & Elliott, 2008), and the Parenting Stress Index, Fourth Edition, Short-Form (PSI-4-SF; Abidin, 2012).

Results: The mean number of videos submitted by parents was 11.9 out of 15. Paired sample t-tests indicated scores on all SRS-2 subscales, PSI-Total, QPQ (invited and hosted playdates), and SSIS-SS significantly improved from pre- to post-intervention (all p’s values<.05). Thus, gains were observed for most P4P participants. Correlations with video self-modeling homework completion and intervention outcomes were not significant. However, the correlation between videos submitted and SRS-2 subdomain of social awareness post-treatment was trending toward significance (r=.38, p=.58), with more videos submitted suggesting greater gains. Change scores for all outcome measures were examined, though not significantly correlated with video submissions.

Conclusions: Findings suggest that overall most participants benefit from P4P using the parent-only telehealth adaptation, including the use of video self-modeling homework assignments. However, gains were not directly related to the number of videos submitted, perhaps related to the fact that parents still received exposure to clinician feedback during the viewing of other family videos. While the current study provides promising evidence for the use of novel techniques for promoting the generalization of parent social coaching outside of treatment settings, future research might examine the differences in treatment outcome when comparing video self-modeling to in-vivo performance feedback of parent social coaching.

Vivanti\textsuperscript{6}, E. Courchesne\textsuperscript{7}, K. Pierce\textsuperscript{8}, M. Schaer\textsuperscript{9}, L. Ruta\textsuperscript{10} and M. V. Lombardo\textsuperscript{11}, (1)Center for Neuroscience and Cognitive Systems, Centre for Mind Brain Sciences (CIMeC), University of Trento, Italy, Rovereto, Italy, (2)Department of Psychiatry, University of Geneva School of Medicine, Geneva, Switzerland, Geneva, Switzerland, (3)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel, (4)Department of Psychology, Bar-Ilan University, Ramat-Gan, ISRAEL, (5)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (6)Neuroscience, UC San Diego Autism Center of Excellence, San Diego, CA, (7)neuroscience, UCSD, san diego, CA, (8)Psychiatry Department, University of Geneva School of Medicine, Geneva, Switzerland, (9)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy, Messina, Italy, (10)Center for Neuroscience and Cognitive Systems, Istituto Italiano di Tecnologia, Rovereto, Italy

Background:

Previous studies have often reported that early intervention and higher baseline cognitive skills would predict more positive treatment outcomes. However, it is still not clear if any cognitive areas have the same benefit from earlier intervention. Furthermore, if earlier intervention and higher pre-treatment cognitive level have such specific impacts, it is unclear for which types of treatment these effects may be most important for.

Objectives:
Examine the influence of age at treatment start and pre-treatment developmental quotient on verbal, visual reception and fine motor abilities during community or Early Start Denver Model intervention

Methods:

Data from the Autism Early Intervention Research (AEIR) consortium was analyzed. Here we included n=429 autistic toddlers (n=342 males, n=87 females, age range = 13-60 months) from 7 different datasets with longitudinal data on early intervention. Participants received between 6-27 months of intervention with variable levels of intensity and with different intervention models that can be described as community intervention (e.g., ABA, PRT, etc) or Early Start Denver Model (ESDM). The Mullen Scales of Early Learning (MSEL) with expressive and receptive language (EL, RL), visual reception (VR) and fine motor (FM) subscales are common across all datasets. Linear mixed effect models were used to model fixed effects of treatment type, age, MSEL subscale, age at treatment start, pre-treatment developmental quotient, intensity, sex and random effects of dataset, subscale, and age grouped by subject (random slopes and intercepts).

Results:

Treatment type, MSEL subscale, and age at treatment start showed a highly significant 3-way interaction (F = 7.32, p = 6.89e-05) for predicting MSEL scores. To decompose this interaction, we split the data by treatment type and by subscale. Age at treatment start significantly affects each MSEL subscale. However, in community intervention the effect of age at treatment start is largest for both EL and RL (EL $R^2 = 0.08; RL R^2 = 0.09; p < 1.79e-09$) and also for VR (VR $R^2 = 0.05; p = 9.31e-07$), while is significantly less relevant for FM (FM $R^2 = 0.01; p = 0.01$). In contrast, in ESDM the effect of age at treatment start is much smaller and more similar across subscales ($R^2 < 0.05; p < 0.47e-03$). No difference between intervention styles were seen in the age treatment start effect, except for EL ($F = 4.86, p = 0.03$) where community intervention has more positive effect of early starts than ESDM (community intervention $R^2 = 0.08; ESDM R^2 = 0.03$). Furthermore, we found that pre-treatment developmental quotient is the characteristic that most impact all cognitive outcomes ($R^2 > 0.35$), but some difference were found between intervention styles. In ESDM the development of EL and VR skills is more influenced by pre-treatment developmental quotient

Conclusions:

These findings suggest that age at treatment start and cognitive level at the baseline are important pre-treatment predictors that may change their influence based on cognitive outcomes and intervention styles.

434.225 (Poster) The Social ABCs Parent-Mediated Intervention for Toddlers with Autism Spectrum Disorder: Feasibility and Evidence of Success in Running the Program in Goa, India.

Background:

Social ABCs is a developmentally informed, parent-mediated intervention developed in Canada to meet the need for evidence-based, manualized and sustainable intervention for toddlers with suspected or confirmed autism spectrum disorder (ASD). The two key targets of this program are directed vocal communication and positive emotion sharing with the caregiver.

Two clinicians from Sethu Centre, Goa received remote training in the Group Social ABCs Model in 2020 from the Social ABCs trainers based in Canada through weekly online supervision sessions and achieved fidelity in implementation of the Social ABCs strategies, parent coaching, training and supervised practice in coding the videos following which the first group was started in February 2021 at Sethu. To date, the Social ABCs program has supported 55 families over 10 groups at Sethu.

Objectives:

This study presents preliminary outcomes from running the Social ABCs group program at Sethu Centre in Goa, India.

Methods:

To date, 55 parent-toddler dyads have enrolled in the 6 weeks Social ABCs Group Program. The program was offered in three formats: in-person at the Centre, online, or as a hybrid format (a mix of online and in-person sessions) to make it feasible for families during COVID-19 pandemic. The program involved 6 weekly online group didactic sessions and 9 one on one coaching sessions, either in person or online.
for each dyad. The selection of the program format was done based on the imposed lockdowns at that time, the network connectivity or convenience of families of coming to the Centre and not based on clinicians’ decision on what would be the best fit for the family. Video clips of parent-child interactions were taken at baseline and in the 6th week (post training). Outcomes were measured using video-coded data to measure parent implementation fidelity and child responsivity.

Results:

Of the 55 families who enrolled, 49 finished the program while 6 families could not complete the entire 6 weeks due to commitment issues. Post 6-week training, significant improvements were observed in parent fidelity of implementation (from $M = 46.14\%$ to $77.6\%$; paired samples $t = -12.8$), child directed vocal responsiveness to parent prompts (from $M = 6.3\%$ to $45.6\%$; $t = -13.9$), and rate of child vocal initiations (from $M = 0.9$ to 3.4 per minute; $t = -4.8$), all $p$’s < .001, in line with the established Canadian data from the published RCT. Over 65% of families achieved the target of >75% fidelity.

Conclusions:

The Social ABCs Group Model shows promise as an evidence-based intervention to help improve directed vocal communication and positive emotion sharing in toddlers with ASD in Goa, India.

Our findings therefore certainly demonstrate that Social ABCs is a feasible model for parents to learn and easy to deliver in the Indian context. Bolstered by our preliminary evidence of promise, next steps include continuing to collect data that will allow us to share data from a larger sample.

434.226 (Poster) Understanding How Behaviour Therapists Use Autism Spectrum Disorder (ASD) Diagnostic Information for Intervention Planning

I. Caven, E. Laframboise, C. Nguyen, J. Wiegelmann and M. Penner, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

Background: Behaviour therapists deliver applied behaviour analysis (ABA)-based therapies, which aim to produce socially significant changes in behaviour. While ABA-based therapies are commonly accessed by autistic children and their families, behaviour therapists are often not part of the diagnostic process. They may receive diagnostic reports from physicians, educators and other clinicians that inform their assessment. Understanding how behaviour therapists incorporate diagnostic assessments into their intervention planning will advance clinical care by identifying the most salient elements of diagnostic assessment, allowing for streamlining of assessment procedures and facilitating communication with care providers.

Objectives: The objectives are to 1) describe what information from the diagnostic assessment is received by behaviour therapists; 2) determine which elements of the diagnostic package are utilized and influence therapeutic planning; 3) identify which elements of the diagnostic package are perceived as being the most important for planning.

Methods: Using a developmental lens, a questionnaire was created to explore how behaviour therapists use diagnostic information in their treatment planning and was piloted with three behaviour therapists prior to dissemination. The cross-sectional descriptive survey was emailed electronically to behaviour therapists using registry from Ontario, Canada. Descriptive statistics were calculated to compare the frequency of information obtained and utilized to inform planning.

Results: From a public registry of approximately 200 Ontarian behaviour therapists, 88 individuals completed the survey, amounting to a response rate of 44%. Most respondents identified as women and their certification as Board Certified Behaviour Analyst (BCBA). There was variability in type of service delivery (one-to-one, mediator model/consultation), role in practice setting (implementation, development, supervision), and age of clients (preschool to high school) amongst respondents. The diagnostic information mostly frequently received by respondents included brief (68.2%) and detailed (52.3%) physician/psychologist report, DSM-5 severity level (54.5%), and speech/language assessment report (54.5%). As for the diagnostic information used to develop interventions, brief (56.8%) and detailed (48.9%) physician/psychologist report, speech/language assessment report (55.7%) and DSM-5 severity level (46.5%) were most frequently selected by respondents. Information most frequently identified as ‘absolutely essential’ to intervention planning included respondents’ own interview (75%) and their client interview (64.8%). Most respondents disagreed (37.5%) or strongly disagreed (42%) with the statement “I do not need other professional’s assessments when developing an intervention plan”. Over 70% of respondents agreed or strongly agreed that the information received in the physician/psychologist assessment report is outdated (older than six months). Finally, when asked to indicate their agreement with two statements about diagnostic assessments influencing the quantity and type of treatments provided, there was variable agreement amongst respondents (Table 1).

Conclusions: These findings demonstrate that while diagnostic assessments received by behaviour therapists are important to their planning, other independently obtained sources of information, such as client interviews, are relatively more important to this process. Of note, assessments are often outdated by the time of intervention planning, leading behaviour therapists to seek out their own information.
The diagnostic assessment is one tool to inform treatment planning; however, up-to-date information about the child’s needs is likely to be more informative, particularly across the lifespan.

434.227 (Poster) Usability Testing of Technology-Assisted Jasper Social Communication Intervention
S. Y. Shire, W. Bao and S. L. Arbuckle, (1)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (2)University of Oregon, Eugene, OR, (3)Special Education, University of Oregon, Eugene, OR

Background: Technology-assisted adaptations of efficacious in person early intervention programs for children with autism spectrum disorder (ASD) have the potential to conserve resources while increasing access to specialized educational services. Usability testing of online programs can support participant engagement by aligning program navigation and content presentation with the needs and preferences of the target end users.

Objectives: The objectives were to: (a) explore initial user experiences of both caregivers and practitioners through qualitative interviews and a quantitative usability questionnaire, and (b) identify program presentation and content revisions based on user feedback.

Methods: Individual usability testing sessions were conducted on Zoom and took 60-90 minutes. Seventeen participants (n=11 caregivers, n=6 practitioners) joined via computers, phones, or tablets. Practitioners were engaged in birth-six services (e.g., teachers, speech language pathologists, interventionists) and caregivers had at least one child with ASD (M=5.05 years, SD=2.62).

Each session included: (a) Think Aloud feedback interviews (Davison et al., 1997), and (b) completion of the System Usability Scale (SUS: Sauro, 2011). The session began with a brief introduction to the Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2021) intervention followed by exploration of two modules: (a) one content module focused on children’s development (e.g., play skills,) and (b) one core JASPER strategy (e.g., play routines) module. Participants were asked to move at their own pace, read and/or listen to the materials, and try the features (e.g., buttons, scroll, videos). They were asked to speak out loud their thoughts, comments, concerns, and questions. The interviews were video recorded and transcribed. Rapid Qualitative Analysis (Vindrola-Padros & Johnson, 2020) was applied. A summary template was developed and applied to each transcript (Hamilton, 2013). The summary information was then transferred into a data display matrix (Averill, 2002). The matrix supported a streamlined process to systematically analyze similarities, differences, and trends across participant responses (Averill, 2002).

The 10-item adapted SUS questionnaire addressed program acceptability (e.g., ease of use, challenges, and user confidence). Each question was scored from strongly agree (score of 4) to strongly disagree (score of 0). Following published scoring procedures (Brooke, 2013), the item scores were summed and multiplied by 2.5 where possible score ranged from 0-100. Scores in the 90s indicated “exceptional” user experience, 80’s “good”, and 70’s “acceptable” (Bangor et al., 2009). Both reliability of the SUS scoring and scale validity have been published (e.g., Sauro, 2011).

Results: The average SUS score for practitioners was 87.0 (SD=8.94) and the average for caregivers was 83.86 (SD=10.08). Feedback was largely positive indicating that the program was straight forward to navigate, content was valued, visuals enhanced the experience, and multiple methods to access information (e.g., listen or read) were appreciated. Suggestions for improvement included adding further video examples, reducing page scrolling, and making some activities optional (e.g., text boxes, multiple-choice questions).

Conclusions: Overall, participants smoothly navigated through the pilot materials and SUS scores (80s) indicate “good” usability of the materials. Revisions will incorporate the participants’ feedback into the program which will be pilot tested in a randomized trial.

434.228 (Poster) Using Music-Assisted Programmes (MAP) to Improve Spoken Language in Autistic Children with No or Few Words: A Feasibility Study
F. Liu, T. Loucas, T. Williams, S. Fincham-Majumdar, M. Jeremic, J. Sin, S. Boseley and S. Meyer, (1)School of Psychology & Clinical Language Sciences, University of Reading, Reading, Reading, United Kingdom, (2)University of Reading, Reading, Reading, United Kingdom, (3)The University of Reading, Reading, United Kingdom, (4)City, University of London, London, United Kingdom

Background: About 30% of autistic children do not develop functional speech, being unable to express their everyday needs using language even after years of speech, language, and educational interventions. By contrast, autistic children tend to show intact or even enhanced musical abilities. Language and communication impairments in autism are associated with reduced streamlines in the left arcuate fasciculus along the fronto-temporal pathway. However, increased activation of the left inferior frontal gyrus and preserved fronto-temporal connectivity are observed during song stimulation and listening in autism. Given the different mechanisms between music and language processing in autism, music-based interventions have potentials to induce structural and functional changes in the brain that may result in functional connectivity of the cortical networks required for normal language functioning.

Objectives: We conducted an online parent-mediated randomised controlled feasibility trial to examine whether spoken language in autism can be improved through music. The target population was 2-5-year-old autistic children with no/few words, who were given 36 target

Virtual Implementation of Pre-K Early Literacy Intervention for Korean American and Autistic Dual Language Learners

Background: Supporting early literacy of preschoolers during the summer transitioning to kindergarten is crucial in ensuring positive social, cognitive, language, and academic outcomes. Read it again! Pre-K, a literacy curriculum, has shown improvements in vocabulary, comprehension, phonological, and print awareness for non-autistic Black and Korean American students. With a growing number of culturally and linguistically diverse students in special education, and Koreans as one of the fastest growing immigrant populations in the U.S., studying literacy intervention for Korean autistic preschoolers could be timely.

Objectives: This study evaluated the effects of a virtual and dual language implementation of Read it again! Pre-K on % responses to vocabulary and comprehension questions (Aim 1); and letter naming, phonemic segmentation, letter sounds, and word reading (Aim 2). We also explored the types and proportions of prompts that preceded students' verbal and gestural responses (Aim 3).

Methods: The study design was a single case experimental, concurrent multiple probe design. Three 4- to 5-year-old Korean autistic students met with a bilingual interventionist 2-3 times every week on Zoom. Participants completed 10-20 sessions across 4-6 weeks. Each session lasted 30 min with the Read it again! Pre-K lesson (25 min) and vocabulary/comprehension assessment (5 min). Dynamic Indicators of Basic Early Literacy Skills 8th edition (DIBELS) was administered before and after the intervention. The curriculum was modified by using (a) 10-20 out of a total of 60 lessons in the curriculum based on student preference, (b) a system of least prompts (verbal; phonemic+visual; mand) and non-contingent reinforcement (e.g., music), and (c) dual language instruction. Aim 1: Visual analysis of graphed data and calculation of effect size, Tau-U, was conducted for % responses. Aim 2: Pre- and post-intervention DIBELS raw scores were calculated. Aim 3: Average % prompts which preceded the responses were calculated.

Results: Aim 1: During baseline, all participants demonstrated 0% responses. Upon intervention, there was an immediacy of effect and high % responses (M = 95.7%) were maintained (Tau-U = 1, [1,1]). See Figure 1. Aim 2: Pre-intervention DIBELS raw scores were 0 for all participants. Participant 1’s phonemic segmentation (raw=5) and letter sounds (raw=1) and Participant 2’s letter sound (raw=3) and nonsense words (raw=1) improved after the intervention. Aim 3: Verbal prompt preceded the highest % all responses, and phonemic+visual prompts preceding the lowest % responses. Mandarin preceded the highest % verbal responses, whereas phonemic+visual prompts preceded the lowest % verbal responses. Verbal prompt preceded the highest % gestural responses, while phonemic+visual prompt preceded the lowest % gestural responses. See Figure 2.

Conclusions: Dual language and virtual implementation of a modified Read it again! Pre-K curriculum with a system of least prompts and non-contingent reinforcement had positive effects on early English literacy skills for Korean bilingual autistic preschoolers. It is important to note that virtual platform may not be accessible for all families. Resources must be available in the community for all students to access and benefit from innovative approaches to curriculum modification/adaptation that could lead to positive learning outcomes.

Background: Despite mounting evidence of efficacy from parent-mediated interventions for toddlers with ASD, questions remain about the impact of different delivery methods and treatment components (“active ingredients”; Vivanti et al., 2018). The Social ABCs entails coaching parents to use ten antecedent and consequence strategies, adapted from Pivotal Response Treatment (Koegel et al., 2006) to foster parent-child social communication and positive affect-sharing. The program is efficacious and effective (Brian et al., 2017; 2022), but like many multi-component interventions, little is known about which components have the greatest impact on outcomes.

Objectives: To identify, among ten specific strategies: (1) differences across delivery methods/settings (in-person – coaches and families together in clinic; virtual – families in-home with virtual coaching); and (2) which of the strategies have the greatest impact on outcomes.

Methods: Families participated in group-based Social ABCs, with significant gains in overall implementation fidelity and toddlers’ social communication (Brian, Solish et al., 2022). Here we examined video-coded and self-report data from 75 families (40 in-person, 35 virtual). Analyses included (1) univariate ANOVA to examine differences in strategy use across delivery methods/settings, and (2) Pearson correlations to explore associations between use of each strategy and outcomes.

Results: (1) Parents were using some strategies before intervention and made significant gains in using all 10 strategies, p’s < .001. At baseline, the virtual setting appeared advantageous regarding parents’ spontaneous use of three strategies (pace, natural reinforcement, and reinforcing all attempts, p’s < .005); only one difference remained significant post-training (natural reinforcement, p = .002). Magnitude of change did not differ across setting for any strategy (Figure 1). (2) Collapsing across settings, four strategies were significantly positively associated with toddlers’ post-intervention responsivity: two antecedent strategies (shared control, r² = .30; clear language opportunities, r² = .32), and two consequence strategies (contingent reinforcement, r² = .60; reinforcing all attempts, r² = .30), p’s < .02. Parents’ gains in positive emotion sharing were associated with strategies of following the child’s motivation (r² = .30), gaining child attention (r² = .31), and providing natural reinforcers (r² = .38) to any attempts (r² = .31), p’s < .009. Parents’ self-efficacy was associated with increased positive emotion sharing (r² = .26, p = .05).

Conclusions: Prior to intervention, some aspects of parent-child interaction were more evident in the home environment, where parent and child may feel more comfortable, with access to familiar toys and activities. However, parents learned the strategies equally well across delivery methods/settings. Active ingredients included clear language opportunities supported by shared control of materials/activities, and contingent reinforcement of toddlers’ directed vocal attempts. Capitalizing on children’s motivation and attention, paired with natural reinforcement, fosters a positive learning context. However, these strategies alone were not enough to increase child responsivity (they may be necessary but not sufficient). Contingent reinforcement had the greatest impact on child responsivity within this positive learning context. Identification of active ingredients will help coaches to focus on training priorities with the greatest impact and promote efficiencies that maximize the feasibility and sustainability of the program.

**434.232 (Poster) A Randomized Controlled Trial of Developmental Reciprocity Treatment in Children with Autism**

(1) Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2) Palo Alto University, Palo Alto, CA, (3) Children’s Health Council, Palo Alto, CA

Background: Despite substantial progress in development and dissemination of early interventions to improve communication skills, there are few effective treatments for targeting core social symptoms in young children with Autism Spectrum Disorder (ASD). Developmental social-pragmatic interventions have historically aimed to improve social reciprocity directly through joining the child in play and responding to sensory needs; however, evaluation of treatment effects using standardized measures in controlled trials has been limited. Preliminary data from a previously published 12-week uncontrolled trial of Developmental Reciprocity Treatment (DRT) indicated promise for improving social and communication skills on several norm-referenced parent questionnaires.

Objectives: This presentation will review data from a new 24-week randomized controlled pilot trial comparing a group receiving DRT to a Delayed Treatment Group (DTG). DRT combined parent training in developmentally-informed methods for enhancing reciprocity and clinician-delivered in-home intervention. Our aim is to examine whether a treatment focused directly on social reciprocity will lead to benefits in social interaction skills.
Methods: Participants include 37 children with ASD, ages 2-5 years (M=47.2 ± 12.1 months). Children were randomly assigned to DTG (N=19) or DRT (N=18). DRT involved weekly parent training and 10 hours per week of in-home therapist-delivered treatment for 3 months, followed by a less-intensive phase (5 hrs per week in-home treatment and bi-weekly parent training). The primary outcome measure was the Social Responsiveness Scale-2 (SRS-2). Additional dependent measures included ratings from Structured Laboratory Observation of parent fidelity of DRT implementation by raters naïve to treatment condition [ICC (2,1) = 0.847], Clinical Global Impression Improvement (CGI-I), as well as the Brief Observation of Social Communication Change (BOSCC) and standardized parent questionnaires. Children in both groups continued stable community treatments during the trial.

Results: Examination of changes with DRT reveal that 83.3% of parents receiving DRT training met fidelity of implementation criteria (80% fidelity) at week 24. When controlling for fidelity, children enrolled in DRT showed significantly greater improvement on the SRS-2 Total T Score between baseline (M=75.3 ± 7.0) and week 24 (M=68.2 ± 7.5), compared to the DTG (BL: M=74.4 ± 11.8; Wk 24: M= 71.7 ± 9.2; F=5.000; p=0.034). CGI-I ratings indicate that the DRT group showed more overall improvement compared to controls (X2(3, N=29)= 11.507; p=0.003). Specifically, 8 children rated as much improved (1 in DTG), 5 children rated as minimally improved (11 in DTG) and none rated “no change” (4 in DTG). No significant group differences in improvement between baseline and week 24 were observed on Vineland Adaptive Behavior Scales, MacArthur-Bates Communicative Development Inventory, or on the BOSCC.

Conclusions: These preliminary data suggest that the DRT approach may be a promising intervention for improving some aspects of social functioning in young children with ASD. Significant group differences in adaptive skills and communication were not observed, suggesting that community treatments may be similarly effective for those skill areas. Future trials including larger sample sizes are warranted to replicate the findings observed in this pilot trial. Considerations for treatment design integrating behavioral and developmental intervention strategies will be discussed.

Panel Discussion — Interventions - Non-pharmacologic - School-Age, Adolescent, Adult

Panel Chair: Jonathan Green, University of Manchester, Manchester, United Kingdom

There have been increasing concerns about the quality of reporting standards in autism intervention science (https://www.spectrumnews.org/news/why-autism-therapies-have-an-evidence-problem/). Only 6/48 trials in an example systematic review (French and Kennedy 2018 https://doi.org/10.1111/jcpp.12828) met minimal standards for absence of risk of bias and Sandbank et al 2020 https://doi.org/10.1037/bul0000215 showed how trial design and reporting had a major impact on inflating treatment effect estimations. The proposal in this Panel is that all specialist Autism Journals institute full CONSORT reporting standards; with mandated publication of Trial registration, Protocols and analysis plans. The panel will debate the mechanics of this and arising concerns about practicality or that such a policy would be restrictive for early phase or exploratory studies, inequitable for low resource centres in global health, or that it would create unbalance submissions if some Journals did this and not others. Potential solutions to these concerns will be described, involving Journals acting together and incorporating existing guidelines for preliminary, proof of concept, pilot studies. The learning goals of this panel are a discussion about the issues involved for Clinical Scientists, Journals, Clinicians, Families and the Autistic Community. What is the reliability of the corpus of intervention science in the field and guidance for practice?

205.001 (Panel Discussion) Clinical Evidence and Evidenced Practice

J. Green, University of Manchester, Manchester, United Kingdom

Background: The importance of ASD as a health condition is increasingly recognised internationally in terms of population prevalence, societal awareness, and clinical and health policy priority (for instance in the WHO Mental Health Action Plan 2013-2020 and UK NHS long-term plan). Concomitantly, the demand for clinical services and the range, variety and cost of clinical support and intervention offered has mushroomed; at least in relatively high resource settings, where services offered for ASD are now a substantive part of child and adolescent mental health provision. However, an increasing concern is that the great majority of interventions currently funded and offered in health systems have little or no solid evidence base of effectiveness or safety. This despite a significant increase in the amount of intervention science reported and related practice recommendations. This situation matters for the rights and welfare of autistic people and their families, and the efficiency, and effectiveness of health systems.

Objectives: To present information on current clinical practice for ASD in the UK as an exemplar of the wider situation. To discuss now we can improve the reporting and dissemination of robust clinical science, as a first step to support ASD health systems to be more efficient, effective and cost-effective.
Methods: Review of literature on currently prevalent interventions and health system responses. Evidence from implementation science on the barriers to the incorporation of currently evidenced practice.

Results: The majority of clinical interventions in common use in the UK currently have little or no effectiveness evidence to justify their use. Some examples of recent studies and reviews will be given, including on interventions to improve anxiety, depression and other mental health outcomes (Linden et al 2022), sensory integration (Randell et al 2022), positive behaviour support (Hassiotis et al 2018, Strydom 2020), Early Bird (Dawson-Squibb et al 2019), Cygnet (Stuttard et al 2016), Ealing and HOPE models and Dynamic Risk Registers. Some of the barriers to the incorporation of interventions that do have demonstrated effectiveness – existing at a policy, management and practitioner level – will be described as identified from implementation science projects.

Conclusions: The combination of hugely increased awareness and clinical demand with a lack of robust evidence behind so much clinical intervention creates a potential crisis of clinical legitimacy. A first step to repair this situation must be the establishment of a shared robust evidence base with related practitioner and policy recommendations. Reliable standards of reporting intervention science are an essential pre-requisite for this to happen.

205.002 (Panel Discussion) Evidence-based Practice: Investigating the Extent and Impacts of Data Accessibility and Selective Reporting
M. Sandbank, The University of Texas at Austin, Austin, TX

Background: The past decade has seen an unprecedented rise in the publication of studies of interventions designed to support young autistic children (Sandbank et al., 2020). However, poor study quality and minimal reporting standards have inhibited reliable summarization of the available evidence. In addition, selective reporting practices may significantly inflate estimates of intervention effectiveness, jeopardizing the findings of meta-analyses, and producing ineffective clinical practice recommendations. The extent to which this problem manifests in studies of autism-focused early childhood interventions is unknown, but there are reasons to suspect it is rife and inappropriately influences corresponding practice recommendations.

Objectives: Estimate the extent to which poor reporting standards and data inaccessibility drive exclusion of a substantial portion of studies from autism intervention meta-analyses.

1. Determine the number and proportion of studies that show evidence of selective reporting and estimate the extent to which selective reporting significantly moderates estimates of intervention effects.
2. Generate corresponding recommendations for trial reporting and preregistration standards.

Methods: This work leverages a representative dataset of studies of interventions for young autistic children from a meta-analysis (Sandbank et al., 2020), which has been updated to include studies published before November 2021. Studies were flagged for data/author inaccessibility if they were excluded because effect size data could not be extracted, even after authors were contacted. Coders are currently documenting whether studies were prospectively registered, locating protocols, and flagging discrepancies between registration and subsequent publications. Studies associated with any of the following discrepancies will be flagged as having high risk of selective reporting bias: (a) failure to report a pre-registered outcome (nonreporting), (b) reporting of unregistered outcomes, (c) reporting an outcome as secondary which was registered as primary, (d) reporting an outcome as primary which was registered as secondary, (d) changes in assessment timepoints, (f) changes in analytic method, and/or (g) registered changes to analysis protocols that do not have an accompanying rationale.

Results: Of 393 reports of autism intervention studies that were potentially eligible for inclusion, only 290 (76%) could be meta-analyzed. Thus, nearly a quarter of available evidence was excluded, either because authors failed to report data in a manner that permitted effect size extraction or to provide such information upon request. In regards to selective reporting, results will detail the number and percentage of reports for which prospective registrations were located, as well as the number and percentage flagged for each of seven potential discrepancies outlined above. Using metaregression, I will estimate whether studies with high risk of selective reporting report significantly larger effects than studies with low or unclear risk of selective reporting.

Conclusions: The combination of hugely increased awareness and clinical demand with a lack of robust evidence behind so much clinical intervention creates a potential crisis of clinical legitimacy. A first step to repair this situation must be the establishment of a shared robust evidence base with related practitioner and policy recommendations. Reliable standards of reporting intervention science are an essential pre-requisite for this to happen.

205.003 (Panel Discussion) A Perspective from Global Health
G. Divan, Child Development Group, Sangath, New Delhi, India

Background: 95% of children with developmental disabilities, including autism, live in low and middle-income countries, where most families have little or no access to evidence based care. The majority of research in the field of autism has been focused in high-income
countries. This inequity of evidence results in interventions being transported to settings in which they have not been developed often without adaptation to the contexts in which they are being delivered. This inequity is particularly acute in intervention science; which results in the few families that may access an intervention; receiving one which is poorly evidenced, with no empirical data that it is acceptable or feasible in the settings in which they live.

Objectives: This presentation will aim to present contextual factors in the Global South which should be considered as we encourage intervention science in settings outside high income countries.

Methods: Review of literature to illustrate examples of a range of practices that can be recommendations for intervention science in low and middle-income countries

Results: Some key areas of contextual relevance while designing and conducting intervention evaluations in the low and middle-income countries include 1. Asymmetry of knowledge between research teams and the population 2. Low awareness of autism and the clustering of the less verbal phenotype in research samples 3. Stigma and discrimination around developmental disabilities 3. Differing explanatory models of a disability and hence 4. Varied expectations from interventions 5. The role of parents and extended family members in the caregiving of an individual with disabilities 6. Outcomes which matter for individuals and families 7. Pragmatic designs for interventions which are scalable in low resource settings

Conclusions: It is imperative that we strive to conduct high quality intervention science in representative populations where most of the world’s children and people with autism live. However as we design these explorations we must aim to bring on board the contextual differences in local communities such that the evidence generated has relevance and value to the communities that this science aims to serve.

205.004 (Panel Discussion) A Journal Editor Perspective

E. Anagnostou, Autism Research Centre, Bloorview Research Institute, University of Toronto, Toronto, ON, Canada; Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada; Department of Pediatrics, University of Toronto, Toronto, ON, Canada; Institute of Medical Science, University of Toronto, Toronto, ON, Canada

Background: There has been an explosion of intervention studies attempting to facilitate skill acquisition, reduce impairing or distressing symptoms, and optimize biology for learning in autistic children youth and adults. Despite this, editorial boards have been struggling to balance the need for evidence to guide clinical practice, with concerns about transparency of reporting to properly evaluate the level of evidence.

Objectives: This presentation will discuss the experience of evaluating intervention studies for publication at Autism Research before and after mandating strict reporting guidelines.

Methods: Autism Research embarked on a process to address concerns about the robustness and transparency of clinical trials published in the field. We reviewed existing guidelines and editorial policies in journals that publish intervention research broadly and in ASD specifically, and considered the priorities of the INSAR scientific standards committee. We then implemented our policy that mandates pre-registration and strict CONSORT reporting for all intervention studies, and have been monitoring the impact of such policies.

Results: We will present the process by which decisions were made to establish strict reporting guidelines and will review the guidelines. We will present the impact of such policies on the numbers of studies submitted, published, geographical distribution, type of interventions involved. We will discuss the risks and benefits of such an approach from the editors’ perspective.

Conclusions: The need for robust evidence to guide intervention research is widely agreed upon but methods to ensure transparency and replicability are still being debated in the autism field. The experience of the INSAR official journal will be used to discuss implications of enforcing strict reporting guidelines and pre-registration and facilitate a discussion on scientific standards in intervention research.

ORAL SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

308 - Adolescents/Transition Age

Moderator: Ofer Golan, Department of Psychology, Bar-Ilan University, Ramat-Gan, ISRAEL

308.001 (Oral) Internet-Delivered Psychoeducation for Transition-Age Autistic Youth

A. Backman1, S. Vigerland2, A. Mellblom3, E. Norman-Claesson4, E. Sundqvist5, E. Zander6, L. Roll-Pettersson1 and T. Hirvikoski7, (1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, (2)Karolinska Institutet, Stockholm, Sweden
Background: Transition-aged autistic youth (TAY) report low functioning and quality of life (QoL). There is a distinct lack of services targeting the transition age period, and few evidence-based internet-delivered interventions exist. SCOPE is an internet-delivered, therapist-supported, first-line psychoeducative intervention co-developed with autistic youth, provided through outpatient habilitation services context – aimed at informing about autism and transitioning issues and facilitating self-reflection and empowerment through knowledge.

Objectives: We aimed to investigate if SCOPE was superior in promoting autism knowledge (primary outcome) as well as QoL, acceptance of their autism diagnosis and mental health problems (secondary outcomes) compared to two control conditions; (1) unsupported online self-study, and (2) treatment as usual.

Methods: The current trial was a pragmatic randomised controlled trial conducted in an outpatient context from 2016 to 2020. In total, the trial included n = 144 TAY (16-25 years; M = 20.5; SD = 2.9), out of whom n = 92 (65.2%) were females. A third, 34% (n = 48) of participants had at least one other neurodevelopmental disorder (such as ADHD) and n = 41 (29.1%) had at least one psychiatric condition in addition to NDDs. Participants were block-randomized (2:1:1 ratio) to one of three trial arms: SCOPE (8 weekly internet-delivered sessions and weekly written contact with a therapist), self-study online (links to informative websites were provided weekly for eight weeks), or treatment as usual (e.g., on-going treatment of co-occurring depression or ADHD). Treatment credibility was rated as equal by the SCOPE and self-study participants when measured at baseline. Outcomes were assessed at baseline before randomization, as well as at post-treatment and 3-month follow-up.

Results: The results are as of yet unpublished. We found that both SCOPE and self-studies, but not treatment as usual, increased autism knowledge at post-treatment. However, the self-study participants’ knowledge scores returned to baseline level at the three-month follow-up. On the contrary, SCOPE participants had increased autism knowledge at follow-up compared to self-study (d = 0.53), and treatment as usual (d = 0.48). The increases in knowledge were not associated with significant changes in mental health problems at post-treatment or 3-month follow-up. Moreover, SCOPE participants reported more improved QoL at post-intervention (d = 0.37) and at 3-month follow-up (d = 0.60) than both control conditions.

Conclusions: Internet-delivered, therapist-supported psychoeducation is effective in disseminating autism knowledge and improving QoL, and the results remained or improved at the 3-month follow-up as opposed to self-study, or treatment as usual. An internet-delivered intervention enables services access to individuals who are unable or unwilling to use traditional face-to-face health care interventions, as well as to individuals who live in geographically remote locations.

308.002 (Oral) Evaluation of Virtual Interview Training for Transition-Age Autistic Youth on Twelve Social Performance Domains

K. Sherwood and M. J. Smith, School of Social Work, University of Michigan, Ann Arbor, MI

Background: Non-autistic people have a tendency to react negatively to autistic individuals’ basic social performance (e.g., eye contact, intonation, social connection) during casual conversation, which has been unfairly judged as socially unacceptable. These tendencies also extend to more formal conversations like job interviews. Recently, a novel job interview intervention demonstrated effectiveness at enhancing specific job interview skills, but has not yet been evaluated for whether its effectiveness generalizes to basic social performance.

Objectives: This study analyzed secondary data from a completed randomized controlled trial (RCT) to evaluate whether Virtual Interview Training for Transition Age Youth (VIT-TAY, an internet-delivered job interview simulator with automated feedback) was associated with unanticipated improvements to basic social performance among autistic transition-age youth.

Methods: A recent RCT revealed that 48 autistic transition-age youth randomized to receiving pre-employment transition services (Pre-ETS) with VIT-TAY improved their job interview skills as compared to 23 autistic transition-age youth receiving Pre-ETS only. Participants in this parent RCT completed video-recorded job interview role-plays at pre- and post-test that were blindly rated for strength of 10 specific interview skills. For the current study, our team blindly re-rated these interview role-plays using an adapted version of the Social Skill Performance Assessment (SSPA) 2.0 rating scale. The SSPA assesses 12 domains of basic social performance: interest, fluency, clarity, focus, intonation/pattern of speech, body language, facial expression, eye contact, reading social cues, connection, overall conversation, and social appropriateness. We then used repeated measures analyses of variance (RM-ANOVA) to conduct an evaluation of whether the Pre-ETS+VIT-TAY group improved in their domains of basic social performance between pre- and post-test as compared to the Pre-ETS only group.

Results: The RM-ANOVA results revealed that the Pre-ETS + VIT-TAY group had significant increases in three domains of general social performance as compared to Pre-ETS only. Specifically, we found significant group-by-time interactions for the domains of intonation/pattern of speech (F1,68 = 4.21, p < 0.05), connection (F1,68 = 6.04, p < 0.05), and overall conversational ability (F1,68 = 4.67, p < 0.05).
Background: Autistic people are often skilled with computers and drawn to STEM fields (Wei et al., 2013) yet encounter difficulties obtaining employment (Shattuck et al., 2012). Strategies to help neurodivergent youth engage with STEM curricula to build employment-related skills are sorely needed. Training for staff who facilitate such programs should prioritize improving staff autism understanding and strengths-based practices (Beverly & Mathews, 2021).

Our research was designed with a participatory team and an informal educational non-profit. Staff facilitated a four-week workshop for autistic youth that sought to teach game design and workforce readiness skills. By triangulating parent and student motivations and workshop ratings with educators’ ratings of instructional strategies, we identify opportunities to improve programming.

Objectives:

1. Evaluate student and parent motivations for participating in the workshop and perceived gains.
2. Assess staff perceptions of workshop effectiveness in achieving learning objectives (LOs).

Methods: Students (n=22) and their parents were surveyed before and after a four-week game design and employment workshop (Table 1). Assessments included a measure of computational thinking (CT; Wiebe et al., 2019), and items to assess student and parent motivations for attending/encouraging their child to attend and perceived gains following the workshop.

Five staff members (one social worker, one occupational therapist and three counselors) were surveyed each Friday of the workshop. Staff were asked to rate two questions for each of five LOs (Table 2).

Results: Students and parents aligned in their motivations for enrolling in the workshop across many areas, including learning computer, game design, and job skills. Parents were more interested in students learning self-advocacy and collaboration skills (p=.04) than students (Table 1). When surveyed post-workshop, students and parents aligned in how much they felt the workshop helped them gain each target skill, with no differences between groups. The student CT assessments showed no improvements after workshop participation (p=.75).

Weekly staff surveys were consistently positive, indicating staff felt teaching methods were effective in teaching LOs to most students and that staff felt their training supported them in achieving LOs. However, review of open-ended feedback from staff revealed that they felt additional training, in effectively working with autistic students and more time dedicated to reviewing CT curriculum prior to instruction, were required to feel equipped to meet workshop objectives.

Conclusions: Although ratings of perceived workshop gains were generally above neutral, results suggest discrepancies between students’ and parents’ motivations for participation and perceived gains. Although direct comparisons are not possible given different rating scales, staff consistently rated instructional strategies more effective in teaching employment-related LOs than parents’ and students’ post-workshop ratings indicated. Reasons for discrepancies may include: (1) skills like time management and self-advocacy were not modeled consistently by staff during workshop administration, (2) curriculum delivery emphasized tech-focused more than employment-focused content, despite agreement that all LOs were equally important to the success of the workshop during planning phases. Tech-focused instruction primarily focused on project completion rather than foundational CT skills. Findings highlight the need to listen to stakeholders to improve employment curriculum for autistic youth.
Background: Accessing needed services and supports is a challenge for many autistic youth as they transition to adulthood. To address this issue, we developed ASSIST (Advocating for Supports to Improve Service Transitions) – a group-based intervention that teaches parents how to advocate for adult services on behalf of their transition-aged autistic youth – and are testing the program in a multi-site randomized-controlled trial. Previous research suggests that participating in ASSIST increases parents’ knowledge of adult services and advocacy skills.

Objectives: Does participating in ASSIST increase service access, as evidenced by receipt of direct services and government programs that fund those services? Given differences between school-based and adult service systems, does the impact of ASSIST on service access depend on whether the autistic youth is in high school?

Methods: 185 caregivers of autistic youth were recruited from study sites in three states in the US (Illinois, Tennessee, Wisconsin). Caregivers were primarily mothers (89.7%) and white, non-Hispanic (84.3%). Autistic youth ranged from 16 to 26 years old (M = 20.1), 75.1% identified as male, 40% had an intellectual disability, and 60.5% were enrolled in high school.

Participants were randomized to either treatment or control conditions. The treatment group participated in ASSIST, meeting weekly (2 hours/week) for 12 weeks. Topics included services and supports related to employment, education, independent living, community participation, and health insurance. Control group participants received all written materials shared with the treatment group. Information on service access was collected prior to randomization and 6-months after the treatment group finished ASSIST. Receipt of direct services was measured by asking parents whether their son/daughter was receiving each of 20 services (e.g., speech/language, transportation, psychological/mental health). Access to government programs was measured by asking parents whether their son/daughter was receiving each of 10 government programs (e.g., SSI, Medicaid waiver services, vocational rehabilitation). Counts of direct services and government programs received were generated at baseline and 6-month follow-up. Analysis of covariance was used to examine whether there were treatment effects on 6-month service receipt after controlling for baseline services; service access was examined for the full sample, as well as for those in (n = 95) and out (n = 67) of high school in separate models.

Results: 162 participants (88%) completed the 6-month follow-up. There were no treatment effects on government programs or direct services in the full sample. However, there was a marginally significant effect of treatment on government programs (but not direct services) for those out of high school, F(1,64) = 3.88, p = .05. Controlling for baseline, treatment group families whose youth was out of high school were receiving an average of 3.8 government programs, compared to 3.3 in the control group.

Conclusions: Providing comprehensive information about adult services may be more effective when youth are out of high school and families can immediately apply the information. Further, access to government programs that fund direct services may not quickly translate to increases in the services themselves. Ongoing analyses will examine service access 12-months after the treatment group took ASSIST.
This study aimed to determine whether RUBI is feasible for use with autistic adults and their caregiver(s) and if participation in RUBI leads to decreases in challenging behaviors and increases in independence for the autistic adult.

Methods:

Using a case study design, we evaluated the preliminary feasibility and acceptability of RUBI with four autistic adults and their caregivers. Trained therapists delivered RUBI in weekly sessions with families to teach skills during 11 core sessions, up to two optional supplemental sessions, and a booster session 1-month post treatment to foster skill generalization and maintenance. Attrition and therapist adherence to the RUBI manual, as well as the RUBI Parent Satisfaction Questionnaire, were examined as measures of feasibility and acceptability. The Aberrant Behavior Checklist (ABC) and Home Situations Questionnaire (HSQ) were collected at pre-treatment, post-treatment, and follow-up (one month after post-treatment) as preliminary outcomes of challenging behavior.

Results:

Results support preliminary feasibility and acceptability, as indicated by low attrition (0%) and high adherence to the RUBI manual (89%). Following intervention, all participants demonstrated decreased levels of challenging behaviors (30-50% decreases in ABC and HSQ) and increased self-reported independence. Additionally, parents reported that the number and length of sessions was acceptable, the session content was appropriate, and that they felt more confident in managing their adult child’s behavior since participating in the program. However, parents reported that wished certain aspects of the program (e.g., videos, vignettes) were more tailored to adults specifically.

Conclusions:

With limitations in mind (i.e., small sample size, lack of study control, etc.), the current case study provides impetus for further evaluation of RUBI for autistic adults and their families. RUBI offers a manualized intervention that can be disseminated into multiple settings once appropriate adaptations can be identified. Further, RUBI holds practical benefits when compared with more intensive approaches to address behaviors, representing a more easily accessible intervention that caregivers can implement at home and in public settings with relatively infrequent clinical contact (i.e., weekly outpatient appointments). Future research should aim to: (a) develop intervention adaptations for autistic adults; and (b) systematically evaluate which aspects of RUBI produce desired outcomes for this population.
The findings suggest that group treatment can work for patients with ASD and co-occurring SUD. Lower levels of alcohol use ($t = 3.61, P = .002, d = 0.75$), craving ($t = 2.65, P = .013, d = 0.51$), passive coping styles ($t = 2.32, P = .030, d = 0.48$), depression ($t = 3.48, P = .002, d = 0.67$), anxiety ($t = 3.02, P = .006, d = 0.58$), and stress ($t = 2.62, P = .015, d = 0.51$) symptoms were reported after completing the group intervention, with even stronger effects at 3 months follow-up.

Conclusions:

An interesting finding of our study is that the alcohol use of clients decreases significantly after the group intervention, while the use of cannabis remains unchanged. The results of this naturalistic pre-post intervention study should be interpreted with caution, as our sample size was quite small ($N = 57$) and we did not include a control group. In the future, we hope to expand our research and look at the effects of different types of substances and the effects of including a ‘buddy’ regarding generalizability. Qualitative research regarding the experiences of clients will also be conducted. Overall, the present study shows promising results of a tailor-made group intervention in a heterogeneous patient population with ASD and co-occurring SUD with positive effects on both symptoms of ASD and SUD.

405.271 (Poster) A Comparative Analysis of Autism Aspectss Design Index and Deafspace Design Guidelines

H. Bauman, MIXdesign, New York City, NY

Background:

This presentation chronicles the parallel development of the Autism ASPECTSS™ Design Index and Gallaudet University’s DeafSpace™ Design Guidelines and their application to architectural design. A comparative analysis including case studies from the Autism Friendly Design Guide for Dublin City University and DeafSpace projects on the Gallaudet campus demonstrates how architecture facilitates intersecting needs of different populations. For example: Escape Space, one of the seven ASPECTSS criterion providing respite for the autistic user from environmental over-stimulation shares similar design recommendations for light, acoustics, and interior finishes recommended by the DeafSpace Design Guide for Conversation Eddies—spaces optimized for visual communication and reduced eye fatigue for deaf signers. Insights like these and user-centered methodologies will be presented to model means and benefits of intersectional design.

Objectives:

ASPECTSS and DeafSpace initiatives share key objectives: 1) to develop inclusive research and design methods attuned to the specific needs unique to each user group, 2) to prioritize inclusive design processes customized to specific project parameters of physical place, user community, and function over the use of design standards, and 3) to develop and disseminate performance-based guidelines in an accessible format mediating vastly different perspectives of users and design professionals.

Methods:

This work highlights how ASPECTSS modifies the Design Thinking framework for greater accessibility for autistic users and compares it with the DeafSpace community-based research method focused on visual communication and space. For example, one ASPECTSS line of research recorded how users occupied various spatial arrangements over time to understand and validate the ways spatial compartmentalization reduces anxiety. Another DeafSpace investigation explores the experiential dynamics of environmental stimuli and visual communication while moving through space using videos recorded with body mounted cameras. The comparative analysis identifies similarities and differences in design outcomes from both the autistic and deaf perspective validated through lived experiences within completed projects.

Results:

Both ASPECTSS and DeafSpace Design Guidelines document findings within a performance-based design guideline. ASPECTSS identifies seven general criteria: Acoustics, Spatial Sequencing, Escape Space, Compartmentalization, Transitions, Sensory Zoning, and Safety as an integrated set of strategies for building choice into the built environment for modulating sensory input. Similarly, the DeafSpace Guidelines articulate socio-spatial conditions optimizing spatial proxemics, light, color, acoustics, and vibration within spaces to optimize acuity of visual language and spatial orientation necessary for a sense of safety and wellbeing. ASPECTSS and DeafSpace guidelines have informed the design of completed building projects which will be presented as case studies demonstrating how inclusive user-driven research and design result in more inclusive and accessible buildings for a majority of individuals.

Conclusions:

Life experiences of the autistic and those who are deaf are distinctly different, yet investigation reveals affinities in their relationship to space calling for a more intersectional as opposed to traditional siloed approach to accessible design. This comparative analysis validates
the need for user-driven design methodologies customized to the needs of specific user groups and for understanding how the needs of different user groups complement one another and inspire a more accessible environment.

405.272 (Poster) A Parent-Led Intervention to Reduce Anxiety in Autistic Children with Severe to Profound Intellectual Disabilities: Current Data from the Ladders Pilot Study
J. Waite, E. Pearson, J. Tarver, J. Hughes, G. Edwards and C. Greenhill, Aston University, Birmingham, United Kingdom

Background: Autistic individuals with severe to profound intellectual disability (ID) are at greater risk of experiencing anxiety. However, there is a lack of evidence-based interventions aimed to reduce anxiety and anxiety-related avoidance behaviour in this group, which is concerning given the elevated mental health difficulties. Psychological approaches such as graded exposure and emotion regulation have been evidenced as effective in gradually reducing anxiety in other clinical populations. Additionally, gradual exposure techniques can reduce escape-maintained behaviours in severe to profound ID. Therefore, it is likely that a combination of these approaches may also be effective and appropriate for autistic individuals with severe to profound ID who experience anxiety.

Objectives:

We have developed LADDERS, a 16-week parent-led intervention comprising of psychoeducation, graded exposure-based tasks and skills building, delivered using a person-centred approach. This pilot study aims to assess whether LADDERS reduces anxiety and avoidance-related behaviour in autistic children with severe to profound ID.

Methods: The study utilises a multiple baseline, single case experimental design. Potential participants were screened according to eligibility criteria and proceeded onto baseline assessment if eligible. After baseline, participants completed the LADDERS intervention. The primary outcome measure (POM) is parent report of child anxiety completed daily from baseline throughout intervention and 2 weeks post-intervention. Secondary outcome measures (SOM) include direct observation of child anxiety, teacher report of anxiety and parent-report questionnaires for mood and behavioural markers of anxiety in their child. All questionnaire measures are validated for use in severe to profound ID and are completed pre-intervention, post-intervention (week 16) and at a 2-month follow up (week 24).

Results: Six parent-child dyads were eligible to proceed from baseline assessment with a 100% retention rate. Post-intervention POM data were available for 3 out of 6 participants at time of analysis. Visual inspection of POM data suggests a decrease in reported anxiety for 2 out of 3 participants, with the third showing a stable trend. Statistical comparison of pre- and post-intervention POM for the 2 participants with decreasing trends was conducted using Non-overlap of all Pairs (NAP), which is appropriate for smaller datasets. NAP effect sizes were 0.70 and 0.79, which are deemed medium effect sizes. Further NAP analysis of POM for the whole sample will be conducted alongside analysis of SOM to further examine the effectiveness of the LADDERS intervention.

Conclusions: Based on preliminary data the effectiveness of the LADDERS intervention at reducing anxiety and anxiety-related avoidance in autistic children with a severe to profound ID looks promising.

405.273 (Poster) A Pilot Trial of SPACE (Supportive Parenting for Anxious Childhood Emotions) in Autism
S. Rozenblat, Y. Shimshoni, E. R. Lebowitz, M. Perez and J. Koller, (1)Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel, (2)Yale Child Study Center, Yale University, New Haven, CT, (3)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (4)The Hebrew University of Jerusalem, Jerusalem, Israel, (5)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel

Background:

Family accommodation (FA) describes the phenomenon in which parents make changes to their own behavior to help their child avoid or alleviate distress caused by a disorder (Shimshoni et al., 2019). In anxiety disorders, studies have shown that while FA alleviates distress in the short term, it associates with more severe symptoms, greater functional impairment, poorer treatment outcomes, increased caregiver burden and disruption to family functioning in the long term (Lebowitz, 2013; Lebowitz et al., 2014; Shimshoni et al., 2019). Recent literature shows high prevalence of FA in comorbid cases of autism and anxiety, with over 97.5% of parents of children with autism and anxiety participating in different studies reporting engaging in at least one form of FA at least once per week (Adams & Emerson, 2020; Frank et al., 2020; Storch et al., 2015). In autism, the most common forms of treatment for anxiety are cognitive behavior therapy (Frank et al., 2020; Storch et al., 2015; Vasa et al., 2020) and medication (Nadeau et al., 2011). These treatments do not target FA and, although they have been found to be effective, they are not always applicable. Supportive Parenting for Anxious Childhood Emotions (SPACE) is a novel parent-based manualized treatment for anxiety and OCD specifically targeting FA (Lebowitz, 2013; Lebowitz et al., 2014). SPACE has been shown to be an acceptable and efficacious treatment for childhood anxiety disorders (Lebowitz et al., 2020). The intervention protocol includes 12 weekly, 60-minute sessions aimed at systematically monitoring and reducing FA while increasing parental support of the child's ability to cope with anxiety (Lebowitz & Majdick, 2020; Lebowitz & Shimshoni, 2018).
Objectives: This pilot trial aimed to assess the feasibility, acceptability, treatment-satisfaction, and preliminary efficacy of SPACE for anxiety in autism.

Methods: Parents of 15 children (ages 6-10) diagnosed with autism and presenting high levels of anxiety participated in 13 weekly sessions of SPACE. Feasibility and acceptability were assessed by calculating enrollment, attendance, attrition, and adverse events. Treatment-satisfaction was assessed with the Client Satisfaction Questionnaire (CSQ-8), administered posttreatment. Anxiety symptom severity and FA were assessed at baseline, posttreatment, and at 2-month follow-up.

Results: Of 26 eligible families, 22 (84.62%) elected to participate in the trial. Of the 22 participating families, 15 (68.18%) completed all 13 weekly treatment sessions. Parents rated the treatment as highly satisfactory (CSQ-8: M = 28.4, SD = 3.29, out of a maximum score of 32). Dropouts reported personal reasons for terminating treatment and did not report any adverse events or effects related to treatment. One family reported an increase in child depressive thoughts and moods during and immediately after treatment, and another family reported manageable tantrums and heightened anxiety during treatment. Anxiety symptom severity and FA were significantly reduced from pre- to posttreatment and this reduction was maintained at 2-month follow-up.

Conclusions: This study provides preliminary evidence that SPACE, a parent-based treatment that focuses on parental responses to anxiety symptoms, is feasible, acceptable, and satisfactory and produces improvement in clinical outcomes in the autistic population.

405.274 (Poster) A Randomised Controlled Effectiveness Trial of Sensory Integration Therapy Plus Usual Care Versus Usual Care Alone for Autistic Children with Sensory Processing Difficulties (SenITA)
R. McNamara and E. Randell, Cardiff University, Cardiff, United Kingdom

Background: At least 90% of autistic children experience sensory processing difficulties, affecting well-being, social relationships, educational performance and family life. Carers report unmet need for Occupational Therapy addressing sensory difficulties in autism. Manualised Ayres Sensory Integration® Therapy (SIT) is an Occupational Therapist-led, play-based intervention, providing sensory-motor engagement in meaningful activities which may provide benefit. The SenITA trial is the first Randomised Controlled effectiveness Trial of SIT for children with autism.

Objectives: To evaluate effectiveness of SIT in addition to usual care (UC), versus UC alone for autistic children with sensory processing difficulties, in terms of impact on problem behaviours, adaptive skills, socialisation, carer stress, and quality of life. Health economic and process evaluations were undertaken (process evaluation reported separately). Participants were recruited from a variety of settings in the UK.

Methods: Parallel group randomised trial incorporating an internal pilot, health economic and process evaluations. Children 4-11 years were recruited via health/social services and self-referral. Inclusion criteria: autism diagnosis; mainstream education; definite/probable sensory processing difficulties. Exclusions: current/previous SIT; current Applied Behaviour Analysis therapy. Intervention: Manualised SIT delivered over 26, one-hour sessions (individual face-to-face sessions twice a week for 10 weeks; twice per month for two months). In-person sessions were followed by two telephone sessions with carers (once per month for two months). Sessions were video recorded, and a sample rated according to the fidelity checklist. Adherence was defined as attending at least 13 of 20 sessions in the intensive phase of intervention delivery (the first 10 weeks). Comparator: UC for sensory processing difficulties only. Main analyses were modified intention-to-treat, with those providing outcome data included. Primary outcome: Irritability/agitation six months (Aberrant Behavior Checklist). Secondary outcomes: other problem/adaptive behaviours; functioning; socialisation; carer stress; quality of life; functional change (intervention arm only); sensory processing; intervention and service use costs.

Results: Of 26 eligible families, 22 (84.62%) elected to participate in the trial. Of the 22 participating families, 15 (68.18%) completed all 13 weekly treatment sessions. Parents rated the treatment as highly satisfactory (CSQ-8: M = 28.4, SD = 3.29, out of a maximum score of 32). Dropouts reported personal reasons for terminating treatment and did not report any adverse events or effects related to treatment. One family reported an increase in child depressive thoughts and moods during and immediately after treatment, and another family reported manageable tantrums and heightened anxiety during treatment. Anxiety symptom severity and FA were significantly reduced from pre- to posttreatment and this reduction was maintained at 2-month follow-up.

Conclusions: Intervention did not demonstrate benefit above UC: subgroup effects are hypothesis-generating only but could be further explored. SIT appears to be effective for individualised goals though it remains unclear whether effects observed are maintained in the longer-term.

405.275 (Poster) A Telehealth Adaptation of Children’s Friendship Training: Preliminary Results of Feasibility, Acceptability, and Efficacy in School-Age Children with Autism and Attention-Deficit/Hyperactivity Disorder
Background: Children’s Friendship Training (CFT) is a parent-assisted, evidence-based, manualized intervention aimed to improve social skills in school-age children with social communication challenges (Frankel & Myatt, 2003). The efficacy of CFT has been demonstrated for youth with autism spectrum disorder (ASD), attention-deficit/hyperactivity disorder (ADHD), and other neurodevelopmental conditions (e.g., Frankel et al., 2010). However, studies to date are based on the in-person delivery of the 12-week outpatient program. Motivated by the challenges of the COVID-19 pandemic, multiple studies have documented the efficacy of parent-assisted autism interventions delivered via telehealth (Simack et al., 2022). Nonetheless, to our knowledge, there have been no studies examining CFT delivered via telehealth.

Objectives: We aimed to examine the feasibility, acceptability and efficacy of a pilot telehealth adapted CFT intervention in school-age children with ASD and ADHD.

Methods: A 12-week CFT treatment program was delivered via telehealth (Zoom). Child groups of 4-5 participants ran simultaneously to caregiver meetings. Participants were assigned to a group according to grade (2nd-3rd or 4th-5th grade), and had an established DSM-5 diagnosis of ASD or ADHD. Didactic content and video roleplays from PEERS® open-access archives in substitution of in-person roleplays were delivered via shared screen. To examine the efficacy of telehealth CFT, the Social Responsiveness Scale-Second Edition (SRS-2) and Friendship Quality Scale (FSQ) were completed pre- and post-treatment by caregivers and children, respectively. To assess feasibility and acceptability, a Caregiver Satisfaction Survey (CSS) was completed following treatment delivery, and attendance and homework completion were recorded each session. Here, we present data from the first four groups completed between April 2021 to January 2022. Given the preliminary nature of the analyses, Cohen’s $d$ effect sizes of within-subject mean score pre- and post-intervention differences are reported.

Results: Participants included 17 parent-child dyads, with 16 completers (n=10 ASD; n=6 ADHD; M age =9.85; 75% male). Rate of session attendance was 98% and 95% for children and parents, respectively. Homework completion rate was 84% for in-group calls, 80% for out-of-group calls, and 73% for get-togethers. Mean caregiver satisfaction total-score on the CSS (possible maximum total=50) was 42.4±4.7. FSQ self-ratings and SRS-2 caregiver-ratings were small regardless of primary diagnosis (Cohen’s $d$=.2-.3). However, there was a diagnostic-specific effect for self-reports: ASD children reported moderate levels of improvement in the quality of their friendships ($d$=.7) relative to negligible effects of those with ASD ($d$=.01). Similarly, a potential diagnostic-specific effect for SRS-2 caregiver-ratings was observed according to the SRS-2 social domain. For example, a small-to-moderate effect ($d$=.4) was observed in Social Awareness and Social Communication in the ASD group, whereas a robust effect ($d$=.9) was noted in Social Cognition within the ADHD group.

Conclusions: This study is the first to deliver CFT via telehealth. Initial results indicate high levels of session attendance, homework completion, and parent satisfaction, supporting the feasibility and acceptability of the telehealth-CFT intervention. Preliminary results of diagnostic differential effects suggest that larger studies are needed to investigate the potential differential utility and mechanisms of response to treatment in school-age children with ASD and ADHD.

405.276 (Poster) A Thematic Analysis of Autistic Adults’ Perceived Value of Dialectical Behavior Therapy Skills Training

Background: Previous studies have shown that 79% of autistic adults without Intellectual Disability meet the criteria for at least one psychiatric condition in their lifetime. The lack of evidence-based practices for autistic adults creates an urgent need for interventions that are informed by and tailored to autistic individuals and their unique needs. Dialectical Behavioral Therapy (DBT), a gold-standard treatment for individuals with borderline personality disorder, consists of weekly individual therapy, weekly group skills training, and weekly consultation team meetings for therapists. DBT Skills Training (DBT-ST) is a condensed version of standard DBT that consists of only weekly group skills training sessions, and there is evidence that DBT-ST can be a valuable transdiagnostic treatment to improve emotion regulation capacity. Prior research has found preliminary support for the use of DBT-ST with autistic adults who experience co-occurring mental health conditions. This study expands upon previous research by gathering and assessing autistic adults’ experiences with DBT-ST to amplify the voices of autistic stakeholders.

Objectives: This study qualitatively examines autistic adults’ experiences with a DBT-ST group.

Methods: Semi-structured interviews were conducted with 11 autistic adults (10 males, aged 19-65) who participated in a 6-month DBT-ST group-based intervention to assess their experiences with and the perceived value of the program. DBT-ST utilizes a group format to teach participants emotion regulation, distress tolerance, interpersonal skills, and mindfulness through a series of four modules. Participants are provided with homework and in-class practice opportunities designed to encourage the application of these skills in a variety of
contexts. All interviews were conducted via Zoom, recorded, and then transcribed verbatim. Thematic analysis is being conducted to analyze participant responses.

**Results:** Overall, participants reported a very positive experience with the DBT-ST intervention. Preliminary analysis revealed three content areas that were most valuable for participants: emotion regulation, distress tolerance, and interpersonal effectiveness. Table 1 provides descriptions and quotations that illustrate common participant experiences with the DBT-ST group.

Recommendations regarding the implementation of DBT-ST, including further modification tailored to the distinct needs of autistic individuals, will also be summarized.

**Conclusions:** The present study is among the first to learn directly from autistic adults about their experience with DBT-ST. Emotion regulation, distress tolerance, and interpersonal effectiveness are primary targets of DBT-ST, and our research shows that autistic adults find each of these areas to be meaningful and impactful. DBT-ST with modifications, such as increasing the use of visual aids and reducing the pace of content presentation, may be a promising treatment to improve emotion regulation, distress tolerance, and interpersonal effectiveness for autistic adults. Future research should include autistic adults in the modification, implementation, and analysis to establish DBT-ST as an effective intervention for autistic adults with a co-occurring psychiatric condition.

**405.277 (Poster) Acceptance, Perceived Ethical Risks, and Effectiveness of a Robot-Assisted Emotion Regulation Therapy Approach for Children on the Autism Spectrum**

**Background:** Increasing evidence shows that children on the autism spectrum (AS) might benefit from robot-assisted therapy (RAT) approaches for aberrant socio-emotional behavior. However, the few existing studies investigating feasibility, acceptance, and effectiveness are limited by methodological problems such as small ample size and lack of control conditions.

**Objectives:** Therefore, in the context of i) an online study and ii) a prospective laboratory study this study aimed at gaining insight into stakeholders’ acceptance of an elaborate RAT scenario as well as its effectiveness.

**Methods:** In the context of a multidisciplinary and multicenter study, a user-centered designed RAT interaction scenario targeting the regulation of negative emotions (frustration) in a competitive game scenario in children on the AS by using the humanoid robot Pepper (Softbank Robotics) was evaluated in controlled designs in terms of acceptance, usability, and ethical risks (online study; N=133), and early effectiveness (laboratory study; N=34) in different stakeholder groups (children and adults on the AS, caregivers, and autism clinical professionals).

**Results:** In the online study, AS stakeholders rated both a video-demonstrated RAT scenario and a comparable tablet-based therapy control condition as highly acceptable. However, stakeholders preferred the tablet-based therapy across measures of global acceptance, perceived usefulness, and ease of use. Negative evaluations regarding RAT mainly addressed the expected effort to implement the technology. Despite recognizing ethical and social risks, 83 % of the stakeholders found RAT to be ethically acceptable. Opinions were more divided on social robots being perceived as friends, possible attachment to robots and replacement of therapists by robots. In the ii) laboratory study six autistic and 11 non-autistic children (7-11 years) engaged in RAT and arousal levels were assessed, which resulted out of the competitive game by the children and their parents (N=17). Results showed a significant decrease in children’s arousal due to frustration and an increase in emotional valence after participating in a robot-assisted breathing exercise. In addition, the parents’ and children’s global acceptance of the presented RAT scenario was high, which was supported by positive ratings of acceptance-related factors (e.g., enjoyment, perceived usefulness).

**Conclusions:** The findings support the acceptance and proposed clinical value of RAT approaches targeting emotion regulation in children on the AS. They furthermore show the importance of enhancing perceived usefulness, ease of use, and reducing deployment effort as well as the relevance of engaging different groups of stakeholders (e.g., autistic children and adults, parents, and therapists) in RAT development in an active and participatory manner.

**405.278 (Poster) Adaptation and Implementation of a Positive Behavioral Intervention Support (PBIS) Program in a Residential Setting for Autistic Adults**

**M. M. Dufour**, I. Préfontaine, V. Martin, M. Argumedes Charles, and M. Hogan, (1) Psychoeducation, University of Montreal, Montreal, QC, Canada, (2) Sociology, Université du Québec à Montréal, Montreal, QC, Canada, (3) School of management-Department of organisation and human resources, Université du Québec à Montréal, Montreal, QC, Canada, (4) Education, University of Sherbrooke, Sherbrooke, QC, Canada, (5) University of Sherbrooke, Sherbrooke, QC, Canada
Background:

Autistic adults have complex needs. In addition to the support needed with the core characteristics of an ASD diagnosis, they are significantly disadvantaged regarding employment, social relationships, physical and mental health, and quality of life (Howlin & Moss, 2012). Indeed, although adaptive functioning and autonomous skills may improve over time (Howlin, 2021), many adults face poor outcomes (Steinhausen et al., 2016). As a result, providing long-term supportive environments, including housing, is an important part of services for autistic adults (MSSS, 2013). Extant housing resources are not always adapted for this population. Local advocates point to limited capacity in residential resources, lack of staff training, inadequate familiarity with clientele and their needs, and mismanagement of crises leading to hospitalizations (Fédération québécoise de l’autisme, 2019). To address these issues, we adapted a positive behavior intervention support (PBIS) program to implement a new innovative Canadian residential resource. This resource was designed for autistic adults, considers their sensory needs, and focuses on their quality of life. PBIS is an evidence-based program that has been implemented primarily in school settings. Recently, PBIS programs have also been launched in clinical settings for adults with intellectual disabilities or on the autism spectrum, including in residential settings (Lubar, 2018; MacDonald et al., 2018). Still, knowledge is limited on social acceptability of PBIS programs and its effects on staff attitudes, and well-being at work in a residential setting for autistic adults.

Objectives:

The objectives are to assess: 1) the social acceptability of the PBIS program according to staff and parents, 2) the effects on staff attribution regarding challenging behaviors, burnout, and perceived stress, and 3) the program implementation (facilitators and barriers).

Methods:

A total of 26 participants were recruited. Employees were educators (n=16), managers (n=1), clinical experts (n=1), and direct care workers and other positions (n=7). Participants completed questionnaires at two points: After the first PBIS training by the research team and at the 1-year post program implementation. A mixed-methods, pre-post design was used to meet the research objectives. We used the Treatment Acceptability Rating Form (TARF-Revised; Reimers & Wacker, 1988) to assess social acceptability. French versions of Challenging Behaviors Attributions Questionnaire (CHABA; Hastings, 1997), Maslach Burnout Inventory (Maslach & Jackson, 1986), and Perceived Stress Scale (PSS-10; Cohen, et al., 1983), were used to assess attributions, burnout, and perceived stress. We analyzed the data using non-parametric tests (Wilcoxon). Analysis of semi-structured interviews with stakeholders and parents will use a thematic analysis approach (Braun & Clarke, 2006).

Results:

After one year of implementation, the level of social acceptability remains high among respondents (x= -0.276, p>0.05). The attributions, level of burnout, and perceived stress are stable between our two-measurement time-points (x=-0.852, -1.34, -0.204, p>0.05). Qualitative analysis of the interview with both stakeholders and parents will be performed by INSAR 2023 to complement these quantitative results.

Conclusions:

Results will guide the implementation of PBIS programs in other residences for adults with autism and thus contribute to improve services for this population. This project will then inform best practices in residential settings.

405.279 (Poster) Adaptation and Preliminary Evaluation of the Hong Kong Version of the Westmead Feelings Program (WFP): Emotion-Based Learning for Chinese Children with Autism Spectrum Disorder in Mainstream Schools Via Telehealth Delivery

L. Lam1, W. Tam† and M. G. Wong†, (1)AIMT2, SAHK, Kowloon, Hong Kong, (2)Psychological Medicine, Sydney Children's Hospitals Network, Westmead, NSW, Australia

Background:

Westmead Feelings Program (WFP) is emotion-based learning for children with Autism Spectrum Disorder (ASD). Its impact to improve emotional competence in children with ASD in Australia has been established. The WFP2 learning materials was translated into Chinese, and adjustments were made in the content and process of intervention sensitive to linguistic, cultural and modality differences. The Hong Kong version was tried out in two groups of children with ASD, their teachers and parents for evaluation.

Objectives:

The present study aimed to identify the adaptations needed in a context culturally different from Australian societies and to evaluate the intervention outcomes on Chinese children with ASD in Hong Kong.
Methods:

The original English version of the WFP2, for children without mild intellectual disability, was translated into traditional Chinese by two trained WFP2 facilitators. To align with the school-based delivery mode, the original children sessions and the parent/teacher workshops were condensed to 12 sessions and 3 sessions respectively.

Other than adaptations made according to local cultural context and Chinese language features, telehealth adaptations were also included to replicate the structure and format of the WFP2.

Participants were 11 primary school-aged children with ASD, as well as their teachers and parents from two mainstream schools. WFP2 sessions were delivered by two trainers under close supervision of trained WFP2 facilitators. The fidelity check of the WFP2 implementation was done by educational-psychologists-in-training under supervision.

The emotion competence skills were rated by parents and teachers separately on Emotions Development Questionnaire (EDQ) prior to and after the WFP2 implementation. Children evaluated how often they applied emotion competence skills at home and at school after each module.

Results:

All WFP2 sessions were conducted with high fidelity and good attendance. Both trainers passed the WFP2 Fidelity Checklist. All children except one attended all sessions. The average attendance rates of parents and teachers were both 77%.

The questionnaire return rates were 100%. Parent and teacher reported mean scores (on EDQ) were reported in Table 1. Results indicated a significant increase in parent reports of children emotion regulation skills and parent emotion coaching skills. No significant changes were found in teacher reports.

The numbers/percentages of children applied emotion competence skills were reported in Table 2. The percentages of children reported the application of emotional competence skills were different among Modules (ranging from 82% to 45%) and across home and school settings (tried to have helpful thoughts and took other perspectives).

Conclusions:

After adjusting for cultural, linguistic and modality differences, the WFP2 appears to bring positive changes in children and parents. Yet, we are not certain this positive impact is the result of the intervention as no control groups were included. The current findings shed light on further improvement of both the adaptation and research methodology. The lowest application rates of skills taught in Module 1 indicates the 15 session WFP2 to be maintained. Future research on the effectiveness of the Hong Kong version should consider a treatment versus control trial.

405.280 (Poster) Adaptation of the Parents Taking Action Intervention to Support Caregivers of Young Children with Autism in Paraguay: Community Members’ Perspectives

A. K. Terol, S. Magana, H. Meadan and L. R. Gomez, (1)University of Illinois at uc, Champaign, IL, (2)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (3)University of Illinois, Champaign, IL, (4)University of Florida, Gainsville, FL

Background: Caregivers of autistic children in low-to-middle income countries experience many challenges to access resources to support their child’s development. Caregiver training may be a cost-effective way to support caregivers in such settings. Researchers agree on the importance of considering cultural factors (e.g., values, traditions, language) when selecting, adapting, or developing interventions for a specific group. Caregivers in Paraguay reported a need for training to support their young autistic children (Terol et al., 2022). Further culturally adapting the Parents Taking Action Intervention (PTA; Magaña et al., 2017), which was originally developed with a culturally responsive framework for Latino caregivers living in the US, may be a feasible and acceptable way to support caregivers of autistic children in Paraguay.

Objectives: (a) Understand the needs of caregivers of young autistic children in Paraguay, a low resource country, and (b) explore the perceptions of community members in Paraguay related to culturally adapting the PTA intervention to Paraguayan context.

Methods: Participants included: (a) caregivers of autistic individuals; (b) professionals who work with young autistic children (i.e., children 0-8 years old); and (c) self-identified autistic individuals. Participants completed a demographic questionnaire and participated in a 2-hour long focus group with other participants who shared their role. A total of six focus groups with 5-6 participants were completed. Each focus group comprised three main sections: (a) perceived needs of caregivers of young autistic children; (b) acceptability and suitability of the
content of the PTA for the Paraguayan context; and (c) practical and logistic considerations for implementing the PTA in Paraguay. Focus groups were conducted via Zoom in Spanish and were transcribed and translated to English for data analysis. Transcriptions were coded using thematic coding and deductive coding based on the Ecological Validity Framework and the Framework for Reporting Adaptations and Modifications to Evidenced-based Implementation Strategies (FRAME-IS).

Results: Results indicate that caregivers of young autistic children in Paraguay need access to information and strategies to support their children’s development. Additionally, participants’ recommendations related to the content including adding information about the inclusive education law in Paraguay, and stories of autistic individuals in Paraguay. Regarding the context, recommendations included a hybrid format and including a team of parents and professionals to deliver the intervention. Results from this study will be used to further document the needs and challenges of caregivers of young autistic children in Paraguay, and to culturally adapt the PTA intervention to the Paraguayan context. Successes and challenges recruiting participants and conducting the focus groups internationally, including collaboration with local community-based organizations and sharing researchers’ positionality as Paraguayan and former service providers for autistic children and their families in the country will also be shared.

Conclusions: Caregivers in Paraguay expressed their need for more support and cultural adaptations are required to make the intervention fit the Paraguayan context. Understanding and utilizing community members’ suggestions to culturally adapt interventions may be an optimal way to meet the needs of the intended recipients in a way that embraces and respects their cultural values.

405.281 (Poster) Adapting Safety Planning Intervention with and for Autistic Adults
J. Rodgers¹, N. Bhattarai², J. Goodwin³, P. Heslop⁴, E. Kharatikoopaei⁵, E. Nielsen⁶, R. O'Connor⁷, E. Ogundimu⁵, S. E. Ramsay⁸, E. Townsend⁹, L. Vale⁹, C. Wilson³ and S. A. Cassidy⁹, (¹)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (²)Newcastle University, Newcastle Upon Tyne, United Kingdom, (³)Other, Newcastle Upon Tyne, United Kingdom, (⁴)Northumbria University, Newcastle Upon Tyne, United Kingdom, (⁵)Durham University, Durham, United Kingdom, (⁶)University of Nottingham, Nottingham, United Kingdom, (⁷)University of Glasgow, Glasgow, United Kingdom, (⁸)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (⁹)School of Psychology, University of Nottingham, Nottingham, UNITED KINGDOM

Background:
Autistic adults are an at-risk group for suicide and up to 65% of autistic people experience self-harm; a significant risk marker for later suicide attempts. Despite this, there is little research exploring suicide prevention interventions developed with, and for, this population. Through co-production, we address this research gap. Safety plans are a simple, potentially cost-effective and life-saving interventions, with demonstrated effectiveness in a range of clinical groups. They consist of a prioritized list of hierarchical steps that can be used prior to or during a crisis to mitigate risk of self-harm and suicidal behaviour. An Autism Adapted Safety Plan, designed with, and for, autistic adults, could be valuable for autistic people in times of crisis.

Objectives:
We aimed to refine and test the acceptability and feasibility of an Autism Adapted Safety Plan. We also aimed to explore data collection tools/methods to inform a subsequent randomised controlled trial.

Methods:
A series of six focus groups and four one-to-one conversations were held. Our involvement work captured the voices of 32 autistic adults, family members and service providers, who recommended adaptations to refine our draft autism adapted safety plan. We then conducted an interventional single arm feasibility trial with 10 autistic adults and 10 service providers to explore data collection tools/methods and gather information to inform a subsequent external pilot randomised control trial.

Results:
There was broad consistency between each participant group. Participants spoke to the content and layout of the autism adapted safety plans (e.g., the use of prompts, more detailed breakdowns around communicating distress, the inclusion of a scale) as well as delivery, resources, and scaffolding (e.g., the inclusion of feelings wheels). Autistic adults emphasised the importance of developing trust and understanding between autistic adults and service providers when developing the autism adapted safety plan. In terms of data tools/methods, autistic participants valued flexibility from researchers (e.g., receiving research documents in advance, having time to process, and adjusting meetings/data collection tools to suit the participant’s needs).

Conclusions:
Community members suggested a range of adaptations and additional supports that could accompany Autism Adapted Safety Plans to make them useful and useable for autistic adults. They also provided feedback on how research processes can be improved. Implications of our results for safety planning with autistic adults, to reduce self-harm, suicidal thoughts and behaviours in this group are discussed.

**405.282 (Poster) An Evaluation of Changes in Emotion Regulation over the Course of a Pilot Telehealth Trauma-Focused CBT for Autistic Youth**

**Background:** Autistic youth who have experienced trauma may also benefit from support for emotion regulation (ER), yet little is known about (a) whether ER changes over the course of trauma-focused therapy, and (b) whether baseline levels of ER relate to response to therapy. Trauma-Focused Cognitive Behavioral Therapy (TF-CBT; Cohen et al., 2016) is a widely used evidence-based program for supporting youth who have experienced trauma involving three phases (stabilization/skills, trauma narration/processing, and integration/consolidation).

**Objectives:** Prior work from this pilot study has shown significant reductions in self- and parent-reported trauma symptoms following TF-CBT. To further understand whether ER also changes over the course of TF-CBT, (1) we examine the change in ER scores from baseline to post-treatment. Then (2) we examine how weekly ratings of ER vary across the three treatment phases, with a particular interest in patterns of ER change during the trauma narrative phase. While this phase is designed to support youth in meaningful communication about their life experiences, caregivers are often fearful that activities involved in this phase (such as sharing stories about their trauma) may worsen symptoms or cause increases in emotional reactivity or dysphoria. Finally, (3) we investigate whether baseline ER correlates with the treatment response observed for core trauma symptoms.

**Methods:** Autistic youth (n=6, M_age=14.36, M_est. verbal IQ=86.5, M_SCQ=22.17) with clinical levels of trauma-related symptoms on the Child and Adolescent Trauma Screen (CATS) (M_CATS=37.67, clinically relevant level ≥ 21) participated in a pilot feasibility study evaluating 12-session telehealth TF-CBT. All participants had a history of trauma, confirmed by parent and self-report. Parent-reported measures are completed at baseline and post-treatment, including the CATS and the Emotion Dysregulation Inventory (EDI; reactivity and dysphoria subscales). The EDI was also collected at each session.

**Results:** (1) Pre-post change in ER (from baseline to post-treatment) was examined using one-tailed paired-sample t-tests. Scores on both EDI subscales, reactivity and dysphoria, decreased from baseline to post-treatment in a meaningful way, with large effect sizes (reactivity: t=-3.15, p=.013, g=1.37, dysphoria: t=-2.19, p=.04, g=-1.180). (2) Figures 1 & 2 demonstrate the mean EDI scores for the sessions before, during and after the trauma narrative phase of treatment per client. Mean EDI scores on both the reactivity and the dysphoria subscales showed no evidence of increase during the trauma narration phase. (3) Finally, baseline reactivity (r=.33, p=.522) and dysphoria (r=.23, p=.66) scores did not correlate with the amount of pre-post change in parent-reported trauma symptoms.

**Conclusions:** Participation in telehealth TF-CBT for autistic youth not only impacts trauma-related symptoms but can also support ER, as demonstrated by decreased levels of emotion dysregulation on the EDI. Examination of changes in ER over the course of the three TF-CBT phases did not show any evidence that reactivity or dysphoria increase during the trauma narrative phase. Since baseline ER scores were not associated with the amount of pre-post change in trauma symptoms, this suggests that pre-existing ER scores were not associated with better or worse treatment response. Future research should further evaluate TF-CBT and emotion regulation for autistic youth.

**405.283 (Poster) Anxiety Related Absence: Development of Recommendations for People Working in and with Schools in Scotland**

**L. Johnston, M. Rutherford** and **D. Maciver**, (1)National Autism Implementation Team, School of Health Sciences, Queen Margaret University, Edinburgh, United Kingdom, (2)National Autism Implementation Team, School of Health Sciences, Queen Margaret University Drive, Musselburgh, Edinburgh, United Kingdom

**Background:**

A disproportionate number of autistic learners are affected by anxiety related school absence, with associated impacts on individual and family wellbeing. This has been exacerbated by the pandemic. Traditional approaches have often been ineffective. Within the neurodiversity paradigm, support occurs best through adaptations to naturally occurring environments, rather than through clinical or separate contexts, and the responsibility for change lies primarily with people around the learner, not with the learner themselves.

**Objectives:**

The National Autism Implementation Team (NAIT) developed an anxiety related absence resource for practitioners supporting autistic learners, and families, in Scotland. This research collaborated with key stakeholders to identify the features that should be included in an evidence-informed set of recommendations. The guide highlights the mindset with which to approach autistic learners, the importance of
considering the 24 hour life of the learner, and key supports. Materials aim to support those working in and with schools to be aware of issues for autistic learners, to take a staged intervention approach, and to develop an inclusive mindset.

Methods:

A review of published literature, and national and local guidance was completed. A collaborative project was conducted, and consultation completed with key stakeholders, including: autistic people, parents, and professionals from health, education and third sector. Working with stakeholders allowed identification of the key elements which should be incorporated. Peer validation strategies were employed to ensure the content remained relevant to lived experiences, including consultation with autistic teenagers and families, teachers, third sector partners, and parent support professionals which enabled co-creation of content. Professional learning (n=550 professionals) with staff from education, health, social care and third sector from 30 local authorities across Scotland included attendees from Early Years, Primary and Secondary provision and a small number of people working with adults.

Results:

In this presentation we highlight lessons learned from development and implementation, identifying critical issues and challenges. We focus on the development of practitioner competence, and how materials have been organised to provide an overview of this complex area. The resource includes practical steps for emotional regulation, social communication and transactional supports. Messages were tailored to meet the needs of those working in and with schools and have been agreed through consultation with the autism community:

- Reduce language
- Provide an individual safe space
- Developmentally appropriate individual timetable
- Planned movement breaks
- Practice and prepare for change
- Two key adults
- Planned home school communication
- Ensure staff have access to help and support
- Listen to parents

Value was placed on ensuring the documentation was underpinned by neurodiversity affirmative principles. The importance of delivering supports in school locations, by the team around the child was highlighted, and stakeholders recognised that the work should be responsive to individuals and be reflective of changes in need.

Conclusions:

The guidance has been funded by the Scottish government and adopted by local authorities across Scotland. Facilitating effective inter-professional, interagency and stakeholder collaboration allowed for effective implementation. This collaboration resulted in high levels of stakeholder involvement and ownership of the materials.

405.284 (Poster) Application of PEERS, a Skills Training Program for Making Friends in Japanese Schools
S. Tanaka and T. Yamada, (1)Research Center for Child Mental Development, Kanazawa University, Kanazawa, Japan, (2)Research Center for Child Mental Development Kanazawa University, Kanazawa, Japan

Background: In life, having close friends is positively associated with self-esteem and independence. Adolescents with autism often have trouble making friends, and the PEERS for Adolescents was developed at UCLA to address this issue. Our earlier study demonstrated that with linguistic and cultural modifications, PEERS is effective in improving social functioning for adolescents with ASD in Japan. However, many parents in Japan usually work and too busy to attend 90-minute sessions with their children. Therefore, we implemented PEERS School-based in a form adapted to Japanese schools and without parental participation, to test its effectiveness.

Objectives: This study examines the effectiveness of the school version of the Program for the Education and Enrichment of Relational Skills (PEERS School-Based), which focuses on improving social functioning through making friends and maintaining good relationships, in adolescents with autistic traits in Japan.

Methods: 29 primary and junior high school adolescents aged 11-14 (M =11.05; SD =15.21) participated in PEERS sessions and pre- and post- psychological tests, interviews and questionnaires. All participants (20 males and 9 females) were born and raised in Japan, were fluent in Japanese and confirmed their willingness and ability to participate in treatment. Thirteen of them participated in the PEERS program first, while the remaining 16 participated only in the survey during that term and joined the program in the following year. Pre- and post-intervention measures of children's behavior problems, social skills and communication in the first year were compared.
Results: Children who had taken part in the program first were more engaged with their peers, had greater knowledge of social skills and showed improvements in the communication domain than those who had not yet taken part in the program. Self-understanding interviews showed more positive or detailed accounts of the self after the intervention.

Conclusions: These results suggest that the PEERS school version is beneficial for Japanese adolescents with ASD in multiple social, communication and self-understanding domains. In addition, it has traditionally been difficult to implement scientific evidence-based programs in Japanese schools, and the fact that this initiative has enabled school teachers to participate in the program in several cities provides suggestions for the creation of future program delivery systems.

**405.285 (Poster) Arts-Based Programs for Neurodiverse Individuals: An Umbrella Review**

**E. D’Arcy**, B. Afsarinejad, B. T. Milbourn, K. Ellis and S. J. Girdler, (1)School of Allied Health, Curtin University, Bentley, Western Australia, Australia, (2)School of Allied Health, School of Allied Health, Curtin University, Bentley, Western Australia, Australia, (3)School of Allied Health, Curtin University, Perth, Australia, (4)Curtin University, Bentley, Western Australia, Australia

Background: Existing literature suggests a menagerie of creative programs developed to support neurodiverse individuals, including those utilising art in their programs. The emergence of the neurodiversity paradigm and endorsement of strengths rather than disability has led to a growth in the body of evidence noting the benefits of art-based programs for neurodiverse individuals. Notably, these programs utilise varied mediums (such as music, dance, visual arts, drama, etc.) to support the different needs of neurodiverse individuals (behavioural, emotional, social, etc.). This variation restricts the evidence available for the full breadth of health impacts produced from all art programs as a collective, resulting in limited knowledge about how factors such as the type of medium and its dose can influence the reported results.

Objectives: To address this limitation, the current umbrella review aimed to identify and synthesise the current evidence relating to arts-based programs for neurodiverse individuals.

Methods: CINAHL, Cochrane Database of Systematic Reviews, EMBASE, Medline, ProQuest, PsychINFO, PubMed, Scopus, and Web of science were searched at a title and abstract level for studies published in English from 2011 to 2021. A complimentary grey literature search, along with a hand search of relevant Art Journals, the articles’ reference lists and citing articles, was also conducted. Eligible records were systematic reviews and/or meta-analyses that utilised an art-based support program for improving outcomes for neurodiverse individuals (as diagnosed by DSM-5). Independent reviewers then delivered quality appraisal and data extraction according to the Joanna Briggs Institute’s (JBI) Umbrella review methodology.

Results: Upon removing duplicates and screening records at a title, abstract and full-text level, 21 remaining articles were critically appraised. Seven studies were excluded for not meeting the minimum acceptable threshold (scored < 4), with the remaining studies (n=14) showing a low to moderate quality. Included reviews were limited to music (75%) and dance (intervention) and mainly targeted autistic individuals (76%). The systematic reviews mainly encompassed studies with a lower level of evidence and largely utilised observation for assessing how their targeted program affected the participants’ outcomes. Large heterogeneity amongst the programs utilised within the reviews, along with no reports on their manulisation, limits the knowledge around the fidelity of the programs and their active ingredients.

Conclusions: Although the existing body of knowledge has demonstrated the acceptability of specific art-based programs, the efficacy of such programs in supporting outcomes for neurodiverse individuals remains mainly unknown. Future studies using a more rigorous approach in evaluating manualised art-based programs can support a further understanding of the benefits of such programs.

**405.286 (Poster) Association between Autistic Traits and Academic Performance in University EFL Courses**

**Y. Miura and A. Nakayama**, Institute for Education and Student Support, Ehime University, Matsuyama, Japan

Background:

Language courses in universities typically include more communicative activities than other lecture-type courses. It is considered possible that students who exhibit Broader Autism Phenotype (BAP) traits may experience disadvantages in classroom, failing to show good performance and participation in front of teachers. Although there are some reports on how autistic students are accommodated in language classroom (Bradley, 2019; Putera et al., 2016; Padmadewi & Artini, 2017), no study has yet demonstrated whether BAP students as well face the necessity of special support. Also, as Ito et al. (2014) reported that the GPA of the first-year foreign language subjects reliably predicts the possibility of subsequent dropouts, it would be meaningful to investigate whether the BAP traits could be a latent risk factor.

Objectives:

This study aimed at examining whether autistic traits in college students affect their academic success in the courses of English as a Foreign Language (EFL).
Methods:

A total of 861 university students (495 males and 366 females) completed Broader Autism Phenotype Questionnaire- Japanese version (BAPQ-J). Their academic performance was assessed by the course completion of four required English subjects taught in their first academic year (passed or failed). Teachers used active-learning methods based on the common syllabi, and the assessment was made based on participation (30%), quizzes and assignments (40%) and the final exam (30%). Students failed the course if the total came to less than 60% or the attendance rate did not reach 80%. Their general English proficiency level in listening and reading was assessed in the first quarter by using the Global Test of English Communication (GTEC).

Results:

Students who scored above the cut-off point in two or more BAPQ-J subscales (Sasson, et al., 2013; Trevisan & Birmingham, 2015), named as high-trait group, comprised 17.1% of participants (N=147). A t-test revealed that their GTEC scores did not differ between high-trait (Mean=212.72, SD=29.72) and low-trait groups (Mean=216.95, SD=31.11). As for their course completion, there were 9.4% of students (N=81) who failed one or more of the English subjects, and they showed significantly higher BAPQ-J scores than those who successfully completed all the four subjects [t(859)=2.84, p=.005] (Table 1). A logistic regression analysis was performed for the BAPQ-J scores as a potential predictor of course completion (Table 2), revealing that the scores reliably discriminated successful and non-successful students with an accuracy of 90.6%.

Conclusions:

Our findings demonstrate that students who strongly exhibit the BAP features are more likely to fail EFL courses, even though their general English proficiency does not differ from that of non-BAP students. It is possible that those students, regardless of their English ability, could not show the best performance in communicative activities and exams due to their characteristics. It is well-known that autistic individuals often have comorbid social anxiety disorder (Simonoff, 2008), which is well associated with failure in EFL subjects (Miura, 2019). This indicates that special attention should be paid to students who show anxiety or stress in classroom, since they might have high autistic traits and need better understanding and support.

405.287 (Poster) Autism Group Therapy for Awareness, Acceptance and Modulation of Emotions (A-GAME): First Findings from a Randomized, Waitlist-Controlled e-Health Trial

H. E. Thaler, H. Schupp, J. Jantl, J. C. Köhler, T. Schuwerk and C. M. Falter-Wagner, (1)Department of Psychiatry and Psychotherapy, Medical Faculty, LMU Munich, Munich, Germany, (2)Department of Psychiatry and Psychotherapy, Medical Faculty, Hospital LMU Munich, Munich, Germany, (3)Department of Clinical Child and Adolescent Psychology, LMU Munich, Munich, Germany

Background:

Autistic adults frequently have comorbid psychiatric disorders such as anxiety and depression (Lai et al., 2019; Roy et al., 2015). This can be partially attributed to difficulties in emotion regulation (ER) and alexithymia (Bloch et al., 2021; Mazefsky et al., 2014). However, therapeutic treatment options focusing on ER are limited (Warwick et al., 2017) and rarely targeted at adults (Linden et al., 2022). To address this treatment gap, we developed the online-based Autism Group Therapy for Awareness, Acceptance and Modulation of Emotions (A-GAME).

Objectives:

The purpose of this study is to evaluate feasibility and acceptance of A-GAME and to collect preliminary, exploratory data on efficacy. Here we will introduce the intervention concept and discuss first findings.

Methods:

In the first treatment cycle, 18 adults (age range 21-56 years) with a confirmed diagnosis of autism spectrum condition were randomly assigned to the intervention group (n=8) or the waitlist-control group (n=10). A-GAME consists of 8 weekly online sessions within a fixed group. It is based on acceptance and commitment therapy and is designed to address specific needs and difficulties of autistic people, also implementing concrete input by autistic experts by lived experience. Sessions consist of informational pieces on emotions, reflection on personal experiences and attitudes, and practical exercises. Prior to and directly after treatment all participants completed self-report instruments on symptoms of depression and anxiety, as well as on difficulties in awareness and regulation of emotions. They took part in pre- and post-treatment clinical evaluations of adaptive functioning and clinical global impression, carried out by psychologists blind to group assignment. They also answered an open questionnaire reflecting on their experience of and attitudes towards emotions, online therapy (if applicable), regulation strategies, and study context such as videoconference environments and the COVID-19 pandemic. In a first exploratory analysis, group comparisons were analyzed using independent t-tests of score differences.
Results:

There were no drop-outs during the first treatment cycle and there is a growing waitlist for future study participation, pointing to good feasibility and acceptability of A-GAME. First findings showed greater improvements of the intervention group in interpersonal ER (d=0.875, p=0.048) and in a subcomponent of alexithymia, concerning difficulties identifying feelings (d=0.95, p=0.036). There was also a somewhat larger improvement in global adaptive functioning (r=0.484, p=0.046). No differences were observed in change of ER skills focused on suppression and reappraisal, and in changes of global clinical impression. Qualitative findings indicate that the online setting may reduce typical stressors of therapy participation, such as commuting via public transport and health concerns, while internet connection problems can be an additional stressor.

Conclusions:

This study is a first step in developing an innovative form of therapeutic support for autistic adults. Preliminary findings suggest that A-GAME might have beneficial effects, improving emotion awareness, selected ER skills, and adaptive functioning. In light of the small sample size, these results need to be interpreted with caution and will be complemented by additional research.

**405.288 (Poster) Autistic Dating Experiences and Needs: Towards Co-Creation of a Dating-Related Social Skills Program**

**A. Arias**, M. Garcia; T. Halmo; T. W. Vernon; (1)University of California, Santa Barbara, Santa Barbara, CA, (2)University of California Santa Barbara, Santa Barbara, CA

Background: There is ample evidence that group social skills interventions can be efficacious for teaching social skills and increasing friendships for autistic adolescents and adults (Jonsson et al., 2019; Vernon et al., 2018). Recently, more attention has been focused on understanding the challenges and experiences autistic people have in romantic relationships (Sala et al., 2020). However, only one study exists that examines a dating-related program designed for autistic adults with input from autistic community members (Rothman et al., 2022). Currently there continues to be a shortage of co-developed dating curriculums informed by the and as a result, the majority of existing programs may not address their unique strengths and challenges.

Objectives: The present study sought to understand the dating and romantic relationship experiences and challenges of autistic individuals, what participants desired from romantic relationships or their partners, as well as their interest in topics to be covered in a future group socialization intervention focused on dating and romantic relationships.

Methods: In this qualitative investigation data were collected from a sample comprised of 8 autistic adults who completed an interview. Participants were recruited using a variety of social media posts and listservs. Participants were gender-diverse, culturally-diverse, and of various sexual orientations. The interview queried participants about (a) challenges in dating/romantic relationships; (b) desirable qualities in a romantic partner or relationship; (c) Topics that would be helpful to include in a future social skills program designed to teach dating-related social skills; (d) experiences of dating another neurodiverse person versus a neurotypical person. A thematic content analysis (TCA; Braun & Clarke, 2006) was conducted to identify themes present within and across participant interviews.

Results: Preliminary results of the TCA revealed common themes of intellectual connection, independence, commonalities, complementary qualities, and understanding and acceptance as characteristics sought in a romantic relationship. When asked about challenges related to initiating and maintaining romantic relationships, safety, being stereotyped, finding people, concern about their appearance, masking, sensory differences, self-discovery, and communication emerged as central themes. Finally, common themes endorsed for topics to include in a future dating social skill program included: (a) sexual education; (b) relationship expectations (c) relationship progression; (d) recognizing red flags/safety; (e) adapting to neurotypical social expectations; (f) dating options/places; (g) where to find people; (g) interpreting implied intentions.

Conclusions: This study provides insight into the unique needs and considerations of autistic adults who are pursuing romantic relationships. Moreover, it provides a preliminary understanding of challenges that autistic individuals across the spectrum of ethnicity, sexual orientation and gender identity experience. Understanding autistic experiences and integrating their input into a future dating skills program ensures that the resulting curriculum aligns with their priorities, relationship expectations, and remains respectful of their autistic identity as well as other identities they may hold.

**405.289 (Poster) Behavior Therapy for Children and Adolescents with Autism Spectrum Disorder in Routine Clinical Care: A Systematic Review and Meta-Analysis**

**M. B. Posserud**, G. J. Wergeland; K. Fjermestad; and U. Njardvik; (1)Child and Adolescent Mental Health, Haukeland University Hospital, Bergen, Norway, (2)Department of Psychology, University of Oslo, Oslo, Norway, (3)Department of Psychology, University of Iceland, Reykjavik, Iceland

Background:
Various behavioral programs have empirical support for autism spectrum disorder (ASD) in children. Most of the evidence is derived from efficacy studies conducted in university settings, and there is less knowledge regarding how these programs perform in routine clinical care.

Objectives:

To assess the effectiveness of behavior therapy (BT)/behavioral interventions for ASD in children in routine clinical care settings.

Methods:

A systematic review and meta-analysis of behavior therapy (BT)/behavioral intervention for ASD in children in routine clinical care was conducted. Ovid MEDLINE, Embase OVID, PsycINFO, ERIC, and Web of Science were searched for articles published until April 2021. The effectiveness of BT, methodological quality, and moderators of treatment outcome were examined, and the effectiveness of the interventions were benchmarked with efficacy studies for the same disorder.

Results:

Thirty-one studies were included, comprising 1448 participants with a mean age of 42.2 months (SD17.7). Medium to large within-group effect sizes (ES; g = 0.78-1.28) were found at post-treatment for the outcome domains adaptive behavior, cognition, communication, and socialization, with a large average ES at follow-up (g = 1.21). The mean attrition rate was 8.8%. Although all ages up to 18 years of age were included in the search, only two studies included children above 60 months.

Conclusions:

Comparison of effectiveness and efficacy studies showed that evidence-based BT in routine clinical care yielded as good effects as in university settings. The findings support evidence-based behavioral treatments delivered in routine clinical care as efficacious in reducing symptoms of ASD. As treatment effects are not lost when evidence-based treatment programs are transported from research clinics to routine clinical care, further implementation of evidence-based interventions is needed in routine clinical care for children with autism disorders. There is however a dearth of behavioral intervention studies including older children with ASD.

405.290 (Poster) Benefits of an Online Small Group Cognitive Behaviour Therapy Program for Autistic Children during the Pandemic: Evidence from a Community-Based Implementation Study

V. Lee, N. Vashi, T. Sellitto, F. H. Roudbarani, P. Tablon-Modica, A. Pouyandehi, A. Ibrahim, S. Amies, A. Elkader, K. Gray, C. M. Kerns, M. C. Lai, J. Lake, M. Legree, K. M. Thomson and J. A. Weiss, (1)Psychology, Carleton University, Ottawa, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)York University, Toronto, ON, Canada, (4)The Margaret and Wallace McCain Centre for Child, Youth, & Family Mental Health, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)University of Toronto, Toronto, ON, Canada, (6)Centre for Addiction and Mental Health, Toronto, ON, Canada, (7)Kinark Child and Family Services, Markham, ON, Canada, (8)Centre for Educational Development, Appraisal and Research, University of Warwick, Coventry, United Kingdom, (9)University of British Columbia, Vancouver, BC, Canada, (10)Autism Research Centre, Department of Psychiatry, University of Toronto, Cambridge, ON, Canada, (11)Centre for Addiction & Mental Health, University of Toronto, Toronto, ON, Canada, (12)Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (13)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (14)Psychiatry, University of Toronto, Toronto, ON, Canada, (15)Social Skills Translated, Whitby, ON, Canada, (16)Applied Disability Studies, Brock University, St. Catharines, ON, Canada

Background: Emotion dysregulation and mental health problems are concerns that impact the wellbeing of autistic children. Support often involves the use of adapted cognitive behaviour therapy (CBT). Randomized controlled trials have demonstrated the efficacy of the Secret Agent Society Small Group (SAS:SG), an adapted CBT-based program, in targeting the development of social and emotional skills in autistic children. However, research is still needed in its effectiveness with improving child outcomes when delivered by publicly funded, community-based autism providers under real-world, ecologically valid conditions, especially within the context of the pandemic.

Objectives: This project aimed to evaluate the clinical utility of a group-based virtual SAS:SG program in improving emotion regulation and social skills, and concerns related to mental health challenges, in autistic children. The project also assessed child factors associated with change in outcomes after participating in the program.

Methods: The 10-week SAS:SG program was delivered by seven community-based autism service providers across Southern Ontario, Canada. SAS therapists led children through a series of computer-based games, role-playing tasks, and home and school missions. Caregivers attended separate group sessions with therapists. Caregivers completed pre-, post-, and 3-month post-intervention surveys that captured family demographics and child’s social and emotion regulation skills (Emotion Regulation and Social Skills Questionnaire [ERSSQ]; Beaumont & Sofronoff, 2008), symptoms related to an array of mental health problems (Child and Adolescent Symptoms...
Conclusions: This study demonstrates the feasibility and effectiveness of community-based virtual socioemotional skill-building programs; according to caregivers, participation benefited children by improving their social and emotion regulation skills, emotion reactivity, as well as symptoms related to anxiety and depression. Limitations include the lack of a control group and the inclusion of only parent-reported measures of child outcomes. In general, the study adds to the growing literature on the utility of evidence-based interventions in real-world, ecologically valid, and community-based settings. Next steps include examining qualitative data from caregiver and child experiences, expanding the implementation of the program to publicly funded youth mental health services and increasing the geographic reach of the program to autism families across Ontario.

405.291 (Poster) Can Virtual Social Skills Intervention Affect Intolerance of Uncertainty in Autistic Adolescents? E. J. Adler, S. A. Lehman; D. M. Glad, S. K. Pardej; H. K. Schiltz; M. Simons; Z. Bella, and A. V. Van Hecke, (1)Psychology, Marquette University, Milwaukee, WI, (2)University of Wisconsin-Milwaukee, Milwaukee, WI, (3)UCLA, Los Angeles, CA, (4)Educational Psychology, University of Wisconsin-Milwaukee, Milwaukee, WI

Background: Intolerance of Uncertainty (IU), which includes negative beliefs about uncertainty and negative emotions, behaviors, or thoughts as reactions to uncertainty (Buhr & Dugas, 2009), has been reported to be a causal factor mediating the relationship between autism and anxiety (Boulter et al., 2014). Specifically, IU has been shown to mediate social responsiveness and anxiety, accounting for over 75% of the variance in both autism and Williams syndrome samples (South et al., 2021), suggesting that IU is a key mechanism of anxiety beyond these social profiles. Furthermore, IU has significant clinical implications; levels of IU in autistic people mediated reported change in clinical anxiety following cognitive behavioral therapy, such that higher IU predicted less change in anxiety after intervention (Keefe et al., 2016). Given that the in-person delivered PEERS intervention (Laugeson & Frankel, 2010) has been found to decrease anxiety in autistic adolescents (Schohl et al., 2014; Hill et al., 2017; Factor et al., 2022), it will be important to explore whether telehealth delivered PEERS also affects adolescents’ levels of IU.

Objectives: The present study explored the effects of the PEERS for Adolescents Telehealth intervention on adolescent level of IU, a key mechanism of anxiety in autism.

Methods: Thirty-one families with adolescents aged 11-17 years (M = 14, SD = 1.54; 84% male) were enrolled in the current study based on 1) documentation of an autism diagnosis, 2) IQ ≥ 70, and 3) access to reliable Wi-Fi on two devices. Participants completed PEERS for Adolescents Telehealth in 16 weeks via video conferencing platforms. Adolescents and caregivers completed parallel versions of the Intolerance of Uncertainty Scale – Child (IUSC: Comer et al., 2009) pre- and post-intervention. The IUSC yields a Total score and two subscales: Factor 1 (idea that uncertainty has negative behavioral and self-reference implications) and Factor 2 (belief that uncertainty is unfair and spoils everything). Using SPSS 28.0, paired samples t-tests examined change pre- to post-intervention. Both null-hypothesis significance testing and effect sizes were used to interpret results.

Results: Analyses revealed significant decreases in caregiver-reported adolescent level of IU via the IUSC Total score (t(30) = 2.56, p < .05) with a medium effect size (d = .46), and via the Factor 2 score (t(30) = 3.41, p = .01) with a large effect size (d = .61). No significant changes were found for caregiver-reported IUSC Factor 1 or any of the adolescent-reported IUSC scores. Means and standard deviations reported in Table 1.

Conclusions: These findings indicate that PEERS for Adolescents Telehealth may yield positive benefits on caregiver-perceived adolescent IU, especially the belief that uncertainty is unfair; while self-reported IU did not. The differential findings for self- vs. caregiver-report could be due to the behavioral (observable) vs. cognitive (internal) aspects of IU. Considering that PEERS seeks to establish some form of certainty in novel social interactions by providing clear rules for nuanced social engagement, perhaps this reinforces a desire for certainty in adolescents. In contrast, caregivers may observe their adolescent behaviorally engaging more effectively in seemingly uncertainty social situations. Future research should examine concordance between improvements in anxiety, IU, and social skills self-efficacy due to PEERS.
405.292 (Poster) Can an Inclusive School-Based Music Program Enhance Social Inclusion and Self-Esteem of Adolescents on the Autism Spectrum?

M. Kaedbey, A. Servant, H. Dahary, N. Labrèche, M. Ghoul and E. M. Quintin, (1)McGill University, Montreal, QC, Canada, (2)Département d’éducation et formation spécialisées, Université du Québec à Montréal, Montréal, QC, Canada, (3)Département d’éducation et formation spécialisées, Université du Québec à Montréal, Montréal, QC, Canada, (4)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada

Background: Group music making possesses an intrinsic communication potential that holds promise for improving communication skills and social interactions. Group music-making is a cooperative structured activity that provides a unique opportunity for social inclusion and support where people with and without disability work as a team to reach a common goal (i.e., music-making). Music programs are also associated with gains in self-esteem of adolescents and young adults on the Autism Spectrum (AS). Furthermore, the self-esteem of people on the AS and within the general population positively influences perceived social support.

Objectives: This study aimed to investigate the impact of an inclusive (vs. non-inclusive) music program on indices of social inclusion, i.e., peer acceptance and social support, and on self-esteem.

Methods: Forty-nine adolescent autistic (n= 23) or non-autistic (n= 26) participants were included in this study implemented in a high school setting. Adolescents were divided into three conditions: an AS group (n = 7), a non-AS group (n = 16), and two inclusive groups (AS: n = 5 and non-AS: n = 5; AS: n = 9 and non-AS: n = 5). Students followed a 16-week music-making curriculum where they learned to play the djembe primarily as well as other percussion instruments. Before and after the music program, students in the inclusive and non-inclusive conditions completed the Social Support Appraisals Scale to measure potential changes in perceived social support, as well as the Rosenberg Self-Esteem Scale to measure changes in self-esteem. In addition, non-AS students in both conditions completed the General Social Subscale of the Shared Activities Questionnaire before and after the music program to measure potential changes in peer acceptance.

Results: A repeated measures mixed ANOVA revealed a significant interaction effect between self-esteem scores and condition, such that scores of students on the AS were statistically significantly higher at post-intervention compared to pre-intervention for the non-inclusive group (M = 2.71, SE = 0.60, \( p < .001 \)) as well as for the inclusive group (M = 5.00, SE = .42, \( p < .001 \)) with the change more pronounced in the inclusive group. There were no statistically significant changes in perceived social support nor in the peer acceptance of students on the AS in either condition (\( ps > .05 \)).

Conclusions: Our results suggests that inclusive music-making has a positive effect on self-esteem and does not have adverse effects on perceived social support and peer acceptance of students on the AS. This research supports the development of a novel line of inclusive interventions that may have beneficial effects for AS and beyond and set the stage for the implementation of music programs in family, educational, community, and mental health settings. This would ultimately improve social inclusion of neurodiversity to foster positive outcomes for many adolescents, with and without developmental disorders.

405.293 (Poster) Central Atrium for All

A. Grinader, E. Friedlaender and S. Choe, (1)Public Health, NORC at the University of Chicago, Bethesda, MD, (2)Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)MIXdesign, New York City, NY

Background:

Increasing research explores how diverse and intersecting identities, such as race, disability, and sexual orientation interact with space to influence an individual’s inclusion within a physical environment. The MIXMuseum Initiative aims to transform public spaces within a museum to increase accessibility by more people, including those with social disabilities and sensory sensitivities. Within this initiative is the Central Atrium for All project at Queens Museum (QM).

Objectives:

To explore feasible and scalable re-design of QM to promote greater accessibility and usability by a diverse range of visitors and staff through user driven feedback.

Methods:

An interdisciplinary mixed methodology study design grounded in public health and architecture research methods.

Qualitative Methods
In line with participatory design (PD) practices, an “Access Cohort” (n=25) of Queens residents was recruited as paid experts of their own lived experience. Investigators conducted 4 focus groups (FG) and 10 PD workshops over multiple rounds with this cohort. FG had facilitated tours of the QM building, followed by discussions around access barriers for key spaces and activities. PD workshops focused on inclusive design solutions through PD activities to address the access barriers. Additionally, QM staff (n=22) completed an open-ended, qualitative survey on observed challenges and desired improvements, while QM Ambassadors completed observation logs (n=5) to report their observations of visitors’ experiences. FG and workshop transcripts, staff surveys, and observation logs were coded and analyzed using NVivo qualitative software.

Quantitative Methods

Visitors (n=136) completed a survey on accessibility and inclusion as related to their visitor experiences. The survey aimed to quantify concerns of physical distancing, physical touch, physical accessibility, signage, visibility/navigation, and inclusion within 7 spaces of QM: Entry, Front Desk, Atriums, Seating, Bathrooms, Circulation, and Panorama using a 5-point Likert scale. All analyses were performed using SAS quantitative software.

Results:

Staff and Ambassadors reported challenges specifically affecting the following user groups: autistic, elderly and children, physically disabled, low vision/blind, trans, and culturally and linguistically diverse visitors. FG themes highlighted how users faced barriers in arriving at the museum, entering, orienting/wayfinding, self-care and caregiving, sitting and resting, circulating, and participating. PD workshops produced user driven design solutions that addressed challenges regarding Entry, Reception, Wellness, and the Atrium.

Concerns were highest in the following spaces: distancing in Seating (Mean = 1.56, SD = 1.01); touch in Bathrooms (M = 1.65 ± 0.98); accessibility in the Panorama (M = 1.44 ± 0.86); signage in Entry (M = 1.61 ± 1.01); visibility/navigation in Entry (M = 1.46 ± 0.91); and inclusion in Entry (M = 1.34 ± 0.95).

Conclusions:

These findings highlight vulnerable groups, including autistic individuals, currently limited in their ability to fully use public spaces and contribute to the understanding of how physical environments influence end users’ accessibility and inclusion within the built environment. This case study showcases a novel interweaving of methodologies from public health and architecture research, as well as the importance of grounding work within users’ lived experiences and solutions. Improving usability of the built environment for more people will allow for greater opportunities for socialization.

405.294 (Poster) Clinical and Behavioral Outcomes from a Pilot RCT of the Selfi Program: A Novel Social Media Skills Group Intervention for Autistic Adults

A. Osuna1, K. Sabini2, J. Flores3, N. Pierce2, E. Yamane2, J. Lemus-Valle4 and T. W. Vernon4, (1)University of Washington, Seattle, WA, (2)University of California, Santa Barbara, Santa Barbara, CA, (3)UCSB, Santa Barbara, CA, (4)University of California Santa Barbara, Santa Barbara, CA

Background: Social media is a popular medium of social communication in which modern relationships are cultivated. Many autistic adults report a preference for computer-mediated communication because it grants them a greater sense of control and comprehension compared to in-person social communication. Benefits associated with autistic social media use include greater levels of friendship quality and happiness, while challenges include increased anxiety, harassment, and cyber-victimization. Anxiety, social connectedness, and social media engagement are factors that have been noted to impact the relationship between social media usage and positive outcomes among autistic individuals. The Socialization, Education, and Learning, For the Internet (SELF2) program is a novel 9-week social media skills group intervention intended to help autistic individuals safely and effectively socialize online.

Objectives: The aim of the following study was to assess clinical and behavioral outcomes after participating in the SELF2 program.

Methods: The present study utilized a pilot RCT with 25 autistic adults (M = 24.6 years; SD = 5.88) to explore preliminary clinical and behavioral outcomes after participating in the 9-week SELF2 program compared to a waitlist control group. Clinical measures related to generalized anxiety, social anxiety, and social connectedness, while behavioral measures evaluated the frequency of Facebook behavior, Facebook improvement, and difficulty related to individualized social media goals.

Results: Compared to the waitlist condition, participants in the treatment condition demonstrated improved Facebook usage (p = .03) and trending improvements (p = .10) in the frequency of Facebook comments and posts. Treatment participants also reported a significant reduction (p < .01) in difficulty on individualized goals. There were non-significant differences between groups on all other measured outcome variables, which was expected considering the small sample size.
Conclusions: After participating in the SELF! program, participants demonstrated increased Facebook engagement, improved Facebook usage, and decreased challenges related to personalized social media goals. These findings represent signals of promise regarding the efficacy of the innovative SELF! program and an emerging area of autism research. Next steps include intervention refinement prior to embarking on a larger and more-robust clinical trial.

405.295 (Poster) Clinician Attitudes, Self-Efficacy, and Knowledge about Safety Planning with Autistic Youth before and after a Tailored Suicide Prevention Intervention Training

Background: There is growing awareness that autistic individuals are a particularly high-risk group for suicide. Alarmingly, autistic individuals are up to nine times more likely to experience suicidal ideation, up to five times more likely to attempt suicide, and over seven times more likely to die by suicide. The autistic community has identified suicide prevention and access to evidence-based practices as top priorities. The Safety Planning Intervention, a brief evidence-based suicide prevention intervention, has demonstrated effectiveness in non-autistic individuals. In a previous study, clinicians reported using Safety Planning with autistic and non-autistic clients at a similar rate but reported greater intervention acceptability for non-autistic clients. The present study will compare the Safety Planning Intervention tailored for Autistic individuals (SPI-A) with the SPI-A plus structured follow-up contacts (SPI-A+). Evaluating clinician attitudes, self-efficacy, and knowledge about safety planning with autistic individuals at-risk for suicide before and after the training on the tailored interventions allows us to assess the effectiveness of the training and better understand important clinician-level factors.

Objectives: We assessed whether there was a significant change in clinicians’ self-reported attitudes, self-efficacy, and knowledge about safety planning with autistic youth after the tailored safety planning training. Additionally, we assessed whether post-training attitudes, self-efficacy, and knowledge differed by intervention condition.

Methods: Clinicians completed a demographic questionnaire and pre-training surveys through REDCap. We assessed attitudes, self-efficacy, and knowledge about safety planning with autistic youth using validated measures adapted for the tailored intervention. Clinician participants were randomized to either SPI-A (n=47) or SPI-A+ (n=50) and then attended a condition-specific training. Following the training, clinicians repeated the surveys.

Results: A total of 97 clinicians (86 female, 11 male) from neurodevelopmental diagnostic clinics, primary care clinics, and medical specialty clinics in four United States healthcare systems completed both the pre- and post-training surveys. Preliminary analyses indicate significant pretest-posttest changes in clinician-rated attitudes, t(96) = 6.76, p < .001; self-efficacy, t(96) = 7.33, p < .001; and knowledge, t(96) = 7.71, p < .001. Additionally, post-training clinician ratings did not differ significantly by intervention condition for attitudes, t(95) = .89, p = .38; self-efficacy, t(95) = 1.42, p = .16; or knowledge, t(95) = 1.35, p = .18.

Conclusions: As hypothesized, attitudes, self-efficacy, and knowledge improved from pre- to post-training, suggesting positive overall effects of the training. Future analyses will look at item-specific changes in attitudes, as this will help to form a more nuanced understanding of the perceptions of the tailored plan. These subtleties are important to consider as we work to bridge the gap between research and implementation of suicide prevention practices with autistic youth. Of note, autistic individuals were involved in the development of the tailored intervention, and the clinician training was co-developed by and co-delivered with autistic partners. The role that stakeholders, including autistic individuals with lived experience of suicidality, their family members, and clinicians, have had in the process likely contributed to the success of this training on improving clinician attitudes, self-efficacy, and knowledge about safety planning with autistic youth.

405.296 (Poster) Clinician Perspectives of Acceptability, Appropriateness, and Feasibility of the Safety Planning Intervention Tailored for Autistic Individuals

Background: Despite elevated rates of suicidal thoughts and behaviors in autistic people, there is relatively little research about the effectiveness of suicide risk interventions and safety plans in this high-risk population. Our team identified a need to make the Safety Planning Intervention (SPI) more accessible and consistent for autistic individuals. With the collaboration and contributions of autistic researchers and advocates, we tailored the intervention for an autistic population and trained clinicians to implement it.

Objectives: The present study compares clinicians’ perceptions about the acceptability, appropriateness, and feasibility of the SPI tailored for autistic individuals (SPI-A) and the same intervention with structured follow-up contacts (SPI-A+). We assess whether intervention condition (SPI-A or SPI-A+) and clinician background information affect perceived acceptability, appropriateness, and feasibility before implementing the intervention.
Methods: Participants were 98 clinicians (87 female, 11 male) from four health systems that serve autistic adolescents and young adults. Participants were randomized to be trained in and implement the SPI-A (n = 48) or the SPI-A+ (n = 50). After the training session, participants completed the Acceptability of Intervention Measure (AIM), Intervention Appropriateness Measure (IAM), and Feasibility of Intervention (FIM) about their assigned intervention. The AIM, IAM, and FIM are widely used four-item measures with strong psychometric properties. Items are scored from 1 (completely disagree) to 5 (completely agree), with higher scores indicating greater acceptability, appropriateness, or feasibility.

Results: Overall, participants rated both interventions highly on the AIM ($M = 4.21, SD = .62$), IAM ($M = 4.28, SD = .64$), and FIM measures ($M = 4.15, SD = .59$). Bivariate correlated analyses indicated there was no significant correlation between AIM, IAM, and FIM scores and years practicing as a clinician ($M = 12.70, SD = 8.63$) or years of experience working with autistic individuals ($M = 11.61, SD = 7.96$; all $p’s > .08$). Furthermore, independent samples $t$-tests indicated there were no significant differences between SPI-A and SPI-A+ for AIM, IAM, and FIM scores (see Table 1). However, clinicians with prior formal training in suicide risk assessment or intervention reported higher FIM scores than clinicians who did not have prior training, $t(96) = -2.86, p = .005$.

Conclusions: Participants gave both SPI-A and SPI-A+ high scores on the AIM, IAM, and FIM. Interestingly, clinicians with prior training in suicide risk assessment or intervention were more likely to view the interventions as more feasible. No other factor significantly affected acceptability, appropriateness, or feasibility. Overall, these results are promising and suggest that clinicians can easily integrate both the SPI-A and SPI-A+ into standard clinical care for autistic youth.

405.297 (Poster) Coherence of Parental Representations Following Therapy for Autistic Children

N. Vashi, A. Ibrahim, A. Pouyandeh and J. A. Weiss; (1)Psychology, York University, Toronto, ON, Canada, (2)York University, Toronto, ON, Canada

Background: Parental representations are the information processing rules that guide parents’ interpretations of their child’s feelings and behaviours (Benoit et al., 1997). These representations can be evaluated for their coherence, which is the clarity, consistency, multidimensionality, and authenticity of parents’ verbal narratives about their child (Main et al., 1985). For autistic people, relationships have been examined between coherence and parent characteristics, and within the context of parent-focused interventions. Research is needed to explore associations between coherence and child characteristics and potential changes in coherence following participation in child-focused interventions.

Objectives: Changes in coherence were investigated following participation in a 10-week cognitive behavioural therapy intervention designed to improve children’s mental health. Additionally, baseline associations were examined between parental coherence and child characteristics (i.e., autism symptoms, mental health), and associations between changes in coherence and child treatment outcomes (i.e., mental health).

Methods: 81 autistic children (89% boys; $M = 9.60$ years, $SD = 1.38$) and their parents (85% mothers; $M = 43.84$ years, $SD = 4.41$) completed the intervention. Coherence was evaluated using the Five Minute Speech Sample Procedure (Magaña et al., 1986). Subscale scores (focus, elaboration, separateness, concern, acceptance, complexity) and overall coherence scores were independently coded on a continuous scale from 1 to 7, with higher scores indicating more coherent representations. Interrater reliability was established by three coders coding 20% of the transcripts and was excellent for the subscale and overall coherence scores ($ICC = .92$ to $.98$). Autism symptoms were assessed at baseline with the Social Communication and Interaction and Restricted Interests and Repetitive Behaviour T-Scores on the Social Responsiveness Scale, Second Edition (Constantino & Gruber, 2012). Child mental health was assessed pre- and post-intervention with the Internalizing Problems, Externalizing Problems, and Behavioural Symptoms Index T-Scores on the Behaviour Assessment Scale for Children, Second/Third Edition (Reynolds & Kamphaus, 2004, 2015).

Results: 30% ($n = 24$) of parents were rated as coherent at pre-intervention, and this increased to 43% ($n = 35$) at post-intervention, though these changes did not meet a statistically significant cut point ($p = .07$). Post-intervention concern subscale scores were lower, $z = -3.38, p < .001$, and post-intervention acceptance scores were higher, $z = 2.48, p = .01$, than pre-intervention scores. Although baseline associations were not observed between coherence and autism symptoms (all $p’s > .10$), links emerged between coherence and internalizing problems, $r_1(79) = -.35, p = .001$, externalizing problems, $r_1(79) = -.34, p = .002$, and behavioural symptoms, $r_1(79) = -.31, p = .005$. Although changes in coherence across therapy were not linked with post-intervention internalizing or externalizing problems, changes in coherence accounted for 3% of unique variance in post-intervention behavioural symptoms, $t = -2.79, p = .007$, after accounting for baseline levels of clinical symptoms.

Conclusions: Understanding the relationships between parental coherence and child characteristics may provide insight into potential targets for intervention. Observed improvements in aspects of coherence following therapy and links with child treatment outcomes, advocates for parent-involved therapy, which will ultimately benefit the well-being of autistic children.

405.298 (Poster) Community-Informed, Autism-Adapted Group Cognitive Behavioral Therapy for Depression in Adolescents: Preliminary Feasibility, Acceptability, and Efficacy of CBT-Day
Background: Depression is more prevalent among autistic adolescents than non-autistic adolescents and associated with distress and safety concerns. Emotion dysregulation and negative self-esteem may be key intervention targets, as they are salient risk factors for adolescent depression and endorsed frequently in autism. However, interventions for depression in autistic adolescents are limited, and neither emotion dysregulation nor negative self-esteem have been formally tested as treatment targets. Although Cognitive Behavioral Therapy (CBT) is a leading intervention for adolescent depression, it lacks an evidence base in depressed autistic adolescents. Furthermore, specialized depression interventions designed for and with autistic adolescents have not been developed and tested.

Objectives: In this pilot nonrandomized trial, we examined the preliminary feasibility, acceptability, and efficacy of a novel community-informed, autism-adapted group CBT intervention, Cognitive Behavioral Therapy for Depression in Autistic Youth (CBT-DAY), in targeting emotion dysregulation and negative self-esteem to improve depression symptom severity in adolescents.

Methods: The sample included 24 autistic adolescents (7 cisgender females, 12 cisgender males, 5 non-binary; M_age=13.62) with elevated depressive symptoms who participated in the 12-week CBT-DAY intervention. Feasibility was assessed by attrition, session attendance, and success of data collection, while acceptability was assessed by family ratings at intervention conclusion. Parent- and self-report measures of hypothesized intervention mechanisms (i.e., emotion dysregulation, self-esteem) and the primary clinical outcome (i.e., severity of depressive symptoms) were collected pre-intervention (T1), at intervention midpoint (T2) and at intervention conclusion (T3). To explore potential changes in related clinical outcomes (i.e., internalizing symptoms), families completed additional questionnaires. A series of linear mixed-effects models, with timepoint as a fixed effect and participants as random intercepts, were employed to examine changes in target mechanisms and primary and exploratory clinical outcomes over time.

Results: The CBT-DAY intervention was feasible to implement in an outpatient setting given relatively low attrition (4/24; 16.67%), high session attendance (85%), and high success of data collection (90%). The majority of adolescents (86%) and parents (95%) were satisfied with CBT-DAY. Table 1 presents data from a series of linear mixed-effects models. Over the full duration of CBT-DAY (T1-T3), the target mechanisms of adolescent emotion dysregulation (EDI-7; β=-2.51, p=0.02, d=0.35) and self-esteem (RSES; β=-2.51, p=0.02, d=0.42) significantly improved. Adolescent depressive symptoms (RCADS) significantly improved over the full duration of CBT-DAY, per self-report only (RCADS-C Depression; β=-7.59, p<.001, d=0.68). Exploratory analyses revealed that adolescent total internalizing symptoms significantly improved over CBT-DAY from T1-T3, per self- (RCADS-C Total; β=-5.29, p=0.01, d=0.44) and parent-report (RCADS-P Total; β=-5.51, p=0.01, d=0.40).

Conclusions: Findings suggest that CBT-DAY is feasible to conduct in an outpatient setting and highly acceptable to adolescents and parents. Participation in CBT-DAY is associated with significant improvements in the target mechanisms (i.e., adolescent emotion dysregulation, self-esteem), primary clinical outcome per self-report (i.e., depressive symptoms severity), and exploratory clinical outcomes (i.e., total internalizing symptoms), per parent- and self-report. A larger controlled trial is needed to robustly investigate the efficacy of CBT-DAY in targeting key intervention mechanisms and improving clinical outcomes.

Objectives: In this pilot nonrandomized trial, we examined the preliminary feasibility, acceptability, and efficacy of a novel community-informed, autism-adapted group CBT intervention, Cognitive Behavioral Therapy for Depression in Autistic Youth (CBT-DAY), in targeting emotion dysregulation and negative self-esteem to improve depression symptom severity in adolescents.

Methods: The sample included 24 autistic adolescents (7 cisgender females, 12 cisgender males, 5 non-binary; M_age=13.62) with elevated depressive symptoms who participated in the 12-week CBT-DAY intervention. Feasibility was assessed by attrition, session attendance, and success of data collection, while acceptability was assessed by family ratings at intervention conclusion. Parent- and self-report measures of hypothesized intervention mechanisms (i.e., emotion dysregulation, self-esteem) and the primary clinical outcome (i.e., severity of depressive symptoms) were collected pre-intervention (T1), at intervention midpoint (T2) and at intervention conclusion (T3). To explore potential changes in related clinical outcomes (i.e., internalizing symptoms), families completed additional questionnaires. A series of linear mixed-effects models, with timepoint as a fixed effect and participants as random intercepts, were employed to examine changes in target mechanisms and primary and exploratory clinical outcomes over time.

Results: The CBT-DAY intervention was feasible to implement in an outpatient setting given relatively low attrition (4/24; 16.67%), high session attendance (85%), and high success of data collection (90%). The majority of adolescents (86%) and parents (95%) were satisfied with CBT-DAY. Table 1 presents data from a series of linear mixed-effects models. Over the full duration of CBT-DAY (T1-T3), the target mechanisms of adolescent emotion dysregulation (EDI-7; β=-2.51, p=0.02, d=0.35) and self-esteem (RSES; β=-2.51, p=0.02, d=0.42) significantly improved. Adolescent depressive symptoms (RCADS) significantly improved over the full duration of CBT-DAY, per self-report only (RCADS-C Depression; β=-7.59, p<.001, d=0.68). Exploratory analyses revealed that adolescent total internalizing symptoms significantly improved over CBT-DAY from T1-T3, per self- (RCADS-C Total; β=-5.29, p=0.01, d=0.44) and parent-report (RCADS-P Total; β=-5.51, p=0.01, d=0.40).

Conclusions: Findings suggest that CBT-DAY is feasible to conduct in an outpatient setting and highly acceptable to adolescents and parents. Participation in CBT-DAY is associated with significant improvements in the target mechanisms (i.e., adolescent emotion dysregulation, self-esteem), primary clinical outcome per self-report (i.e., depressive symptoms severity), and exploratory clinical outcomes (i.e., total internalizing symptoms), per parent- and self-report. A larger controlled trial is needed to robustly investigate the efficacy of CBT-DAY in targeting key intervention mechanisms and improving clinical outcomes.

Background: Many adolescents with autism experience more loneliness, social isolation, and poorer friendship quality than their peers, resulting from difficulties with making friends and peer victimization (Cresswell et al., 2019; Mazurek, 2013). The Social Tools And Rules for Teens (START; Vernon et al. 2016) Program is an intervention for increasing social competencies and motivation while reducing autism-related social communication challenges. This program for adolescents with autism combines a 20-topic social curriculum with immersive experiential learning with peers during unstructured socialization periods to provide a supportive, natural context for social experimentation and skill building.

Objectives: The aim of this study was to compare the outcomes from post intervention to the outcomes at a follow-up period of a telehealth adaptation of the START Program to see if treatment gains were sustained. Specifically, we assessed the parent reported social skills, social motivation, and emotion regulation and adolescent self-reported social skill use. We hypothesized that adolescent and parent reports would show a significant improvement in social skills, social motivation, and emotion regulation from pre to post, and at the follow-up period. Additionally, we hypothesized that participants’ social skill use coded from naturalistic conversations would improve from pre to post and at follow-up.

Methods: Participants were 12 adolescents with autism aged 12-16 (Mean age= 14.25) and their parents. Inclusion criteria included the use of full sentence phrases to communicate, the ability to respond to and ask questions, a verbal IQ ≥ 70, and verification of their autism.
diagnosis. Participants were diverse across genders (41.7% female) and racial and ethnic identities (16.7% Latinx, 50% white, 25% Asian, and 25% other or mixed race). The bi-weekly START Connections program consisted of an individual therapeutic check-in, group socialization time, group discussion and practice of 20 social skill topics, group activity, and individual checkout via Basecamp and Zoom software programs. Pre intervention data was collected within 2 weeks of the program beginning, post intervention data was collected within 2 weeks of the program ending, and follow up data was collected between 20 and 22 weeks after the program ended.

Results: Results indicate that socialization measures significantly improved following participation in telehealth START. Using repeated measure ANOVAs and paired sample t-tests, analysis of treatment gains in START participants yielded significant changes at both post and follow-up time points (p <.05) with medium to large effects on several parent-report and adolescent self-report measures including: emotion regulation (EDI; d= .57), autism symptom severity (SRS-2; d= -.5), social skill use (SSIS; d= .67) and social motivation and competency (SMCS; d= .58). Additionally, significant improvements in individual target skills (questions asked and comments made) were observed for 75% of participants through observations of naturalistic conversations with unfamiliar peers and these gains were found to be significant from pre to follow up (p <.05).

Conclusions: Results show promise for the telehealth START model in improving social communication in autistic teens and sustaining gains after the intervention is complete. These results warrant a full scale RCT study to determine efficacy of this program.

405.300 (Poster) Comparing the Effectiveness of Two Virtual Job Interview Interventions: Community Adaptation Matters

M. J. Smith and K. Sherwood, School of Social Work, University of Michigan, Ann Arbor, MI

Background: Two virtual job interview interventions have yielded initial support via randomized controlled trials (RCTs) for their real-world effectiveness at increasing competitive employment rates. The first intervention, Virtual Reality Job Interview Training (VR-JIT), has mostly been evaluated among adults with serious mental illness. A pilot RCT found that VR-JIT improved interview skills and vocational outcomes among young autistic adults. Subsequently, we used community-engaged methods to adapt VR-JIT into the second interview intervention: Virtual Interview Training for Transition Age Youth (VIT-TAY). The adaptation process was facilitated by 21 autistic transition-age youth, 4 employed autistic adults and 20 teachers, parents, and employers who reviewed VR-JIT and made recommendations to tailor it for autistic transition-age youth. Recently, VR-JIT and VIT-TAY were delivered and evaluated across 47 pre-employment transition services (Pre-ETS) programs for 635 youth with disabilities. Both evaluations found the interventions to be effective at increasing access to competitive employment across their respective samples. However, VR-JIT and VIT-TAY have not yet been directly compared regarding their effectiveness for autistic transition age youth.

Objectives: To conduct a secondary data analysis to compare intervention engagement and competitive employment outcomes among autistic transition-age youth who used VR-JIT or VIT-TAY.

Methods: Forty-seven schools were recruited to participate in a quasi-experimental study of either VR-JIT (15 schools, n=279 youth with disabilities) or VIT-TAY (32 schools, n=356 youth with disabilities) within Pre-ETS programming. Fifty-five staff were trained to fidelity to implement VR-JIT or VIT-TAY. Sixty autistic youth used VR-JIT, while 75 autistic youth used VIT-TAY. The proposed implementation strategy for each intervention occurred over 6-8 weeks with 1-3 virtual interview sessions per week. A prior evaluation of the participating schools found no differences between school type (VR-JIT vs. VIT-TAY; regarding how, where, when, and by whom, the virtual interview interventions were delivered). All schools monitored and reported student competitive employment outcomes by six-month follow-up. We used t-test, chi-square, and logistic regression analyses to evaluate study outcomes.

Results: Groups did not differ with respect to their number of completed virtual interviews (VR-JIT: M=11.5 [SD=7.3] vs. VIT-TAY: M=10.6 [SD=8.8]; p=.53), while the VR-JIT group spent more time in virtual interviews compared to the VIT-TAY group (M=213.5 [SD=119.7] minutes vs. M=160.3 [SD=129.6] minutes; p=.01). The VIT-TAY group, compared to the VR-JIT group, had a higher unadjusted employment rate (57.3% vs. 40.0%, p=.045). The VIT-TAY group, compared to the VR-JIT group, had greater odds of competitive employment by six-month follow-up (OR=3.1, p=.01) after adjusting for employment-related covariates (age, sex, reading level, IQ, prior employment, and co-occurring disabilities).

Conclusions: Autistic transition-age youth had stronger employment outcomes after using VIT-TAY—an intervention tailored by their community—compared to VR-JIT, which was designed for adults with serious mental illness. This finding is critical as Pre-ETS currently lack evidence-based practices to support job interview training. Notably, youth using VR-JIT spent more time practicing their interview skills; however, VIT-TAY was adapted to intentionally shorten the length of the virtual interview sessions. Overall, VIT-TAY is emerging as an evidence-informed option for autism services (e.g., Pre-ETS) that requires scientific replication.

405.301 (Poster) Comprehensive Therapy for Irritability in Adolescents with Autism: Study Design and Pilot Data

D. G. Sukhodolsky, J. Zhong; J. Snyder; A. Steel; J. Linde; K. Ibrahim; and C. Kalvin; (1)Child Study Center, Yale University, New Haven, CT, (2)Yale Child Study Center, Yale University, New Haven, CT, (3)Child Study Center, Yale School of Medicine, New Haven, CT, (4)Yale Child Study Center, Yale University School of Medicine, New Haven, CT
Background: Approximately 50 percent of children and adolescents on the autism spectrum experience significant irritability, such as being easily frustrated or having frequent and impairing anger outbursts. Strikingly, no evidence-based psychosocial interventions are available for autistic adolescents who experience clinically significant irritability. To address this gap, we are conducting a treatment study of a novel intervention aimed at helping adolescents develop emotion regulation skills to handle frustration and navigate challenging social situations.

Objectives: This presentation will describe the design of the ongoing randomized controlled trial and present the results of an open pilot study.

Methods: The randomized controlled trial of Comprehensive Therapy for Irritability in Autism (CTIA) enrolls 12-to-19-year-old autistic adolescents with significant levels of irritability. Primary outcome measures include the Aberrant Behavior Checklist (ABC) Irritability subscale, the Modified Overt Aggression Scale (MOAS) and the Clinical Global Impression - Improvement (CGI-I) scale completed by an independent evaluator (a.k.a. “blinded” rater). Outcome measures are collected at study midpoint (week 8), endpoint (week 16) and six-month follow-up (week 42). CTIA consists of 15 ninety-minute weekly sessions delivered either in person or by telehealth using a detailed manual and targets both common and ASD-specific mechanisms of irritability. It includes illustrated activities for teaching emotion regulation and problem-solving skills to the adolescent; a parent component that teaches antecedent management and reward strategies; and a school component for addressing behavioral difficulties at school (Fig1). The study uses Psychoeducation and Supportive Therapy as a control condition because during adolescence, many individuals with ASD may become more acutely aware of their differences from peers and may benefit from psychological support.

Results: In preparation for the randomized trial, CTIA was piloted in eight adolescents with ASD complicated by irritability. Subjects included seven boys and one girl with ASD, mean age=14.3±1.4 and mean IQ=94.6±12.8. Six subjects were receiving medication (aripiprazole, citalopram, quetiapine, atomoxetine, and sertraline) that had been stable for at least six weeks prior to initiating CTIA and remained stable during the study. For consistency with clinical trials of medication for disruptive behavior in ASD, we used the ABC Irritability subscale as an outcome measure in this pilot. Treatment significantly reduced the mean ABC Irritability score from 19.0±4.0 at baseline to 6.9±2.3 at endpoint (paired samples t=10.6, p<0.01)(Fig2). Of note, the 12-point reduction in the ABC Irritability score is a clinically meaningful change and is similar to the mean improvement in drug trials.

Conclusions: Comprehensive therapy for irritability in autism consists of 15 ninety-minute weekly therapy sessions conducted with the teens and their parents. During treatment, adolescents learn emotion regulation and problem-solving strategies for managing frustration, and parents learn practical skills for coaching their children to acquire emotional resilience in potentially frustrating situations. If proven effective, this will become a useful treatment option for adolescents with autism complicated by disruptive behavior. Most importantly, we hope that this treatment will improve the lives of adolescents on the autism spectrum by building their confidence and empowering them to navigate increasingly complex social situations in the transition from adolescence to adulthood.

405.302 (Poster) Design Your Own Supportive Lifeworld: An Enactive Approach
J. C. van Hutzen, J. van Dijk, T. Waardenburg, W. G. Staal and M. C. van der Voort, (1)Twente University, Enschede, Netherlands, (2)HAN University of Applied Sciences, Nijmegen, Netherlands, (3)Radboud University Medical Center, Donders Institute for Brain, Cognition and Behaviour, Department of Cognitive Neuroscience, Nijmegen, Netherlands

Background:

Supportive technologies for autistic young adults are promising in principle, yet their uptake remains limited. Critics argue that many supportive technologies have their origins in healthcare and thus are designed to teach autistic people – children, usually – skills that they supposedly lack. Overall, there is a strong focus on functional limitations, with little attention to the real-life experience that users have with these technologies. This may evoke a sense of disempowerment and result in the rejection of valuable supportive technology.

Objectives:

Lived experience has recently gained attention in enactive psychiatry, which foregrounds a holistic understanding of autism. Treatment rationale should consider the real-life physical and social environments in which autism manifests itself, other than only its pathological features as a ‘brain disorder’. By focusing on the lived experience of autistic people within their unique environments, it also becomes easier to tailor effective therapeutic interventions.

Inspired by enactive psychiatry, the aim is to bring the lived experience of autistic individuals also to supportive technology design. In the ongoing Design Your Life-research project (DYL), we are developing a toolkit that helps young autistic adults design supportive technologies based on their own preferences. The toolkit should help (1) users to explore and map their physical and social environment, (2) understand the supportive role that technology can play in that environment and (3) bring technology to fruition.

Methods:
Over the course of two years, the DYL-toolkit was developed at the intersection of design research and psychiatry. First, we investigated which design tools and techniques could be used for the collection and analysis of experiential data. Second, we investigated how the context of design - context-mapping, idea generation, testing, evaluation, reflection - could help young autistic adults learn more about themselves and their personal support needs.

To answer these questions, we initiated eleven design case studies with autistic young adults - including their caregivers, if applicable - each time trying out a different version of the toolkit. Data was analysed using a grounded theory approach.

Results:

The toolkit was completed in October 2022, consisting of twenty-six design tools. Among others, the Think-Tell-Recognize-tool helps users to reflect on sensory, sensorimotor, social and emotional components of supportive technologies they are already using. At the end of the design process, the My Solution in My Lifeworld-tool helps users to investigate how these components can be further enhanced or improved in a follow-up design iteration. For these and other tools, the emphasis is on experiential knowledge.

Conclusions:

From the case studies, we observed that the toolkit was indeed used to develop supportive technology going beyond only functionality: users considered aesthetics and existing routines and social networks in which the technology would interfere. Whenever the user was asked to clarify their design decisions, this seemed to provoke delicate discussions about one’s situation – regarding existential, family or domestic affairs –, yet shifts ‘responsibility’ from the autistic person themselves to their surroundings. Design empowers a person to reflect on their own lifeworld and personal, pragmatic support needs therein.

405.303 (Poster) Development of a Group-Based Job Interview Training Program with 3D Computer Graphic Humanoid Robots for Individuals with Autism Spectrum Disorders

Y. Yoshikawa, H. Kumazaki, T. Muramatsu, K. Sakai, H. Haraguchi, A. Kudor and H. Ishiguro, (1)Graduate School of Engineering Science, Osaka University, Toyonaka, Japan, (2)Department of Future Psychiatric Medicine, Graduate school of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, (3)Department of Neuropsychiatry, Keio University, School of Medicine, Tokyo, Japan, (4)National Institute of Mental Health, National Center of Neurology and Psychiatry, Tokyo, Japan

Background: Job interviews are significant barriers to employment for individuals with autism spectrum disorders (ASD), as nonverbal and verbal communication with multiple interviewers, required routinely in job interview setting, may be challenging for them. Recent data published by the Office for National Statistics show that only 22% of adults with ASD are in any kind of employment that imply an urgent need for intervention. Obtaining job interview training remotely during this covid pandemic may prove to be an indispensable skill, for individuals with communication barriers.

Objectives: To facilitate interview skill acquisition for individuals with ASD while staying at home, we developed a new group-based online training program using a novel robotic conferencing system in which the users can talk to each other virtually using 3D computer graphics (CG) of a humanoid robot as their own avatar. This study was conducted to investigate the effectiveness of the proposed program in facilitating interview skill acquisition required for face-to-face job interviews.

Methods: This study was approved by the ethics committee of Kanazawa University. The study included individuals aged 20–29 years, unemployed, seeking employment, and with a diagnosis of ASD based on the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5). They were divided into three groups consisting of five individuals. The group members participated in the program sessions where they alternately played the roles of interviewer, interviewee, and meta-evaluator for eight or nine days over three consecutive weeks. During the sessions, mock job interviews were held in an online robotic conferencing system where an interviewee and two interviewers used their own CG robots as proxy agents (or avatars). Subsequently, meeting with remaining two members were held over a conventional online video conferencing system (Zoom®) to provide the interviewee with feedback about his last performance. For feedback, the interview scene with CG robots was replayed while preparing the scoring for both verbal and nonverbal communication. The participants underwent a mock face-to-face interview (MFI) with two experienced human interviewers, both before and after the program.

Results: Fourteen participants who completed the trial procedures, without any technological challenges or distress leading to session termination, were analyzed. In subjective evaluations by experienced psychotherapists, a significant increase between the first and the second MFIs and the second MFI in several aspects in both verbal and nonverbal aspects, such as appropriate word use (3.86 vs 5.00, \( p = 0.017 \)) and appropriate eye contact (3.00 vs. 4.29, \( p = 0.002 \)).

Conclusions: The results showed the potential efficacy of the proposed method in facilitating remote interview training at home. The current program allowed participants to obtain the experience of being an interviewee and performing evaluating roles as an interviewer and a meta-evaluator; therefore, it can be expected to understand others’ perspectives (i.e., the perspectives of the interviewer and meta-evaluator). Further evaluations need to be conducted to verify this interpretation and the efficacy of the proposed method as compared to
Background: The ongoing COVID-19 pandemic, a major stressor, has impacted the mental health of youth. Those on the autism spectrum are also at risk of encountering mental health problems in present times. To prevent the consequences of stress, we implemented the De-stress for Success© program within eight high schools with the objective of sharing scientifically valid knowledge on stress and coping strategies with autistic students. This program comprises of five workshops given once a week, group exercises and a student logbook. Because of intermittent school closures due to the spreading of COVID-19, workshops were given online (11.3%) or in class.

Objectives: To estimate the effects of the adapted De-stress for success program on the perception of stress and adaptive behaviours of autistic students

Methods: We proceeded with between-subject analyses of repeated measures. Before attending the five workshops (T1), one week after the end of the program (T2) and five weeks later (T3), 50 autistic students (M = 14.7, SD = 1.07; 8 girls; M IQ = 93.89, SD = 16.57), their parents and their teachers completed the Behavior Assessment System for Children (Reynolds et Kamphaus, 2015). Students also completed a Facial recognition test of six emotions (Diehl-Schmid et al., 2007), the 10-item Perceived stress scale (PSS; Cohen, Kamarck et Mermelstein, 1983) and a translated version of the Stress Survey Schedule (SSS; Groden et al., 2001). They answered verbally to a satisfaction and retention of knowledge questionnaire at T2.

Results: Students’ perception of stress (PSS), reaction to different stressors (SSS), maladaptive and adaptive behaviours (BASC) did not change in time. They identified the facial expression of emotions with higher success (F(2,82)= 4.094, p<.05, R²=.091), namely joy and disgust. As for their teachers, they perceived a positive impact on problematic behaviours (e.g. somatization F(1.528,55)= 6.417, p <.01, R²=.151; atypicality F(2,72) = 3.531, p <.05, R²=.089) and adaptive behaviors (e.g. adaptability F(1.648,59.132)= 8.145, p <.001, R²=.185; functional communication F(1.706, 61.425)= 11.284, p <.001, R²=.239). Parents on their part perceived less behaviors related to hyperactivity (F(2,34)= 3.628, p <.05, R²=.158) and tendency towards less anxiety (F(2,34)= 3.135, p =.056).

Overall satisfaction was high: 88% would recommend the program to their friends. Those who received the workshops online would have preferred to have been in class. More than half of the students did not appreciate nor find the logbook useful (56%). They retained the basics of the program. However, only 20% mentioned applying the knowledge and changing their behaviours. Nearly 2/3 (64%) said their teacher or parents did not support them in reinvesting the knowledge outside the workshops.

Conclusions: Workshops did not have the expected results on the perception of stress and adaptive behaviours as perceived by the participants. Teachers and parents saw a change in adaptive and maladaptive behaviours. Based on satisfaction interviews with the youth, we recommend avoiding online implementation of the workshops. Finally, reinvestment of knowledge in day-to-day activities is necessary to reinforce the generalization of skills with the help of the main actors in the youth’s environment.

Objectives: To evaluate if BBAT may be effective for improving movement quality in people with autism.

Methods: People with autism, 15-30 years were randomized to either an individual BBAT intervention of 12 weekly sessions and treatment-asusual, or to a control group receiving treatment-asusual only. Winsteps transformed data of BAS MQ at baseline and post-intervention were used to analyze changes in movement quality for each group.
Results: The preliminary results indicate significant improvements in BAS MQ for 7 out of 28 participants in the intervention group, while none had deteriorated. In the control group, there was no significant changes. Three participants discontinued participation due to high anxiety from travelling to and from the sessions.

Conclusions: The preliminary result suggests that BBAT may be a method to improve movement quality in people with autism. The special needs in autism require being acknowledged in all service delivery. Further clinical trials of BBAT should be carried out to investigate possible impacts on everyday functioning.

405.306 (Poster) Effects of Transcranial Direct Current Stimulation of the Bilateral Tpj on Neural Correlates of Intention Attribution in ASD – Neural Outcomes of the Stimat Study
C. Luckhardt, A. Dempflé, M. Schütz, A. Mühlberr, S. Boxhoorn, M. Siniatchkin, J. Siemann, F. Schlechter, M. Castelo-Branco, H. C. Pereira, F. Bonnet-Brilhaut, M. Latinius, C. Ricou and C. M. Freitag, (1)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, GERMANY, (2)Institute of Medical Informatics and Statistics, Kiel University, Kiel, Germany, (3)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany, (4)Department of Child and Adolescent Psychiatry and Psychotherapy, Protestant Hospital Bethel, Bielefeld, Germany, (5)Coimbra Institute for Biomedical Imaging and Translational Research, ICNAS, University of Coimbra, Coimbra, Portugal, (6)CIBIT & IBILI - Institute for Biomedical Imaging and Life Sciences, Faculty of Medicine – University of Coimbra, Portugal, Coimbra, Portugal, (7)UMR iBrain 1253, Inserm, University of Tours, TOURS, France, (8)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (9)Autism Research and Intervention Center of Excellence Frankfurt, Goethe Universität Frankfurt am Main, Frankfurt, GERMANY

Background: Transcranial direct current stimulation (tDCS) is an innovative treatment option for autism spectrum disorders (ASD), which has the potential to specifically target and improve altered patterns of brain activation and functional connectivity. The tempo-parietal junction (TPJ) is a key-hub within the “social brain” and shows decreased activation in individuals with ASD, making it a promising target region for brain stimulation ASD. To characterize neural changes elicited by tDCS, testing electroencephalography (EEG) combined with a TPJ related neurocognitive paradigm as outcome in a randomized-controlled clinical trial can help track changes in neural functioning and elucidate neural mechanisms underlying effects of tDCS.

Objectives: The present study has two objectives. First, we will show results of the adaption and evaluation of an EEG paradigm assessing intention attribution, in order to establish event-related potential (ERP) markers of social cognitive functioning in children and adolescents with and without ASD. Second, we will report neural change captured by ERPs induced by anodal tDCS over bilateral TPJ within a phase-IIa randomized-controlled clinical trial.

Methods: The European multi-centre, phase-IIa pilot randomized, double-blind, sham-controlled, parallel-group clinical trial StimAT investigated the effect of 10 days of 20-minute multi-channel tDCS stimulation of the bilateral TPJ at 2.0 mA in combination with a computer-based cognitive training on core ASD symptoms in 24 children and adolescents with ASD aged 10 to 17. One outcome measure were ERP components recorded during the “sequential comic strip paradigm”, which captures the attribution of intentions and related neural processes of contextual integration and processing of expectations. ERPs were assessed prior to tDCS treatment (T2), directly afterwards (T3) and at 4 weeks follow-up (T4). The paradigm was previously adapted and analyzed in a sample of 26 children and adolescents with ASD and 24 typically developing controls.

Results: Results from the cross-sectional data show that contextual integration during intention attribution, represented by a P3-like component, are not per se altered in ASD. Instead, higher amplitudes in later prefrontal and parietal components indicate stronger processing of incongruent information in the context of intention attribution in ASD. Analysis of the longitudinal data is still ongoing, but first results indicate that TPJ associated P3 components are not enhanced by tDCS.

Conclusions: Combined EEG and neurocognitive paradigms are a helpful tool to characterize and analyze the effects of tDCS interventions, but tDCS may not have the anticipated direct effects on TPJ function.

405.307 (Poster) Efficacy and Social Validity of the Polish Version of the PEERS for Young Adults Curriculum: A Randomized Controlled Trial
M. Plato, K. Wojaczek and E. A. Laugeson, (1)Faculty of Psychology, University of Warsaw, Warsaw, Poland, (2)Association for Social Innovation "Mary and Max", Warsaw, Poland, (3)UCLA Semel Institute for Neuroscience and Human Behavior, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA

Background: Although most autistic people express interest in friendship and romantic relationships (Strunz et al., 2017), they report having fewer friends, less often having romantic relationships, and receiving less social support than non-autistic people (Bishop-Fitzpatrick et al., 2018). PEERS for Young Adults is an evidence-based program aimed at teaching social skills needed to establish and maintain close relationships, including friendship and romantic relationships.
Objectives: To examine the efficacy and social validity of the culturally adapted version of the PEERS for Young Adults in Poland.

Methods: Fifteen young adults (aged 18-32; $M_{age} = 23.5; SD = 4.2; 73.3\%$ males) were randomly allocated to a Treatment Group (TG) or a Waitlist Control Group (WCG). All the adults were diagnosed with autism spectrum disorder and had no intellectual disability, as confirmed by the administration of the Autism Diagnostic Observation Schedule (2nd edition) and the Abbreviated Battery of the Stanford-Binet Intelligence Scales (5th edition). Young adults and their parents reported on the outcome measures before the intervention phase (T1), after the intervention phase (T2), and at the 6-month follow-up (T3 for TG; T4 for WCG). Outcome variables included social difficulties related to the autism spectrum (Social Responsiveness Scale-2; SRS-2; Constantino & Gruber, 2012; and Autism Spectrum Rating Scales; ASRS; Goldstein & Naglieri, 2010), knowledge about social skills (Test of Young Adult Social Skills Knowledge; TYASSK; Laugeson, 2017), empathy, including social cognition (Empathy Quotient; EQ; Baron-Cohen & Wheelwright, 2004), and social engagement with peers (Quality of Socialization Questionnaire; QSQ; Laugeson, 2017). Treatment fidelity and social validity of the intervention were also measured. The lockdown imposed due to the COVID-19 pandemic forced the authors to move the last seven (out of 16) sessions of TG to an online setting, while WCG received all the sessions in person.

Results: As compared to WCG, young adults that completed the PEERS program showed significant improvements in self-reported knowledge about social skills (TYASSK), parent-reported level of autism-related difficulties (SRS-2 and ASRS total scores), the parent-reported quality of socialization with peers (ASRS Peer Socialization subscale), and the parent-reported (but not self-reported) social engagement (QSO). The effects were medium for social engagement and large for the rest of the variables ($\eta^2 > .14$) and were maintained over six months after the treatment, except for the social engagement (QSO). There was an additional gain in empathy, that was not significant immediately after the treatment. The intervention was well-accepted and deemed feasible by young adults, their parents, and peers involved in the program. Treatment effects were comparable across delivery modes (mixed online/in-person vs. in-person).

Conclusions: The study represents one of the few cultural adaptations of the social skills programs for autistic adults. It provides initial evidence for the sustained effects of this intervention in improving the social skills, social cognition, and social knowledge of young adults on the autism spectrum, although gains in social engagement were limited. Moreover, the Polish adaptation of PEERS for Young Adults showed high feasibility and acceptability that should foster its successful implementation.

405.308 (Poster) Elaborative Reminiscence with Children and Young People: A Systematic Review

Background:

Forty five percent of children with Autism Spectrum Disorder (ASD) show no additional language or intellectual disabilities and attend mainstream schools, yet their long-term outcomes are poor (Baird et al., 2006). Poorer quality of life in older autistic adults (Roestorf, 2018) has been associated with difficulties with theory of mind (ToM; Baron-Cohen, 1995), autobiographical memory (Bowler et al., 2007; Crane et al., 2009) and self-understanding (Lind, 2010) have been associated. Despite their poor long-term outcomes, school-aged children with ASD have access to few theoretically informed and empirically supported interventions. This makes the development of effective evidence-based interventions an urgent priority.

A growing body of research has reported encouraging findings on the relationship between training parents to speak more elaboratively (“elaborative reminiscence”; ER) and improvement to child outcomes, including memory and mental-state understanding (Fivush et al., 2006, Salmon and Reese 2016, Waters et al., 2019). Such findings have prompted speculation that ER could be a beneficial intervention for children with autism (McDonnell et al., 2017). However, systematic reviews of ER effectiveness have been narrow in scope, only reporting results for a small number of child outcomes and only for young (≤ 5 years), neurotypical children (Wu & Jobson, 2019, Waters et al. 2019).

Objectives:

A systematic review and meta-analysis was conducted to address the limitations of previous reviews by evaluating the impact of an ER intervention on a broad range of outcomes (e.g., cognitive, emotional, behavioural and social) for all children up to 18 years, unrestricted by diagnostic status. Moderators of ER effects were also investigated according to training, participant and ER characteristics.

Methods:

Unique articles were identified from searches of three EBSCO interface databases, the Web of Science database, clinical trial registers and grey literature searches. Literature was independently screened by two authors according to pre-specified criteria to include experimental ER studies that assessed quantitative child outcomes. Data were qualitatively synthesised in accordance with guidance from Popay et al. (2006) and meta-analysed where possible according to outcome categories.
Results:

The search screened 2350 records and included 10 articles. Results suggest significant benefits of ER for children’s memory, receptive vocabulary, use of emotion content during reminiscence, and indirect ER benefits were reported by one study for children’s ToM. ER was not found to improve children's expressive vocabulary, narrative quantity, story comprehension, or behaviour. Older child age and shorter intervention length were found to improve effect sizes for child memory and ER interventions that included more emotion-talk were also associated with improved outcomes. The review identified no studies that investigated ER effectiveness with neurodiverse populations.

Conclusions:

The fact that these findings show that ER can benefit outcomes for neurotypical children in areas of known difficulty for high-functioning children with autism suggest that an ER intervention could have promising clinical implications for children with atypical development or developmental disabilities (e.g., autism). Results from this review informed the design and implementation of a randomised pilot study that investigated the feasibility and acceptability of an ER intervention for autistic children aged 7-12 years.

405.309 (Poster) Emotion Regulation Program for Children with Autism Spectrum Disorder and Intellectual Disability – Preliminary Findings

T. J. Goh, B. L. J. Tan, W. J. Soh and M. Sung, Department of Developmental Psychiatry, Institute of Mental Health, Singapore, Singapore

Background:

There is a high concordance rate of anxiety and other emotion-related issues with Autism Spectrum Disorders (ASD). Cognitive Behavioural Therapy (CBT) programs developed to address emotion issues in individuals with ASD have largely been used with individuals with intact cognitive functioning.

Objectives:

We aimed to examine the efficacy of an emotion regulation program based on CBT principles adapted for ASD individuals with lower cognitive abilities in the community. The intervention program was adapted from an original CBT program (Sung et. al., 2011; Goh et al., 2017) to be conducted in a small group setting in the school environment, with a 1:3 teacher-to-students ratio. The program was conducted over fourteen 60-minute sessions.

Methods:

Seventeen children ($M_{age} = 12.5$ years old, $SD = 2.79$) from 2 special education schools with a diagnosis of ASD and intellectual disability (ID) were randomized into either the intervention group ($n = 9; M_{age} = 13.7, SD = 2.41$) or waitlist control group ($n = 8; M_{age} = 11.07, SD = 2.59$). Participants were assessed on the Social Responsiveness Scale – parent report (SRS-2; Constantino 2012), and the SPENCE Children Anxiety Scale (SCAS; Spence 1998) before and after the program.

Results:

A one-way ANCOVA was conducted to compare pre-post differences between the Intervention and Control group, while controlling for age. There was a significant improvement in the SRS communication domain scores for the Intervention group, $F(1,14)=7.705, p=0.015$, as compared to the Control group. On the other hand, children in the Control group reported a significant reduction in the SCAS-Child fears of physical injury score, $F(1,14)=6.447, p=0.024$. No other significant differences were found on the other measures.

Conclusions:

Our results suggest that an emotion regulation program can be beneficial to ASD individuals with ID, when the program is adapted to meet their verbal, behavioral and cognitive level of understanding. Although we did not find significant reductions in anxiety related symptoms, participants in the intervention group were reported to display improvements in their communication. Replication of the study with a larger sample is needed.

405.310 (Poster) Employer Workshops in Concrete Communication - Supporting a Neurodiverse Workforce

B. Schwartzman, A. Sturm and C. J. Grantz, (1)Vanderbilt University, Nashville, TN, (2)Loyola Marymount University, Los Angeles, CA, (3)Grantz Psychological Services, Inc., Portland, OR
Background: Current research demonstrates that awareness of neurodiversity among supervisors and co-workers results in improved morale and increased productivity through maximizing talents and putting all employees in positions to succeed (Krzeminska et al., 2016). As neurodivergent individuals achieve employment in a range of careers and settings, it is clear there are specific areas of need impacting their success within the workplace. This study aims to evaluate the efficacy of an employer-based training intended to support greater awareness of neurodiversity and provide concrete communication strategies effective for all employees.

Objectives: We partnered with one large employer to pilot our workshop that we developed on the topic of concrete neurodivergent-friendly communication principles. Our training is based on leveraging current evidence-based practices related to universal design, neurodiversity, and neurodivergent success in the workplace. We proposed to: (1) conduct a pilot survey to establish the current baseline of staff awareness of neurodiversity, (2) assess the implementation of neurodivergent-friendly communication practices, (3) re-assess awareness of neurodiversity and neurodivergent-friendly communication techniques in the populations receiving training.

We hypothesized that by increasing neurodiversity awareness and promoting neurodivergent-friendly communication practices and tools, employee morale and inclusion will be enhanced.

Methods: To accomplish these aims, the study is made up of three components: (1) a brief online pre-survey addressing topics of neurodiversity awareness and use of concrete communication strategies (2) participation in a neurodiversity awareness and concrete communication strategy workshop (3) a brief online post-survey addressing the same topics as the pre-survey. Participants included only employees at one specific partner employer. Participants (N=34) took the pre-survey one month prior to the workshop, then attended the workshop, then took the post-survey one month after the workshop (N=13, still in process of collecting). Study survey participation and training took place entirely online.

Results: Preliminary results show: 8 out of 34 participants reported having never heard of the term “neurodiversity” prior to the survey; participants reported (1) an increase in co-workers’ awareness of neurodiversity from before the workshop (between 40-50% awareness, depending on the department) to after the workshop (60-70% awareness), (2) a decrease in use of concrete communication strategies decreased following the workshop, and (3) that they would like additional training in neurodiversity and concrete communication.

Conclusions: Preliminary results indicate that additional training, beyond just one neurodiversity-focused workshop, is needed to make a lasting change in a particular workplace. The reported Autistic self-advocates, other communities of neurodivergent adults, and those working with these communities have increasingly highlighted the potential societal contributions available when the workforce recognizes and develops the strengths of individuals with diagnoses of Autism, ADHD, Dyslexia, etc. Rather than pathologizing the weaknesses of neurodivergent individuals, it is paramount that we promote strategies to successfully include the full range of human neurodiversity in the workforce (Doyle, 2020). As not all neurodivergent individuals are aware of or comfortable disclosing their neurodivergent status, it is essential for employers to increase implementation of communication strategies that are effective for a diverse workforce.

Background:

The ‘Roim Rachok’ Program (RRP; "Looking Ahead" in Hebrew) is an innovative program designed to integrate cognitively able young adults with autism spectrum disorder (ASD) within the Israel Defense Forces (IDF) and the civilian work world. The first phase in the program is a three-month training course prior to army recruitment provides professional training, along with social communication skills, work and life skills, yoga, and emotional support adjusting to military life.

Objectives:

1. Examine changes in self-reports among the ASD group in adaptive behavior, autism symptom severity, and social communication abilities over time. 2. Compare self-reports of the ASD group to typically-developed (TD) soldier control group.

Methods: The study cohort was participants with ASD (n=49; Mage=19.09, 47:2 males to females) with average to above-average cognitive ability (ASD group) and TD soldiers (n=46) matched for gender/age and serving in the same units (control group). The ASD group underwent comprehensive evaluations at the training course’s beginning (T1) and end (T2); the control group was similarly evaluated only at T2, upon recruitment. Evaluation included standard measurements for adaptive behavior (Adaptive Behavior Assessment Scale 2nd edition- ABAS-II), autism severity (Social Responsiveness Scale 2nd edition- SRS-II), conversation skills (based on Yale in vivo Pragmatic Protocol- YiPP), theory of mind (“ToM”; Faux Pas), and empathy (Empathy Quotient- EQ).
Results:

From T1 to T2, a significant increase was noted in all three ABAS-II subdomains for the ASD group, suggesting substantial improvement in adaptive behavior over the training course (Figure 1). Additionally, a significant decrease in SRS-II social communication impairment (SCI) subdomain, an increase in the faux pas criteria for detecting and interpreting awkward statements and in EQ emotional empathy subdomain scores were noted. These findings may reflect the improvement of the participants’ social communication skills following the training course. Group comparisons in T2 yielded differences in most examined measures. TD soldiers scored significantly higher than ASD group in the ABAS-II total and social subdomain scores. ASD group scores were lower than TD soldiers in conversation skills total score and in specific background, topic maintenance, comments and asking for information subdomains. Regarding ToM capabilities, the ASD group did not differ significantly from the TD group in detecting and interpreting awkward statements in faux pas situations but did have lower scores interpreting non-faux pas situations as “neutral” compared to the TD group. Finally, the ASD group scored lower than the TD group on the EQ total and its cognitive and emotional subdomains (table 2).

Conclusions:

Positive changes in adaptive behavior and social communication were found among young adults with ASD matriculating into the IDF after the RRP training course. Improvement may be attributable to the course’s effectiveness, but lack of a control group within the course prevents a definitive conclusion. Nonetheless, comparison to matched TD peers at the time of IDF matriculation indicates some of the social-communication differences between the two populations. These findings characterize the potential challenges of integration into social-work environment, such as military service, and point to the appropriate support for a successful integration.

405.312 (Poster) Evolution of the Intellectual Structure of Virtual Reality and Augmented Reality Interventions for Children and Adolescents during the Period 2010-2022

A. Nordahl-Hansen; A. Dechsling and G. Lorenzo Lledó, (1)Østfold University College, Halden, Norway, (2)Faculty of Teacher Education and Languages, Østfold University College, Fredrikstad, Norway, (3)Departamento Psicología Evolutiva y Didáctica, University of Alicante, Alicante, Spain

Background: Emerging technologies such as virtual reality (VR) and augmented reality (AR) are being increasingly used in interventions aimed at helping autistic children and adolescents. The reason is that they provide flexibility that can be adapted to different learning styles for this group. Also, the visual information they provide the user with can be the well suited for autistic children and adolescents.

Objectives: To analyze the intellectual structure of global trends in the use of VR/AR for learning by autistic students through scientific mapping in the period 2010-2022.

Methods: We have used a bibliometric methodology which is a group of techniques that allow us to scientifically map the representation of the intellectual structure in research areas. Similarly, the representation of the information collected in the documents were performed using the bibliometrix software. In order to extract the information to be processed in bibliometrix, a systematic review with inclusion and exclusion criteria has been applied, resulting in a final sample of 57 documents analyzed during the period 2010-2022.

Results:

The analysis of the intellectual structure based on the keyword Plus that the documents have in common shows two clusters. The first cluster includes adolescents (100%), “High Functioning autism” (90%), interventions (83.3%), with Ke et al. (2022) being the most relevant document. In the second cluster, individuals (90.9%), children (61.1%) and spectrum disorders (56.2%) stand out, and the most important document is Chen et al. (2015). The analysis based on the Keyword Authors shows five clusters of documents. In the first, autism spectrum disorder (100%), virtual reality (21%), augmented reality (25%) is relevant. Lee et al. (2018) is the study obtaining the highest impact. In the second cluster autism (100%), virtual reality (78.9%), augmented reality (75%) stands out. Ke et al. (2022) obtained the most relevant document. For the third cluster, the words augmented reality, 3d facial animation and emotions are similar in 100% of the publications. The paper by Chen et al. (2010) is in the most important position. In the fourth cluster, the words social competence, 3d expressive avatar, 3d virtual environments are present in 100% of the papers. The work of Cheng et al. (2010) receives the highest recognition. In the last cluster, ASD (100%), collaboration (100%) and autism spectrum disorders (55.6%) are the most prominent. The greatest impact in their research is for Burke et al. (2021).

Conclusions: We present illustrations showing that VR works with desktop virtual reality, being collaborative work one of the most used approaches, while AR has as its main objective the work of emotions and all the factors that influence them. The most recognized works are those of Ke et al. (2022) for VR and Lee (2021) for AR.

405.313 (Poster) Examination of Autism Knowledge, Self-Efficacy, and Educator Competence in Teaching Autistic Students
Examining Moderators of a Transition Intervention for Autistic Adolescents and Young Adults

cite{K. A. Buchanan, C. A. Mulcahy, and J. M. Gillis, (1)Binghamton University, Binghamton, NY, (2)Department of Teaching, Learning and Educational Leadership, Binghamton University, Binghamton, NY}

**Background:** Given the prevalence of diagnoses and educational classifications of autism, educators are likely to serve autistic students across a variety of school settings. Previous research has suggested that autism knowledge is insufficient among educators and that poorer understanding of autism may impact educator effectiveness (Gómez-Mari et al., 2021). However, inconsistent measurement of autism knowledge (Harrison et al., 2017) and limited scale of existing samples has hindered a fuller understanding of existing knowledge and how knowledge relates to educator efficacy.

**Objectives:** Evaluate levels of autism-related knowledge in a large sample of US educators using a psychometrically sound instrument; examine relations between Autism knowledge, self-efficacy, and knowledge of evidence-based inclusive educational strategies to serve autistic students.

**Methods:** A sample of 389 educators from across New York state participated in an online survey about knowledge and attitudes toward inclusion of students with disabilities. This survey included the Autism Stigma and Knowledge Questionnaire (ASK-Q), as well as multiple items assessing educators’ self-efficacy (including self-reported ratings of their knowledge about autism, knowledge of inclusive instructional strategies for autistic students, and their ability to prepare autistic students for adulthood). Finally, educators read a vignette describing an autistic student in an inclusive setting and were asked to nominate strategies they would use to support this student’s educational progress. Content analysis is being used (in progress) to score educator responses for the number and quality of evidence-based strategies educators were able to name in their open-ended responses.

**Results:** Most participants were female (77.3%). Over half of the participants were currently employed as a general education teacher (n=213, 54.8%), 118 were employed as a special education teacher (30.3%), 11 were school counselors (2.8%), 2 were paraprofessionals or instructional aides (0.5%), 13 were school administrators (3.3%), and 30 chose to describe their current position as “Other” (7.7%).

Self-reported autism knowledge among educators was generally high, with most participants demonstrating “Adequate” knowledge across subscales (diagnosis/symptoms – 94.3%, etiology – 98.4%, treatment – 95.3%) and only 3.4% of educators endorsing autism-related stigma. ASK-Q scores were positively and significantly correlated with educators’ self-rated autism knowledge (r = .153, p = .009), knowledge of inclusive instructional strategies for autistic students (r = .134, p = .002), and belief in their ability to prepare autistic students for adulthood (r = .106, p = .038). Relationships between ASK-Q scores and self-efficacy with educator ability to nominate evidence-based inclusive strategies will also be explored when content analysis is completed.

**Conclusions:** Initial results support the hypothesis that autism knowledge relates to educators’ self-efficacy and ability to support autistic students within the classroom, even among educators with relatively high levels of autism knowledge. Results from qualitative content analysis will further elucidate if factual autism knowledge and self-efficacy are significantly related to educators’ actual ability to nominate evidence-based strategies to help autistic students succeed in inclusive settings. These findings inform efforts to assess educator autism knowledge, identify training needs among educators, and improve educational interventions for autistic students.

**405.314** (Poster) Examining Moderators of a Transition Intervention for Autistic Adolescents and Young Adults

**B. Tomaszewski, E. M. Lamarche, K. Bowman, C. B. Klein, M. L. Cook and L. G. Klinger, (1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, TEACH Autism Program, Chapel Hill, NC, (2)TEACH Autism Program; Psychiatry, UNC TEACH Autism Program, Chapel Hill, NC, (3)TEACH Autism Program; Psychiatry, University of Georgia, Chapel Hill, NC, (4)Psychiatry, TEACH Autism Program, UNC Chapel Hill, Chapel Hill, NC, (5)TEACH Autism Program, UNC Chapel Hill, Carrboro, NC

**Background:** The TEACH School Transition to Employment and Postsecondary Education (T-STEP) has demonstrated efficacy. Compared to a waitlist group, students receiving the T-STEP made greater improvements in parent-reported executive function and self-determination and student-reported self-determination, anxiety, and depression (Klinger et al., 2021). Few studies have examined the differential efficacy of transition interventions to identify for whom the intervention may work best.

**Objectives:** The objective of the current study was to examine moderators of T-STEP efficacy to identify characteristics of adolescents and young adults (e.g., IQ and symptom severity) who benefit most from the program.

**Methods:** 92 autistic adolescents and young adults ages 16-21 (M=18.47, SD=1.18) with average to above-average IQ (M=105.89, SD=15.21) were randomly assigned to complete the 12-week (5 hours/week) T-STEP program (N=45) or the Waitlist Control group (N=47). 73.9% of the participants were male, 70.8% were White, 19.1% were Black, 7.9% were Asian, and 7.6% were Hispanic or Latino. At pre-test, caregivers completed measures of autism symptom severity using the Social Responsiveness Scale-2nd edition (SRS-2), and autistic participants completed the WASI Full-Scale IQ-2. During the pre-test and post-test, autistic participants completed anxiety ratings using the State-Trait Anxiety Inventory and self-determination ratings using the AIR Self-Determination Scale (AIR-SDS). At pre-and post-test, caregivers completed measures of workplace readiness using the Becker Workplace Adjustment Profile (BWAP-2), executive
function using the Behavior Rating Inventory of Executive Function- Adult version, and self-determination using the AIR-SDS. Linear mixed models tested the moderation of autism symptom severity and IQ on the T-STEP intervention comparing the T-STEP intervention group and the Waitlist Control group from pre-test to post-test of self-determination, work adjustment skills, and executive function. Moderation was tested by incorporating a three-way interaction of InterventionGroupXTimeXModerator.

Results: There were significant three-way interactions for parent-reported BWAP-2 work adjustment, Est. = 0.33, SE = 0.12, t(73.11) = 2.72, p = .01, and parent-reported AIR self-determination, Est. = 0.24, SE = 0.09, t(79.8) = 2.59, p = .01 (See Figure 1). Parents of students receiving the T-STEP with SRS-2 scores one standard deviation above the sample mean (T-Score= 76.19) reported the highest increases in work adjustment scores on the BWAP-2 and AIR-SDS compared to the waitlist group, as compared to individuals with sample mean SRS-2 scores (T-Score =67.14) or those with SRS-2 scores one standard deviation below the sample mean (T-Score= 58.10). No other statistically significant moderators were identified.

Conclusions: Autism symptom severity was a moderator of the intervention effect, indicating that students receiving the T-STEP with the highest parent-reported autism symptom severity ratings in the severe range on the SRS-2 had the greatest improvement in parent-reported work adjustment skills and self-determination capacity compared to students with lower levels of autism symptom severity ratings. Notably, autistic students with milder symptoms, below the SRS-2 diagnostic cutoff, showed less significant change. IQ was not a moderator of treatment efficacy. This analysis suggests that the T-STEP is an effective intervention for students with significant autism symptoms and that those with fewer symptoms may not need as intensive of an intervention.

405.315 (Poster) Explore the Impacts of Continuous Theta Burst Stimulation over the Left Dorsolateral Prefrontal Cortex in Autism: A Double-Blind Randomized Sham-Controlled Trial
H. Y. Lin and H. C. Ni, (1)Department of Psychiatry, Centre for Addiction and Mental Health, Taipei, Canada, (2)Psychiatry, Chang Gung Memorial Hospital, Taoyuan, Taiwan

Background:

Despite previous open-label studies found the therapeutic potential of inhibitory repetitive transcranial magnetic stimulation (rTMS) over the dorsolateral prefrontal cortex (DLPFC) in autism spectrum disorder (ASD), there exist several methodological caveats especially lack of sham-controlled comparison group.

Objectives:

In our randomized, double-blind and sham-controlled trial, we aim to explore the feasibility and therapeutic effect of inhibitory continuous theta burst stimulation (cTBS, a modified variant of rTMS) over the DLPFC in individuals with ASD.

Methods:

We enrolled sixty intellectually able children and emerging adults with ASD (55 males/5 females, aged 8-30 years). Participants were randomized to a 16-session 8-week courses of cTBS (600 pulses/session)(n=30) vs. sham stimulation (n=30) targeting the left DLPFC. Outcome measurements included adverse events, clinical symptoms and adaptive and neuropsychological function at baseline, Week 8 and Week 12 (4 weeks after the last stimulation).

Results:

Most of the participants could tolerate the cTBS protocol. Ninety-eight percent of participants completed the protocol with mild and transient side effects. The Active stimulation was not superior to the Sham condition (null treatment by time interaction effects from baseline to Week 8 and to Week 12, respectively) on any clinical or neuropsychological metrics. We found remarkable time effects of 8-week cTBS on autistic symptoms and executive function from baseline to Week 8 and to Week 12, respectively, for both Active and Sham groups, with comparable effect sizes of changes in symptoms/cognition between groups. The response rates of 8-week cTBS over the left DLPFC were comparable between Active and Sham groups.

Conclusions:

Inconsistent with earlier findings, our RCT trial does not endorse that the inhibitory rTMS paradigm (cTBS) over the left DLPFC is an effective treatment for children and emerging adults with ASD. This study highlights the urgent need of double-blind and sham-controlled trials of rTMS/TBS for individuals with ASD, which is an infrequent practice in the existing literature.

405.316 (Poster) Factors Associated with Clinicians' Attitudes Toward the Delivery of Psychotherapy for Autistic Youth
**Background:** Despite evidence for the efficacy of psychotherapeutic approaches to address mental health challenges in autistic youth (Weston et al., 2016), they often struggle to receive interventions (Brookman-Frazee et al., 2012). Clinicians’ attitudes - their perceptions of the advantages and disadvantages of starting therapy – have been identified as an important correlate of clinicians’ intentions to deliver treatment (Maddox et al., 2019), though this work has largely focused on autistic adults. The Contact Hypothesis suggests that meaningful contact with, knowledge about, and experiences with individuals with disabilities are associated with positive attitudes and perceptions (Allport, 1954). It is important to understand, therefore, whether knowledge about autistic mental health and contact with autistic people may inform attitudes toward providing psychotherapy to autistic young people with mental health problems.

**Objectives:** To examine variables associated with clinicians’ attitudes toward delivering therapy for autistic youth.

**Methods:** Data were collected from 611 publicly funded clinicians across Ontario who provide psychotherapy to children and youth. Clinicians were 20 to 75 years old (M = 40.2, SD = 10.8; 84% Women; 79% White). Clinicians reported how favourable or unfavourable they felt towards delivering psychotherapy using opposite adjective pairs (e.g., Pleasant-Unpleasant, Good-Bad) and a sliding scale (10 to 0) (Fishbein & Ajzen, 2010). Clinicians self-rated their knowledge about mental health specific to autistic youth using a 5-point Likert Scale (1 = Not at All Knowledgeable; 5 = Extremely Knowledgeable; Maddox et al., 2019). They were asked if they knew an autistic person outside of their work (e.g., friends, family) and if yes, they were asked to report the frequency of contact with this individual (0 = No contact; 1 = Very rarely; 2 = Rarely; 3 = Occasionally; 4 = Frequently; 5 = Very frequently).

**Results:** Spearman’s correlations indicated that clinicians’ attitudes towards treatment were positively correlated with knowledge ratings (r = .48, p < .001) and their frequency of contact with an autistic individual outside of their work (r = .16, p < .001). Using multiple regression, clinician age was entered as a control variable, followed by knowledge and contact frequency. The model explained 21.8% of the variance in attitudes, with knowledge accounting for 18% (p < .001) and contact frequency no longer being a significant predictor (p = .39).

**Conclusions:** Our findings indicate that it may be important to increase knowledge about supporting autistic youth with mental health problems, and encourage contact with autistic people, given that these factors relate to clinicians’ attitudes toward treatment. There are several limitations to this research, including its correlational approach and the use of a single item to represent the frequency of contact. Future research could examine how clinicians’ attitudes toward providing mental health therapy may change following training initiatives and educational programs.

**405.317 (Poster) Factors Influencing the Sustained Use of Nine Programs from the Csesa High School Based Study for Autistic Students**

**L. J. Hall**, S. L. Odom, K. Hume, B. Kraemer, and L. E. Smith DaWalt. (1)Special Education, San Diego State University, San Diego, CA, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)University of Wisconsin-Madison Waisman Center, Madison, WI

**Background:** Although sustainability is one of the key phases of implementation frameworks (EPIS, NIRN) it is frequently an unstated aim of intervention and efficacy studies. Evaluations of the sustained use of interventions targeted in research is scarce, in part due to a lack of funding support. The data on the sustained use of each of nine intervention components in four areas (Social, Transition, Reading Comprehension, Independence & Behavior) that were part of a two-year CRCT study with 564 autistic youth is presented. This Institute for Education Sciences funded multi-site project – the Center on Secondary Education for Students with Autism (CSESAA) was conducted with 2 cohorts of 10 schools in each of three US states. The study model provided the opportunity to evaluate the sustained use of the targeted components for the 15 intervention schools from cohort 1 during the 3rd year.

**Objectives:**

- Identify which of nine program components implemented in 15 schools as part of a 2-year CRCT were reported to be used in the year following school participation.
- In the follow up year for 5 schools at one implementation site: Describe the fidelity of implementation for program components sustained; summarize responses to a Teaming and Impact survey and describe the impact of attrition of school personnel.

**Methods:** Data from a brief survey was collected from the site coordinator for each of the 15 intervention schools to determine which of the programs that were implemented with coaching sustained after the research ended. A mixed method evaluation of implementation was conducted at one of the sites for a dissertation study. Fidelity observations of sustained programs took place in schools. Site coordinators
completed a survey rating the teaming that occurred during the study and the impact of the study on students. Data on school personnel attrition was also obtained.

Results: Approximately 2/3 of the programs implemented during the two-year study were sustained at each of the three sites. Promoting Responsibility, Independence, and Self-Management (PRISM) was the only component implemented and sustained at all schools. Peer Supports (PS) and Alternative Achievement Literacy (AAL) were among the most sustained components and Transitioning Together (TT), Social Competence Intervention (SCI-H), and Collaborative Strategic Reading (CSR) among the least. There was a significant correlation at the .02 level ($r=.77$) between the percentage of the component sustained and the number of coaching sessions during the two-year study. Fidelity observations in the 5 schools at one site all achieved a score of 2.0 or more out of 3.0, which is considered moderate to high. There was a moderate and positive correlation between the mean score of the Teaming and Impact Survey and the number of components that sustained ($r=.68$).

Conclusions: The number of coaching sessions during the 2 year study was related to sustainment in the school. Other factors that also influenced sustainment included: if the component was similar to established programs in the schedule; if attrition in school personnel was high; if teams worked collaboratively; and if personnel found value in the program.

405.318 (Poster) Feasibility Study of Telehealth ESDM-Informed Caregiver Coaching Adapted for School-Aged Autistic Children with Co-Occurring ADHD

Background: Many autistic children have co-occurring ADHD. They are often diagnosed later, have more challenges with behavior, school functioning and friendships, and have caregivers with higher stress levels than those with autism alone. Effective services are needed, but medications are less effective and no therapy has yet been developed that supports the unique needs of autistic children with co-occurring ADHD.

Objectives: We evaluated the feasibility of a telehealth Early Start Denver Model (ESDM)-informed caregiver coaching intervention for school-aged autistic children with co-occurring ADHD. We offered 8 weekly, 1-hour coaching sessions and conducted a single arm pilot study to assess the acceptability, feasibility, and appropriateness of the approach and intervention impact.

Methods: Adaptations to traditional ESDM were documented using the Witseley Stirman Framework. Participants had confirmed DSM-5 diagnoses of ASD and ADHD. Mixed methods were used to assess acceptability, feasibility, and appropriateness of the approach, with qualitative data analyzed using directed content analysis and quantitative data analyzed using descriptive statistics. Impact on child and caregiver outcomes was assessed using longitudinal mixed effects models implemented in R (using lmer() from the lme4 package). Three specific adaptations were made to the intervention: (1) Strategies were included that support ADHD-related behaviors, while maintaining a primary focus on social communication; (2) The approach was adapted for older participants; and (3) Synchronous and asynchronous telehealth versions were developed. 24 caregiver-child dyads completed coaching. Participant mean age was 103 months (SD=20), mean IQ was 95 (SD=19), 75% were male, 42% were Black/more than one race, 30% had co-occurring conditions other than ADHD, and 75% were on a psychotropic medication. 80% of caregivers were mothers, 50% were not working, 35% reported household income less than the US median, and on average participants lived 50 miles from the study site.

Results: Caregivers reported the intervention was acceptable, feasible and appropriate, suggested adaptations to improve fit, and noted improvements (See Table 1). Caregiver ratings of coaching were high on 3 pragmatic measures of acceptability, appropriateness and feasibility (AIM mean=4.7/5, SD=0.4; IAM mean=4.6/5, SD=0.7; FIM mean=4.6/5, SD=0.5). Children demonstrated improvements in social communication abilities and decreases in ADHD-related behaviors. Joint Engagement Rating Inventory composite scores increased significantly over time ($t=3.74, p=0.006, ES d=1.25$). There was a significant increase in Vineland Adaptive Behavior Scales-3 Communication ($B=0.32, t=2.42, p=0.02, ES d=0.32$) and Socialization scores ($B=0.44, t=4.70, p<0.0001, ES d=0.57$). Social Responsiveness Scale-2 total t-score significantly decreased ($B=-0.33, t=-4.39, p=0.0001, ES d=-0.57$), as did total ADHD-Rating Scale score ($B=-0.32, t=-2.78, p=0.008, ES d=-0.70$). Caregivers learned to use intervention strategies and reported decreases in caregiver strain, reflected by ESDM caregiver fidelity ratings increasing significantly ($B=0.43, t=5.79, p=0.0001, ES d=1.87$), and Caregiver Strain global scores decreasing significantly ($B=-0.06, t=-3.38, p=0.002, ES d=-0.58$).

Conclusions: This feasibility study is an initial step towards addressing the intervention gap impacting school-aged autistic children with co-occurring ADHD. We demonstrated the approach was acceptable, feasible, and appropriate and positively impacted child and caregiver outcomes. A planned hybrid type I effectiveness-implementation trial will evaluate intervention efficacy and identify implementation determinants.
Feasibility of the Yoga Bali Program Intervention for Adolescents with Autism Spectrum Disorder and Their Parents: Exploring the Effect of Yoga Practice on Anxiety, Quality of Life and Attention.

M. J. Beaudoin and N. Poirier, (1)Université du Québec à Montréal, Montréal, QC, Canada, (2)Psychology, Université du Québec à Montréal, Montréal, QC, Canada

Background: Adolescents with autism spectrum disorder (ASD) and their parents are at risk of presenting low levels of quality of life (QoL). Comorbidities, such as anxiety disorder and attentional deficits, are known to be risk factors of a poor QoL in this clinical population. Among parents, lack of professional resources, feeling of social isolation and parental stress are transactional factors that contribute to reducing their QoL. Studies have suggested that yoga, as a complementary intervention for adolescents with ASD and their parents, can reduce anxiety and enhance QoL and concentration.

Objectives: Therefore, our study aims to explore the effect of yoga practice among adolescents with ASD and their parents using the model of attentional regulation of Gard and al. (2014) as a theoretical framework.

Methods: We first adapted the yoga Bali program to the needs of adolescents with ASD and their parents. An exploratory study on the feasibility of the program has been done with six families (6 adolescents with ASD: 5 boys; 1 girl; age: M = 15.17; SD = 1.83; 6 mothers; 2 fathers; age: M= 47.5; SD = 2.77) completing the 8 weeks yoga program. Participants responded to the TARF-R questionnaire and took part in semi-structured interviews. Anxiety symptoms, QoL and attention abilities were measured before and after the program with the MASC-2, WODQOL-Brief and D2-R. Nonparametric Wilcoxon rank comparison, descriptive and frequency analyses were run using SPSS 28 and thematic qualitative analyses were completed.

Results: Feasibility analyses showed a zero dropout rate with 93% of the participants that completed all the yoga classes. Of all participants, 71.5% reported that yoga helped them managed their anxiety. Qualitative analyses showed three key thematic brought up by parents: lack of professional resources, stress related to work and social cohesion in the program. In adolescents, two main thematic were highlighted: stress related to school and appreciation of the relaxation during yoga classes. Results showed no significant changes on the MASC-2 scales score of anxiety levels of symptoms. For parents, QoL global index score on the WHOQOL-Brief was significantly higher after the program (p < .05). For adolescents, concentration performance scores on the D2-R test were significantly higher after the program (p < .05).

Conclusions: Results suggest that the yoga Bali program has a good level of social acceptability and an acceptable feasibility. Our findings highlighted positive outcomes of yoga practice on anxiety, stress management, QoL and concentration levels. These results corroborate previous scientific findings and is in line with Gard and al. (2014) theoretical framework. Compared to previous studies, our study did not find significant changes in adolescents’ level of anxiety after their participation in the yoga program. Statistical test sensibility could have been reduced due to our low number of participants paired with high baseline levels of anxiety. Nonetheless, most participants perceived that yoga practice helped them manage their anxiety symptoms. Finally, our findings bring new insight on the effect of yoga practice and the social response to yoga as an intervention among adolescents with ASD and their parents.

Food Selectivity Inventory: Proof of Concept of a Novel Self-Report Measure

Background:

Food selectivity is a critical concern for many autistic school-age children and adolescents. As treatments for food selectivity are developed and refined, identifying meaningful, sensitive, and developmentally appropriate outcome measures is crucial. Existing measures capture treatment changes that may be too distal and do not reflect the incremental changes observed when expanding flexibility to eat new or nonpreferred foods. Moreover, existing food selectivity treatment outcome measures do not capture the direct, lived experience of autistic youth.

Objectives:

1. Develop the Food Selectivity Inventory (FSI), an online, picture-based assessment tool designed for child self-report.
2. Explore novel characterization variables that could be outcome variables in food selectivity treatment trials.
3. Evaluate preliminary psychometrics of the FSI.

Methods:
Eighty-seven autistic youth (7-16 years, M=10.8, SD=2.8; 26F:61M) and their parents completed the online FSI. Participants viewed pictures of foods within a particular food group or category (Figure 1) and indicated which foods they eat among those presented (food repertoire). Further ratings characterized novel possible outcome variables, including cognitive willingness, idiosyncratic eating, eating accommodations, and domain-specific impact (Table 1).

Results:

Across five food groups (grains, fruit, protein, dairy, vegetable), participants reported a food repertoire ranging from 3 to 53 (M=26.8, SD=26.8) of the 55 overarching food categories (e.g., berries, beans, green vegetables) presented. Participants then indicated a willingness to taste an additional 0 to 24 (M=6.5, SD=4.6) foods if they were asked. Thirty-two (36.8%) participants reported that their child is idiosyncratic about eating food. Of the foods participants reported eating, they described idiosyncrasies for 0-100% foods (M=29.6%, SD=28.8%).

Parents reported the most frequently endorsed accommodation strategies were to give their child only what she/he will easily eat and to send separate meals/snacks to events outside the home (mean accommodations used=4.6, SD=3.2; of 15 total accommodations). 10% of parents reported not using any of the possible accommodations. Both children and parents reported eating to interfere with emotional well-being, relationships, daily life activities, social experiences, and health/nutrition, at an average of a few times a week.

Psychometric evaluation of the FSI suggests evidence of criterion validity. 66 parents (76%) reported that they would describe their child as a picky eater. Picky eaters had a significantly smaller food repertoire, $F(1,85)=55.4, p<.001$ and a significantly more idiosyncrasies about foods than those described as not picky. Total food repertoire was negatively correlated with overall impact of eating on daily life ($r=-.48, p<.01$), such that eating fewer foods was associated with a greater impact of eating on daily life.

Conclusions:

The FSI offers promise as a characterization and possible outcome measure for food selectivity. Results document children’s cognitive willingness to eat foods not currently in their food repertoire, identifying a treatment entry point and potential measure of food flexibility and treatment change that is missed in food repertoire or intake measures. Individual differences and use of the full range of responses suggests that these novel variables may provide granular measurements of treatment progress. Preliminary evidence of criterion validity is a first step toward validating this new measure.

405.321 (Poster) Gaming Therapy: A Realist Evaluation

M. H. Black¹²³, O. Falkmer⁴, H. H. Wee³, A. Lilford³, E. Walker³, T. V. Nguyen³ and S. McGarry³, (1)Center for Neurodevelopmental Disorders & Center for Psychiatry Research, Dept. of Women's and Children's Health, Karolinska Institutet, Stockholm, WA, Sweden, (2)Child and Adolescent Psychiatry Stockholm, Stockholm, Sweden, (3)Curtin School of Allied Health, Curtin University, Perth, Western Australia, Australia, (4)Humdrum, Perth, Western Australia, Australia

Background:

Neurodivergent youth can experience challenges in social functioning that can adversely affect their overall well-being and health. An increasingly used form of intervention to support neurodivergent youth to develop skills is Gaming Therapy. As Gaming Therapy is an emerging intervention, its active ingredients contributing to outcomes are still ambiguous.

Objectives:

The aim of this study was to explore the contexts, mechanisms and outcomes of a Gaming Therapy program for neurodivergent youth.

Methods:

A qualitative ethnographic study guided by a realist evaluation approach was employed to determine the contexts, mechanisms, and outcomes (CMOs) of a Gaming Therapy program delivered at a disability service and support organization located in Perth, Western Australia. A realist evaluation approach is concerned with identifying what works, for whom, and under what conditions. Interviews and observations were undertaken with neurodivergent youth attending the gaming therapy (n=4) and gaming therapy facilitators (n=2). Interviews were also conducted with caregivers of neurodivergent youth attending gaming therapy (n=5).

Results:
Four context themes, three mechanisms themes, and three outcome themes were identified. Contextual factors included personal factors of the neurodivergent youth (skills, interests, and support needs), personal factors of the caregiver (their attitudes toward technology, gaming, and family goals), facilitator factors (their interests and clinical experience), and institutional factors (resources and funding). Mechanisms included activity design (therapy goals and activity choice, fun, online engagement), and environment (peer interaction, parental involvement, physical environment). Whilst outcomes found included skill development (social skills, emotion regulation), motivation (motivation to attend current and future services, confidence).

Conclusions:

The realist evaluation demonstrates the complex interaction between the contexts, mechanisms, and outcomes associated with gaming therapy. Harnessing the interests of youth in gaming therapy and allowing them to demonstrate expertise during the therapy process provided children with a safe environment through which to practice and develop their skills. Engaging in the gaming therapy motivated youth to be willing to engage in future interventions and supported them to develop their skills in communicating their needs, engaging with others, and regulating their emotions. Through the realist evaluation, this study provides a framework for the why, how, and for whom gaming therapy works.

405.322 (Poster) Gender Differences in the Wellbeing of Autistic Adolescents in Contrasting School Placements: A Cohort Study with a Control Group

A. H. Cook, Department of Psychology, Goldsmiths, University of London, London, United Kingdom

Background:

The most appropriate educational setting for a child is one in which they are fully included in the life of the school community, and which gives them a sense of belonging and achievement (Warnock & Norwich, 2010). Inclusion is important for reasons of social justice, but research from the UK’s National Autistic Society (NAS) and All-Party Parliamentary Group on Autism in 2017 reported lack of teacher understanding, low levels of happiness in autistic pupils and rising levels of school exclusions. In response, specialist resource centres (SRCs) were established in five mainstream secondary schools in Southeast England, providing specialist support and a calm space to which autistic students can retreat. The provision of this ‘zone of safety’ aims to give students a sense of control and develop their sense of school belongingness (SOSB) leading to improved academic, social and emotional outcomes. Previous research documents gender variations in mental health and wellbeing of autistic adolescents, but to date there is a scarcity of research on the impact of contrasting school placements on SOSB, mental health and social outcomes according to gender.

Objectives:

The current study explored whether autistic adolescents’ SOSB, social outcomes and mental health varied according to gender and school placement (SRC vs. non-SRC placement).

Methods:

Survey data were collected from 100 autistic pupils aged 11 – 15 (72 identifying as male; 28 identifying as female) from seven mainstream schools: five with SRCs and two without. Participants completed measures of internalising symptoms (peer problems and emotional problems) at the beginning and end of their school year. In addition, SOSB, friendship quality and victimisation were measured at the second time-point. Two-way between-groups analyses of variance were conducted to explore interactions between gender and school placement.

Results:

Regardless of placement type, girls' internalising symptoms increased more than boys’ over the course of the year, with a large effect size ($\eta^2 = 0.11$). Furthermore, there were significant gender x school placement interactions for all cross-sectional measures: While no gender differences occurred for students with SRC placements, significant differences were found in non-SRC placements, whereby girls displayed lower SOSB, lower friendship quality and higher victimization than boys when they are in non-SRC placements.

Conclusions:

While autistic girls show poorer social and mental health outcomes than boys overall, placement in a SRC may help to close the gap, improving their SOSB and social outcomes in contrast to those in non-SRC placements. These findings can be interpreted according to the theory of camouflaging in females, which explains how girls are more likely to mask autistic characteristics due to increased sensitivity to social pressure to fit in. Placement in a SRC may decrease this pressure, reducing the psychological burden. The less favourable findings for boys in SRC placements may relate to level of support needs/co-occurring conditions but may also be accounted for by a heightened
sense of stigma associated with their placement. The findings highlight a growing need to consider gender differences in school placement and have implications for inclusive practice and policy.

405.323 (Poster) How Autism Educators May Better Support Their Students’ Challenging Behaviors and Emotion Regulation: A Needs Assessment

S. Deswert, F. Khan, A. Young, E. Palermo, E. Becker-Haim et al., A. Brown, C. A. Mazefsky, R. S. Beidas, L. Brookman-Frazee, D. S. Mandell, and H. J. Nuske, (1)Penn Center for Mental Health, University of Pennsylvania School of Medicine, Philadelphia, PA, (2)Sociomedical Sciences Department, Mailman School of Public Health, Columbia University, New York, NY, (3)Penn Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (4)University of Pennsylvania Health System, Hall Mercer Community Mental Health, Philadelphia, PA, (5)Penn Center for Mental Health, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, (6)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (7)Northwestern University Feinberg School of Medicine, Chicago, IL, (8)Psychiatry, University of California, San Diego, La Jolla, CA

Background: Children on the autism spectrum often engage in behaviors, such as aggressive behaviors towards self or others, that are dangerous to the student, others, or interfere with learning and development. Autism educators are responsible for supporting their students’ educational development while addressing these challenging behaviors (CBs) and supporting students’ emotion regulation. Educators often feel ill equipped to fulfill the demands of their role, which jeopardizes students’ educational and personal success. Previous research has identified that autism educators need staff training, collaboration between educators and with parents, and physical resources. To our knowledge, no study has examined the barriers and facilitators educators and administrators face in supporting students on the autism spectrum with emotion regulation and addressing CBs.

Objectives: To elucidate the facilitators and barriers autism educators face in addressing challenging behaviors and supporting emotion regulation in students on the autism spectrum.

Methods: We conducted semi-structured interviews with 38 educators/administrators working with students on the autism spectrum in preschools or elementary schools in a large urban public school district regarding needs, barriers, and facilitators to supporting emotion regulation and addressing CBs in their students. The sample included 28 autism support teachers, 3 classroom aides, 1 special education liaison, and 6 school administrators to incorporate multiple perspectives. We utilized a modified grounded theory approach to iteratively develop a codebook and identify emergent themes across these perspectives on the needs, barriers, and facilitators expressed in these conversations.

Results: Educators expressed needs relating to increased physical resources (e.g., sensory supports for self-regulation), human resources (e.g., one-to-one instruction on calming techniques), and quality of staff training (e.g., training on identifying behavior triggers). Educators expressed barriers relating to poor school team collaboration (e.g., general education teachers stigmatizing CBs), difficulty understanding students (e.g., students’ difficulty with verbally communicating needs and stress), and inadequate resources (e.g., high staff turnover leading to inconsistent support for students). Educators expressed facilitators relating to good school team collaboration (e.g., teamwork in addressing and de-escalating CBs) and positive parental involvement (e.g., parents’ willingness to implement emotion regulation strategies at home). Administrators concurred that an important barrier to address is a lack of team communication surrounding triggers to behaviors and CBs and that facilitators include providing training/support to educators and an interdisciplinary approach to good school team collaboration. Of all responses from educators/administrators, 79% described needs, 74% described barriers, and 53% described facilitators.

Conclusions: Educators and administrators identified several barriers, but also identified potential facilitators that help minimize the impact of these barriers for particular students/instances of CB, such as good school team collaboration and positive parental involvement. They also expressed that ultimately the majority of these barriers could be addressed with investments in the identified needs such as more physical and human resources as well as higher quality staff training. This qualitative analysis provides a nuanced understanding of how school districts and preschools could empower their staff to effectively support their students’ educational, behavioral, and emotional development. Further research is needed to analyze whether these findings generalize to other school districts.

405.324 (Poster) How Is Social Validity Measured in Intervention Research on Transition-Age Autistic Youth?

K. Bottema-Beutel, S. Y. Kim, S. LaPoint, S. Mohiuddin, Q. Yu, and R. McKinnon, (1)Lynch School of Education and Human Development, Boston College, Chestnut Hill, MA, (2)Duksgn Women’s University, Seoul, Korea, Republic of (South), (3)University of North Carolina-Chapel Hill, TEACCH Autism Program, Carrboro, NC

Background: We recently conducted a systematic review/evaluation of intervention research on transition-age autistic youth. Of the 193 studies in this review, 181 studies used single-case research designs (SCDs), and ~70% examined behaviorally-based interventions. Research guidance on SCDs stipulates social validity should be examined alongside intervention efficacy, to ensure the intervention is acceptable to stakeholders (Horner et al., 2005). We conducted a secondary analysis of this review, to determine how social validity was defined, assessed, and interpreted. Our motivation was two-fold. First, research quality is increasingly questioned in autism research (Sandbank et al., 2019), and this has included critiques of social validation procedures (Schwartz & Baer, 1991; Ledford et al., 2016).
Second, social validity may be particularly important to examine in intervention studies that involve autistic youth, because many of these youth have expressed dissatisfaction toward the services available to them (Bottema-Beutel et al., 2019).

Objectives: We sought to determine:

- What proportion of studies assessed social validity?
- What dimensions of social validity were assessed, including the acceptability of the goals, acceptability/feasibility of the procedures, and perceived importance of the outcome?
- What were the features of the social validation procedures, in terms of data collection methods and measures, timing of the assessment (e.g., before, during, and/or after the intervention), scoring/analysis procedures, and selection of informants?
- How were the findings of social validity assessments interpreted?

Methods: Two coders examined each study according to whether social validity was assessed, the dimensions included in the assessment, the assessment procedures, and how the results of the assessment were reported and interpreted. Inter-coder agreement ranged from 80%-100% across categories.

Results: Studies included 987 youth (809 Male, Mean age = 17 years), and 53% of studies measured social validity. Of these, 51% assessed the acceptability of the goals, 86% assessed the acceptability of the procedures, 82% assessed the perceived importance of the outcomes, and 43% assessed all three dimensions. Table 1 shows the percentage of studies that employed various social validation procedures, and Table 2 shows how assessment results were interpreted.

Conclusions: Social validation assessments are too infrequently used in intervention research on transition-age autistic youth, and when they are used the assessment procedures are often incomplete, poorly described, rely on unvalidated data collection instruments, and/or are not analyzed by robust procedures. Interpretations of social validity assessments are heavily skewed in favor of the intervention. Given the cursory nature of social validation procedures, we are unable to say whether current interventions hold promise in terms of the acceptability of the goals, the acceptability and feasibility of the procedures, and the perceived importance of the outcomes. Given that the transition period is a point at which autistic youth are expected to have more autonomy and choice in regards to the types of educational strategies they receive, it is critical that these youth are given socially valid intervention options. To be neurodiversity-affirming, autism interventions should be designed with autistic people’s input, focused on priorities they endorse, and adapted to meet individual preferences and needs.

Background: Anxiety is common for autistic people and impacts on quality of life and social participation. Autistic people may experience multiple anxiety disorders concurrently and the features/presentation of anxiety may differ from neurotypical populations. Clinical guidance recommends psychological therapies as the first-line treatment for anxiety, with some emerging evidence they can be effective with autistic people. However, for these therapies to be accessible they need to be individualised. PAT-A is an intervention comprising modular, adapted psychological treatments designed to tailor flexibly to the individual needs of autistic adults experiencing anxiety.

Objectives: To explore preliminary evidence for the utility of PAT-A in treating anxiety experienced by autistic adults.

Methods: We recruited thirty-four autistic adults with clinically significant anxiety via UK clinical services for an RCT designed to assess the feasibility and acceptability of PAT-A (feasibility and acceptability findings have been reported previously). Participants were randomised to receive PAT-A (N= 17; 65% male; mean age= 39.5) or Enhanced Services as Usual [ESAU] (N= 17; 65% male; mean age= 33.1). The median number of current anxiety disorders experienced by participants in each group was three. Participants completed several outcome measures at baseline and three months post-intervention. Key outcome measures included Target Situations Vignettes: an established procedure to assess real-life change in two pertinent anxiety-related situations (assessed by four independent, blinded researchers). The Global Clinical Impression of Improvement (CGI-I) rating scale involved a blinded independent researcher rating change across a variety of clinical outcome measures. Participants in the PAT-A group were interviewed at end of trial about their experiences of treatment: thematic analysis undertaken of verbatim responses.

Results: All participants were recruited and completed baseline measures pre-COVID-19 pandemic. In the PAT-A group, 11/16 participants completed their follow up measures during the pandemic compared with 4/14 in ESAU. Some outcome measures could not be rated due to pandemic restrictions (e.g., target situation was to eat at a restaurant but at follow up restaurants were closed). Of the target situation vignettes rated, 48% in PAT-A group were judged to have showed evidence of improvement compared with 41% of ESAU group.
Using CGI-I, 62% of rated participants in PAT-A group showed evidence of positive change vs 30% in ESAU. Thematic analysis revealed four themes: 1) transferable skills; 2) adjusted to meet the needs of autistic people; 3) positive impact of PAT-A; 4) more sessions needed. One participant (female, aged 37) reported: “I’ve had therapy since I was 17 and this was by far the best therapy I have had...it has helped me so much... I have grown so much and learned so much about myself.”

Conclusions: This flexible and modular intervention shows promise in treating anxiety in a sample of autistic adults with multiple anxiety disorders. COVID-19 impacted on both the anxiety experiences of people and the interpretability of the findings. Despite this, the evidence of feasibility and successful recruitment and delivery of both interventions support the need for a future fully powered RCT to evaluate the clinical efficacy of PAT-A in autistic adults with anxiety.

405.326 (Poster) Rubi Goes to Town: Child Outcomes and Providers' Views on Implementing an Evidence-Based, Parent-Mediated Intervention for Autism and Disruptive Behavior in the Community

Y. Sinai-Gavrilov, S. Netzer, A. Rose, E. Y. Cohen, A. Binet, D. Costa and J. Koller, (1)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel, (2)Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel, (3)Autism Treatment and Research Center, Association for Children at Risk, Givat Shmuel, Israel

Background: The importance of disseminating and integrating high-quality, evidenced-based interventions for autistic children and their families cannot be overstated. One such intervention, designated for parents of children with autism and disturbing behaviors (DBs; e.g. noncompliance, aggression, and tantrums), is the Research Unit in Behavioral Intervention (RUBI). This is a time-limited, manualized, and parent-mediated intervention protocol, shown to be effective in one-on-one (Bearss et al., 2015) and group settings, in face-to-face or an online format (Graucher et al., 2022). As up to 50% of children with autism also present DBs, there is significant need for effective, community-delivered interventions that target such behaviors. However, up until now, the integration and implementation of RUBI in community settings has not been examined.

Objectives: The current study assesses the dissemination of RUBI program in community settings in Israel, focusing on child outcomes (i.e. reduction in DBs), and clinician perceptions of the intervention and its’ implementation process.

Methods: 17 parents of children aged 3-10, and 9 therapists, from 3 community sites participated in the current study, which is ongoing. RUBI was delivered for 12 weeks, in group and one-on-one formats, by clinicians supervised by a certified behavioral analyst. Child outcome was measured using the parent-report Aberrant Behavior Checklist (ABC). Additionally, clinicians who delivered the intervention participated in semi-structured interviews after their completion, to assess their perceptions of this intervention and its’ integration process in their respective settings.

Results: Paired sample t-tests demonstrated a significant decrease in ABC Irritability (t[16] = 2.26, p < .05), Social Withdrawal (t[16] = 2.65, p < .05) and Hyperactivity (t[16] = 2.61, p < .05) scores, from pre to post intervention. Qualitative investigation of the interviews with therapists revealed several facilitative factors in the protocol’s implementation, including the protocol’s practicality and accessibility, staff beliefs regarding the evidentiary support of the RUBI, parental attendance, commitment and collaboration, and the relationship between the research teams and the implementing staff. Barriers to successful implementation included time limitations, funding issues, and logistical challenges.

Conclusions: This study provides support for the effectiveness of RUBI when integrated in community settings and implemented by community practitioners. RUBI is an evidence-based protocol that lends itself to effective integration and implementation in community-based settings. However, barriers to successful implementation were observed by community practitioners and must be addressed. Increased longitudinal exploration of RUBI’s implementation process is necessary in order to assess the long-term feasibility, acceptability, and demand for the protocol in community settings.

405.327 (Poster) Self-Set Goals: Facilitating Self-Support for Autistic Adults.

L. Camilleri, K. L. Maras and M. Brosnan, (1)Psychology, University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom

Background:

Most interventions for autism seek to address perceived challenges associated with autism, rather than identify what the autistic individual wants support with. Digitally-mediated social stories are a highly acceptable intervention within the autistic community, that offer the potential to empower autistic people to support themselves.

Objectives: A participatory research design was carried out to investigate the usefulness and the effectiveness of digitally-mediated social stories for autistic adults to support themselves.

Methods:
Thirty-three participants self-set goals and self-developed social stories to address these goals using a free digital application co-developed with the autistic community (SOFA-app.org). Measures of closeness to self-set goal (from 0 to 10) were collected at baseline and after two weeks of developing then reading their digital stories to themselves.

Results:

The participants reported closeness-to-goal mean ratings at baseline (M = 2.73, SD = 2.43) and after for two weeks (M = 6.94, SD = 2.62). The use of a digitally mediated social stories elicited a significant mean increase of 4.21 (SD = 2.57), 95% CI [3.30, 5.12] in closeness-to-goal ratings, 95% CA [3.30, 9.41], t(32) = 9.41, p < .001. A Cohen’s d of 1.67 is indicative of a large effect size.

The participants’ self-set goals were inductively analysed by two judges independently, with any disagreements resolved by a third judge. This analysis resulted in five categories of self-set goals: (1) decrease non-social behaviours, (2) increase non-social behaviours, (3) decrease social behaviour, (4) increase social behaviour, and (5) decrease anxiety. The interrater agreement was 97%. Cohen’s κ was also run to determine if there was agreement between the researchers’ judgement. There was a very strong agreement between judgements, κ = .944, p < .001. There was no statistically significant difference between type of self-set goal and change in closeness-to-goal ratings, F(1, 31) = 0.01, p = .99.

Twenty (n=20) of the participants also self-set a ‘Control Goal’ that was not supported by a social story. There was a statistically significant increase in closeness-to-goal ratings for the Control Goal from baseline ratings (M = 1.80, SD = 1.77) to outcome ratings after 2 weeks (M = 3.30, SD = 1.69) of 1.50 (SD = 1.00), 95% CI [1.03, 1.97], t(19) = 6.71, p < .001, d = 0.87. The mean change in closeness-to-goal for the Control Goal (M = 1.50, SD = 1.00) was lower than for the self-set goal for which a digitally-mediated social story was written (M = 4.30, SD = 2.18). There was a significant difference in mean change in closeness-to-goal ratings of 2.80, 95% CI [1.66, 3.94], t(19) = 5.13, p < .001, d = 1.65. There were no discernible differences in the attainment of self-set goals between those who did and did not set a Control Goal.

Conclusions:

The findings highlight that digitally mediated social stories can enable autistic adults to support themselves to address self-set goals they themselves want to achieve. Analysis of the participants’ self-set goals indicated that autistic adults predominantly identified a need for support with increasing non-social behaviours.

405.328 (Poster) Using Digitally-Mediated Social Stories to Improve Procedural Integrity and Support Engagement with ‘Social Humility’ in Parents of Autistic Children.

L. Camilleri, K. L. Maras1 and M. Brosnan1, (1)Psychology, University of Bath, Bath, United Kingdom, (2)university of bath, bath, United Kingdom, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom

Background:

Social stories are a support tool which are widely-used by the broader autism community. However, poor procedural integrity has resulted in a high degree of variability in outcome research. Poor procedural integrity can be addressed through a free digitally mediated social stories co-developed with the autistic community (SOFA-app.org). Recent guidelines on the development of social stories have highlighted ‘social humility’ as key for effectiveness of the intervention. Social humility involves acknowledging that lack of understanding between autistic and non-autistic people is a two-way issue. Digitally mediated social stories can increase procedural integrity, and also encourage social humility in parents, by actively engaging with their children when identifying goals in the process of developing social stories.

Objectives:

A pre-and-post quasi experimental design was carried out with 17 parents of autistic children, to investigate the effectiveness of parent-developed social stories, and to explore the impact of engaging with children in the development of stories. 8 parents identified goals with their children, and 9 parents identified goals for their children.

Methods: Stories were developed and delivered in a digital modality (SOFA-app). Autistic children accessed the stories daily for two weeks by using the digital application. Parents completed closeness to goal rating (from 0 to 10) at baseline and after two weeks. A control goal was also identified and rated, that was not addressed with a social story.

Results:
Mean baseline closeness to goal was 3.12 (SD = 1.90) and outcome closeness to goal rating after 2 weeks was 7.41 (SD = 2.09). There was a statistically significant mean increase of 4.29, 95% CI [2.90, 5.69], t(16) = 6.53, p < .001. A Cohen’s d of 1.58 indicates a large effect size.

The mean closeness to control goal rating at baseline was 2.82 (SD = 1.94) and the mean outcome closeness to goal ratings after 2 weeks was 2.88 (SD = 2.18). The mean difference of 0.59 was not statistically significant, 95% CI [-0.353, 0.471], t(16) = 0.251, p = .80.

From the 17 participants, 8 consulted with their children prior to creating a social story, and 9 did not. An independent-samples t-test was run to determine if there were differences in change in closeness to goal rating between the parents who consulted and those who did not consult with their children. The change in closeness to goal was higher for parents who consulted with their children (M = 5.88, SD = 2.23) than parents who did not consult with their children (M = 2.89, SD = 2.37). The difference, M = 2.98, is a statistically significant difference, 95% CI [0.598, 5.374], t(15) = 2.67, p = .018.

Conclusions:

The findings indicate that digitally mediated social stories are effective at supporting parents of autistic children to reach the social story goal. Furthermore, social stories that were developed together with the children were more effective. Digitally-mediated social stories, therefore, have the potential to improve procedural integrity and can enable parents to engage with social humility when developing social stories, which enhances effectiveness.

### POSTER SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

**435 - Interventions - Non-pharmacologic - School-Age, Adolescent, Adult II**

**435.233 (Poster)** Improvements in Internalizing Symptoms in Autistic Adolescents in Response to a Single Session Online Growth Mindset Intervention

_A. S. Nahmias, S. Honovic, A. H. Gerber, J. Schleider, and M. D. Lerner_, (1)Department of Psychiatry and Behavioral Health, Renaissance School of Medicine at Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY, (3)Yale University Child Study Center, New Haven, CT, (4)Department of Psychology, Stony Brook University, Stony Brook, NY

Background: Autistic youth experience elevated rates of co-occurring internalizing disorders (Rosen et al., 2018), but standard interventions are often time-intensive and costly (Buescher et al., 2014; Kazdin & Blase, 2011). The COVID-19 pandemic further exacerbated the need for brief, scalable mental health interventions due to increased mental health symptoms and barriers to care for autistic youth (Ameis et al., 2020; Colizzi et al., 2020; Manning et al., 2020; L.C. White et al., 2021; S.W. White et al., 2021). Single-session interventions (SSIs) offer a scalable solution to this challenge. Project Personality (PP), a growth-mindset SSI, has shown reliable, replicated, and robust effects on depression and anxiety symptoms in neurotypical adolescents (ds = .28-.60; Schleider et al, 2019, Schleider & Weisz, 2018; Schleider & Weisz, 2016). If beneficial for autistic youth, the scalability of SSIs makes them a prime option to reduce barriers and increase equitable access to care for underserved populations, such as those from low-income or economically marginalized (LIEM) backgrounds.

Objectives: To assess the preliminary results of a randomized control trial of an online growth-mindset SSI in autistic adolescents from across the United States.

Methods: 12 autistic adolescents (Mage = 13.9, SDage = 1.7; 83.3% male; 41.7% LIEM) with a parent-reported Autism Spectrum Disorder diagnosis and parent-reported IQ ≥ 70 were randomly assigned to a 30-minute growth-mindset SSI (PP) or active control (a structurally similar computer-based program mimicking supportive therapy; ST). All study activities were completed online. Adolescents and a caregiver completed standardized questionnaires related to depression (Children’s Depression Inventory 2; CDI-2; Kovacs, 2010), anxiety (Multidimensional Anxiety Scale for Children-2; MASC-2; March, 2012) and executive functioning (Behavior Rating Inventory of Executive Function-2; BRIEF-2; Gioia et al., 2015) before the SSI and 3 months later. ANCOVA of change analyses controlling for pre-intervention scores were run. Data collection is ongoing. To date, nine youth have completed three-month follow-up questionnaires.

Results: There were no differences across the measures between groups pre-intervention. At three-month follow-up, the PP group self-reported greater decreases in CDI-2 Total (B = -5.1, p < .03) and MASC-2 Tense/Restless (B = -16.9, p < .02) t-scores than the ST group. Additionally, caregivers of PP adolescents reported greater decreases in MASC-2 Tense/Restless (B = -8.1, p < .01), Separation Anxiety/Phobias (B = -7.8, p < .02), Generalized Anxiety (B = -13.3, p < .05), and Social Anxiety (B = -11.8, p < .02) and BRIEF-2 Shift (B = -10.3, p < .001) and Emotional Control (B = -6.5, p < .026) subscale t-scores than those randomized to ST.
Conclusions: Decreases in anxiety and depression symptoms were reported by autistic adolescents and their caregivers three months after participation in a brief online growth-mindset SSI. Caregivers also reported decreased inflexibility and emotion regulation challenges. These results suggest that Project Personality may be a promising, time- and cost-effective intervention for addressing internalizing symptoms in autistic youth, particularly for those from LIEM backgrounds who face increased challenges accessing traditional services. Future research should continue to evaluate the efficacy of SSIs and for which individuals these interventions are most beneficial.

435.234 (Poster) Improving Psychosocial Adaptation in Adults with Autism Spectrum Disorder through an Intervention Program Focused on Executive Functioning

J. Kim, D. Y. Song, H. S. Han, G. Bong, K. H. Choi and H. Yoo, (1)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Department of Psychiatry, Seoul National University, Seoul, MD, Korea, Republic of (South), (3)Department of Neurology, Samsung Medical Center, Seoul, Korea, Republic of (South), (4)Department of Psychiatry, Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of (South), (5)Psychiatry, Seoul National Univ Bundang Hospital, Seongnam, Korea, Republic of (South)

Background: Individuals with autism spectrum disorder (ASD) experience difficulties with executive functioning (EF), which is often correlated with adaptive skills and is used in various daily activities throughout one's lifespan.

Objectives: The purpose of this study is to conduct a randomized controlled trial to investigate the changes in psychosocial adaptation of high-functioning adults with ASD (HFASD) by participating in an intervention program targeting to enhance EF skills.

Methods: The program, which aims to improve everyday EF and adaptive behavior, consists of sessions covering topics related to EF skills (i.e., organization, planning, time management, emotional regulation, and cognitive flexibility), and sessions that promote the application of EF skills in daily living activities (i.e., financial management, adaptation to new environments, and job searching). Thirty adults with HFASD were randomly assigned to either the active treatment or waitlist control group. Various questionnaires, such as the Personal Growth Initiative Scale-II (PGIS-II), Self-Efficacy Scale (SES), and the Career Decision Making Self-Efficacy Short Form (CDMSE-SF), were used to measure self-efficacy. We performed linear mixed-effect modeling to demonstrate the effectiveness of the program.

Results: Significant group x time interaction effects based on the linear mixed effect model were found in the PGIS-II planning ability ($F=4.59$, $p<.05$), CDMSE-SF total score ($F=4.76$, $p<.05$), and self-appraisal ($F=4.4$, $p<.05$) (Figure 1). Assessments of the intervention effects for the treatment group after the three-month follow-up showed significant changes across time (pre-, post-, and follow-up) in the PGIS total score ($F=5.52$, $p<.05$), readiness for change ($F=3.96$, $p<.05$), planning ($F=7.16$, $p<.01$), SES total score ($F=4.57$, $p<.05$), general self-efficacy ($F=4.3$, $p<.05$), CDMSE-SF total score ($F=5.52$, $p<.05$), and planning ($F=9.86$, $p<.01$) (Figure 2).

Conclusions: As the first evidence-based intervention for adults with HFASD in Korea to enhance EF skills, the program also demonstrated improvements in personal growth initiative and self-efficacy. Our findings suggest that psychosocial adaptation and independence can be improved in individuals with HFASD during their transitional period from adolescence to adulthood.

S. Thompson-Hodgetts, M. Couture, A. McKillop, S. Y. Shire, J. A. Weiss and L. Zwaigenbaum, (1)Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (2)Rehabilitation, Universite de Sherbrooke, Sherbrooke, QC, Canada, (3)University of Alberta, Edmonton, AB, Canada, (4)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (5)Psychology, York University, Toronto, ON, Canada, (6)Autism Research Centre, University of Alberta, Edmonton, AB, Canada

Background: Autistic children are at high risk of experiencing social exclusion, including in community programs. Educational interventions aimed at increasing peers' understanding of autism might support their social inclusion.

Objectives: To explore the benefits of a brief, individualized, peer-directed autism education intervention on peer engagement and inclusion of autistic children at day camp.

Methods: A convergent, parallel, two-arm (intervention/no intervention), non-randomized, mixed-methods design was used. The 5-10 minutes, peer-directed, educational intervention, included four components: (1) diagnostic label, (2) description and purpose of unique behaviors, (3) favorite activities and interests, and (4) strategies to engage them. Each individualized intervention script was co-constructed by the autistic camper (if able), their parent and a researcher, then delivered by the researcher. Videos (10-15 minutes) were taken on days 1, 2 and 5 of each camp during consistent activities within each camp. In the intervention group, the education intervention was conducted after the first video. A timed-interval behavior-coding system was used to evaluate engagement between each autistic camper and their peers (% intervals jointly engaged/not jointly engaged). Change scores across days were calculated within each group, and Eta-squared
Internet-Delivered Acceptance and Commitment Therapy for Parents of Children with Disabilities (I-Navigator ACT): An Open Feasibility Study

E. J. Renhorn1, T. M. Holmberg Bergman1, M. Melin, B. Berg and T. Hirvikoski1, 2, 3 1Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, 2Habilitation & Health, Stockholm County Council, Stockholm, Sweden, 3Habilitation & Health, Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden

Background: Parents of children with autism and other disabilities are more likely to experience stress, distress and lower satisfaction in their parental role compared to parents of typically developing children. Known risk factors include child behavioral problems, lack of community support, high parental care burden, and social stigma. Despite an abundance of research, there is still a lack of evidence-based interventions that cater to these parents’ needs. In response to this, we have developed a manualized Acceptance and Commitment Therapy group intervention (Navigator ACT) that has so far been assessed in an open feasibility study (n = 94) with promising results. To facilitate wider access to the Navigator ACT program without geographic restrictions, we have developed an individual internet-delivered version of the treatment: I-Navigator ACT.

Objectives: The current study aims to evaluate the feasibility of the internet-delivered I-Navigator ACT treatment when it comes to improving parental well-being and reducing stress and distress.

Methods: We conducted a mixed methods open feasibility trial within an outpatient habilitation services context in Stockholm, Sweden. We enrolled n = 34 parents of children with disabilities to participate in the internet-delivered Navigator ACT program. The program consisted of 10 modules with weekly written support from a coach. Feasibility was measured regarding treatment completion, parental satisfaction, treatment credibility and preliminary outcomes using self-rated psychometric questionnaires administered at baseline, post-intervention, and 3-month follow-up. As part of our mixed methods approach, we also conducted interviews with 9 participants post-intervention.

Results: Thus far, we have analyzed participant baseline data as well as overall satisfaction with the treatment program. Of the 34 parents who enrolled, 24 completed the intervention (71%). The participants rated their satisfaction 4.2 (averaged over all 10 modules) on a 5-point Likert scale, which suggests that the participants were satisfied with the treatment program. In the qualitative post-intervention interviews the participants indicated that the treatment program was helpful, especially with weekly support from the I-Navigator ACT coach. The participants also provided several suggestions for treatment improvements and revisions.

Conclusions: While all results have not yet been fully evaluated, the preliminary results regarding treatment satisfaction are promising. By offering the Navigator ACT intervention as an individual internet-delivered treatment, we anticipate that we can provide parents of children with disabilities a safe, readily available, and efficacious form of treatment for parental stress and distress. To fully evaluate effectiveness of I-Navigator ACT compared to the group-based Navigator ACT, randomized controlled trials are needed.

Intervention Use and Effectiveness in Families with Autistic Children with Eating and Drinking Difficulties

E. Shaw1, H. Taylor1, L. Pennington1, C. Morris1, D. Craig2, H. McConachie1, J. E. Cadoghan1, D. Sellers1, M. Andrew1, J. Smith1, D. Garland1 and J. R. Parr1, 2 1Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, 2College of Medicine and Health, University of Exeter, Exeter, United Kingdom

Background: The current study aims to evaluate the feasibility of the internet-delivered I-Navigator ACT treatment when it comes to improving parental well-being and reducing stress and distress.

Methods: We conducted a mixed methods open feasibility trial within an outpatient habilitation services context in Stockholm, Sweden. We enrolled n = 34 parents of children with disabilities to participate in the internet-delivered Navigator ACT program. The program consisted of 10 modules with weekly written support from a coach. Feasibility was measured regarding treatment completion, parental satisfaction, treatment credibility and preliminary outcomes using self-rated psychometric questionnaires administered at baseline, post-intervention, and 3-month follow-up. As part of our mixed methods approach, we also conducted interviews with 9 participants post-intervention.

Results: Thus far, we have analyzed participant baseline data as well as overall satisfaction with the treatment program. Of the 34 parents who enrolled, 24 completed the intervention (71%). The participants rated their satisfaction 4.2 (averaged over all 10 modules) on a 5-point Likert scale, which suggests that the participants were satisfied with the treatment program. In the qualitative post-intervention interviews the participants indicated that the treatment program was helpful, especially with weekly support from the I-Navigator ACT coach. The participants also provided several suggestions for treatment improvements and revisions.

Conclusions: While all results have not yet been fully evaluated, the preliminary results regarding treatment satisfaction are promising. By offering the Navigator ACT intervention as an individual internet-delivered treatment, we anticipate that we can provide parents of children with disabilities a safe, readily available, and efficacious form of treatment for parental stress and distress. To fully evaluate effectiveness of I-Navigator ACT compared to the group-based Navigator ACT, randomized controlled trials are needed.
Background: The FEEDS (Focus on Early Eating, Drinking and Swallowing) Toolkit is a clinical and evidence-based resource that explains the reasons for eating, drinking and swallowing difficulties (EDSD) in children with neurodisability, and provides a decision aid for choosing among interventions that can be used to improve feeding. It is being developed following the National Institute for Health and Care Research (NIHR) funded FEEDS review, which included a UK national survey of parents’ use of home-based interventions. This study analysed responses from the parents of autistic children.

Objectives: To understand which interventions are used by families of autistic children with EDSD and their perceived effectiveness.

Methods: Questionnaires for parents of children with neurodisability and EDSD were distributed through UK parent networks and mainstream and specialist schools. The content of the survey was determined by previous stages of the FEEDS review, including systematic reviews of interventions, a mapping review, and focus groups involving parents and healthcare professionals with experience of EDSD. 359 parents of children with EDSD participated. Parents of autistic children formed the largest proportion of responses (n=183). Answers regarding the use of an intervention and the parent’s opinion on their effectiveness were analysed.

Results: On average, parents of autistic children with EDSD in the UK have tried 6.25 interventions (SD= 4.05) to improve their child’s feeding. Interventions most commonly tried by families of autistic children with EDSD include being aware of the impact of sensory difficulties on eating/drinking (58%), use of visual supports (58%), desensitisation programmes for food avoidance (55%), enhancing child/feeder communication (53%) and changing behaviour at mealtimes (52%). However, the most used interventions were often not perceived to be the most effective, with effectiveness rates of 49% (for being aware of the impact of sensory difficulties on eating/drinking), 41% (for visual supports) and 32% (for desensitisation programmes for food avoidance). The interventions that were most commonly perceived to work amongst autistic children with EDSD include hand over hand prompting (used by 32%, viewed as effective by 62%), sensory aids (used by 13%, viewed as effective by 59%) and modification to environment at mealtimes (used by 51%, viewed as effective by 58%).

Conclusions: Families of autistic children with EDSD try a number of interventions to improve feeding, with variable success. A cumulative approach to EDSD intervention use, first utilising the interventions most often tried and those with the highest effectiveness rate in autistic children, and then trying less common or less successful interventions, may be beneficial for this cohort. The FEEDS Toolkit will utilise these findings and encourage an individualised approach to the management of EDSD by providing families with accessible information regarding the different interventions available, how they are implemented, how to evaluate their effectiveness and a recommended duration to trial the intervention.

435.238 (Poster) Interventions for Autistic Adults and Their Close Relations in an Outpatient Stepped Care Model

H. Agius, D. Sjöwall, N. Jayaram Lindström, S. Bolte and T. Hirvikoski, (1)Karolinska Institutet, Stockholm, Sweden, (2)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (3)Habilitation & Health, Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden

Background: In stepped care models, psychoeducative first-line interventions are provided soon after confirmed autism diagnosis to include most autistic adults presenting in an outpatient habilitation context. Family members/close relations are included in the first-line interventions, if desirable and acceptable for the autistic adult. More demanding skills training interventions follow later in the care process based on each individual’s needs. An example of a second step intervention would be a stress reduction intervention addressing the frequently reported high stress and impaired ability to cope with stressors among autistic adults.

Objectives: To evaluate feasibility (acceptability and intervention completion) of (1) Prisma, a new first-line intervention for autistic adults and their close relations, and (2) Mindfulness-based stress reduction (MBSR) groups targeting individual’s internal resources to regulate stress responses, in an outpatient context.

Methods: Prisma was evaluated in an open feasibility study including 92 intellectually able autistic adults and their 94 close relations. The MBSR groups were also evaluated in an open feasibility study recruiting 50 intellectually able autistic adults. Both studies thus included several intervention groups provided by outpatient services. The interventions were guided by trained group leaders, and followed a manualized protocols including adaptations to autistic adults’ needs.

Results: Completion rate in Prisma was 77% for autistic adults and 73% for close relations. The participants reported good acceptability; however, the qualitative analysis indicated that Prisma could be improved by enhancing active participation. Preliminary effectiveness analyses indicated increase in autism knowledge and some improvements in relationship quality, mental health, quality of life, acceptance of diagnosis and burden of care. In the MBSR study, n=43 (86%) attended at least one session and n=34 of these (79%) completed the intervention. Participants found MBSR logical, likely to lead to improvement and recommendable to autistic peers. Measures of preliminary effectiveness indicated reduced symptoms of stress (p < 0.001; d = 0.51) and improved stress-coping skills (p = 0.017; d = 0.43) from pre- to post- intervention, as well as a reduction in anxiety symptoms and depression. No changes were observed in mindful attention awareness, life satisfaction or acceptance of the autism diagnosis.
Conclusions: Overall, results indicate that both interventions are feasible and acceptable in outpatient services. The participant feedback has been used to further improve the interventions for on-going randomized controlled trials.

435.239 (Poster) Investigating the Utility of Teaching Autism Acceptance and Neurodiversity in the College Classroom: An Exploratory Study
E. Hotez, J. Rava and A. Kuo, (1)David Geffen School of Medicine at UCLA, New York, NY, (2)David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: There is an increasing number of autistic college students. Autism stigma has significant and lifelong negative health and educational consequences for autistic individuals during and post-college. In contrast, autism acceptance and alignment with the neurodiversity movement in interpersonal, educational, healthcare, and other contexts has positive impacts on their quality of life. The college environment represents a potential opportunity to address autism stigma and, in turn, prevent the negative health consequences of stigma as autistic college students transition into adulthood.

Objectives: The purpose of the current study was to investigate the general college student body and: 1) describe their level of autism acceptance based on the neurodiversity framework utilizing the Autism Attitude Acceptance Scale (AAAS); and 2) qualitatively capture their open-ended questions surrounding neurodiversity.

Methods: The sample (n = 49, M age = 21.93, SD = 21.14) featured undergraduates enrolled in a large, diverse, public university in the U.S. The sample was diverse with respect to race (White: 45%, Asian: 25%, Black / African American: 8%, Native American / Alaska Native: 4%, Other: 18%) and ethnicity (Hispanic: 31%). Approximately 39% (n = 19) identified as neurodivergent, with 2 identifying as autistic. Students completed the AAAS—administered via Qualtrics—in February of 2022. The AAAS elicits cognitive, behavioral, and affective beliefs about accepting and accommodating autistic individuals without trying to change them, based on the neurodiversity framework. In the AAAS, participants responded to statements in relation to a hypothetical vignette about “Andy,” who is autistic. In addition, students were provided the opportunity to ask up to three questions each about neurodiversity within the same Qualtrics survey. We utilized qualitative thematic coding to extract themes from the neurodiversity questions.

Results: We derived frequency and descriptive statistics for each item and the total AAAS score (Cronbach’s Alpha =0.801). The majority of participants’ responses reflected high self-reported autism acceptance. For example, 90% or more endorsed statements such as “people need to learn more about autism to support individuals with autism better” and “autism is a unique way of being that should be appreciated.” Responses demonstrated greater variability, however, with respect to statements about curing or normalizing autistic individuals, with almost 30% and 45% endorsing the statements, “eliminating individuals' autistic symptoms can support a better quality of life for them” and “it is important for an individual with autism to get interventions about how to pick up on social cues to make friends,” respectively. Qualitative findings derived from students’ questions about neurodiversity revealed both a high degree of interest in the neurodiversity movement, as well as high variability in knowledge and familiarity with its tenets.

Conclusions: The current study represents one of the few studies to investigate autism acceptance based on the neurodiversity framework among the general college student body. In this research, a focus on undergraduate students facilitates the translation of findings to the development of strategies for cultivating an understanding of autism and neurodiversity in higher education. Such strategies have the potential to address and prevent stigma towards neurodivergent individuals into adulthood.

435.240 (Poster) Measuring Effectiveness of a Family-Centered Treatment Program on Autistic Latinx Children’s Mental Health

Background:

Parents and caregivers of Latinx children with autism spectrum disorder (ASD) report receiving less services and having more unmet needs than those of white children (Angell, et al. 2018). Additionally, Latinx parents have less access to information about ASD and have a general lack of knowledge, compared to white counterparts (Angell, et al. 2018). Issues often are compounded by a language barrier and lack of culturally sensitive services. These problems were compounded with the COVID-19 pandemic which exacerbated the issues of current programs along with increasing the mental health crisis. Implementing family-centered, caregiver-mediated programs may help bridge this gap. The Functional Natural Curriculum (FNC), developed by the Centro Ann Sullivan del Peru (CASP) is one of these programs that focuses on providing caregivers with the necessary tools to teach their children essential skills to promote independence, facilitate academic learning, and enable inclusion in all aspects of life.

Objectives:
This study aimed to assess the effectiveness of the CASP online curriculum on child outcomes, in particular on their mental health and adaptive functioning.

Methods:

Thirty-one children with ASD between the ages of 3 and 15 were enrolled in the study across two phases. Only participants that completed the study are included in the analysis of outcome measures (intervention n=13, Mage=9.7 years, 4 females; control n=7, Mage= 11.7 years, 3 females). The 16-week, virtual intervention consists of different sessions in which caregivers attend 3-5 hours of weekly sessions through individual training between caregiver-child dyads, small group parent sessions, large group parent classes, and optional extracurricular activities for the family. Outcome measures were collected electronically at baseline, week 8, and week 16 to assess mental health and at baseline and 16 weeks adaptive outcomes. Child outcomes were measured with the Aberrant Behavior Checklist (ABC), the Vinelands Behavior Scales- Third Edition (Vineland 3), the Caregiver Strain Questionnaire (CGSQ), the Family Empowerment Scale (FES), and the Family Quality of Life Scale (FQOL).

Results:

Relative to waitlist controls, children whose families participated in the intervention showed significantly greater decline, from Baseline to Week 16, in irritability (t=-2.77, p=0.006), hyperactivity (t=-2.15, p=0.02, and lethargy/social withdrawal (t=-2.04, p=0.03) on the ABC. On the CBCL there were also score improvements that were significantly larger for the intervention group on internalizing (t=-1.92, p=0.03), externalizing (t=-2.16, p=0.02) and total (t=-1.79, p=0.04). Regarding adaptive behavior, the difference in improvement between intervention in controls approached statistically significant, with large effect size, for the Adaptive Behavior Composite (t=1.78, p=0.053; Cohen’s d=0.83) and with personal skills significantly improving for the intervention group (t= -2.7888, p=.05).

Conclusions:

These results indicate that the that the CASP family-centered, online intervention program may improve outcomes for Latinx children with ASD based on the ABC, CBCL, and Vineland measures. These results indicate a potentially effective program for underserved populations in which accessing and providing care is more complex. Focusing on increasing parent-caregiver knowledge about ASD as well by giving them the tools to help their children directly may be particularly effective in this population.

435.241 (Poster) Mental Health Challenges and Emotion Dysregulation: In-Person Vs. Online Cognitive Behaviour Therapy for Autistic Youth
N. Eddy, C. Gallant and J. A. Weiss, Psychology, York University, Toronto, ON, Canada

Background: Previous research has shown that mental health challenges are more common among autistic children and youth (Arim et al., 2015). These challenges are often accompanied by emotion regulation difficulties, which impact a child’s ability to effectively monitor and modulate their emotional reactions (Mazebsky & White, 2014). Cognitive behaviour therapy (CBT) is an effective way to mitigate these challenges. The COVID-19 pandemic has led to a rapid shift to the online delivery of CBT, however there is limited research examining whether this adapted format is helpful and the predictors of change.

Objectives: To evaluate the benefits of a CBT program in addressing emotion dysregulation in autistic children when delivered in an online or an in-person format.

Methods: Sixty autistic children and youth (8-13 years old) without intellectual disability engaged in an adapted, manualized CBT program (Secret Agent Society: Operation Regulation [SASOR]; Beaumont, 2013) for emotion regulation difficulties. The program was delivered individually over 10 weekly sessions, either as an in-person (SASOR; n = 42) or online intervention (VSAS; n = 18). Parents completed several measures assessing their child’s emotion regulation, health-related quality of life (HRQoL), and mental health symptoms. Pre-to post-program changes were compared between the two groups (SASOR, VSAS) using mixed ANOVAs and Pearson’s correlations were used to examine associations among demographic (i.e., age, gender) variables, pre-program scores, and changes (i.e., pre- minus post-scores).

Results: Main effects for time indicated that both VSAS and SASOR youth experienced pre- to post-program improvements in emotion regulation (p < .001), externalizing (p = .009), internalizing (p < .001), adaptive skills (p < .001), behaviour symptoms (p < .001), and the HRQoL psychological wellbeing scale (p = .008). There was an interaction of group and time for the HRQoL scale of parent relations and autonomy (p = .008); simple main effects comparisons indicated only the SASOR group exhibited pre to post improvements (p < .001). For the in-person group, greater internalizing (r = .44, p = .004) and fewer adaptive skills (r = .34, p = .03) pre-intervention were related to greater improvements in each outcome at post. Additionally, younger participants demonstrated greater pre-to-post improvements on HRQoL parent relations and autonomy scores (r = .31, p = .048). For the VSAS group, lower HRQoL psychological wellbeing (r = .52, p = .03) and parent relations and autonomy pre-intervention scores (r = .66, p = .003) were related to greater improvements post-intervention.
Conclusions: Overall, the modality of treatment was not related to parent-reported changes in emotion regulation or mental health symptoms pre- to post-program, with the exception of the in-person group showing improvements in relationships with their parent and autonomy. For both modalities, more severe challenges prior to intervention were associated with greater improvements thereafter, though the specific associations varied between groups. This research provides support for the use of CBT with autistic youth, and suggests that adapted, online therapy may be a suitable intervention to address emotion regulation difficulties of some children. Further research using randomized trials and larger samples is recommended.

435.242 (Poster) Mental Health Therapist and Caregiver Perspectives on Improving Community Mental Health Services for Autistic Youth: A Focus on Executive Functioning

K. S. Dickson, M. R. Galligan, T. Holt, L. Kenworthy, L. Anthony and L. Brookman-Frazee, (1)San Diego State University, San Diego, CA, (2)College of Education, San Diego State University, San Diego, CA, (3)SDSU, San Diego, CA, (4)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (5)University of Colorado, Denver, Aurora, CO, (6)Psychiatry, University of California, San Diego, La Jolla, CA

Background: Publicly-funded mental health (MH) services play a significant role in caring for autistic youth given the high rates of co-occurring MH conditions common among these youth. Executive functioning (EF) deficits play an integral role in both autism and co-occurring MH conditions, including predicting increased MH symptoms. Our prior work highlights the impact of EF on MH services, including on psychotherapy engagement and progress. Research examining multi-stakeholder (therapist and caregiver) perspectives on the impact of and the need for EF and EF tools, including evidence-based interventions (EBIs), within the context of children’s MH for autistic youth is limited. Such perspectives are key to informing efforts to improve children’s MH services for autism.

Objectives: The current mixed-methods study aims to: 1) expand our prior work with MH therapists to examine caregiver perspectives regarding the role and impact of EF in MH services for autistic youth and 2) examine therapist and caregiver perspectives of key implementation outcomes (e.g., adoption, acceptability, feasibility) of Unstuck and On Target, an EF EBI, specifically adapted for use in children’s MH services.

Methods: Data were drawn from two aims of a multiphase study aimed to conduct a needs assessment to inform the adaptation and testing of Unstuck and On Target in publicly-funded MH services. We conducted an initial needs assessment examining the perspectives of therapists (n_quarter=35, 83% female, 44% Marriage and Family Therapists; n_quarter=14, 100% female, 21% Marriage and Family Therapists) and caregivers of autistic youth (n_quarter=35, 82% female; n_quarter=17, 83% female) regarding the relevance and impact of EF and need for EF-specific tools in MH services via a web-based survey and corresponding qualitative data collection. We subsequently examined therapist (N=13, 85% female, 46% Marriage and Family Therapists) and caregiver (N=8, 100% female) perspectives of the acceptability, feasibility, and utility of Unstuck via web-based survey and corresponding qualitative interview following participation in a randomized feasibility trial of an adapted version of Unstuck for autistic youth in MH services.

Results: Needs assessment findings indicate moderate knowledge and experience with behaviors consistent with EF challenges but more limited knowledge and experience with EF in autism and EF EBIs, particularly among MH therapists. Caregivers and providers agree that youth and families would benefit from EF EBIs. Subsequent feasibility trial findings indicate high adoption, acceptability, feasibility and appropriateness of Unstuck, but more limited adoption of the corresponding parent manual. Corresponding qualitative data also supported the feasibility, acceptability, and utility of the Unstuck and On Target in MH settings. See Tables 1 and 2 for full results.

Conclusions: Needs assessments indicate community support for the potential of EF interventions for MH settings. Validating these findings, subsequent trial results indicate the acceptability, feasibility, and appropriateness of Unstuck and On Target in MH settings. Overall, findings highlight the importance of gaining community perspectives to improve MH services and underscore the need and acceptability of EF-specific tools such as Unstuck and On Target within community MH services. Findings have implications for the importance of these tools for ongoing efforts to improve MH services for autistic youth.

435.243 (Poster) Moderators of Treatment Outcome in a RCT of Parent Training for Dental Care in Families of Children with ASD

M. Norris, K. G. Stephenson, C. M. Albright, J. F. Scherr, J. M. Moffitt, R. steinberg Epstein, E. M. Butter and R. M. Fenning, (1)Nationwide Children’s Hospital, Columbus, OH, (2)Developmental Assessment Program, Nationwide Children’s Hospital, Columbus, OH, (3)Behavioral Health, Nationwide Children’s Hospital, Columbus, OH, (4)University of Miami, Coral Gables, FL, (5)Pediatrics, The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (6)Psychological Science, Claremont McKenna College, Claremont, CA

Background: Dental care is a significant unmet health need for individuals with ASD. In a randomized controlled trial, we established the efficacy of parent training (PT) compared to a psychoeducational Tool Kit (Control) for improving oral health and hygiene behaviors in 119 Medicaid-eligible children with ASD aged 3 to 13 years recruited from AIR-P sites. To better understand these results and to provide additional context regarding for whom the treatment works best, we examined possible moderating child characteristics. Based upon past literature (e.g., Farmer et al., 2012; Lecavalier et al., 2017), we anticipated that PT would be equally effective for participants across a
range of factors, with the exception of children presenting with greater initial behavior problems, for whom we expected stronger PT effects.

Objectives: To examine child characteristics as moderators of treatment response, including age, ethnicity, cognitive level (SB5-ABIQ), Autism Diagnostic Observation Schedule-2 (ADOS-2) comparison score, psychotropic medication status (yes/no), and parent-reported CBCL symptoms of inattention, aggression, anxiety/depression, and general behavioral noncompliance (HSQ-PDD).

Methods: Nine child variables were assessed as possible moderators on three outcome variables: parent-reported frequency of past-week twice-daily tooth brushing; parent-reported behavior problems during home dental care; and dentist-rated visual plaque. Parent-reported child gender was included as a control variable. Linear mixed effects models with random intercepts were used with potential moderators included as three-way interactions with Treatment Group and Timepoint (baseline, 3 months, 6 months). All moderators were included simultaneously.

Results: Despite randomization, baseline differences unexpectedly existed between PT and Control, with PT having a higher proportion of female primary caregivers and less frequent daily tooth brushing. Ethnicity was a significant moderating effect of treatment outcome with participants identifying as Hispanic/Latino showing the most improvement in PT vs. Control conditions in both frequency of tooth brushing and behavior during home dental care. PT also produced a larger reduction in behavior problems during home dental care relative to the Control at lower levels of IQ and lower ADOS-2 scores. However, differences in baseline levels of daily tooth brushing may have been confounded with moderator variables. PT-dependent improvements in twice-daily tooth brushing held across levels of aggression, but Control children with greater aggression displayed poorer dental hygiene over time. Moderators of visual plaque included ASD symptoms, inattention, and aggressive symptoms, with inconsistent patterns of differences.

Conclusions: Somewhat contrary to hypotheses, significant moderation effects were found for certain variables. Findings suggest that children who identify as Hispanic/Latino, have lower IQs, milder ASD symptoms, or more aggression may be especially likely to benefit from directed PT for dental care. In contrast, the Tool Kit may be sufficient to improve oral hygiene and dental health in other cases, particularly for children with higher IQs. The considerable ethnic, socioeconomic, and cognitive diversity of our sample is unusual for RCTs involving children with ASD, and may have increased our ability to detect moderation effects, which underscores the importance of diversifying samples in efforts to develop personalized interventions.

435.244 (Poster) Multi-Sensory Wayfinding: Lessons from the Margins Towards the Design of Equitable and Healthy Public Spaces

Background: MIXdesign investigates how the built environment may enable spatial orientation, agency, and a sense of security in public spaces through the study of the autistic, individuals requiring assisted mobility, and the deaf. Space planning principles begin where buildings meet their surroundings. They emerge from an ongoing exploration of a prototypical public entry sequence within institutional buildings with deliberate focus on optimizing spatial orientation and environmental stimulation for the three distinct but intersecting end-user populations with unexpected commonalities. This promotes the authentic exploration of the autistic, physically disabled, and deaf experiences within discrete elements of buildings as essential to problem-solving accessibility and usability.

Objectives: To design feasible and scalable buildings deliberately imagined to support greater successful interaction among and usability of space by more users within a residential college at a university as an exemplar case.

Methods: Investigators completed a comparative analysis of three end-user community perspectives to uncover affinities and differences between autistic, physically disabled, and deaf individuals. The results informed design strategies to meet the majority of needs of the three end-user groups and be relevant to the general public.

Results:

Identified barriers to accessible and usable spaces center on acoustics, lighting, wayfinding, signage, cavernous spaces without clear definition, unpredictable paths, and crowds. The outcome of our study yielded a set of design principles called Multi-Sensory Wayfinding illustrated for the entry sequence for a residential college at an American University. Multi-Sensory Wayfinding augments conventional signage and uses color, materials, lighting, and acoustics to differentiate two kinds of legible activity zones: Barrier Free Circulation Paths and Multi-Sensory Microclimates as a means to balance social distancing and human connectivity while minimizing environmental stressors and increasing spatial awareness for everyone. A discrete example: a central planter and separate entry/exit circulation aisles prevent unwanted collisions in the vestibule. This transition threshold, a concept found in the ASPECTS Design Index to support autistic sensory adjustment, demarcates the intersection where circulation paths cross to allow occupants of all abilities to slow down, acclimate to changes in direction, and adjust their senses to recalibrate between indoors and outdoors, two very different environments with different levels of stimulation. We also applied Multi-sensory Wayfinding to the area adjacent to reception, the study lounge, illustrated figure 1. It is subdivided into barrier free circulation zones and micro-climates. The Barrier Free Zone features a color-contrast floor with a detectable edge for cane users and provides a wide differentiated circulation path for pairs of people and wheelchairs to pass. The Calm
Zone features semi-enclosed nooks for small-group conversations with adjustable low-level lighting that reduces unwanted stimulation (a frequent comfort for autistic individuals as well as many others) and high back seating as a visually calm background for viewing American Sign Language.

Conclusions: Identifying elements of structures allows us to leverage the potential of place-based and population-level interventions in support of inclusion. This complements and reinforces the individual level adjustments and accommodations that have proven helpful for autistics but incompletely effective.

435.245 (Poster) Music Therapy for Autistic People: Update of a Cochrane Review
L. Fusar-Poli, M. Ruiz Loria, M. Geretsegger, C. Elefant, G. Vitale and C. Gold, (1)Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy, (2)GAMUT - The Grieg Academy Music Therapy Research Centre, NORCE Norwegian Research Centre AS, Bergen, Norway, (3)The School of Creative Arts Therapies, University of Haifa, Haifa, Israel, (4)Child and Adolescent Neuropsychiatry, University of Naples Federico II, Naples, Italy, (5)Department of Clinical and Health Psychology, University of Vienna, Vienna, Austria

Background: Music therapy (MT) uses music experiences and the relationships developed to enable communication and expression, thus attempting to address some of the core problems of autistic people. The application of MT requires specialised academic and clinical training to tailor the intervention to the specific needs of the individual.

Objectives: To update a review on the effects of MT, or MT plus standard care, for autistic people, and evaluate potential predictors of response.

Methods: In August 2021, we searched 14 databases and two trials registers; an update search was conducted in October 2022. Trials comparing MT (or MT alongside standard care) to 'placebo' therapy, no treatment, or standard care for people with a diagnosis of autism spectrum disorder were considered for inclusion. Results were synthesised in meta-analyses. For studies where individual participant data (IPD) of relevant outcomes and potential moderators (age, sex, severity) were available, we conducted meta-regression analyses to identify predictors of effects.

Results: We included 26 studies (1165 participants) examining the short- and medium-term effect of MT for autistic people. No new studies were identified in the update search. IPD were available from three large studies (448 participants). Twenty-one studies included children aged from two to 12 years. Five studies included children and adolescents, and/or young adults. Severity levels, language skills, and cognition were widely variable across studies. Measured immediately post-intervention, MT compared with placebo therapy or standard care was more likely to positively affect global improvement (RR 1.22, 95% CI 1.06 to 1.40) and to slightly increase quality of life (SMD 0.28, 95% CI 0.06 to 0.49). In addition, MT probably results in a large reduction in total autism symptom severity (SMD −0.83, 95% CI −1.41 to −0.24). No clear evidence of a difference between MT and comparison groups at immediately post-intervention was found for social interaction (SMD 0.26, 95% CI −0.05 to 0.57); non-verbal communication (SMD 0.26, 95% CI −0.03 to 0.55); and verbal communication (SMD 0.30, 95% CI −0.18 to 0.78). Two studies investigated adverse events with one reporting no adverse events; the other study found no difference between MT and standard care. Results of meta-regression analyses will be presented at the conference.

Conclusions: The studies included in the present review increased the certainty and applicability of the findings compared with earlier versions of this review through larger sample sizes, extended age groups, longer periods of intervention and follow-up, and by predominantly using validated scales measuring generalised behaviour (i.e. behaviour outside of the therapy context). Meta-regression results will provide much-needed knowledge on who benefits most from which type of therapy. This new evidence is important for autistic individuals and their families as well as for policymakers, service providers and clinicians, to help in decisions around the types and amount of intervention that should be provided and in the planning of resources. More research using rigorous designs, relevant outcome measures, and longer-term follow-up periods is needed to corroborate these findings and to examine whether the effects of MT are enduring.

435.246 (Poster) Examining the Effects of Online Mathematics Instruction Using Video Modeling and Other Supports in Teaching Autistic Secondary School Students
G. Yakubova, B. B. Chen, S. Gupta and M. Al-Dubayan, (1)Counseling, Higher Education, and Special Education, University of Maryland at College Park, College Park, MD, (2)Special Education, Towson University, Towson, MD, (3)University of Maryland, College Park, MD

Background: In the last few years, there has been an increase in the use of online platforms to support the learning of autistic children both due to pandemic and growing research in online learning to support autistic learners. For online learning to be effective, studies need to examine the use of instruction via technology supports to effectively engage students.
**Objectives:** The purpose of this study was to empirically evaluate the effects of synchronous, virtual instruction using video-based intervention, virtual mathematical games and manipulative, and guided supports on mathematics learning of lower-secondary autistic students.

**Methods:** This study used a multiple probe across three skills design with each participant (2 participants) of a single-case experimental methodology. Prior to selecting target skills and intervention techniques, researchers collaborated both with children and their caregivers to discuss children’s learning needs and strengths both from children’s and caregivers’ perspectives. Using participant perspectives, we selected skills and designed the intervention accordingly. Following a baseline assessment with stable trend, each student used a variety of instructional supports (video modeling, mathematical games, and virtual manipulatives along with instructor guided supports) to learn a variety of mathematics skills. We also examined skill maintenance following the completion of the study. At the end of the study, we examined social validity of the study goals, skills, and procedures both from the children’s and caregivers’ perspectives.

**Results:** Both participants demonstrated mastery (100% accuracy) for different mathematics skills, with continued demonstration of 100% accuracy during maintenance assessment. Social validity assessment results from participants and their parents revealed that participants and parents found the skills, interventions, study procedures, and learning outcomes meaningful and useful.

**Conclusions:** The findings of this study contribute to emerging research on best practices to teach autistic students in an online platform to supplement in-person learning. The results offer insight into ways to develop and implement video-based interventions, engage in hands-on exploration of online mathematics games to support learning, and virtual manipulatives to teach mathematics skills to autistic children with autism during virtual instruction. Furthermore, the findings will provide insights on how to effectively work with parents and enable them as active partners in the support of their child’s learning during virtual instruction.

---

435.247  *(Poster)* On Strike: The Impact of Labor Disruptions on Autistic Postsecondary Students and How We Can Help

**I. Yusupov**, K. T. Shaikh, A. Porthukaran, E. Greenglass and J. M. Bebko, (1)York University, Toronto, ON, Canada, (2)Psychology, Centre for Addiction and Mental Health, Toronto, ON, Canada

---

Background: Labor strikes on postsecondary campuses can negatively impact students’ well-being. However, research to date has focused solely on the impact on non-autistic students. Autistic students may be differentially impacted by a strike due to core features of autism. In addition, autistic students have lower rates of successful graduation from postsecondary institutions compared to the general population.

**Objectives:** It is therefore important to better understand autistic students’ experience and needs in order to inform interventions and institutional policy to support students during such academic disruptions.

**Methods:** Twelve autistic students participated in semi-structured interviews exploring their experiences during a strike at a North American postsecondary institution. Interviews were transcribed and a thematic analysis was conducted to identify themes related to the students’ experience during the strike.

**Results:** Eight themes and three subthemes were identified and categorized in broad domains of 1) engagement in the strike, 2) consequences of the strike on everyday activities, stress, and mental health, and 3) coping with the strike. Although students differed in their level of engagement with the strike, common reactions were feelings of confusion related to strike information. Nevertheless, students felt that the strike was justified and it did not affect their level of satisfaction with their programs of study. In terms of the consequences of the strike, students expressed an increased sense of isolation and stress, as well as mood symptoms that negatively impacted daily functioning. Three main areas of coping were identified, including utilizing mental health and mentorship services, family support, and using academic accommodations.

**Conclusions:** The current study revealed important themes related to the experience of autistic postsecondary students during a strike. Through York University’s Autism Mentorship Program, we have been able to offer autistic students support that targeted identified many of these areas, including optimizing social connection, providing stress-management techniques, bolstering overall well-being, and accessing academic accommodations and other resources. We will discuss our Autism Mentorship Program’s response and will highlight the program’s scalability and adaptability to other academic settings. Lastly, seven recommendations will be provided for postsecondary institutions to consider in the event of a strike to better support the success and well-being of autistic students.

---

435.248  *(Poster)* One-Size-Fits-One: Empowering Caregivers of Autistic Young Adults to Design Everyday Solutions

**T. Waardenburg**, J. C. van Huizen, M. Magnee, J. van Dijk, J. P. Teunisse and M. C. van der Voort, (1)HAN University of Applied Sciences, Nijmegen, Netherlands, (2)University of Twente, Enschede, Netherlands, (3)Twente University, Enschede, Netherlands, (4)Research group Innovation in Healthcare, HAN University of Applied Sciences, Nijmegen, Netherlands

---

**Background:**
Assistive technologies are increasingly being designed to support people with autism in everyday life. However, the actual uptake in care practices of such technologies seems to be limited. We see several possible causes. On the one hand, it may be because technologies often focus on 'functional limitations', with less attention given to the overall experience people have with the technology and the environment in which it is used. On the other hand, this may be because autistic people and their caregivers have limited or no involvement in the development of technologies. Moreover, the relationship between the autistic person and caregiver and the role technology plays between them is often completely overlooked.

Objectives:

The aim is to provide caregivers with a design-based intervention perspective, aimed at self-designing technological environments that caregivers can use to support autistic young adults (AYA) in designing everyday 'one-size-fits-one' solutions. This will be done without the intervention of a designer or engineer. The toolset will put design tools in the hands of people using technology themselves.

Methods:

The first version of the toolkit was developed using insights from ten design case studies conducted with AYA and caregivers. These cases were conducted using a research-through-design approach. Promising methods from the design literature were applied in these and contrasted with the lived experiences and practical contexts of AYA and their caregivers. The results of the case studies were then analyzed using grounded theory (GT). For this purpose, the data from the case studies were spread out in data boards. Three coders then interacted to look for similarities, differences, and salient aspects. These were noted down on sticky notes.

Results:

The GT-analyses resulted in a total of 347 observations. From these, ten different categories were identified for the design direction of the toolkit. For example, what both the AYA and the caregiver appreciated was the 'bottom-up approach', where the AYA is more central, the caregiver has a more supportive role and (technological) solutions are not provided top-down by the organization. Another category is about 'autism-specificness'. In most case studies, the focus was precisely not on specific autism characteristics. The autistic participants indicated that interventions that put a lot of emphasis on their 'autistic disabilities' could be counterproductive. On the other hand, we also noted difficulties in activities involving thinking or imagining the future. This may be due to autism. Design activities will need to devote specific attention to the caregiver's supportive role for this aspect.

Conclusions:

The added value of this method for caregivers is that it allows them to support AYAs in a practical, "designerly" way to realize technological solutions. To this end, the existing design tools will have to be carefully selected and adapted. Moreover, the extent to which the findings are generic or unique will be further investigated. Thus, how the method itself should be adaptable to users' preferences will have to be examined more closely. In a series of test studies that will follow, the toolkit will be iteratively further developed and evaluated in practice.

435.249 (Poster) Grandparents of Autistic Children – Needs and Intervention

R. Zakirova Engstrand1, L. Roll-Pettersson1, M. Alldén Westling1 and T. Hirvikoski1, (1)Stockholm University, Stockholm, Sweden, (2)Department of Special Education, Stockholm University, Nyköping, Sweden, (3)Special education, Stockholm University, Stockholm, Sweden, (4)Habilitation & Health, Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden

Background: In a family system where an autistic child is present, grandparents’ role has become increasingly important: they provide instrumental and emotional support to their grandchild and adult children. Research has shown that grandparents of autistic children may have their own needs and require support in relation to their autistic grandchildren. To support grandparents of autistic, preschool-aged children, the Autism Center for Young Children (ACYC) at Habilitation & Health in Stockholm offers a day-long, group-based manualized intervention with the main goal to address grandparents’ heterogenous needs and challenges they may face when grandparenting an autistic child. The intervention is multimodal as it combines components from various approaches—psychoeducation, skills training, and the use of support groups.

Objectives: The research project consists of three interrelated studies. Study 1 examined perceived needs of grandparents of preschool-aged autistic children in the areas of information, family and social support, financial support, explaining to others, child care, professional support, and community service; and explored associations between grandparents’ needs and their socio-demographic characteristics, and perceptions of grandchildren’s difficulties. Study 2 assessed feasibility and preliminary effectiveness of the group-based psychoeducational intervention program offered to grandparents of young autistic children. Study 3 explores experiences of the grandparents five years after their participation in the intervention program in 2017.
Methods: In Study 1 the participants were 120 grandparents of children enrolled into autism intervention programs provided by the public disability services in Stockholm. The Grandparents’ Needs Survey, the SDQ Impact supplement, and the demographic survey were used to collect data. Study 2 used an open pragmatic design and applied a mixed-methods approach to evaluate the intervention’s feasibility and preliminary effectiveness. Study 3 uses a qualitative design with 14 grandparents who participated in semi-structured follow-up interviews.

Results: The results from Study 1 showed that grandparents expressed most needs in topic areas of information and childcare. No significant relations were found between grandparents’ demographics and perceptions of needs; grandparents’ needs were predicted by their perceived burden. Findings from Study 2 demonstrated good feasibility: completion rate was 95%. The results showed increased knowledge about ASD from pre- to post-intervention; qualitative analyses showed grandparents’ appreciation of the opportunity to meet and share experiences with other grandparents. Preliminary findings from Study 3 show grandparents’ active involvement in grandchild’s lives: they babysit, provide transportation and other instrumental support to their adult children. Findings also indicate higher levels of distress among grandparents who had grandchildren with co-occurring neurodevelopmental conditions, e.g., ADHD, intellectual disability or with chronic medical conditions such as diabetes type 1. Some grandparents may experience social stigma and discrimination toward their grandchild with a disability in local communities.

Conclusions: Findings contribute with increased knowledge about needs and perspectives of grandmothers and grandfathers of autistic children in the context of disability services provision in Sweden. There is a need to design and implement a transdiagnostic intervention aiming at grandparents of children with co-occurring neurodevelopmental conditions to promote the mental health and wellbeing of this population.

435.250 (Poster) Parent Outcomes Following Cognitive Behaviour Therapy for Autistic Children in a Community Setting

A. Ibrahim, V. Lee, N. Vashi, T. Sellitto, F. H. Roudbarani, P. Tablon-Modica, A. Pouyandehe, S. Ameis, A. Elkader, K. Gray, C. M. Kerns, J. Lake, M. Leggree, K. M. Thomson and J. A. Weiss; (1)Psychology, York University, Toronto, ON, Canada, (2)Psychology, Carleton University, Ottawa, ON, Canada, (3)The Margaret and Wallace McCain Centre for Child, Youth, & Family Mental Health, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)Kinark Child and Family Services, Markham, ON, Canada, (5)Centre for Educational Development, Appraisal and Research, University of Warwick, Coventry, United Kingdom, (6)University of British Columbia, Vancouver, BC, Canada, (7)Psychiatry, University of Toronto, Toronto, ON, Canada, (8)Social Skills Translated, Whitby, ON, Canada, (9)Applied Disability Studies, Brock University, St. Catharines, ON, Canada

Background: Parents of autistic children are at higher risk for mental health problems, including anxiety, depression and stress (Lai et al., 2015), and these experiences may be related to children’s mental health and behaviours as well as family functioning more broadly (Smith, 2004; Hastings, 2003; Allik et al., 2006). Cognitive behaviour therapy (CBT) that targets children’s emotion regulation difficulties (i.e., reactivity; inability to regulate intense and highly rising negative emotions, and dysphoria; lack of positive affect, motivation and the presence of sadness and anxiousness) may have an indirect influence on parent outcomes, especially if they play a supporting role in the intervention (Beaumont, 2015). Indirect benefits of participation may include improvements in family functioning (Keeton et al., 2013), parent anxiety (Reaven et al., 2015), stress (Weiss et al., 2014), and depression (Maughan & Weiss, 2017). However, the majority of these studies were carried out in highly controlled research settings. To the best of our knowledge, no study has examined the parent outcomes of child-focused CBT in a community setting.

Objectives: This study examined parent outcomes (i.e., mental health and mindful parenting) following a community-based CBT program for autistic children, delivered across 7 community-based agencies in an online format. The study also explored associations between parent (i.e., mental health and mindful parenting) and child outcomes (autism symptoms and emotion dysregulation) using change scores.

Methods: 77 parents (94% women; M = 42.5 years, SD = 5.7 years) and their children (79% males; M = 9.9 years, SD = 1.3 years) completed a 10-week virtual, group-based CBT intervention, the Secret Agent Society (Beaumont, 2015). All children had a confirmed autism diagnosis from a regulated health care professional. At pre- and post-intervention, parents completed the 21-item Depression Anxiety Stress Scales (Lovibond & Lovibond, 1995) and the Bangor Mindful Parenting Scale (Jones et al., 2014) for parent outcomes, and the Social Responsiveness Scale, Second Edition (Constantino & Gruber, 2012) and the Emotion Dysregulation Inventory (Mazefsky et al., 2018) for child outcomes.

Results: Paired sample t-tests indicated greater mindful parenting post-intervention compared to pre-intervention, t(74) = -3.5, p < .001. There was no significant change in parent mental health pre- to post-intervention, t(76) = 0.6, p = .60. Pearson correlations demonstrated that improvements in mindful parenting were associated with reductions in child dysphoria (r(72) = .33, p = .004) and greater improvements in parent mental health were associated with reductions in child emotional dysregulation: reactivity (r(72) = .25, p = .04) and dysphoria (r(72) = .31, p = .007). Changes in mindful parenting and parent mental health were not associated with changes in children’s autism symptoms.

Conclusions: This study contributes to our understanding of the potential impact of implementing evidence-based interventions in real-world settings for parents, indicating that parent changes are associated with child changes in emotion regulation. Understanding variability
in parent outcomes for families can help inform intervention design by involving parents in their children’s interventions. Study limitations include the use of only parent-report measures and the lack of a control group or randomization.

435.251 (Poster) Parental High Elaborative Reminiscing Predicts Improvement in Autistic Children’s Episodic Memory and Theory of Mind

A. Brien and T. Hutchins, (1)Speech Language Pathology, California State University at San Marcos, San Marcos, CA, (2)UVM, Burlington, VT

Background: Episodic memory (EM) - memory for past personal experiences - is foundational for the development of a range of social-cognitive functions. One of these is theory of mind (ToM) which is developmentally and functionally intertwined with EM. An impressive body of literature has documented that one particular caregiver interaction style (i.e., elaborative reminiscing (ER)) causally and positively impacts neurotypical children’s EM and ToM. Despite its empirical basis and theoretical importance, no formal interventions have been developed to support EM in autism.

Objectives: This study evaluated a new caregiver-mediated intervention that adapts the principles of ER in ways that align with best practices for supporting EM and ToM in autistic children. We used an uncontrolled pre-/post-intervention/8-week maintenance design to evaluate the intervention’s potential for therapeutic outcomes: 1) parents will increase and maintain their use of an elaborative reminiscing interaction style, 2) children will demonstrate and maintain improvements in EM and ToM.

Methods: Participants were 24 caregivers and their autistic children (20 males; ages 6-15 years; \( M = 9.25 \)). Parent training in elaborate reminiscing (total time = 3 hours) was modeled after well-established training programs and manualized in a standard operating procedure. Parents implemented the intervention for eight weeks (5 minutes a day/5 times a week). During the maintenance phase, parents determined and recorded the frequency/duration of intervention. To assess the quality of parental talk across phases of study, structured parent-child interactions were transcribed and coded reliably for the presence of elaborative statements. Children’s EM was assessed using a cueing task (to tap memory specificity) and a Remember/Know task (memory accuracy), and ToM was assessed using a task battery. Parents’ impressions of the social validity of intervention were collected and analyzed qualitatively.

Results: From pre- to post-intervention, parents increased their use of elaborate reminiscing, and children demonstrated improvements in EM specificity and ToM. Memory accuracy also improved but only among children with high or age-typical language developmental levels. At follow-up, parents maintained a high elaborative style, and children maintained ToM gains; however gains in EM specificity returned to pre-intervention level: an outcome that was associated with a drop in intervention dosage during the maintenance phase. Parents reported that elaborate reminiscing supported successful communication with their children.

Conclusions: Parents can be taught to use and maintain a high elaborative style. High elaborative reminiscing predicts improvement in autistic children’s EM and ToM but diminution of intervention dosage after a brief intervention period may obviate gains in cued memory performance. The findings justify further study of the therapeutic potential of this novel caregiver-delivered intervention. Future research should employ experimental designs to address threats to internal validity, and explore how duration and intensity of intervention affect children’s performance on various measures of EM and ToM.

435.252 (Poster) Pilot Randomized Control Trial of a Theory of Mind Caregiver Training in Iran

N. Goharbakhshe, F. Palizgar, S. Fathabadipour', H. Balf and E. Salomone', (1)Università Milano Bicocca, Milano, Italy, (2)Keele University, Newcastle under Lyme, United Kingdom, (3)Islamic Azad University, Karaj, Iran (Islamic Republic of), (4)Department of Psychology, University of Milan-Bicocca, Milan, Italy

Background: Theory of Mind (ToM) skills in children with ASD are often impaired, with consequences on the ability to create and maintain effective social relationships with others. Teacher or parent-mediated ToM interventions have been shown to be effective, however few studies have been conducted in non-Western settings. In Iran, therapist-led ToM interventions have recently been tested (Adibsereshki et al. 2015; Yaghooti et al. 2019), but parent-mediated interventions have not been examined.

Objectives: To examine preliminary effectiveness of a ToM caregiver-mediated intervention in Iran

Methods: The study is a two-arm pilot RCT conducted in private health settings in Iran. Participants were parents of children with ASD. Inclusion criteria for children were: (a) clinical diagnosis of ASD, (b) age 6-10 years, (b) Autism Spectrum Screening Questionnaire (ASSQ) score above cutoff. Participants were randomized to an 8-sessions parent-mediated ToM intervention based on “Teaching Children with Autism to Mind Read” (Howlin et al. 1999) adapted for use by caregivers (n=25) and a treatment as usual (TAU) condition (n=25). The groups (N = 50; mean age = 86.66 months; 26 boys) did not differ on child age, gender, ASSQ, WISC-IV FSIQ and parent educational level (all ps > 0.05). Intervention contents include emotional understanding and information state ToM skills; children are taught ToM skills through a question-answer approach with corrective feedback. In weekly 1-hour training sessions with a clinician caregivers practiced through role play. Caregiver independent practice at home consisted of applying the same question-answer approach to the children with provided materials. The primary outcomes were ToM skills measured with the Persian version (Ghamrani et al., 2006) of the TOM test
(Muris et al., 1999). The TOM test, consisting of vignettes, stories, and drawings, yields a Total score and three subscales: Precursors of Theory of Mind, First Manifestations of a Real Theory of Mind, and More Advanced Aspects of Theory of Mind. The α in our sample was excellent for the Total TOM Score (α = 0.86) and the three subscales (respectively, α = 0.81, α = 0.77 and α = 0.74).

Results: To assess the effect of group membership, between-subjects ANCOVA models were run on post-intervention change scores of the primary outcomes, adjusting for baseline scores. The intervention group improved significantly more on the TOM Total Score (F = 13.25, p = 0.01), with a large effect size (0.22) and at subscale level, on the Precursors of ToM and First manifestations of TOM subscales respectively with large (0.11) and medium (0.08) effect sizes, but not on the Advanced TOM subscale (F = 2.90, p = 0.09).

Conclusions: To our knowledge, this was the first randomized controlled study of a ToM caregiver training conducted in Iran. Findings showed that an acceptable and feasible caregiver-mediated intervention for ToM skills in children with ASD can lead to benefits on precursors and first manifestations of ToM. Study limitations include lack of formal assessment of fidelity of implementation and small sample size. Future studies are needed to examine factors affecting treatment effectiveness on the more advanced ToM components.

435.253 *(Poster) Pilot Results from a Novel Social Functioning Treatment Program Study
J. A. Rankin, G. Di Giovanni, M. Yoon and E. S. Brodkin, (1)Department of Psychiatry, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, (2)The University of Pennsylvania, Philadelphia, PA, (3)Department of Psychiatry, Perelman School of Medicine University of Pennsylvania, Philadelphia, PA

Background: Few social functioning treatment programs exist for adults on the autism spectrum. TUNE In (Training to Understand and Navigate Emotions and Interactions), a 17-week cognitive behavioral treatment program, was developed at the University of Pennsylvania to support social functioning in autistic adults by addressing social anxiety and motivation (component 1), social skills and cognition (component 2), and generalization to community settings (component 3). Component 1 consisted of 5 individual sessions, component 2 consisted of 8 group sessions broken into two parts (didactic and conversation practice), and component 3 consisted of 4 advocacy group project sessions. Components were designed based off Pallathra et al (2018).

Objectives: The current study aimed to test the efficacy of TUNE In to improve social functioning via a randomized control trial.

Methods: To date, 19 participants (7 randomly assigned to active treatment, and 12 to control) completed participation and study measures. Reliable change index (RCI) was utilized to examine improvements in informant-reported social functioning via the Social Responsiveness Scale, Second Edition (SRS-2). RCI evaluates whether an individual’s change over time is statistically significant considering standard error of measurement. After completing the treatment, 6 treatment group participants agreed to provide feedback on TUNE In via an interview. Responses were recorded verbatim.

Results: Of the 7 participants in the treatment group, 3 (43%) reliably improved, while 4 (57 %) did not show any reliable change. Of the 12 participants assigned to the control group, 2 (17%) reliably improved, 6 (50%) did not show reliable change, and 4 (33%) reliably deteriorated. The majority of participants stated that they were able to apply skills from component 1 (5/6 participants) and component 2 (4/6) to component 3 and to their daily lives. More than half of participants (4/6), felt that the didactic portion of component 2 (focused on social cognition) translated into the conversation practice portions of component 2 and half (3/6) felt that the conversation practice was the most useful part of component 2. Generally, participants found benefit from component 3 (5/6), with all participants (6/6) indicating they felt empowered by component 3.

Conclusions: Overall, this pattern of results suggests that a greater portion of participants in the treatment group improved in social functioning during the study. However, results also suggest variable response within both groups. Overall participants indicated receptiveness to TUNE In, with varying views on the most useful parts of sessions and the most applicable skills and tools. A second cohort is currently enrolled in the TUNE In RCT and additional data collected will be presented at the INSAR 2023 meeting. With this larger sample size, future analyses will examine potential moderators and mediators of treatment response.

T. Hutchins and A. Brien, (1)UVM, Burlington, VT, (2)Speech Language Pathology, California State University at San Marcos, San Marcos, CA

Background: Autobiographical memory (ABM) is memory about the self, including facts about oneself (semantic memory [SM]) and recall for past personal experiences (episodic memory [EM]). SM and EM are integrated in typical ABM development but may diverge in autism; whereas SM appears relatively intact, disruptions in EM are well documented. Several theories have been proposed to explain ABM differences in autism and experimental research has implicated a variety of potential mechanisms and cognitive processes. Still, the most common task paradigms lack ecological validity and are not well suited for understanding how ABM in autism might operate in situations that are personally meaningful and relevant for the individual. This information is crucial for understanding the heterogeneity, practical
impact, and subjective experience of ABM in autism and for the development of individualized interventions to support learning and cognition.

Objectives: In study one, we sought to capture parents’ impressions of their autistic children’s ABM to understand ABM strengths and challenges for the purpose of treatment planning. In study two, we solicited testimony from autistic adults to identify themes across participants, describe heterogeneity, and apprehend the phenomenology, or subjective experience associated with ABM differences.

Methods: We conducted two separate qualitative studies. In study one, parents (n=20) of autistic children (ages 6-15 years) completed the ABM Caregiver Interview (ABMCI) prior to their participation in an ABM parent-training intervention. The ABMCI is a semi-structured interview comprised of 12 open-ended, non-leading questions with standardized prompts. Initial questions were broad to be as inclusive as possible with regard to the potential variation in responses. In study two, 123 autistic adults rated the quality of their ABM and provided open-ended responses that described their subjective ABM experiences. All responses were analyzed using an inductive, open-coding process. In an initial analysis, data were scrutinized by survey item. In a subsequent analysis, subthemes were identified across items and respondents.

Results: In study one, parent report revealed individual child ABM profiles (strength and challenge areas) as well as the following themes: 1) strength/superiority in SM accompanied by impoverished EM, 2) a facilitative effect of task support, 3) the deployment of alternative memory frames (e.g., books, play episodes, focused interests), and 4) wide variability in functionally-related domains (e.g., spatial grounding). The results of study two were highly consistent with these themes but went beyond them by describing the practical impact and subjective experience of ABM from a first-person perspective.

Conclusions: Parents provided rich descriptions of their children’s ABM that are informative for designing and implementing parent interventions (described in the following presentation). The themes identified in parent testimony largely corroborated existing research providing tentative evidence for the validity of the qualitative assessment procedures. Moreover, the heterogeneity in reports by both parents and autistic adults involving the quality of ABM and ABM-related functions was notable, theoretically potent, and clinically meaningful. Analyses suggest new insights into the potential for different structures, organizations, and experiences of ABM among autistic people.

435.255 (Poster) Quality of Life: An Overlooked Health Outcome for Children with ASD

K. L. Staples, N. Miodrag and L. R. Ketcheson; (1)School of Health Promotion and Kinesiology, Texas Woman's University, Denton, TX, (2)Child and Adolescent Development, California State University Northridge, Northridge, CA, (3)Department of Kinesiology, Health and Sport Studies, Wayne State University, Detroit, MI

Background: Children with autism spectrum disorder (ASD) experience greater health disparities compared to neurotypical (NT) children of the same age. Previous intervention research has emphasized increasing levels of physical activity and decreasing rates of obesity among children with ASD, but there has been limited impact on either outcome. Of greater concern should be that parents of children with ASD have reported lower levels of overall health-related quality of life (QOL).

Objectives: The primary objective of this research was to examine health related QOL among children with ASD and children with NT development. To understand patterns of change with increasing age, comparisons from early to middle childhood were also examined.

Methods: 50 children with ASD (39 boys) and 51 NT children (40 boys) between the ages of 3 and 9 years (MASD = 6.39 ± 1.98, MN = 7.15 ± 2.00) were divided into two age groups reflecting early (3 to 5 years) and middle (5 to 9 years) childhood. ASD diagnosis was confirmed using the ADOS-2; comparison scores ranged from 4 to 10 (M = 7.15 ± 1.59). Cognitive level was estimated for children with ASD. The MSEL was administered to all children with ASD between 3 years of age to 9 years of age. Depending on level of expressive language, the WASI-2 or Leiter-3 was administered to children with ASD between 6 and 9 years of age. Overall, 33% of children with ASD were estimated to have IQ scores below 70 and were classified as having an intellectual disability. The Pediatric Quality of Life Inventory (PedsQL) was completed by parents as an estimate of each child’s QOL. The PedsQL includes 23 items across 4 scales to measure dimensions of physical, emotional, social, and school/daycare functioning. Two summary scores were calculated: (1) Physical QOL (physical functioning) and (2) Psychosocial QOL (emotional, social, and school functioning). Independent samples t-tests were used to compare QOL scores between children with ASD and same aged NT children for each age group. To assess the effect of age on QOL, independent samples t-tests were used to compare QOL scores between early and middle childhood. Cohen’s d was used to calculate effect sizes.

Results: Across early and middle childhood, children with ASD had significantly lower parental estimates of physical QOL (p-values < .001; d = 1.58 – 1.68) and psychosocial QOL (p-values < .001; d = 1.90 – 1.99). With increasing age, physical QOL scores remained relatively consistent and psychosocial QOL scores decreased (ns) for children with ASD and NT.

Conclusions: In early childhood, parent perceptions of their child’s health-related QOL is already significantly lower among children with ASD. Although the pattern of change with increasing age is similar, the significantly lower QOL scores for children with ASD in early and middle childhood warrant further exploration. These results support the need to focus on interventions that improve QOL and well-being in
Background: Reading comprehension impairments impact as many as 60% of individuals with autism spectrum disorder (autism) and are associated with language, cognitive, and social communication challenges (e.g., McIntyre et al., 2017). There are very few evidence-based interventions to support reading comprehension for children with autism, and education professionals have expressed that they lack the training and resources to support these students (Accardo & Finnegan, 2019). This is especially true with learners with autism who have co-occurring intellectual disability (ID; Knight et al., 2019). Few studies have examined reading instruction in autistic children with ID (an estimated 32% of individuals with autism), and those that have often focus on decontextualized approaches such as sight word or letter-sound instruction.

Objectives: This presentation will provide information the feasibility, acceptability, and initial efficacy of an adaptation of an evidenced-based reading intervention, Building Vocabulary and Early Reading Strategies (BVERS; Henry & Solari, 2020; Solari et al., 2020), with children with autism and ID. We will discuss data answering two research questions: (1) Is the adapted BVERS intervention feasible and acceptable to educators for use with elementary-aged children with autism and ID? (2) Does the adapted BVERS intervention demonstrate promise for supporting language and literacy growth for elementary-aged children with autism and ID?

Methods: Eleven children with autism (grades K-2) who had mild to moderate intellectual disability participated in this 4-week trial of the adapted BVERS shared reading intervention. Child language and literacy data was collected at pretest and posttest using the CUBED Narrative Language Measure Listening subtest and Concepts About Print (Clendon et al., 2021). Five educators enrolled in the study and implemented the adapted BVERS curriculum 4 times per week for 4 weeks. Following the intervention, educators completed a feasibility and acceptability survey. Intervention activities included a read-aloud of a target text, an emergent writing activity, and explicit instruction in key story vocabulary. Adaptable to the intervention included visual supports and hand gestures to allow students to access comprehension concepts and demonstrate their learning through verbal and nonverbal means.

Results: At pretest, children’s mean nonverbal IQ as measured by the Raven’s-2 = 62.1 (SD=18.8) and mean receptive vocabulary as measured by the PPVT-5 = 54.5 (SD=14.8). There was no attrition in this sample across the four-week intervention period. Educators reported high levels of feasibility and acceptability. Wilcoxon Signed-Rank tests showed statistically significant growth in concepts of print, $z = -2.25, p<0.05, r = -0.59$. There was no significant difference in participants’ CUBED narrative language scores from pretest to posttest.

Conclusions: The results of this pilot trial find that this intervention is feasible to implement on a regular basis in school settings and has strong social validity, and that teachers find the intervention acceptable for use in this population. Additionally, there is evidence that a key element of literacy development, concepts of print, showed improvement following the BVERS intervention. When including adaptations such as tactile and visual supports, shared reading activities can offer students with autism and ID increased opportunities for reading and language development.

**References:**

Results: Following PRT, there was a significant reduction in the RBS-R Total Score from baseline ($M = 25.92$) to posttreatment ($M = 22.68$): $t(24) = 1.753, p = .046$. There was also a significant decline between the baseline ($M = 4.04$) and posttreatment ($M = 3.36$): $t(24) = 1.846, p = .039$. While not statistically significant, there was a decline across all other subdomains of the RBS-R: Self-Injurious Behavior, Compulsive Behavior, Ritualistic Behaviors, Sameness Behaviors, and Restricted Behaviors.

Conclusions: On average, RRB symptom severity was significantly reduced following a 16-week trial of PRT. Notably, there is a significant difference in the Total score and Stereotyped Behavior score on the RBS-R from baseline to posttreatment. The participants demonstrated improvements in the other subdomains of Self-Injurious Behavior, Compulsive Behavior, Ritualistic Behaviors, Sameness Behaviors, and Restricted Behaviors; however, the magnitude of the difference was not significant, likely because the behaviors were low frequency and/or mild at baseline. In this trial, PRT directly emphasized social communication skills, such as initiation and reciprocity. These results, therefore, indicate that focusing on social communication skills may have an indirect effect on reducing RRBs among children with ASD.

435.258 (Poster) Robot Vs. Tablet: How Do Children with ASD Perform and What Do They Prefer? A Preliminary Study

L. Charpiot, E. Nittenwilm1, D. Paulus, C. Godinho1, M. Vintila1, M. Hoffmann1, S. Martins1, A. P. Costa2 and G. Steffgen2, (1)Université du Luxembourg, Esch-sur-Alzette, Luxembourg, (2)University of Luxembourg, Esch-sur-Alzette, Luxembourg, (3)Institute for Health and Behaviour, University ofLuxembourg, Luxembourg, Luxembourg

Background: Society faces several challenges in the care and education of people with autism regarding cost, accessibility, and turnover. One promising tool receiving researcher’s attention is the use of robots in the care of children with autism spectrum disorder (ASD). Robots offer numerous possibilities in terms of therapeutic and educational applications, knowledge transfer, and care’s accessibility (e.g. Diehl et al., 2012; Huijen et al., 2016). Even if robots seem to be a promising tool for children with autism, they are not widely available on the market, are not necessarily easy to use, and are relatively expensive. Even, if robots provide an embodiment of multi-modal aspects, which may play an important role in interpersonal relations (Dautenhahn & Werry, 2004), it is uncertain how much benefit it brings compared to tablets that provide almost the same advantages.

Objectives: Our study investigated which difference may exist between the use of these two technologies. Therefore, we examined how children with ASD interacted with each device and how they enjoyed similar interactions.

Methods: Eleven boys diagnosed with ASD aged 9 to 17 years ($M = 12.45, SD = 3.30$) listened to two stories for children provided by a tablet or robot. Children’s characteristics are visible in Table 1. Both devices displayed the same face, and both stories were of similar content, duration and number of questions. The design was repeated and counterbalanced, and conditions were similar. Before the interaction started, the children could interact freely with the device (tablet or robot) for one minute in a restricted area. The interactions were video recorded, and children’s behavior, proximity, eye gaze, answers, and preference were assessed.

Results: Statistical analyses demonstrated no difference regarding children’s proximity and eye gaze. Children also responded a little more correctly to the three questions asked with the tablet ($M =1.64, SD =.67$) than to the ones asked by the robot ($M =1.27, SD =1.01$) but this difference wasn’t significant ($Z =- .48, p =.63$). However, children showed more stereotyped and repetitive behaviors when interacting with the robot than with the tablet ($Z =-2.55, p <.01; r =.76$). Finally, children expressed a clear preference for the tablet storyteller (72.7%) than with their usual teacher (9.1%) or the robot (0%).

Conclusions: Despite not finding significant differences in children’s performance across devices, children preferred the tablet to the robot. Tablets might be easier to handle and more familiar, as children are more likely to have had previous contact with tablets. Finally, our results raise questions about the embodied multi-modal advantage that robots are thought to provide to children with ASD compared to tablets (Dautenhahn & Werry, 2004).

435.259 (Poster) “Peeling Back the Layers of the Onions”: Refining an Emotion Focused Therapy Expressive Writing Intervention for Autistic-LGBQ Individuals

M. R. Maroney1, E. Coombs1 and H. Levitt1, (1) Counselling Psychology, University of Calgary, Calgary, AB, Canada, (2) Clinical Psychology Department, University of Massachusetts, Boston, Boston, MA

Background: Emerging research has documented the high prevalence of gender and sexual minority individuals within the autistic community (George & Stokes, 2018; Warrier et al., 2020), but there has been limited research on the impact of prejudice events on this population. Expressive writing interventions have been found to effectively reduce symptoms of psychological distress, including coping with distress related to one’s sexual minority identity and identity-based hate speech (Pachankis & Goldfried, 2010).
Objectives: The present study explored the experiences of autistic, gay, bisexual, and queer (LGBQ+) individuals completing an online expressive writing intervention designed to process distressing heterosexist events. The central question of this study was, how did participants experience the Emotion Focused Therapy condition when processing heterosexist events?

Methods: Ten autistic-LGBQ+ participants who completed the month-long intervention study were invited to participate in a follow-up interview. All participants were from the experimental condition, which consisted of semi-guided prompts informed by an Emotion Focused Therapy approach to deepen processing (Elliot & Greenberg, 2007). The mean age of participants was 33.1 (SD = 11.7), and most participants identified as White. All participants were autistic and LGBTQ-identified and had endorsed a distressing heterosexist event, as this was part of the study criteria for the intervention study. We analyzed our data using a modified version of grounded theory methodology (Glaser & Strauss, 1967), which consisted of breaking data from each interview into meaning units or labels describing the main ideas in the transcript (Giorgi, 1970).

Results: Results of this grounded theory study consisted of six clusters comprised of multiple subcategories and 360 meaning units (see Table 1). The first three clusters focused on participant changes and engagement with the exercises over the course of three days of writing, for instance as found in cluster 3: It was “liberating” to notice positive changes in meeting my needs, speaking out, and develop new insights about myself as an LGBTQ autistic person. For instance, “In the weeks following, I found myself a lot more confident advocating...I don't feel that hesitancy now that I've like processed stuff that happened the night before.” The third clusters spoke to larger considerations for intervention research due to their positionality as autistic queer people, as highlighted in cluster 4: Adding prompts to increase accessibility and transparency of the exercises, would strengthen this already helpful intervention for many LGBTQ+ autistic people in processing stigma.

Conclusions: There are several implications for the present research. Firstly, the results provide support on the importance of centering autistic voices in the development and refinement of interventions to meet their needs. Participants identified aspects of the intervention that were helpful, as well as changes that could better support them, which we will discuss. Secondly, the study demonstrates the benefits of an online EFT expressive writing intervention in processing autistic LGBTQ people’s experiences of heterosexism. This semi-structured and open method appears to empower autistic people to engage in meaning-making and identify ways to meet their needs following experiences of sexual minority-based stigma.

435.260 (Poster) Services for Adolescents with Autism Spectrum Disorder and Intellectual Disability in Vietnam: A Qualitative Study

C. V. Tran, H. S. Vu, G. Le, P. H. Nguyen and H. T. Hoang, (1)Department of Educational Sciences, Vietnam National University, Hanoi, Viet Nam, (2)Center for Creative Initiatives in Health and Population, Hanoi, Viet Nam, (3)VNU University of Education, Hanoi, Viet Nam, (4)Vietnam-France Psychology Institute, Hanoi, Viet Nam

Background:

Early interventions for young children with autism spectrum disorders (ASD) have been intensively researched and applied during past decades in Vietnam. Meanwhile, services for older children, such as social skills training and career guidance, are usually for adolescents with better potential. Besides, the connection between stakeholders, including education, medicine, and society, is loose and uneven across regions.

Objectives:

This study aimed to explore the model of services for adolescents with ASD and intellectual disabilities (ID) in 3 areas, including special and inclusive education, medical, and society, based on the report of parents, special educators, and medical staff.

Methods:

Qualitative study design was implemented with three main research methods: literature review, focus group discussions, and in-depth interviews. Twenty-five studies in Vietnam were identified, and 40 participants participated in this study (Table 1). The materials, discussions, and interviews focused on 2 objectives: (1) Needs for support in education, medical, and society of families with children with ASD and/or ID aged 10 – 16 years old; (2) Service and support provision for this population.

Results:

The families faced barriers in accessing instructional materials to support their children at home, especially difficulties in career orientation and future life. The information in Vietnam was limited and focused mainly on early intervention. They expected a friendly medical network with doctors who could interact with special children; expressed the need for social integration was reflected in not only employment but also in making friends and expanding social relationships through a social group with support from the university’s volunteers. Besides, they desired to receive psychological counseling for themselves and siblings of children with ASD/ID.
Currently, comprehensive and multi-stakeholder support in education, medicine, and society for adolescents with ASD/ID has not been developed in Vietnam. Only a slight connection between special education and medicine or the community exists. Regarding intervention centers, there are three activities provided in special centers: adaptive behavior assessment, intervention and career guidance for children, and parents training (Figure 1). As children get older, the participation rate in inclusive education decreases because the curriculum is more complicated, and there are no consistent policies on academic support for children in the classroom. Laws and policies for professional development for inclusive teachers are not uniformly enforced.

Current public vocational schools do not focus on children with ASD/ID, and parent-created vocational and career guidance models are challenging to maintain and cannot reach many children. In addition, employers do not welcome employees who are disabled, and the government does not have policies to support enterprises that receive workers with disabilities.

Conclusions:

Services for adolescents with ASD/ID in Vietnam are generally limited due to low resources from families after a costly early intervention process and a lack of care from professionals and policies. More attention needs to be paid to this population in future research and policies.

435.261 (Poster) Sexual Assistance for Autistic Adults: Experiences of Autistic Adults and Service Providers

J. Dewinter1 and I. Noens3, (1)GGzE, Eindhoven, Netherlands, (2)Tilburg School of Social and Behavioral Sciences - Tranzo, Scientific Centre for Care and Wellbeing, Tilburg University, Tilburg, Netherlands, (3)Parenting and Special Education Research Unit, Faculty of Educational Sciences, KU Leuven, Leuven, Belgium

Background:

Although a large part of autistic adults has partnered sexual experience, some individuals experience barriers in finding a (sex) partner or handling an intimate relationship. Anxiety, fewer positive ideas about sexuality, less interest, and less sexual desire were reported by those with less partnered activity (Byers et al., 2013). In some countries, sexual assistance is available for individuals with special needs or disabilities. In Belgium and the Netherlands, sexual assistance providers reported that autistic persons or their supportive network regularly apply for sexual assistance. Sexual assistance aims to create learning opportunities regarding intimate and sexual interactions, for adults with limited sexual experiences or for adults who show inappropriate interests or behaviours.

Objectives:

The current study was designed to gain insight into the experiences and needs of autistic adults who apply for sexual assistance, aiming to understand facilitators and barriers for enjoying sexuality. These insights were expected to be helpful to improve sexuality education and support.

Methods:

A qualitative semi-structured interview study was set up in two groups (n = 15 participants): 4 autistic adults without co-occurring intellectual disability and 11 service providers with experience in sexual assistance to autistic adults with or without co-occurring intellectual disabilities. Three dyads were interviewed separately on their collaboration, other participants more broadly on their experience as service user or provider. Data were analyzed according to the Qualitative Analysis Guide of Leuven (QUAGOL) guidelines. The research topic and the preliminary results were discussed with an autistic advisory group.

Results:

Preliminary analysis of more than half of the dataset revealed a variety of experiences and needs before, during and after intimate, sexual interactions. Autistic adults apply for sexual assistance with a variety of backgrounds; from a lack of experience and ideas to very specific preferences about intimate and sexual interactions. Autistic adults and sexual assistants describe the need for predictability, clear and explicit communication, a step-wise approach when introducing new experiences, attunement to anxiety levels and sensory issues, and clear feedback on the interaction and the experiences of the sex partner. Sexual assistants need to be very proactive in adapting to the needs of the adults they work with and to create a safe space to learn about sexuality: they have to take the daily living context and abilities of the adults into account, be sensitive to previous (sometimes traumatic) experiences, discuss mutual expectations and limits explicitly, observe and attune to verbal and non-verbal reactions. By May 2023, data analysis will be completed.

Conclusions:
Some autistic adults experience barriers in entering and maintaining healthy sexual relationships. The interviews revealed a variety of barriers and needs to learn about and enjoy sexual interactions. Professional sexual assistants had a very proactive role in creating safe situations that can promote healthy sexual development and wellbeing. Yet, managing these professional relationships and stimulating transfer to their daily lives could be challenging. This study’s results offer cues for sexuality education and support to autistic adults and demonstrate the value of sexual assistance in terms of learning by experience.

435.262  (Poster) Skolkontakt(TM) - Pilot RCT of School-Based Social Skills Group Training for Autistic Youth
A. Fridell1, C. Coco2, A. Borg3 and S. Bolte4, (1)CAP Research Center, Department of Women’s and Children’s Health, Karolinska Institutet, Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, Sweden, (2)Department of Women's and Children's Health, KIND Karolinska Institutet Center of Neurodevelopmental Disorders, Stockholm, Sweden, (3)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden

Background:
Atypical socio-communicative behaviors, a hallmark feature of autism, contribute to social challenges which in turn are associated with increased risk for negative, long-term outcomes, such as educational underachievement, social exclusion, loneliness, and mental health issues. The clinically-based social skills group training KONTAKT™ has demonstrated solid evidence in improving social communication outcomes and individual social goal-attainment in autism. Given that interventions in natural educational context may enhance generalization of skills, build support capacities in society and have practical advantages for youth and families, SKOLKONTAKT™ has been adapted from KONTAKT to provide school-staff with a manualized method to conduct the intervention at school. Previous multi-perspective qualitative research on SKOLKONTAKT found that student, teachers and school leaders experienced the program to be feasible and adding value to practice and social climate.

Objectives:
To investigate the preliminary effectiveness of school-based, teacher-led social skills training (SKOLKONTAKT) to improving socio-communicative behaviors and accomplish personalized social goals in autistic students and others with social communication challenges.

Methods:
A pilot randomized, controlled trial with an active control group was conducted in a mainstream, extra resourced high school in Stockholm, Sweden. High-school students (N=26; age M=17.5; age range=16-21) diagnosed with autism or exhibiting social skills challenges were randomized to SKOLKONTAKT (n=12; boys=5) or a social activities group (n=14; boys=7). Pre to post or pre to follow-up intervention changes in self-, parent- and teacher (single-blind) reported outcomes as assessed by the Social Skills Group Questionnaire (SSGQ) (primary outcome) were analyzed. In addition, self-reported changes in quality on the KIDSCREEN-27, and social goal attainment using the Goal Attainment Scaling (secondary outcomes) were measured.

Results:
Despite challenges due to pandemic situation during the study, 70% (n=12) completed SKOLKONTAKT and 87.5% (n=14) completed social activity control groups. Drop-out in SKOLKONTAKT predominantly occurred following week one and rationales included overall anxiety and school attendance. SKOLKONTAKT participants improved SSGQ item level for across informants for Meeting new people”, as well as a range of other items for single raters. Subjective life quality improved following SKOLKONTAKT for indices physical health and friends. A larger proportion of social goals were attained during SKOLKONTAKT than in social activity control groups. Side-effects by interventions were reported as low-impact and proportionally fewer in SKOLKONTAKT.

Conclusions:
School-based social skills group training by SKOLKONTAKT is a safe and feasible intervention option for autistic students in educational settings. Preliminary findings following the pilot RCT suggests that the method enhances certain social skills, aspects of life quality and social goal attainment. A larger-scale study is desirable to confirm effects identified in this pilot.

435.263  (Poster) Social and Aberrant Behavior Longitudinal Data: Findings from a Specialized School in Autism

Background:
Monitoring the progress of children with an autism spectrum disorder (ASD) both in school and at home to promote a school-based integrated care model between parents, teachers, and medical providers has proven to be feasible. We have conducted a longitudinal cohort study at a specialized school for ASD in California for the past 5.5 years using an online platform developed for teachers and caregivers.

Objectives:

Examining the average change over time for the following outcomes: Aberrant Behavior Checklist (ABC), Social Responsive Scale (SRS) and Pediatric Quality of Life (PedsQL) 4.0 for individuals with ASD at a specialized ASD School.

Methods:

This five-year longitudinal cohort study included 50 participants (aged 7-19 years) with ASD from a specialized school. Evaluations were completed by parents and teachers every 3 months included ABC, SRS and PedsQL. For the SRS, evaluations were done every year after January 2019. Recruitment for participants was ongoing throughout the study period, resulting in staggered entry.

Repeated measures analysis using mixed-effects models was used to determine whether there were significant changes in the mean ABC, SRS and PedsQL across the timepoints, with the participant (‘subject ID’) being defined as a random effect. Parent-reported and teacher-reported measures were analyzed separately.

Results:

The mean age for the participants at baseline was 14.5 ± 3.5 years, with males comprising 90% of the population. There were statistically significant improvements in the mean teacher-reported ABC (p=0.047), parent-reported SRS (p=0.038) and teacher-reported SRS (p=0.014), and quality of life (p<0.001) over time for all participants with ASD at Oak Hill School. On average, after five years in the study, there was a 13.4-point decrease in teacher-reported ABC (p=0.041), 15.3-point decrease in teacher-reported SRS (p=0.026), and a 16.5-point increase in PedsQL (p=0.026) compared to baseline. Parent-reported SRS decreased by 14.6 points compared to baseline after 3 years in the study (p=0.025). The average parent-reported ABC did not improve over time (p=0.5).

Conclusions:

The value of longitudinal outcome study is key to developing more efficacious and collaborative treatment plans for children with ASD. Several studies have generally shown that adolescent ratings of autism worsen over time. Therefore, it is an interesting finding to see overall improvement over 5.5 years. This specialized learning environment was beneficial as it led to significant improvements in their behavior, social skills and quality of life throughout their enrollment in the school. Future research will determine factors associated with the greatest and the least improvement with hope of matching focused treatments.

435.264 (Poster) Supporting Autistic Learners in School with Triple-a: Attention, Arousal and Anxiety
M. Hanley1, J. R. Hirst2, E. Waddington2, D. M. Riby3 and E. McDougal4, (1)South Road, Durham University, Durham, UNITED KINGDOM, (2)Durham University, Durham, United Kingdom, (3)Department of Psychology, Durham University, Durham, United Kingdom, (4)Surrey University, Surrey, United Kingdom

Background: School classrooms are typically busy, complex multisensory environments, which are often quite unpredictable. They can lead to particular challenges for autistic learners, especially because many of these learners experience differences with “Triple-A” – namely, attention, arousal (sensory processing) and anxiety. Research from our group has shown how attention, sensory arousal and anxiety have an impact on the engagement and learning of autistic learners (Hanley et al., 2017; Jones et al., 2020, McDougall et al., 2020a, 2020b). On this basis, we developed an evidence-based online training tool targeted at educators (but freely accessible to all) to change understanding of Triple-A and confidence for supporting learners with Triple-A needs.

Objectives: The main objectives were to evaluate the data from users of the Triple-A training tool on pre and post measures of their knowledge and confidence with supporting Triple-A needs at school. As well as that, data on users ratings of the training as well as intention to change were evaluated.

Methods: The Triple-A training tool was co-designed with key stakeholders (autistic people, parents, teachers, educational psychologists). Development work involved focus groups and workshops with key stakeholders to assess feasibility and acceptability. It was launched in March 2022. Data from users was collected via the online training tool. At this point (Oct 2022), over 2000 users have registered for the training.
Results: To date, 47% of completers have provided evaluation data. Feedback has been overwhelmingly positive, and paired samples t-tests show that participants reported significant increases of both knowledge, \(t(82) = -12.115, p<.001\), and confidence, \(t(83) = -10.52, p<.001\), with supporting Triple-A needs. Ninety-two percent of participants reported they would change their practice based on the training.

Conclusions: The Triple-A training tool improves knowledge of a hidden set of challenges commonly experienced by autistic pupils - Triple-A needs - as well as confidence for supporting autistic learners at school.

435.265 (Poster) Supporting Secondary Teachers to Successfully Implement a Self-Determination Curriculum
K. M. Malone\(^1\) and D. Kan, (1) Applied Developmental Science and Special Education, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)NA??, Chapel Hill, NC, (3)School of Education, The University of North Carolina - Chapel Hill, Chapel Hill, NC

Background: Self-determination has been consistently identified as a transition predictor for improving post-school outcomes for students with disabilities through multiple rigorous systematic literature reviews. Youth with higher self-determination scores were shown to have better employment and higher pay, and enhanced recreation and leisure participation post-school. However, autistic students have lower levels of self-determination compared to peers with and without disabilities. Direct teaching of skills and infusion of self-determination components into the school curriculum support students in learning and taking more self-determined actions. Self-determination interventions have been developed to help structure lessons and provide teachers with strategies that can be infused into current classroom practices.

Objectives: A teaching model that has seen success in high school classrooms is the Self-Determined Learning Model of Instruction (SDLMI). SDLMI allows students to self-direct the instructional process across multiple academic and non-academic content areas by setting goals, planning actions, and evaluating progress. However, as every classroom is different and students each have their own unique needs, there is a need to tweak the intervention in ways that will allow teachers to best deliver the intervention while meeting their students’ needs. Through working and learning alongside teachers on the Propel Project (a classroom-based intervention study for autistic high school students that includes SDLMI), this presentation aims to discuss ways that the SDLMI can be adapted in classrooms to support student goal attainment and outcomes.

Methods: Teacher modifications to the SDLMI curriculum were recorded by coaches on the research team during coaching sessions throughout the implementation year. We also gathered student (n=19) and teachers (n=14)’ perspectives about the SDLMI through individual and group interviews, and all participants completed a User Rating Profile (URP) survey post-intervention.

Results: Teachers shared enthusiasm about implementing SDLMI in their classrooms (mean=5.2/6), and felt administrators are supportive of their use of this intervention (mean=5.4/6). Ways that teachers adapted the SDLMI include modifying the language and vocabulary used to be more accessible and engaging to students, incorporating visuals to help students better envision goals and increase accessibility (e.g., collage activity, visual supports), and using multi-modal resources (e.g., podcasts or videos with sign language) and personal connections (e.g., student interests) related to SDLMI lessons.

Conclusions: Teachers can successfully implement SDLMI in their classrooms and support the development of self-determination in autistic students by adjusting and adapting existing intervention materials to meet the specific needs of students in their high school classrooms.

435.266 (Poster) Systematic Review of First-Person Accounts of Autistic People about Mental Health-Related Services
L. Andoni\(^1\), A. Eisenhower\(^1\) and H. Levitt, (1) Department of Psychology, University of Massachusetts, Boston, Boston, MA, (2)Department of Psychology, University of Massachusetts Boston, Boston, MA, (3)Clinical Psychology Department, University of Massachusetts, Boston, Boston, MA

Background: Autistic adults are at high risk of co-occurring mental health disorders, including depression, anxiety, and suicidality (Buck et al., 2014; Cassidy et al., 2014; Lever & Geurts, 2016). Among the autistic community, the available mental health-related services are often critiqued as inadequate or unsatisfactory for autistic clients’ needs. Overall, there appears to be a mismatch between the services that are offered and the preferences of many autistic people. Unfortunately, research about mental health-related services for autistic people has been evaluated by healthcare professionals, parents, or siblings, while the voices of autistic individuals have been largely left out (Prince 2010), despite clear research evidencing autistic people want to be listened to, consulted, and involved in the field of autism services (DePape & Lindsay, 2016).

Objectives: Through a qualitative meta-analysis, to synthesize and integrate results from studies examining first-person perspectives of autistic people’s experiences with mental health-related services.

Methods: We identified 33 studies of first-person experiences from autistic adults about mental health-related services that met inclusion criteria for this review. Eight studies examined participants’ experiences and needs with mental-health related services generally (i.e., studies that asked about different types of services), and twenty-five studies explored participants’ experiences attending specific services...
such as social skills trainings, support groups, peer mentoring programs, and therapy services. The studies used obtained first-person perspectives through interviews (n=17), surveys (n=7), focus groups (n=5), mixed method approach (n=3), and diaries (n=1) and ranged from 1 to 200 participants in sample size; most samples fell between 7-52 participants. To analyze the data, we used a modified grounded theory method (Glaser & Strauss, 1967), such that the main themes from each of the 33 studies were summarized and labeled in the form of meaning units. These meaning units were compared to one another, and categories were formed based on commonalities. These categories were then compared to create higher-order categories to come up with our themes.

Results: Five overarching themes emerged from qualitative analysis; these included: (1) the need to individualize and tailor services towards the heterogeneity of the autistic community, (e.g., teaching how to cope with overwhelming sensory experiences as opposed to focusing on thoughts, using more concrete strategies and visuals during therapy as opposed to typical “talk therapy,” asking more concrete questions) (2) a need for accessible environments that take into account sensory sensitivities and time structures that accommodate autistic people’s preferences (e.g., desire for routine), (3) a desire for services that provide practical support (e.g., employment tips, filling out paperwork) (4) desire for service providers to have autism-specific knowledge as well as humility in not considering themselves “autism experts,” and (5) importance of embracing autism culture and connectedness with other group members.

Conclusions: Overall, autistic people indicated a desire for greater variation in types of services offered, greater training and humility among service providers, and a clear need for more affirming and strength-based views of autism and disability. Implications for clinical practice and research directions will be addressed.

C. Butera, J. Zhou, M. R. Rosales, R. B. Wilson, H. Zhao, J. Chow, A. Dao, J. Freeman; and S. Dusing; (1)Division of Biokinesiology and Physical Therapy, University of Southern California, Los Angeles, CA, (2)Division of Biokinesiology and Physical Therapy, University of Southern California, Los Angeles, CA, (3)Semel Institute for Neuroscience and Human Behavior, UCLA Medical Center, Los Angeles, CA, (4)School of Education, University of California Irvine, Irvine, CA, (5)College of Education, University of Maryland at College Park, College Park, MD

Background: Autism Spectrum Disorder (ASD) is defined by differences in social communication, social interaction and restricted/repetitive behaviors and interests. Difficulty with imitation, motor control, and coordination are also common in this population. Motor interventions have resulted in positive outcomes in motor skills in individuals with ASD. However, the overall effects of motor intervention on social, communication, or cognitive skills in individuals with ASD is unclear.

Objectives: To systematically review the literature for motor/physical activity interventions for individuals with ASD from 0-21 years of age and assess effects on motor, social, cognitive, or communication outcomes.

Methods: This review was conducted in accordance with the Cochrane Handbook for Systematic Reviews and the PRISMA guideline, see Prospero CRD42022331576. Electronic searches were conducted on EMBASE, PUBMED/Medline, PEDro, Cochrane Library, Web of Knowledge/Web of Science, CINAHL, and Clinical Trials databases in May 2021. Each abstract and full-text was independently rated by two reviewers using Covidence systematic review software and disagreements were resolved by a third reviewer. Eligible studies met the following inclusion criteria: (a) 0 - 21 years old, (b) males and females, (c) clinical ASD diagnosis, (d) less than 30% born preterm or had intellectual disability (IQ < 70), (e) RCT, (f) English, (g) published after the year 2000, (h) motor intervention, (i) uses social, communicative, or cognitive outcome measures. We used random-effects meta-analysis with robust variance estimation to estimate the overall effect of interventions on participant outcomes and meta-regression for moderator analysis; we used a trim-and-fill analysis and meta-regression to assess the potential for publication bias.

Results: Twenty three eligible studies were selected with 52 available outcomes. There were 620 participants, 87 females, mean age range of 4.3 - 12.25 years. Motor interventions had significant, positive effect on 1) all domains combined (synthesized standardized mean difference [SSMD]: 0.37, p=.026) 2) social domain (SSMD: 0.50, p=.012) and 3) combined social/communication domains (SSMD: 0.50, p=.012), but not for the motor or cognitive domains alone. There were too few combination measures for that domain to be analyzed alone. Age was not a significant moderator (p=.08) of the overall effect. However, in children above age nine, a one year increase in age corresponded to a 0.30 decrease in SMD (interventions were less effective). Analyses suggested that publication bias was unlikely in the dataset.

Conclusions: Motor interventions were associated with improvements in combined developmental domains, particularly in social communication outcomes for children with ASD. Participant age may play a role in intervention effectiveness, but more intervention studies are needed. Although this meta-analysis did not suggest effectiveness for improvements in motor skills, many studies used motor measures as a baseline evaluation rather than an outcome measure. Some interventions were specifically designed to improve social or cognitive skills, so further research is needed. These results support the evidence that motor interventions can have a positive impact on developmental domains and should be increasingly considered as a routine clinical intervention for children with ASD.

435.268 (Poster) Testing the Efficacy of Training Parents to Use an Elaborative Reminiscence Intervention for Children with ASD

Background: Autism Spectrum Disorder (ASD) is defined by differences in social communication, social interaction and restricted/repetitive behaviors and interests. Difficulty with imitation, motor control, and coordination are also common in this population. Motor interventions have resulted in positive outcomes in motor skills in individuals with ASD. However, the overall effects of motor intervention on social, communication, or cognitive skills in individuals with ASD is unclear.

Objectives: To systematically review the literature for motor/physical activity interventions for individuals with ASD from 0-21 years of age and assess effects on motor, social, cognitive, or communication outcomes.

Methods: This review was conducted in accordance with the Cochrane Handbook for Systematic Reviews and the PRISMA guideline, see Prospero CRD42022331576. Electronic searches were conducted on EMBASE, PUBMED/Medline, PEDro, Cochrane Library, Web of Knowledge/Web of Science, CINAHL, and Clinical Trials databases in May 2021. Each abstract and full-text was independently rated by two reviewers using Covidence systematic review software and disagreements were resolved by a third reviewer. Eligible studies met the following inclusion criteria: (a) 0 - 21 years old, (b) males and females, (c) clinical ASD diagnosis, (d) less than 30% born preterm or had intellectual disability (IQ < 70), (e) RCT, (f) English, (g) published after the year 2000, (h) motor intervention, (i) uses social, communicative, or cognitive outcome measures. We used random-effects meta-analysis with robust variance estimation to estimate the overall effect of interventions on participant outcomes and meta-regression for moderator analysis; we used a trim-and-fill analysis and meta-regression to assess the potential for publication bias.

Results: Twenty three eligible studies were selected with 52 available outcomes. There were 620 participants, 87 females, mean age range of 4.3 - 12.25 years. Motor interventions had significant, positive effect on 1) all domains combined (synthesized standardized mean difference [SSMD]: 0.37, p=.026) 2) social domain (SSMD: 0.50, p=.012) and 3) combined social/communication domains (SSMD: 0.50, p=.012), but not for the motor or cognitive domains alone. There were too few combination measures for that domain to be analyzed alone. Age was not a significant moderator (p=.08) of the overall effect. However, in children above age nine, a one year increase in age corresponded to a 0.30 decrease in SMD (interventions were less effective). Analyses suggested that publication bias was unlikely in the dataset.

Conclusions: Motor interventions were associated with improvements in combined developmental domains, particularly in social communication outcomes for children with ASD. Participant age may play a role in intervention effectiveness, but more intervention studies are needed. Although this meta-analysis did not suggest effectiveness for improvements in motor skills, many studies used motor measures as a baseline evaluation rather than an outcome measure. Some interventions were specifically designed to improve social or cognitive skills, so further research is needed. These results support the evidence that motor interventions can have a positive impact on developmental domains and should be increasingly considered as a routine clinical intervention for children with ASD.
Background:

Training parents to engage in elaborative reminiscing (ER) with their typically developing children has been found to significantly improve outcomes for typically developing children. Studies have reported significant benefits of ER for improving children’s memory (Waters et al., 2019, Wu & Jobson, 2019) and associations between ER and improvements to children’s theory of mind (ToM; Taumoepeau & Reese, 2013), and self-concept (Bird & Reese, 2006). This prompts speculation that ER could be a beneficial intervention for children with autism spectrum disorder (ASD), who have known difficulties in these areas (McDonnell et al., 2017). However, no randomised trials have yet evaluated the potential of an ER intervention for autistic children.

Objectives:

A two-arm randomised feasibility trial was designed to evaluate the preliminary effectiveness of training parents to use an ER intervention compared with an active control (“present-tense-talk”; PTT), with autistic children aged 7-12 years. From baseline to post-intervention, it was hypothesised there would be improvements to children’s i) episodic memory, ii) theory of mind (ToM), and iii) self-concept, for participants in the ER group vs PTT.

Methods:

Nineteen parent-child dyads were randomised to receive ER or PTT and instructed to use the intervention for 5-minutes a day, 6 days per week for 20-weeks. Children were tested pre- and post-intervention on measures of direct memory (CVLT-C: Delis et al., 1994) and functional memory (children’s memory elaborations and reminiscence quality; Reese & Newcombe, 2007), self-concept (SDQ-I: Marsh, H. W., 1992) and ToM (Theory of Mind Battery: Wellman & Liu, 2004). Post-intervention change to children’s performance on outcome measures were analysed for intervention differences using bootstrapped multiple regressions. Parent-child conversations were reliably coded (manual adapted from Reese & Newcombe, 2007) for change to parent “elaborativeness” to test for associations between this and change in child outcomes.

Results:

ER was a significant, large predictor of children’s immediate recall ($\beta = .67$, $p = .009$, [BCa 95% CI: .92, 3.25]) and was a positive (though not-significant) predictor for other aspects of children’s direct memory. Although not significant, ER was found to be a weak to moderate predictor of children’s reminiscence frequency ($\beta = .16$, [BCa 95% CI: -21.71, 38.88]) and quality ($\beta = .48$, [BCa 95% CI: -.74, 3.06]). ER was not found to predict children’s ToM ($\beta = .08$, $p = .66$, [BCa 95% CI: -.474, .696]) or self-concept ($\beta’s = -.27$ to -.11, $p’s > 0.5$) but these measures were unfeasible (e.g., ceiling effects). Significant positive correlations were found between change to parent elaborativeness and children’s functional memory ($r’s 0.57$ to $0.52$, $p’s <0.05$) but correlations with all other outcomes were weak and not significant.

Conclusions:

Results provide prima facie evidence that training parents to elaboratively reminisce with their autistic child can benefit aspects of children’s direct and functional memory, particularly their immediate free recall, but could be less beneficial for children’s ToM and self-concept. These first-stage preliminary findings indicate the potential benefits of using ER as an intervention for autistic children. Results are discussed with reference to recommendations for future research.
families of children with developmental disorders and delays and is delivered through caregiver-mediated engagement strategies. The CST which is recommended for use in low-resource settings, consists of nine interactive group sessions and three home visits delivered by trained non-specialists.

**Objectives:** 1) To investigate the acceptability and feasibility of implementing the CST programme in rural and urban settings in Kenya; 2) To evaluate the effect of the caregiver-based intervention on behavior, communication, and the quality-of-life outcomes of children with DDs and their families.

**Methods:** Using a sequential mixed-methods design, we adapted, and pilot tested the CST programme in Nairobi’s urban informal settlements and rural Kilifi. First, CST materials were translated to Kiswahili and pre-tested using qualitative approaches among caregivers and community stakeholders (n=85) to assess their acceptability and cultural appropriateness. In the second phase, 105 caregivers of children aged 2 -13 years with different neurodisabilities (including autism, attention deficit hyperactivity disorder [ADHD], cerebral palsy, intellectual disability, and epilepsy), participated in the CST pilot. Baseline and endline data were collected using a battery of measures (Child Behavior Check List [CBCL], Patient Health Questionnaire-9 [PHQ-9], Pediatrics Quality of Life TM [PedsQL], Parental Stress Index), and analyzed using descriptive statistics. Post CST intervention focus group discussions were conducted with caregivers to assess their experiences of the programme, and the data were analyzed thematically.

**Results:** The CST programme was considered acceptable and feasible to implement in different socio-cultural settings. Evaluation of the CST programme showed a decrease in mean difference scores (Endline-Baseline) for all outcome measures. This decrease was greater in the CST group than the non-CST group; mean differences in PedsQL average scores and preschool CBCL total scores were significant (P<0.05). Caregivers reported that the CST programme addresses the need for management and care for DDs, increased social support and contends with stigma and discrimination among families and the larger community.

**Conclusions:** The CST program is a promising intervention, and with adaptations to its content, structure, and delivery, serves an important and urgent need in Kenya and other resource constrained settings.

435.270 (Poster) The Effect of the Yoga Bali Program on the Anxiety of Children with Autism Spectrum Disorder As Well As on Their Quality of Life at School.

J. Toman and N. Poirier, Psychology, Université du Québec à Montréal, Montréal, QC, Canada

**Background:** Anxiety disorders are the most common associated disorders in children with autism spectrum disorder (ASD). Without necessarily meeting the diagnostic criteria for a disorder, 80% of these children have anxious behaviors. This anxiety interferes with their quality of life (QoL). Among anxiety-provoking situations, school is one of them (e.g. change of teacher, oral presentations, exams). Besides medical and psychological interventions, new body-mind approach treatments, including yoga, are offered in a complementary way. Studies suggest that yoga appears to have the potential to ease anxiety symptoms in children with ASD.

**Objectives:** The objective of this study is to explore the effect of yoga practice on the anxiety of children with ASD and on their QoL in a school environment.

**Methods:** The sample is composed of 6 children with ASD (4 boys and 2 girls). The average age of this sample is 9 years old. The 8-week yoga Bali program was first adapted for children with ASD. A socio-demographic questionnaire was initially completed with one of their parents. A QoL questionnaire, the Systemic Quality of Life Inventory for Children (ISQV-E), and an anxiety questionnaire, the State Trait Anxiety Inventory for Children (STAIC), were completed with the children before the start of the yoga program and after it.

**Results:** The ISQV-E assesses the QoL of children in 20 domains of life, including school and grades, by measuring the gap between the current conditions in which they live compared to the conditions in which they would like to live for all domains (Dupuis et al., 1989). No significant difference was found on the “satisfaction with school” quality of life scales before (M = 3.22; SD = 6.86) and after (M = 1.20; SD = 1.39) the program (p > 0.05) and “school performance” before (M= 4.15; SD= 5.69) and after (M= 1.85; SD= 2.00) the program (p > 0.05), but analyzes showed an acceptable to medium effect size for both scales (d = 0.3-0.6.). The State Trait Anxiety Inventory for Children (STAIC) is a 20-item self-report scale to assess the severity of anxiety in children (Spielberger et al., 1973). A marginally significant difference between the mean global scores of the STAIC questionnaire before (M= 39.83; SD= 6.05) and after (M=36.50; SD= 5.54) the program (p = 0.06) was obtained with a high effect size (d = 0.74).
Conclusions:

Based on the effect size coefficients, the results suggest that yoga helps children with ASD to manage their anxiety symptoms and improve their QoL at school. The results demonstrate acceptable to large effect sizes. Therefore, the small sample size may have reduced statistical power, which would explain why the results are not statistically significant.

435.271 (Poster) The Effects of a School-Based Group Music-Making Program on Engagement Behaviors of Adolescents on the Autism Spectrum
A. Servant, M. Kaedbey, H. Dahary, M. Ghoul, M. de la Sablonnière, S. T. S. Wong, M. J. Lanovaz and E. M. Quintin, (1)McGill University, Montreal, QC, Canada, (2)Département d’éducation et formation spécialisées, Université du Québec à Montréal, Montreal, QC, Canada, (3)Département d’éducation et formation spécialisées, Université du Québec à Montréal, Montréal, QC, Canada, (4)Department of Occupational Therapy, Université de Montréal, Montreal, QC, Canada, (5)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (6)École de psychoéducation, Université de Montréal, Montréal, QC, Canada

Background:

Autistic adolescents respond well to music therapy and intervention, given their strong musical strengths, interests and abilities in music. Consequently, music interventions are considered strength-based interventions as they shift the focus away from a deficit approach by highlighting the person’s unique set of qualities, strengths and interests. Music interventions are usually performed in one-on-one settings and are associated with significant costs. Moreover, one-on-one settings do not allow for the assessment of “on-task behaviours” in a group (e.g. following along with peers), which are proxies for engagement and are necessary to foster appropriate learning, the development of student-teacher relationships and adhering to social rules.

Objectives:

Thus, this study aimed to investigate the engagement of autistic students during a school-based group music-making program, as measured by observable on-task behaviours, to assess if findings from studies in one-on-one settings hold true in a group setting. We also aimed to explore if potential changes in engagement during the musical activities (e.g. playing percussions) would generalize to non-musical activities (e.g. the warm-up).

Methods:

A music program, implemented by the community organization ÉducaTED, was conducted over a period of 11 weeks in a high school setting with autistic students (N=10) from 12 to 17 years old. All sessions of the music program were recorded, allowing for behavioural data coding of on-task behaviours.

Results:

There was a high initial engagement for the musical activity (M=.87, SD=.12) and non-musical activity (M=.75, SD=.16) respectively at the first session, which remained high throughout the program until the last session for the musical activity (M=.91, SD=.08), but not for the non-musical activity (M=.58, SD=.30). Paired-sample T-tests were conducted and also showed more on-task behaviours during the musical compared to the non-musical activity throughout the duration of the music program. Further, we conducted a homogeneity of regression assumption test which was violated (p=.046) thus revealing that the slope coefficients between the musical activity and warm-up were significantly different. This suggested that there were continuously more on-task behaviours within the musical activity compared to the non-musical activity.

Conclusions:

Our results indicate that autistic students show high and continuous engagement in group-based musical activities. In contrast to individual instruction, group-based music programs can benefit a greater population by increasing accessibility to music-based interventions. Group-based music programs could be implemented in the adapted educational curriculum for students with special needs, which is lacking in arts education.

S. L. Curtiss, School of Education, University of Delaware, Newark, DE

Background:
Mealtimes are often a significant source of stress for families with autistic children (Anderson et al., 2012; Curtin et al., 2015; DeGrace, 2004; Marquenie et al., 2011; Postorino et al., 2015; Thullen & Bonsall, 2017). Yet, there have been very few empirical evaluations of parent education and training programs regarding family mealtimes (Sharp et al., 2013).

Objectives:

This project examined the feasibility and efficacy of an online toolkit, Mealtimes on the Spectrum (https://www.mealtimesonthespectrum.org/), for supporting parents with family meals. Mealtimes on the Spectrum uses a relational feeding model (Satter, 2005) which promotes self-regulation of eating behavior and is based on observations of family meals, interviews with parents, and interviews with autistic children. An advisory board of autistic adults reviewed the toolkit and consulted on the research.

Methods:

This study was approved through the institutional review board (IRB) at the author’s university and funded by an internal grant. Parents of autistic children (N=135) were recruited through autism parent support groups. Once registered, they completed a pre-test and were randomized into intervention or a waitlist control group. The intervention group received weekly emails with content from the online toolkit for eight weeks. After this period, both groups were sent a post-test. Upon completion, the control group got access to the toolkit, and both groups received a $40 Amazon gift card (N=112). See table 1 for demographic information. To examine the efficacy of the toolkit, we conducted a repeated measures analysis of variance (ANOVA) with intervention or control group as a between-subjects factor. We used (1) the Comprehensive Feeding Practices Questionnaire (CFPQ; Musher-Eizenman & Holub, 2007): a 49-item questionnaire about parent feeding practices, and (2) the Positive Affect Index (PAI; Bengtson, 1973): a 15-item measure of a parent’s affect toward their child. To examine the feasibility, we explored toolkit use and satisfaction.

Results:

Regarding initial efficacy, table 2 summarizes the results of the repeated measures ANOVA with group as the between-subjects factor. There were expected outcomes for many of the sub-scales of the CFPQ and PAI with small effect sizes. Regarding feasibility, most participants assigned to the intervention group opened the emails each week (M = 6.81, SD = 1.59). Of those in the intervention group, 64% found the emails helpful and learned new information; however, 79% felt they needed more support to make their mealtimes successful.

Conclusions:

The initial exploration of the efficacy and feasibility of the online toolkit, Mealtimes on the Spectrum, shows preliminary indicators that the toolkit can be useful for families. Autistic children are at increased risk for being overweight or obese compared to their non-disabled peers (Broder-Fingert & Van Cleave, 2014). Thus even small improvements in parents’ mealtime behavior, such as decreasing pressure to eat, are important improvements. The small effect sizes coupled with the parent feedback suggest families need a more intensive intervention. Given that families have a difficult time receiving any information in this area, Mealtimes on the Spectrum may be a useful resource.
Overall, 12 autistic youth (11 males; 1 female) with an IQ > 70 aged 15 to 25 years (mean=18.92 years; SD=2.43) participated in the feasibility study, with 11 attending the program and completing pre and post-test assessments. Allied health professionals from Therapy Focus delivered the program over 20 weeks, commencing with a 90-minute individual goal-setting session followed by eight 90-minute group sessions and eleven 15-minute individual mentoring sessions. A pre and post-test design was used to assess whether the program changed the participants’ adaptive functioning scores, as assessed by the Adaptive Behavior Assessment System, Third Edition (ABAS-3). Focus groups were conducted post-completion of the program to capture the views of the participants and clinicians regarding the acceptability of the Tele-TRANSITION® and analysed using thematic analysis.

Results: Normality tests indicated a normal distribution of the data. Findings from the t-test demonstrated significant improvements under the leisure (p = .02) and social (p =.03) domains of ABAS-3, with large effect sizes (Cohen’s d) of 0.90 (leisure) and 0.84 (social). Findings from the thematic analysis indicated overall satisfaction with the online delivery format and the program’s content, citing group discussions and sharing experiences with other members as an important learning strategy. Autistic youth believed that working individually with a clinician was beneficial for achieving their goals set for the program. Despite their satisfaction with the program, both clinicians and participants expressed a need for further modifications, such as increasing individual mentoring sessions’ time, using resources that facilitate group discussions and ideas for warm-up activities for group meetings.

Conclusions: The results of this study demonstrate the feasibility and acceptability of the Tele-TRANSITION® program in improving daily living skills for adulthood for Australian autistic youth. The results also indicate the need to evaluate Tele-TRANSITION® in a more rigorous study design to explore its efficacy.

435.274 (Poster) The Italian Validation of the Social Skills Program PEERS® in Adolescents with Autism Spectrum Disorders (ASD): A Randomized Controlled Trial during COVID-19

Background: Social difficulties are a lifespan characteristic of the autism spectrum disorder (ASD), targeted in interventions for preschoolers and children, while evidence of their effectiveness in adolescents is lacking. The Program for the Education and Enrichment of Relational Skills (PEERS®) is an internationally recognized parent-assisted program on social skills, but in Italy there is no validated adaptation of this specific intervention.

Objectives: A two-arm Randomized Controlled Trial to evaluate the effectiveness of the PEERS® intervention in the Italian context was conducted.

Methods: The study was conducted according to CONSORT guidelines (Schulz et al., 2010) and registered in Clinical Trial (NCT05473104) (Figure 1). Adolescents with ASD (Level 1) were recruited through national stakeholders and public clinical services. Participants were randomly assigned to two groups stratified by gender and age: the experimental group (TG), attending training immediately, and the delay treatment group (WL), which participated after 14 weeks. Evaluation of primary (social abilities) and secondary outcomes (co-occurring conditions, executive functions) (Figure 2) was performed at 4 time-points: T0 (baseline), T1 (TG post-intervention and WL second baseline), T2 (TG follow-up and WL post-intervention), T3 (WL follow-up). A total of 99 teleconference interviews were conducted by an expert clinician, and 55 participants were excluded. Due to COVID-19, PEERS® training was delivered via telehealth (January-July 2021) and only questionnaires to multi-informant assessors (adolescents, parents, and teachers) were collected. No differences were found at T0 between TG and WL groups in baseline characteristics and primary outcomes. Significant groups differences emerged instead between T0 vs. T1 on primary (TASSK-R, F(1,22) = 40.79, p < .001, ηp² = .65; QSQ-Social Initiative Scale parent version z = -3.412, p < .001; adolescent version z = -3.086, p = .002) and secondary outcomes (BRIEF-2 Emotion Regulation Index, F(1,22) = 15.20, p < .001, ηp² = .41). To test additional treatment-related effects, we evaluated the changes in overall group (TG+WL) among pre- and post-intervention, and follow-up. Further changes from pre- to post-intervention emerged in secondary outcomes -(BRIEF-2 Global Executive Composite Score; CBCL-Youth version internalizing, externalizing, total problems; CDI-2 Functional Problems). All the improvements detected in post-treatment were also maintained at a 3-months follow-up.

Conclusions: The efficacy of the Italian version of PEERS®— with minor changes to the original content's program – was ascertained on primary and secondary outcomes. Innovative findings on emotion regulation and depression symptoms have also emerged. Study limitations are due to blinding outcome assessors' bias and the absence of qualitative measures. Future studies should confirm the PEERS®
efficacy in community settings with traditional administration methods.

435.275  *(Poster)* The Role of Alexithymia in Mental Health Functioning and Cognitive Treatment Strategies Among Autistic Adults

**J. E. Pappagianopoulos**, S. M. Brunt; E. Sadikova; and M. O. Mazurek; (1) Clinical and School Psychology, School of Education and Human Development, University of Virginia, Charlottesville, VA, (2) University of Virginia, Charlottesville, VA

**Background:**

Autistic adults experience high rates of co-occurring anxiety and depression, although there is limited research on mental health interventions for this population. Currently, the most utilized therapeutic approach for autistic adults is cognitive-behavioral therapy (CBT), which includes cognitive strategies that require identifying and understanding emotions and thoughts. Given the heterogeneity of ASD, it is crucial to consider individual differences, such as alexithymia, that may make some strategies challenging to implement. Prior research indicates that alexithymia (difficulty identifying and describing emotions) may be heightened in the autism population and associated with higher rates of anxiety and depression. Research is needed to better understand the role that alexithymia may play for autistic adults in mental health outcomes and implementation of therapeutic strategies.

**Objectives:**

The current study investigated associations between alexithymia and mental health conditions (depression and anxiety), as well as the use of cognitive therapy strategies within an autistic adult sample.

**Methods:**

The sample included 303 autistic adults 21-77 years of age (M = 37.1; 49.5% cis female) who were recruited via the Simons Foundation Powering Autism Research for Knowledge (SPARK) Research Match process. Participants completed a demographic survey, the AQ-Short, the TAS-20 to measure alexithymia, and the PHQ to assess depression and anxiety. Autistic adults provided ratings for ease of use (1=very difficult, to 5=very easy) for cognitive mental health strategies (i.e., paying attention to thoughts, identifying, and challenging/reframing negative thoughts). Separate linear regressions were conducted with alexithymia predicting depression and anxiety as outcomes. An ordinal logistic regression model was run with alexithymia as the predictor and perceived ease of using cognitive strategies as the outcome. Age, gender identity, race, and autism characteristics were included as covariates in all models.

**Results:**

Approximately half of the sample (48.8%) met the clinical cut-off for alexithymia (score≥61). Accounting for other model covariates, results revealed that age (B=-.19, p<.001) was negatively associated with anxiety, while AQ Total Score (B=.13, p=.038) and alexithymia (B=.27, p<.001) were positively associated with anxiety. Findings also indicated that age (B=.13, p=.023) was negatively associated, while alexithymia (B=.28, p<.001) was positively associated, with depression. For the final analysis, approximate likelihood-ratio test indicated that the proportional odds assumption was met. Results found a significant negative relationship between alexithymia and perceived ease of using cognitive strategies in therapy (B=-.03, p=.015).

**Conclusions:**

Consistent with prior research regarding the prevalence of alexithymia (49.93% in the autism population vs. 4.89% in the general population), findings revealed that approximately half of the autistic adults in the sample reported clinical-level alexithymia. Results indicated that difficulty accurately identifying and describing one’s emotions is associated with mental health outcomes (i.e., higher levels of co-occurring anxiety and depression) and greater difficulty with using cognitive mental health strategies. Given that CBT is the most common mental health intervention for autistic adults, it is crucial to consider the presence of alexithymia, and the potential integration of specific strategies addressing emotional recognition, when implementing and individualizing therapeutic techniques.

435.276  *(Poster)* The Role of Organizational Climate and Teacher Stress in Predicting Attitudes Towards Evidence-Based Practices and Implementation Outcomes of School-Based Facing Your Fears

**K. M. Frost**, K. Pickard; A. T. Meyer; A. Blakeley-Smith; R. E. Boles; L. Hayutin; C. Middleton; N. Reyes; A. C. Stahmer and J. Reaven; (1) Psychology, Michigan State University, East Lansing, MI, (2) University of Colorado School of Medicine, Aurora, CO, (3) Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (4) JFK Partners, University of Colorado School of Medicine, Aurora, CO, (5) JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (6) University of Colorado Anschutz Medical Campus, Aurora, CO, (7) University of Colorado, AMC, Aurora, CO, (8) UC Davis MIND Institute, University of California, Davis, Sacramento, CA
Background: Autistic children with anxiety have difficulty accessing evidence-based practices (EBPs) due to long wait lists and lack of trained providers (Elkins et al. 2011). Fortunately, interdisciplinary school providers (ISPs) can be trained to deliver mental health EBPs like Facing Your Fears-School Based (FYF-SB) to autistic students with anxiety with good success (Reaven et al. 2021). However, there is little information regarding the implementation of EBPs in schools for autistic youth. Examining provider and organizational factors may clarify the adoption and eventual sustainment of mental health interventions within schools. The purpose of this study is to examine the association of provider and organizational factors with provider attitudes of EBPs and perceptions of FYF-SB following program delivery.

Objectives: To determine the extent to which provider factors (stress) and organizational climate impact provider attitudes towards EBPs and provider perceptions of acceptability and appropriateness of FYF-SB.

Methods: Seventy-seven ISPs (91% female; 4% Latinx; 91% White; 59% non-mental health professionals) from 27 school teams across 3 school districts were trained to deliver FYF-SB to autistic students, ages 8-14, with anxiety. Prior to training, ISPs completed the Teacher Stress Inventory (TSI; Fimian & Fasteneau, 1990); the Organizational Climate Measure (OCM: Patterson et al. 2005); and the Evidence-Based Practices Attitudes Scale (EPAS: Aarons, 2004). After implementing FYF-SB, ISPs completed an implementation survey examining perceived appropriateness and acceptability of FYF-SB. We first examined intraclass correlations to evaluate the nested structure of the data. ISP attitudes toward EBPs, collected pre-training, did not indicate a need for multilevel data structure, therefore we used multiple regression to analyze this outcome. Perceived acceptability (ICC = .43) and appropriateness (ICC = .29) were more similar within school teams than between school teams and were therefore analyzed using multilevel models.

Results: Results for models predicting attitudes toward EBPs are presented in Table 1, and models predicting implementation outcomes are presented in Table 2. ISPs with greater concerns related to student discipline and motivation self-reported that EBPs were less appealing, but they would use them if required. Yet, post-training, ISPs with more concerns regarding student discipline and motivation reported higher levels of FYF-SB acceptability. Provider stress around time management and other work-related stressors were associated with lower self-reported adoption if required and lower acceptability, respectively. Providers reporting high levels of organizational pressure to produce reported more positive attitudes toward EBPs.

Conclusions: Results suggest that teacher stress and organizational climate are related to EBP attitudes and perceived acceptability of an EBP (FYF-SB), which has implications for eventual adoption and sustainment of mental health EBPs in school settings. For example, ISPs with concerns about classroom management were reluctant to try a new EBP but they found FYF-SB to be a good fit for their student need once they tried it. Additionally, work-related stressors were associated with lower treatment acceptability. These results suggest that pre-implementation strategies focused on supporting time management and workplace stressors, as well as student discipline and motivation, may enhance receptivity to EBPs. Limitations and future directions will be discussed.

D. MacEvilly, K. Maguire and G. Brosnan, (1)Speech & Language Therapy, Lucena Clinic, Bray, Co. Wicklow, Ireland, (2)Speech & Language Therapy, Lucena Clinic, Dublin, Ireland

Background: SAS is an innovative, evidence-based therapy programme for children with emotional regulation and social communication difficulties (Beaumont & Sofronoff, 2008). It uses interactive technology as well as home, school and clinic interventions in a child centered, espionage themed package. Based on the principles of Cognitive Behaviour Therapy, SAS teaches children how to identify and cope with their emotions and how to understand and manage social interaction. SAS was originally developed for children with autism and has a robust published evidence base for this client group across university clinics and schools in Australia, America and Canada. It has been shown to effect clinically significant changes in the social-emotional skills of children with a range of other neurodevelopmental disorders. However, no published evidence currently exists for the use of SAS for children with moderate-severe mental health disorders attending community CAMHS.

Objectives: To evaluate the efficacy of the SAS programme up to 6 months post intervention in an Irish outpatient community CAMHS.

Methods: 51 children (30 boys, 21 girls) aged 8-12 years (mean age 10:11) with moderate-severe mental health disorders completed the 14-week programme within their local CAMHS clinic. Children presented with complex diagnostic profiles including autism and/or Attention Deficit Hyperactivity Disorder and/or Anxiety Disorder. Autism was the most common diagnosis (59%). Children attended nine weekly group sessions and completed the SAS computer game at home. Parents attended four, two-hour training sessions. Children's teachers attended a two-hour information session and received weekly teacher tip sheets. Children and parents then attended 3 and 6 month follow-up sessions. Questionnaires were completed by children, their parents (51 mothers, 45 fathers) and teachers at baseline, post-treatment and at 3 and 6 month follow up. Quantitative analysis was employed to evaluate the overall treatment effect.

Results: Statistically significant improvements were made in children’s social communication ($F(1.558, 15.581) = 6.552, P = 0.012$) and emotional regulation skills ($F(1.331, 14.645) = 9.213, P = 0.005$) across home and school settings. Children’s knowledge of emotional regulation strategies also significantly improved. Treatment gains were maintained up to 6 months post intervention. 75% of both parents
and teachers reported lasting changes in children’s skills and behaviour at the 6-month time point. Qualitative feedback highlighted clinically significant change in children’s emotional regulation, including reduced aggression and/or anxiety and improvements in children’s mood and self-esteem.

**Conclusions:** This study extends the existing international evidence base for SAS by examining its effectiveness in community CAMHS clinics in Ireland. SAS allows children with complex diagnostic profiles, especially those with a diagnosis of autism, to access an evidence-based treatment that develops social-emotional resilience, thereby potentially preventing escalation of difficulties into adolescence. Incorporation of SAS into a child’s multi-disciplinary care plan has the potential to enhance overall mental health treatment outcomes.

435.278 (*Poster*) Thinking Together the Neurodiversity Paradigm and Autism Care Practices

**Background:**

The field of autism research and practice finds itself amidst structural change. Neurodiversity proponents and their allies increasingly challenge the conventional, medical approach to autism. Rather than focussing on deficits, they claim autism is an expression of neurodiversity. Rather than limiting autistic challenges to the boundaries of the individual, they point to social and societal contexts as potentially enabling or disabling for autistic people. Rather than staying side-lined, autistic people demand their place at the discussion table. Against the backdrop of this reconceptualization of autism, researchers and caregivers are confronted with the question of how good and just autism care could look like in the age of neurodiversity. How can caregivers support autistic people and their relatives with the actual problems they experience without pathologizing autism as such? How can individual interactions in caring practices contribute to the political demand of societal change which neurodiversity proponents call for? How can expertise built on lived experiences find its place alongside professional expertise of (non-autistic) caregivers?

**Objectives:**

In this study we conducted an ethical analysis of autism care to propose a groundwork for ‘neurodiversity-affirmative autism care’.

**Methods:**

Our methodological approach was grounded in feminist bioethics. We reinterpreted the feminist bioethical conceptualization of ‘vulnerability’ in a neurodiversity-sensitive way to critically analyze current autism care practices and constructively propose alternatives.

**Results:**

Feminist interpretations of vulnerability point to both universal and political dimensions of this concept. All children, irrespective of their neurotype, have ongoing biological, psychological and social needs. The ever-present risk of unmet needs, underscores vulnerability as a universal phenomenon. Vulnerability’s universal dimension helps to destabilize the borders between neurotypical and neurodivergent children. This way, mobilizing vulnerability offers moral grounds for solidarity and a shared responsibility to help meet each other’s needs, instead of viewing support measures as costly, burdensome accommodations or “special needs”. Of course, vulnerability is not experienced equally. Vulnerability ties in with existing power dynamics and can even be worsened in the process of “protecting the vulnerable”. Growing up in a neurotypical-dominated society, autistic children experience more physical and mental health issues, their environments risk being less adapted to foster healthy, autistic development, and some strictly behavioral or alternative interventions are even considered harmful, rather than helpful for autistic children. Political dimensions of vulnerability offer grounds for the structural empowerment of neurodivergent children and their caregivers through emancipating, instead of patronizing care practices.

**Conclusions:**

The neurodiversity paradigm is not incompatible with autism care practices. Our analysis rather shows that care can be considered a political activity with the potential to contribute to social change advocated for by neurodiversity proponents. We propose the principles of solidarity and empowerment as key ethical foundations for neurodiversity-affirmative autism care and provide practical examples on how to apply these principles in practice.

435.279 (*Poster*) Treatment Engagement As a Predictor of Therapy Outcome Following Cognitive Behaviour Therapy for Autistic Children
Background: Autistic children often experience mental health challenges that can sometimes be addressed with cognitive behaviour therapy (CBT); however, some children who take part in CBT do not show clinically meaningful improvement at the end of treatment. Focusing on the nuances of the therapeutic process may help to identify addressable and modifiable factors that contribute to variation in treatment success. Active engagement in one’s therapy is a key contributor to successful outcomes, yet research on child engagement in cognitive behaviour therapy (CBT) has largely focused on youth without autism.

Objectives: To examine multiple indicators of child engagement in relation to outcomes for autistic children who took part in CBT for emotion regulation.

Methods: A within-subject longitudinal design was used to assess treatment engagement over the course of therapy, in relation to outcomes. Data were collected from 60 autistic children who were between 8 and 13 years of age (86.7% male; $M_{age} = 9.58$ years, $SD = 1.44$ years; 75% White). Indicators of child engagement included independent observer ratings of in-session involvement (ISI), as measured by the Child Involvement Rating Scale (Chu & Kendall, 1999), and therapist ratings of the therapeutic relationship and homework completion using single-item post-session measures. Indicators of engagement were measured at early (i.e., first third), middle (i.e., mid third), and late (i.e., final third) stages of treatment. Parent-reported emotion regulation was the primary treatment outcome, as measured by the Lability/Negativity and Emotion Regulation subscales of the Emotion Regulation Checklist (ERC; Shields & Cicchetti, 1997). Multiple linear regressions were computed to assess whether indicators of child engagement predicted treatment response, after controlling for baseline levels of emotion regulation.

Results: After controlling for baseline levels, mid-stage and late-stage engagement significantly predicted post-treatment ERC Lability/Negativity scores. Mid-stage ISI uniquely accounted for 5.76% of variance in post-treatment ERC Lability/Negativity. Late-stage ISI was trending as a unique predictor of post-treatment ERC Lability/Negativity, accounting for 3.61% of variance. Overall, early child engagement did not significantly predict post-treatment ERC Lability/Negativity, but early-stage ISI was trending as a predictor of post-treatment ERC Lability/Negativity, accounting for 3.24% of unique variance. After controlling for baseline levels, post-treatment ERC Emotion Regulation was not significantly predicted by early-stage, mid-stage, or late-stage overall engagement. Approximately 4.41% of variance in post-treatment ERC Emotion Regulation was uniquely accounted for by early-stage ISI.

Conclusions: Treatment engagement is a fundamental consideration in determining whether autistic children will benefit from CBT. Child in-session involvement throughout therapy may be particularly relevant for treatment change. The therapeutic relationship and homework completion should continue to be considered and evaluated in relation to treatment outcomes to better understand the relevance of these factors in CBT for autistic youth. Future research should aim to operationalize and assess treatment engagement in a consistent way to allow for replication and comparability of findings across studies. Addressing issues related to in-session involvement early in treatment would likely be beneficial for promoting positive engagement from autistic clients for the remainder of therapy, in turn increasing the likelihood of therapeutic success.

Background: Autistic individuals commonly exhibit executive function (EF) deficits which influence functioning in a variety of domains (Pellicano et al., 2012). Recent research has supported the efficacy of an online executive function program, e-Unstuck and On Target Course for Parents (Cannon et al., 2018; Kenworthy et al., 2014), in improving children’s EF abilities and reducing parental strain (Kenworthy et al., 2022). A hybrid delivery model, combining the e-Unstuck and On Target Course with group-based clinician coaching, has shown success in other intervention programs but has yet to be studied in this context (Taylor et al., 2008).

Objectives: The present study aimed to explore the subjective experiences of parents participating in a virtual coaching program while completing an online executive function program.

Methods: Fifteen parents (2 fathers, 13 mothers) of autistic children aged 5-14 years participated in a virtual coaching program while completing the e-Unstuck and On Target Course. Parents completed online modules and attended weekly, telehealth coaching sessions for a duration of nine weeks. At the mid- and endpoint of the program, parents completed surveys to assess acceptability and program satisfaction. Participants responded to the following open-ended questions: “Please describe what you enjoyed most about these modules;”, “Please describe what you have enjoyed most about the coaching group;”, and “If I could, I would change (BLANK) about the program.”

Results: Parents’ open-ended survey responses suggested that the modules provided them a new perspective from which to approach their child’s EF challenges (60% responses) as well as new skills (63% responses) or language (17% responses) to implement. Other notable themes related to the interactive and engaging nature of the modules. Importantly, a prominent theme within the coaching group responses were related to the opportunity for parents to learn from other parents (80% responses). Many parents enjoyed learning about others’
experiences and the skills other parents implement. Relatedly, responses commonly included phrases such as “knowing I’m not alone”, “feel less isolated”, “similar struggles”, and “same challenges”. When asked what they would change about the program, 50% of parents reported that they would not change anything. Commonly reported other themes were related to extending the coaching group length and the time between sessions for skill practice, as well as interest in added coaching group components (e.g., general time to “connect” with other parents, specific recommendation requests).

Conclusions: Parent responses indicate a high level of satisfaction with the virtual coaching group and online executive function modules. Survey results suggest parental satisfaction with the perspectives, skills, and language provided by the modules. Moreover, the modules are reported to be engaging and enjoyable for parents to watch. Responses related to the coaching group provide insight into a fortuitous consequence of the program, one which likely would have been missed by traditional outcome measures. Specifically, many parents report gaining a sense of community and support from other parents. Combined, findings point to the importance of understanding subjective experiences of parents when assessing the acceptability and feasibility of parent-mediated interventions, as they may likely fall outside of the bounds of traditional outcome measures.

435.281 (Poster) Understanding the Impact of an Inclusive Maker Program: Engineering Design Process Thinking and Teacher Reflections

Background: Hands-on making involves participants in the engineering design process (EDP) where students learn to identify a problem, brainstorm, plan, make, test, improve, and finalize projects (Halverson & Peppler, 2018). EDP skills are valued in formal and informal education and workforce settings (Martin & Dixon, 2016). Although autistic youth often have deep interests in STEM (South et al., 2015), autistic adults often have difficulty entering the STEM workforce (Shattuck et al., 2012). To address these needs, a multidisciplinary team created the Inventing, Designing, and Engineering for All Students (IDEAS) Maker Program.

Objectives: Evaluate the impact of IDEAS on EDP understanding using pre- and post-test assessments and teacher surveys.

Methods: IDEAS was an out-of-school club for students at six autism-inclusion middle and high schools in 2021-22. Pre- and post-assessments included a two-question, spoken-response EDP assessment administered via Zoom (Hsu et al., 2012). Students were asked what they thought about a process depicted in a cartoon diagram and how they might do it differently. Responses were coded on a three-point scale across EDP domains (0 = no evidence noted, 1 = evidence noted, and 2 = evidence noted and elaborated).

Fifty-five weekly post-club surveys were collected from ten teachers across six sites. Surveys included closed-ended prompts to assess perceptions of student gains in various areas on a scale from 1 (strongly disagree) to 5 (strongly agree). Teachers also answered open-ended prompts about student engagement and growth.

Results: Thirty-eight students (25 middle and 13 high school) completed assessments. Results showed significant pre-test ($M = 2.50, SD = 1.61$) to post-test ($M = 4.05, SD = 1.64$) gains on summed EDP assessment scores (Figure 1). We observed a trend of fewer students receiving a “0” and more students receiving a “1” or a “2” on all items. Pre- to post-test differences across individual items were statistically significant for the Plan, Improve, and Test domains. Significantly fewer students failed to note the Plan (29% fewer, $p<.001$) or Test (26% fewer, $p<.05$) domains and significantly more students elaborated on the Plan and Improve domains at post-test (13% more, each; $ps <.001$).

When asked if they felt their students improved their EDP skills after participating, the majority of teachers strongly agreed or agreed (83.9%). When asked if their students made social connections at maker club, 91.1% of teachers strongly agreed or agreed. Open-ended responses yielded valuable insight for the team’s understanding of how students pursued their interests and connected with others while participating in IDEAS (Table 1).

Conclusions:

Assessments suggest the positive impact of IDEAS on students’ understanding of the EDP. Teacher surveys indicate that educators feel students gained social and EDP skills after completing IDEAS, demonstrating its utility in teaching these skills across a variety of age groups. Creating products based on interests can help students draw connections to the larger world and gain skills that may lead to higher education and career pathways. For educators interested in pathways to improve student STEM skills and social outcomes, results indicate that making may offer students these opportunities.

435.282 (Poster) “There Is a Lot of People like Me” : Virtual Social Skills Groups Based on Special Interest for Autistic Adolescents and Young Adults.
Evidence based social skills (SSI) interventions for autistic adolescents and young adults are very limited, this population can be isolated, and might have a hard time finding their tribe. Additionally there is very few strength and special interest based approaches in autism. Due to COVID-19 pandemic social isolation became even more challenging for this population and our sample population was very limited in their social life for a long period of time due to restrictions.

Objectives:

In this pilot we designed a 9 month weekly virtual intervention of conversational skills and problem solving intervention based on special interests: Art /Photography and Manga/Anime for autistic adolescents and Young adults without intellectual disability. The aim of the project was to design and pilot a SSI virtually adjusting intervention to the COVID pandemic limitations.

Methods:

The pilot had two groups of participants of 6 individuals each, (N 12, gender: 7 females, 5 males 1 non binary) from 15 (N 2) to 25 years. The Art and Photography Group was only females. The session was an hour long, and the conversation would start about the special interest selected and turn into more spontaneous conversation. We designed special conversation activities based on Art and photography for one group and Manga and Animé for the other. We would use different instructional cognitive behavior methodologies including some lessons from PEERS Young Adults (Bi-directional Conversation, Managing Disagreements, Teasing and Bullying, Finding Friends) as well. To measure outcomes we design two questionnaires for participants (N 12) and for families (N 12) for some variables in a 5 point Likert scale and compared the results and also qualitative questions about the experience. We analyzed the preliminary quantitative descriptive data in this pilot.

Results:

The motivation was high for participants (75% almost always motivated), and also perceived by families (41% almost always motivated), initiation of conversation, reciprocity and problem solving did improve for an important number of participants (58,53%, 72,7% 58%) and was also perceived by parents (58,3%, 66,7% 81%), benefits of the intervention was also high perceived by participants (50% very, 41,7% some) and families (66,7% very, 25% some) 75% of participants made new friends, and all of them of them said they expanded their social circle and social life even during pandemic times.

Conclusions:

In spite of the small size of the sample and limited methodology, preliminary results for participants and their families reported improvement in key areas for socialization in the virtual pilot. Available evidence based techniques from PEERS A/YA might be useful also in this kind of groups. Moreover, the results suggest that virtual interventions to connect people through their special interest might be a promissory and novel way of working social skills as well as connecting autistic individuals and their passions, in order to find out like one of our participants said "there is a lot of people like me".

435.283 (Poster) Virtual Reality Police Safety Teletherapy Intervention: Results of a Randomized Controlled Trial

Background: Up to 20% of autistic individuals will be stopped and questioned by police before their early twenties (Rava et al., 2016). Providing opportunities to practice police encounters is essential; police interactions are unexpected, challenging, include unusual sensory stimulation, require novel problem solving, and necessitate rapidly processing social situations in real time (Channon et al., 2001; Salerno-Ferraro & Schuller, 2020; Vanmarcke et al., 2016). Considering that up to half of officers do not receive autism training, preparation on the part of autistic individuals can support smooth interactions (Christiansen, Minich, & Clark, 2021). Immersive virtual reality (VR) affords individuals the opportunity to practice interacting with police officers in a safe, simulated environment. VR practice can also be administered via teletherapy, providing an accessible, adaptable tool for home use. In this study, we outline preliminary efficacy analysis of an immersive, virtually administered VR-based intervention, the Floreo Police Safety Module (PSM).
Objectives: Evaluate the efficacy of a virtually administered VR-based intervention by assessing masked behavioral ratings of immersive, simulated police interactions.

Methods: Thirty verbally fluent autistic adolescents and adults were randomly assigned to either an immersive VR-based intervention (Floreo PSM) or no intervention group. All participants underwent three VR-based assessments of virtual police officer interactions and completed online surveys about their knowledge of and experiences with police at three timepoints (pre- and post-intervention, and follow-up). Individuals in the intervention group received three 30-minute sessions of intervention. Assessments and the viewpoint inside the VR were recorded. All aspects of the study were virtually administered (participants at home). Interactions were recorded and scored in 15-second segments. Each segment was double-coded for: appropriateness of verbal response, orienting behavior, fidgeting behavior, and overall behavior. Scores were averaged across each behavioral category and compared at each timepoint. Kappa coefficients were in the fair-to-moderate range. The final sample is currently being coded and will consist of 48 participants (24 in each condition), with pre-/post-assessments and a follow-up assessment evaluating key skills.

Results: Preliminary analysis suggests positive impact of the immersive VR intervention. Linear mixed effects regression revealed significant main effects of time (pre-/post-intervention) on ratings of orienting behavior (estimate: 0.22, t=2.10, p=.04) and appropriate verbal response (estimate: 0.14, t=2.30, p=.02). Pre-planned pairwise comparisons of Tukey-corrected estimated marginal means revealed that the effects of time for appropriate response were driven by improved scores in the intervention condition (p=.001). Tukey-corrected estimated marginal means revealed significant improvements from pre- to post-intervention in the intervention condition as compared to no intervention on two out of four variables (Figure a-d).

Conclusions: Preliminary results indicate that teletherapy-delivered VR holds potential as a comfortable, motivating, and effective platform for autistic people to safely practice interacting with police officers. Data collection is complete, and analysis of all participants will be completed before May 2023, offering further insight into the efficacy of VR-based teletherapy intervention.

435.284  (Poster) Strengths-Based Programs Participation for Autistic Adolescents: ‘What Matters?’

E. A. Lee, M. T. Scott, M. H. Black, E. D’Arcy, T. Tan, L. Sheehy, V. Berg, S. Bolte and S. J. Girdler, (1)School of Allied Health, Curtin University, Bentley, Western Australia, Australia, (2)Center for Neurodevelopmental Disorders & Center for Psychiatry Research, Dept. of Women’s and Children’s Health, Karolinska Institutet, Stockholm, WA, Sweden, (3)School of Mechanical Engineering, Curtin University, Perth, Australia, (4)MatchWorks, Perth, Western Australia, Australia, (5)Spectrum Space, Perth, Western Australia, Australia, (6)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden

Background: ‘Disability’ according to the social model is the interaction between a person’s physical or mental traits and their environment. The social model advocates for removing social and environmental barriers to impairments and focuses on the abilities and strengths of an individual. Over the last decade, prompted by the neurodiversity movement, there has been wide recognition of the strengths of autistic individuals and a need for strengths-based approaches. In Western Australia, community strengths-based programs are delivered through the Autism Academy for Software Quality Assurance (AASQA) and Spectrum Space (formerly Autism West) aiming to develop the interests of autistic adolescents aged 10 to 18 years in Science, Technology, Engineering, Arts, and Mathematics (STEAM).

Both providers deliver a range of STEAM activities including coding, Lego Robotics, Arduino, Nao Robotics, mathematics, visual arts, music, and digital media in a supportive group environment. Recent studies have reported that strength-based programs that target autistic adolescents’ strengths, harnessing their skills, knowledge, and interests in a supported environment could promote promising outcomes in the transition to adulthood, however, little is known regarding the factors that influence their participation in strengths-based programs.

Objectives: This study explored the factors that influence autistic adolescents’ participation in community strengths-based programs designed to develop their interests and skills in STEAM from the parents’ perspectives.

Methods: A repeated cross-sectional design using an online survey was conducted over three consecutive years. Participants were parents of autistic adolescents who had participated in the strengths-based program at AASQA or Spectrum Space for more than one school term (approximately 10 weeks). Factors influencing participation were explored from the open-ended questions that captured the parents’ perception of the impact of the program on the domains of health and well-being, social relationships and interactions, confidence and self-esteem, sense of belonging, activities, and participation. In total, 52 parents responded in 2018 and 2019, and 40 in 2020. Data were analysed using directed content analysis based on the International Classification of Functioning, Disability and Health (ICF) and supplemented by the personal factors proposed by Grotkamp and colleagues that are not included in the ICF. Based on the frameworks, responses were coded in reference to the ICF concepts of body functions and structures, activities and participation, and contextual (personal and environmental factors).

Results: We found that both personal-related and external factors, acting as facilitators and barriers, influence autistic adolescents’ participation in community strengths-based programs. The personal-related factors included the participants’ enthusiasm towards the program and self-perception while the external factors included the learning environment, the program approach, and the mentors’ attitudes.
Conclusions: While further research is needed, five key elements from internal and external factors including participants’ enthusiasm towards the program; participants’ self-perception; the learning environment; the program approach; and the attitudes of the mentors appeared to underpin successful participation in the community strengths-based programs. The findings could provide a framework that may underpin future community strengths-based programs.

435.285 (Poster) ‘I Made a New Friend Today and I Was so Happy’: Experience of Autistic Young People Participating in Life Skills Programs

Background: Many autistic people experience significant difficulties with everyday life skills. Compromised life skills can lead to marginalisation, social exclusion, disengagement with the community, and dependence on others. Everyday life skills are essential for independent living and community participation. However, limited autism friendly programs are available to successfully support autistic people to learn and gain life skills.

Objectives: This study investigated the experience of autistic young adults who participated in a series of life skills programs which were delivered through a strength-based approach. Three domains were included and evaluated; Daily Living Skills, Positive Relationships, and Money Skills. The learning content and its applicability to real life were explored as well as the perceived qualities of the program facilitators and program activities.

Methods: A qualitative study with one-on-one interviews and focus groups to explore the perceived value of the life skills program was conducted. The program was co-designed with participants focussing on three key life domains as mentioned above that are in line with the National Disability Insurance Scheme (NDIS) domains in Australia. The duration of the program was 10 weeks for each domain. Forty-five young autistic adults (Mage = 22, SD=3.7, 58% male) participated in the study. Thematic analysis was used to analyse the data.

Results: The results of the life skills program show positive outcomes across all three domains. Participants felt more confident in their ability to apply the learned skills in their life and reported improvements in daily living skills, relationship skills, and money handling skills. In the Daily Living Skills program participants described improvements in their active listening skills, home management skills, personal care, and clothing etiquette. Additionally, knowledge was gained in safe food handling, kitchen incident prevention, and nutrition. Numerous new and improved skills were also reported from attending the Positive Relationship Skills program including improved communication skills, a reduction in stress, more confidence in communicating with family and friends, maintaining relationships, and increased confidence to go on a date. Furthermore, new friendships were forged among the participants. Participants learned about budgeting and consequently reported saving money from the Money Skill Program. Notably, the program helped them to pay their bills on time and extended their knowledge of tax and superannuation. Participants were happy with the support they received from the facilitators who were inclusive, patient, and responsive. Lastly, most participants found the program activities useful (e.g., group discussions, role-play activities, worksheets, self-reflection, and videos).

Conclusions: This study highlights the positive impact of the life skills program on participants’ daily living skills, relationships skills, communication skills, self-confidence, and financial responsibilities. The outcomes of this program not only provide evidence that life skills can be taught but also show that participants are able to apply these skills to improve important areas in their life, increasing independence at home and in the community.

435.286 (Poster) Non-Pharmacological Interventions for Emotion Regulation in Children and Adolescents with Autism Spectrum Disorder: A Systematic Review and Meta-Analysis

J. Lugo Marin, M. Oriol Escude, D. Restoy Serrano, I. Setien, M. Magan Maganto, E. Diez Villoria, R. Canal-Bedia, J. A. ramos-Quiroga and L. Gisbert, (1)Psychiatry, Hospital Universitari Vall d’Hebron, Barcelona, Spain, (2)Hospital Universitari Vall d’Hebron, Barcelona, Spain, (3)UNIVERSITY OF SALAMANCA, Salamanca, SPAIN, (4)University of Salamanca, Salamanca, Spain, (5)Instituto Universitario de Integración a la Comunidad INICO-InFoAutismo, Universidad de Salamanca, Salamanca, Spain

Background: There is evidence that indicates that children with Autism Spectrum Disorder (ASD) usually present difficulties in emotional regulation that interfere with their adaptive functioning. These difficulties can be manifested in problems in recognizing one’s own and others’ emotions and less use of adaptive emotional self-regulation strategies. These difficulties can trigger episodes of disruptive behavior At the present time, pharmacological interventions have shown efficacy at the level of externalizing symptoms (e.g., irritability) and internalizing symptoms (e.g., anxiety), although many children continue to present problems in emotional regulation that do not respond to pharmacological treatment.

Objectives: The objective of this study was to systematically review the evidence on improvements in clinically relevant measures after a specific non-pharmacological intervention for emotional regulation in children and/or adolescents with ASD.
Methods: An electronic search of four databases (PsycInfo, PubMed, Scopus, Web of Science) was conducted to identify potential studies. The manual search consisted in the screening of the reference list of related articles and contacting corresponding authors of topic-related studies in order to request unpublished data. Only peer-reviewed English-written articles addressing interventions targeting emotion regulation in children and/or adolescents were included. Non-empirical study (e.g. review articles) and studies with less than 5 participants with ASD were excluded.

Results: A total of 16 studies were included in the systematic review. The meta-analysis found statistical significant within-group differences after the non-pharmacological intervention for emotion regulation (Cohen’s $d = .72$, 95% CI [0.54, 0.92], $p < .001$); internalizing symptoms (Cohen’s $d = .74$, 95% CI [0.56, 0.91], $p < .001$); externalizing symptoms (Cohen’s $d = .86$, 95% CI [0.59, 1.13], $p < .001$); social skills (Cohen’s $d = .55$, 95% CI [0.31, 0.80], $p < .001$); and parent-related outcomes (Cohen’s $d = .23$, 95% CI [0.11, 0.34], $p < .001$). Also, statistical significant differences were found between-groups, with the ASD showing greater improvement than the control group (Cohen’s $d = 1.01$, 95% CI [0.38, 1.63], $p = .002$) after the intervention being completed.

Conclusions: Non-pharmacological interventions appear to improve not only emotion regulation, but also clinically relevant outcomes for children/adolescents with ASD, as well as parental outcomes. Furthermore, it is suggested that this improvement is greater than the control condition (e.g. treatment as usual) with a large effect size. The limited number of studies and the subjective nature of the measures compromise the interpretation of the results. More research is needed to study the efficacy of non-pharmacological interventions for emotion regulation in children and adolescents with ASD, and to study the impact of potentially interfering variables, such as the concomitant presence of Attention Deficit Hyperactivity Disorder and/or intellectual disability.

435.287 (Poster) Online Parent Training for Sleep Disturbances in Children with Autism Spectrum Disorder: A Pilot Study

Methods: Parents/Caregivers of 26 children aged between 3 and 12 years with ASD and concomitant sleep disturbances were included. Exclusion criteria were (i) participants diagnosed with medical conditions that have a relationship with sleep behavior (e.g., restless leg syndrome); (ii) participants identified as having exclusively sleep difficulties for which behavioral treatment has not shown efficacy (e.g., breathing-related sleep disorders); and (iii) modification of pharmacological status (either by introduction/withdrawal or dose modification). The online parent training consisted of four 1-hour sessions with a group format and a weekly frequency. One month after the end of the intervention, a follow-up telephone session was carried out. Evaluation measures included sleep disturbances (CSHQ), chronotype (Morningness-Eveningness Scale for Children, MESC) and maladaptive behaviors (Aberrant Behavior Checklist, ABC). Also parent quality of life (The PedsQL Family Impact Module) was assessed. A set of repeated-measure t-tests were conducted in order to analyze differences at post intervention and one-month follow-up for each outcome measure. A self-developed social validation survey was included in order to assess satisfaction and goal achievement.

Results: At the end of the intervention, statistical significant differences were found for the CSHQ total score ($t = 5.13$, 95% CI [4.21, 9.86], $p < .001$, $d = 8.00$) suggesting a reduction in the sleep disturbances in the children with ASD. Also, statistical significant differences were found in the MESC ($t = 2.56$, 95% CI [3.9, 3.61], $p = .02$, $d = .37$) with a reduction in the group mean score pointing to a decrease in the extreme predominantly evening chronotype of the children with ASD. The ABC did not show significant differences at the end of the intervention, but in the one-month follow-up after the intervention ($t = 2.26$, 95% CI [.65, 14.15], $p = .03$, $d = .26$), pointing to a reduction in the maladaptive behaviors in the children with ASD. Parent quality of life did not show significant differences in either of the two evaluation moments. Parents showed high scores on the social validation survey.

Conclusions: The four-session online parent training appears to show improvement in sleep problems in children with ASD. At the same time, it seems to decrease maladaptive behaviors and regulate the circadian rhythm. The small sample size, as well as the lack of a control group, limit the generalizability of the results. More studies are needed to verify the efficacy of the online training program in this population as well as to study the predictive variables of improvement.

Interventions - Pharmacologic
Background: Brain function is the dynamic output of coordinated Excitatory (E) glutamate and Inhibitory (I) γ-aminobutyric acid (GABA) activity. Although alterations in the GABA system have been implicated in autism spectrum disorders (ASD), human studies have largely relied upon ‘correlational’ approaches to establish a link between e.g. ‘GABA’ genes or bulk tissue levels of GABA and spontaneous brain activity (at rest) and task-related sensory processes. Correlations are not causal; a more direct way to establish that a neurosignalling system is involved in candidate brain process is to challenge it and observe a change in the mechanism. This is basis of animal study designs, but there has been limited translation to humans.

Objectives: Here we used EEG to measure the aperiodic slope (1/f) and response to repeated auditory stimulation (event-related spectral perturbation; ERSP) to test the hypotheses that the control of resting brain activity and auditory sensory suppression is GABA-dependent (modulated by the GABA_A receptor agonist, arbaclofen) and is altered in ASD.

Methods: EEG data was available from 66 adults (n = 28 ASD). Resting state aperiodic 1/f and event-related neurophysiological responses (temporal and frequency domains) to repetitive standard tones and novel deviants presented in an oddball paradigm were compared after double-blind administration of placebo, 15 or 30 mg of arbaclofen (STX209), a GABA type B (GABA_B) receptor agonist in randomized and double-blind order. The oddball paradigm comprised repetitive standard tones (1066 trials) and intermittent deviant tones that differed from the standard in terms of frequency (78 trials), duration (78 trials) or both (78 trials).

Results: We demonstrate that GABA control of brain activity at rest is altered in ASD. Specifically, an aperiodic shift was elicited at a lower (15mg) dose of arbaclofen in autistic individuals as compared to non-autistic individuals. We also demonstrate differences in GABA control of auditory suppression. Specifically, weaker auditory suppression in autistic individuals was strengthened by arbaclofen; stronger auditory suppression in non-autistic individuals was weakened by arbaclofen. We also report that the extent of GABA-dependent differences in auditory processing in ASD is strongly correlated with autistic symptomatology measured using Autism Quotient (AQ).

Conclusions: Our ‘resting-state’ results suggest that autistic individuals have homeostatic differences in the GABAergic regulation of ‘background’ E-I. Next, our results confirm that GABAergic dysfunction is fundamental to the neurophysiology of auditory sensory processing alterations in ASD. Finally, these GABA-dependent differences in ‘fundamental’ brain processes appear to be upstream of more complex autistic phenotypes.
A Randomized Placebo-Controlled Trial of Arbaclofen Vs. Placebo in the Treatment of Children and Adolescents with ASD. the "Arba Study"

E. Anagnostou, J. Frei, L. Capano, J. Lim and R. Nicolson, (1)Autism Research Centre, Bloorview Research Institute, University of Toronto, Toronto, ON, Canada, (2)McMaster University, Hamilton, ON, Canada, (3)Queen's University, Kingston, ON, Canada, (4)Holland Bloorview, Toronto, ON, Canada, (5)Department of Psychiatry, University of Western Ontario, London, ON, Canada

Background:
Alterations in neuronal excitation and inhibition (E/I), potentially leading to an altered signal to noise ratio, have been suggested as a potential mechanism for impairment in autistic individuals, a theory is supported by genomics, systems neuroscience and cross species studies. In this context, it is reasonable to interrogate E:I balance as a potential therapeutic target. Arbaclofen, the R enantiomer of baclofen and a GABAB agonist, has been evaluated in both FXS and ASD, and previous data suggested potential benefits for subgroups of individuals.

Objectives:
Primary Objective: To examine the effect of arbaclofen vs. placebo on social function as measured by the Vineland-3 – social domain.

Secondary /exploratory objectives: To examine a) safety and the effect of arbaclofen vs. placebo on measures of global function, associated symptoms, and quality of life, and b) the utility of electrophysiology (EEG, MEG) and sensory discrimination in predicting response to treatment.

Methods:
This is a 4-site, double-blind, placebo-controlled, phase II RCT. We aligned primary and secondary aims, trial design and inclusion/exclusion criteria, across two networks and jurisdictions, to allow for a pre-specified, secondary pooled analysis. Modifications to previous protocols were made based on lessons learnt from previous trials, so as to extend both duration of exposure (16 weeks) and increase dose range (up to 20 mg tid), and restrict inclusion criteria. Participants were ages 5:0-17:11 years, with an ASD diagnosis and complex language (ADOS modules 3 or 4). They were randomized 1:1 to arbaclofen or placebo. Without breaking the blind, participants were offered participation in open label continuation with identical protocol. Biomarkers included EEG and sensory discrimination tasks, and the study was embedded within the POND network, which contributed genomic and imaging data. Safety and tolerability were assessed via the SMURF interview, ESS-CHAD and C-SSRS.

Results:
Ninety participants (80 % male, mean age 12.4 years) were randomized. At the time of submission, all RCT procedures are complete with 82 participants completing all visits and 8 premature discontinuations (4 due to adverse events, 4 due to withdrawal of consent). The database has been locked and is in the analytic phase. Efficacy data will be available by end of 2022. We report here safety data for the full sample. Arbaclofen was overall well tolerated. The majority of AEs were mild to moderate, with most commonly reported AEs related to fatigue and psychomotor agitation. There were two participants that experienced a serious adverse event related to decreased level of consciousness at the highest dose. The events were deemed to be likely related to Arbaclofen, requiring protocol modification.

Conclusions:
We leveraged lessons learned from previous trials of Arbaclofen in ASD, to develop a mostly shared protocol and pre-specified pooled analyses across Canada and Europe. Arbaclofen was relatively well tolerated. We will present efficacy, safety and biomarker of treatment response data to further inform the value of E:I balance as a therapeutic target, explore the utility of the pre-specified biomarkers in prediction of treatment response and discuss models of collaboration.
Background:

Developing drugs for ASD defining symptoms (i.e. social reciprocity difficulties and stereotyped/repetitive behaviours/movements, with functional impact) is challenging because of a limited understanding of their underlying pathophysiology(ies). With the accumulating evidence suggesting a role for the excitatory/inhibitory imbalance as key for the development of pathological trajectories compatible with ASD, some molecules that impact such balance and have proved benefit in preclinical studies are being tested in clinical trials. We therefore setup a publicly funded academic-industry collaborative double-blind Randomized Control Trial (RCT) with arbaclofen (GABA-B agonist) versus placebo, to assess its effect on core and/or comorbid symptoms in ASD.

Objectives:

Primary objective: to assess the effect of arbaclofen versus placebo on social function in a sample of autistic children and adolescents with fluent speech; secondary objectives: 1. To examine the effect of arbaclofen versus placebo on measures of global function, other adaptive domains and measures of ASD defining and associated behaviours. 2. To examine safety and tolerability of arbaclofen in children and adolescents with ASD.

Methods:

AIMS-CT1 is an international, multi-site, double-blind, parallel group Phase II randomized clinical trial. Males and females aged 5:0-17:11 years, with a diagnosis of ASD and fluent speech were included. Eligible participants from 7 sites were randomized on a ratio of 1:1 for a 16-week treatment period. Medication was titrated over 5 weeks. The primary outcome is the effect on social function from weeks 0 to 16 measured on the Socialization domain of the Vineland Adaptive Behavior Scales, 3rd editionTM. Secondary outcome measures included the CGI-S (Clinical Global Impression-Severity), CGI-I (Clinical Global Impression-Improvement), other areas of adaptive function, social communication and other autism symptoms, co-occurring behavior problems and health-related quality of life. Electrophysiological markers (together with genetic and digital biomarker metrics) were also acquired. Safety and tolerability were assessed via several instruments including the SMURF, ESS-CHAD and C-SSRS.

Clinical Trial Registration: EudraCT number: 2018-000942-21 and ClinicalTrials.gov registry number: NCT03682978. Currently under protocol v.9.1, dated 18.06.2022.

Results:

124 participants (80 % male, mean age 11.8 years old) were randomized (randomization closed on September/2022). At the time of this submission 99 patients had completed the study, 14 participants were ongoing, 8 had dropped-out and 3 were lost to follow-up. Last visit of the last patient will take place on January/2023. Closing of the database is expected by March/2023 and primary outcome analysis by April/2023.

Conclusions:

AIMS-2-TRIALS has proved to be an efficient network in setting up and deliver an academic-designed clinical trials for core symptoms of ASD and support future drug development. Most patients completed the protocol, with no major adverse event. The outcomes of this trial (primary outcomes will be available in April/2023), together with the parallel Canadian trial (also presented in this panel) will contribute to the evidence base for medications used to help social difficulties among young autistic individuals.
particularly relevant for the randomized placebo-controlled trial of ARBaclofen in the treatment of children and adolescents with ASD. ARBaclofen is a GABAα agonist, a potential therapeutic target for the E/I balance. The E/I balance is posited to be altered in several neurodevelopmental disorders including ASD. In preclinical models of FXS, Baclofen normalized the gamma resting state power aberrant increase. In humans, Arbaclofen was found to normalize visual processing measured by EEG in a small group of adult ASD (Janz et al, 2022; Jonak et al, 2022; Huang et al, 2022).

**Objectives:** The first objective was to evaluate whether EEG metrics were modified by Arbaclofen in ASD children.

**Methods:** The study was multisite over Canadian and European hospitals. An EEG battery of measures was used to assess 192 (68 CND, 124 European) participants at baseline, and after the 4.5 months of treatment or placebo. The EEG battery consisted of social, nonsocial and pure resting state, face ERPs, auditory steady state, visual steady state and auditory oddball. These tasks were chosen because they were found abnormal in ASD. After preprocessing the data to clean the signal from artefacts, EEG metrics reflecting synchronization of the signal, spectral density and distribution, connectivity, repetition effect, and response to deviants will be extracted. Statistical analyses will verify the differences between treatment groups using an analysis of covariance with baseline and age as covariates. Analyses of stratified groups according to behavioral symptoms severity and EEG metrics at baseline will be conducted.

**Results:** We hypothesize most EEG metrics will be correlated with the level of severity of ASD symptomatology. We further hypothesize that Arbaclofen will modify EEG metrics, in particular the gamma power, and synchronization of the response of the steady-state evoked potentials. The treatment associated modifications will be predicted by the baseline severity of symptoms.

**Conclusions:** Implications of this study are multiple. First, it will demonstrate the relevance of using EEG as an outcome measure in a multisite ASD clinical randomized clinical trial. Second, it will identify the brain function mechanisms affected by GABAα agonists. Third, it will confirm the EEG metrics sensitive to E/I imbalance. Last, it may identify potential treatments for ASD children.

### PANEL DISCUSSION — INTERVENTIONS - PHARMACOLOGIC

#### 225 - Oxytocin Therapy for Autism: An Overview of the State-of-the-Art and Future Directions to Take

Discussant: Keith Kendrick, University of Electronic Science and Technology of China, Chengdu, China

Social interactions are an inherent corner stone of human behavior. One neurobiological system that is suggested to underlie and facilitate pro-social behavior is the oxytocinergic system. In the human brain, oxytocin is produced in the hypothalamus where it acts as an important neuromodulator for mediating a broad range of affiliative behaviors, including inter-personal bonding, social attunement and attachment, primarily through its top-down effects for modulating ‘social salience’ and its bottom-up function in regulating central and autonomic nervous system function impacting (social) stress and anxiety responses. Especially in the field of autism spectrum disorders (ASD), intranasal administration of oxytocin is increasingly considered as a potential novel treatment for elevating the socio-communicative problems that are at the core of this condition. The panel session will provide an overview of the state-of-the-art of the oxytocin research field, ranging from preclinical, mechanistic research to the clinical application of (chronic) intranasal oxytocin therapy in human trials with individuals with ASD. Also recent insights into the importance of optimizing frequency, dosing and administration routes will be discussed. Together, gaining integrated treatment-mechanistic insights from animal models, pharmaco-neuroimaging studies, oxytocin biology and (epi-)genetics will allow delineating challenges and opportunities for the field to move forward.

**225.001 (Panel Discussion) A History of Oxytocin Research in Autism and Beyond: A Road from Mechanistic Models to Efficacy RCTs in Clinical Populations

N. Daniels, Rehabilitation Sciences, KU Leuven, Leuven, Belgium

Background: Intranasal administration of the neuropeptide oxytocin has been suggested as a potential therapy for autism spectrum disorders (ASD). However, current scientific findings are complex and inconsistent, and the bridge to clinical practice applications is still fragile.

**Objectives:** In this first panel contribution, we will provide a brief history of theoretical models regarding the proposed prosocial effects of oxytocin. Next, we review existing evidence for a dysfunctional oxytocinergic system in ASD and recent insights into the efficacy and safety of oxytocin interventions in ASD populations. Here, we particularly focus on insights obtained from our recent, large-scale oxytocin trial investigating the immediate and long-term effectiveness of daily intranasal oxytocin administration in children with ASD.

**Methods:** Both preclinical single-dose administration studies with neurotypicals will be presented, as well as clinical, multiple-dose oxytocin administration studies with individuals with ASD. A main focus will lie on empirical data from our recent multiple-dose RCT
including 77 children with ASD (61 boys, 16 girls) aged 8-12 years examining the clinical efficacy and safety of a four-week treatment of 12 IU of oxytocin dosed twice daily.

Results: While introducing some key theoretical mechanistic models underlying oxytocin’s action, empirical results will be presented from some of our recent single-dose administration studies, demonstrating oxytocin’s role in modulating social attention processes (‘salience’) and reducing anxiety and stress. Next, existing evidence regarding a dysfunctional oxytocinergic system in people with autism will be presented based on our recent meta-analytic analyses of altered oxytocin hormonal levels and epigenetic modifications of the oxytocin receptor gene. Finally, a comprehensive review will be provided of oxytocin RCTs in both children and adults with autism, with a special focus on new emerging insights from our recent RCT with school-aged children. In short, novel, unpublished results will be discussed indicating that children who received oxytocin in combination with concomitant psychosocial treatment displayed greater benefits than those who received oxytocin alone (p < .05). Further, an interaction between parental belief about treatment allocation and treatment response was identified, however, only in the experimental oxytocin group, not in the placebo group, ruling out the possibility of a general parental-expectancy-induced placebo effect. Accordingly, the possibility of ‘responder/non-responder’ subgroups will be discussed, suggesting that parents might have been able to correctly detect ‘real’ treatment responders from non-responders.

Conclusions: We will conclude this first panel presentation with some key take home messages regarding the state-of-the-art of oxytocin treatment for ASD. The talk will also conclude with the formulation of several directions and opportunities for future research, introducing some of the emerging topics of the subsequent panel talks.

225.002 (Panel Discussion) Common and Differential Molecular Mechanisms of Acute and Repeated Oxytocin Effects in Autism: Human Genome-Wide Exploration / Pharmaco-Neuroimaging Trial and Back Translational Animal Study

H. Yamasue, Hamamatsu University School of Medicine, Tokyo, Japan

Background: Although oxytocin is expected as a candidate therapeutic for the core symptoms of autism spectrum disorders (ASD), its unknown mechanism of actions and the significant variability in oxytocin efficacy among individuals impede the development of oxytocin-based therapies.

Objectives: First, we explored common molecular mechanisms underlying acute and repeated oxytocin effects on ASD core symptoms by exploring single nucleotide polymorphism (SNP) associated with individual variability in oxytocin efficacy. Next, considering recent notions of differential effects of acute- versus repeated-dosing, a comparison in neurochemical changes induced by acute versus repeated dosing was conducted, using data from a preclinical animal study and a human clinical pharmaco-neuroimaging trial. Methods: Genome-wide association studies (GWAS) were conducted on placebo-controlled, double-blind trials datasets in adult males with ASD administered with intranasal oxytocin: 1st dataset was from a single-site, crossover, within individual, single-dose administration trial (40 participants, UMIN000002241/000004393); 2nd dataset was from a multi-site, parallel-group, six-week administration trial (106 participants, UMIN000015264); 3rd dataset was from a multi-site, crossover, within individual, four-week intranasal administration of oxytocin with enhanced bio-availability (109 participants, NCT03466671/UMIN00003141). The outcomes on which efficacy of oxytocin was detected were extracted from these trials, and genomic datasets were collected. Finally, neurochemical changes in glutamatergic function were assessed after single- or repeated administration in a cohort of adult male C57BL/6J mice (medial frontal transcript expression levels; 16 mice) and a human cohort of men with ASD (medial prefrontal H-magnetic resonance spectroscopy; 19 participants).

Results: A GWAS in the 1st dataset revealed that a SNP was associated with acute oxytocin-induced improvements of medial prefrontal functional MRI activity during a social judgment task at a genome-wide significance level. The 2nd dataset confirmed the same SNP’s significant association with repeated oxytocin-related improvements in Autism Diagnostic Observation Schedule (ADOS) repetitive behavior and those in quantified facial expressions during social interaction in ADOS administrations, but not associated with the placebo effects. Furthermore, the 3rd dataset also showed a significant association between the same SNP and efficacy of repeated oxytocin to reduce ADOS social reciprocity score. Although the SNP was identified with genome-wide exploration, it was annotated to a gene which belongs downstream of oxytocin signaling. Finally, both in mice and humans, the glutamatergic system showed a unique sensitivity to repeated, not single-dose, oxytocin administration which may explain differential behavioral effects of oxytocin between acute and repeated administration.

Conclusions: Three independent datasets demonstrated the association of the same SNP with both acute and repeated oxytocin’s efficacy on clinical, behavioral, and neural outcomes linked with ASD core symptoms, and revealed the first clinical evidence for the role of the gene in modulating oxytocin’s efficacy in treating ASD symptoms. Together, the current results suggest that further integrative and comprehensive analyses with multi-layer omics data from the multiple RCT datasets including metabolomic, proteomic, and micro RNA data as well as genomic data should be promising. It can be expected that such analyses identify molecular networks underlying acute and repeated effects of oxytocin for integrative understanding and also provide novel therapeutic molecular targets for ASD core symptoms.

225.003 (Panel Discussion) Oxytocin Therapy for Autism: Importance of Dose Frequency, Context and Route of Administration

K. M. Kendrick, University of Electronic Science and Technology of China, Chengdu, China
Background: In recent years a number of clinical trials have reported variable effects of repeated intranasal oxytocin treatment on social symptoms of children and adults with autism. Inconsistent findings may have been contributed to by a number of factors including dose and dose frequency (i.e. problems related to inverted U response curves and receptor desensitization) and absence of associating treatment in some way with receipt of a positive social experience. Person-specific factors such as age, gender and genotype may also influence effects. Additionally, the use of an intranasal administration route may not be essential for oxytocin to produce functional effects and an oral route could be more efficient for delivering the peptide and better tolerated, especially in young children. In terms of objective measurement of oxytocin treatment outcomes on social attention utilizing eye-tracking measures could also be valuable. Over the past 5 years, we have been investigating the importance of many of these aspects in a series of both pre-clinical and clinical trials.

Objectives: To determine if: (1) dose frequency of intranasal oxytocin and oxytocin receptor genotype may influence its neural and behavioral efficacy, (2) giving a positive social experience after treatment can improve intervention outcomes (3) eye-tracking measures or social attention can be used as an additional objective measure of improvement in social symptoms and (4) an oral administration route can produce comparable or improved functional outcomes relative to an intranasal one.

Methods: Both randomized, placebo-controlled pre-clinical and clinical trials involving neurotypical adults or young children (3-8 years) with autism. Preclinical trials incorporated behavioral and brain imaging (fMRI or fNIRS) measures as well as eye-tracking and peripheral measures of oxytocin concentrations in response to intranasal or orally administered oxytocin. A clinical trial on autistic children used objective clinical assessments (ADOS-2), parent completed questionnaires together with eye-tracking and oxytocin measurements to determine effects of a 6-week intervention with less frequent doses of intranasal oxytocin (every other day) given in conjunction with a subsequent positive social interaction involving play.

Results: Overall, results demonstrated that when given less frequently intranasal oxytocin produces more consistent neural and behavioral responses to social stimuli in healthy adults, and in conjunction with positive social interactions can also significantly improve social symptoms (notably improved ADOS-2 scores and greater interest in social stimuli) in young autistic children. Eye-tracking measures were also sensitive to oxytocin interventions. Preclinical studies in healthy adults demonstrated that acute oral administration of oxytocin had similar effects to intranasal administration in terms of influencing social attention and responses to social touch and producing greater activation in brain reward regions in response to positive facial emotions.

Conclusions: Oxytocin-based interventions in autism still have therapeutic potential but more studies are needed to determine optimal dosing strategy and duration as well as its use as an adjunct to positive behavioral interactions. Oral as opposed to intranasal administration may provide a more effective route. The importance of factors such as age, gender and genotype in determining treatment responses still need to be better established.

225.004 (Panel Discussion) The Effects of Multiple-Dose Oxytocin Treatment on Human Neural Circuitry: Initial Insights from Recent Pharmaco-Neuroimaging Studies in Autism.

Background: The past decade, intranasal administration of oxytocin is increasingly explored as a new treatment for alleviating the core symptoms of autism spectrum disorder (ASD). However, previous behavioral clinical trials have yielded an inconsistent pattern of clinical effects, with some studies showing beneficial effects, while others identified no benefit of oxytocin over placebo treatment. Objectives: To further our understanding of variability in (clinical) treatment responses, it is of great importance to gain deeper insights into the neural substrates that underlie oxytocin treatment effects. Particularly the impact of multiple-dose oxytocin treatment on human neural circuitry is largely unknown, and also the possibility that long-term oxytocin use may induce long-lasting neural adaptations remains fairly unexplored.

Methods: Results from our recent randomized placebo-controlled pharmaco-neuroimaging clinical trials with adults and children with autism will be presented, evaluating the clinical efficacy and neural effects of continual intranasal oxytocin treatment, administered daily over a period of four-weeks. Multi-modal characterizations, including fMRI neuroimaging, electroencephalographic recordings and assessments of stress physiology were performed to evaluate neurophysiological basis of oxytocin’s treatment effects. Also biological evaluations, including epi-genetic characterizations and oxytocin hormonal levels were performed. To assess the possibility of long-lasting neural consequences of multiple-dose oxytocin treatment, neuroimaging was performed up to four weeks and even one year after cessation of the treatment.

Results: Irrespective of the age group, significant effects of oxytocin treatment on amygdala circuitry were evident, indicating reduced functional coupling of the amygdala to prefrontal regions in the oxytocin group, compared to the placebo treatment group. A retention of neural circuitry changes was evident up to four weeks in the pediatric sample, and up to one year in adults with ASD. Also, irrespective of the age group, stronger neural responses were associated with more pronounced behavioral improvements on core autism symptom.
Background: Phelan-McDermid syndrome (PMS) is a rare neurodevelopmental disorder caused by haploinsufficiency of the \textit{SHANK3} gene. PMS is associated with intellectual disability, autism, and behavioral abnormalities. Epilepsy occurs in ~25% of cases, and when present significantly impacts quality of life for affected individuals and their families (Celik, et al., 2021). AMO-01 is an experimental therapeutic that acts as a Ras-ERK pathway inhibitor. Activation of the Ras-ERK pathway has been previously implicated in seizure generation and Ras-ERK pathway inhibitors may reduce seizure frequency. In a \textit{Shank3} mouse model (\textit{Shank3b−/−}), significantly reduced audiogenic seizures were observed after a single dose of AMO-01. However, AMO-01 has never been tested as an anti-epileptic in humans with PMS.

Objectives: The objectives of this pilot, open-label trial were to assess: 1) safety and tolerability of AMO-01, and 2) reduction in seizure frequency.

Methods: Six individuals were enrolled and five were included in the analysis (3 male, mean=20.6 years). One participant was excluded since epilepsy was well-controlled and no seizures occurred during the Screening-Baseline period. Eligibility criteria included (1) confirmed PMS diagnosis (loss of \textit{SHANK3} by deletion or sequence variant), (2) 12-45 years and post-pubertal, (3) epilepsy diagnosis, (4) rated at least “moderately ill” on the Clinical Global Impression Severity scale. The trial consisted of five main visits: pre-trial Screening, Baseline, and three post-drug follow-up visits at Weeks 1, 2 and 4. A single 6-hour intravenous infusion of 120 mg/m² of AMO-01 occurred at Baseline. Adverse Events (AE) were assessed using the Systematic Longitudinal Assessment of Adverse Events form during the infusion, the day after, and at all follow-up visits. Caregivers completed a Seizure Diary, recording each seizure during the trial, from Screening to Week 4. Change in weekly seizure frequency was assessed from Baseline to Weeks 1, 2 and 4 using Wilcoxon signed-rank tests on log-transformed data to look for relative change. Criteria for 25% reduction of seizures were met if the upper-end of the 2-sided 95% confidence interval was equal to or lower than 0.75 of the Baseline scale.

Results: No serious AEs were reported. The most common AEs were increase in stereotypies, rituals, repetitive behaviors and in appetite, both reported in 2/5 (Table 1). Weekly seizure frequency was significantly reduced at all timepoints. From Baseline to Week 1, seizures reduced from an average of 39±59 to 5±9 \((p=0.043)\), to 23±50 \((p=0.043)\) at Week 2, and 10±20 \((p=0.042)\) at Week 4. Seizure frequency was reduced by at least 25% at all timepoints (Figure 1). Seizure reduction ranged from 38% to 100% per person at Week 1, 18% to 100% at Week 2, and 67% to 100% at Week 4.

Conclusions: Results from this preliminary study show the safety and tolerability of AMO-01. Seizures were significantly reduced in this cohort. Future studies with larger sample sizes, repeated dosing, and placebo control are needed to confirm the impact on seizure frequency, test for possible impact on secondary clinical outcomes, and determine optimal dosing and infusion schedule.

415.260 \textit{(Poster)} Assessment of the Impact of Standard-of-Care Treatment for ASD-Associated Enterocolitis: A Longitudinal Study
Background: Chronic gastrointestinal (GI) symptoms, common in children with an autism spectrum disorder (ASD) diagnosis, are difficult to properly diagnose and effectively treat. The paucity of published information regarding specific therapeutic strategies and corresponding treatment outcomes in this unique patient population continues to complicate an already challenging situation. The treatment study described here was undertaken to address this information gap by providing a longitudinal assessment of the efficacy of standard-of-care treatment on GI symptoms and ASD characteristics in a group of GI-symptomatic children with ASD.

Objectives: The clinical effect of treating ASD-associated inflammatory bowel disease (IBD) has not yet been systematically evaluated, documented, analyzed, or reported. The objective of this study was to determine whether conventional treatment of IBD in children with ASD positively impacts both GI symptoms and core ASD behaviors and cognition. The overall goal of this pilot trial was to obtain data that would be exceptionally beneficial in generating a uniform “standard of care” for children with ASD who were being evaluated for chronic GI symptoms and shown to have treatable intestinal inflammation.

Methods: Following diagnostic assessment by a pediatric gastroenterologist and confirmation of eligibility (i.e., evidence of enteroocolitis at endoscopy, capsule endoscopy, and/or biopsy), eleven male children with ASD were enrolled in the study and evaluated for one year during their ongoing treatment regimen which included induction corticosteroids followed by non-steroidal 5-ASA agents (and immunomodulators/biologics - as clinically warranted). Patient caregivers completed baseline GI symptom and ASD questionnaires at various time points over a 12-month period: at baseline just prior to treatment initiation, weekly (GI questionnaires); (1) Gastrointestinal Symptom Survey Bowel Movement Chart (GISS-BMC), and (2) Gastrointestinal Symptom Survey Externalizing GI Behaviors (GISS-EB)), quarterly (Aberrant Behavior Checklist (ABC)), semiannually (Social Responsiveness Scale (SRS-2)), and annually (Vineland Adaptive Behavior Scale II (VABS II)). Non-parametric Wilcoxon Signed-Rank Test was used to compare data between time points; p ≤ 0.05 was considered statistically significant.

Results: Eleven participants completed the 52-week study. A total of 877 GiSS weekly surveys (426 GiSS-BMC; 451 GiSS-EB) were included in the analysis. In addition, data from 103 ASD questionnaires (50 ABC; 31 SRS-2; 22 VABS II) were analyzed. Although outcomes (i.e., magnitude of change) varied from individual to individual, data from ten of eleven participants indicated significant improvements in both GI symptoms (Figure 1) and ASD behaviors and cognition (Figure 2) during, and following, one year of treatment.

Conclusions: This pilot study, part of a larger ongoing trial that will enroll and evaluate an additional 20 children, provides compelling preliminary evidence for the efficacy of standard-of-care treatment in children with ASD and co-occurring enterocolitis to improve both the gastrointestinal symptom profile as well as ASD-associated behaviors and cognition.

415.261 (Poster) Autologous Umbilical Cord Blood Infusion for the Treatment of Autism - a within-Subject Open-Label Study on Safety and Efficacy

Background: Stem cell therapy for autism has been performed in recent years, both within the remit of clinical trials, but also offered as paid treatment by some facilities. The treatments have ranged from intravenous infusions of umbilical cord blood (UCB) and human cord tissue mesenchymal stromal cells, to intrathecal injections of bone marrow mononuclear and mesenchymal stem cells. UCB possesses paracrine regulatory functions and can alter immune dysfunction via cellular messaging, repair T and B cell pro-inflammatory activity and counterbalance overproduction of gial cells. This study commenced in December 2019 when early publications on UCB infusion indicated the potential for treatment benefit. The use of autologous UCB in a within-subject open-label clinical trial was approved by the local Institutional Review Board.

Objectives: To document the safety and efficacy of a single infusion of autologous UCB in 20 children aged 24 to 72 months with autism.

Methods: A pre-post treatment within-subjects design was used for this open label trial. Participants underwent baseline psychometric measures at T=0, and no changes were made to their standard care (early intervention programme) for 6 months. The same measures were repeated at T=6 months, and participants then received a single infusion of autologous umbilical cord blood. Safety evaluations were administered at 3-monthly intervals after treatment, and the psychometric measures were repeated at T=12 and T=18 months. These measures were: Vineland Adaptive Behaviour Scale (VABS-II), Stanford Binet Intelligence Scale (SB-5), Expressive One-Word Picture Vocabulary Test (EOWPVT), Brief Observation of Social Communication Change (BOSCC), Pervasive Developmental Disorder-Behaviour Inventory (PDDBI), Repetitive Behaviour Scale-Revised (RBS-R), Sensory Experience Questionnaire (SEQ-2.1), Child Behaviour Checklist (CBCL), and Clinical Global Impression- Severity and Improvement Scales (CGI).
Results: 20 children were recruited (16 male; 13 Chinese, 4 Indian, 3 Other Races). Mean (SD) age was 4.08 (0.67) years. 19 completed the study and 1 was withdrawn due to cord blood not meeting quality control criteria on pre-release testing. Mean (SD) cell dose administered was 38.16 (9.82) million cells/kg. None of the children suffered serious adverse events and the infusion was well-tolerated. The commonest side effects were mood swings (n=7), irritability (n=5), increased repetitive behaviours (n=5) and hyperactivity (n=4), but were generally self-limiting. Data on efficacy are being analysed but will be ready for INSAR 2023.

Conclusions: A single infusion of autologous UCB in children with autism may be well-tolerated, but does come with possible side effects. Benefits remain to be seen. Stem cell therapies for autism should therefore still be conducted under strict unbiased clinical trial conditions in order to inform about all risk-benefit considerations towards evidence-based best practices.

415.262 (Poster) Cannabidiol Study in Children with Autism Spectrum Disorder (CASCADE): A Double-Blind, Placebo-Controlled Study to Investigate Efficacy and Safety of Cannabidiol in Children and Adolescents with Autism

R. Robinson, E. Sannar, R. Franke, S. Brukardt, K. Regan, E. Werner, C. Natvig, H. Fleming, S. Mikulich and N. Tartaglia, (1)Neuroscience Institute at Children’s Hospital Colorado, Aurora, CO, (2)Children’s Hospital Colorado, Aurora, CO, (3)Developmental Pediatrics, Children’s Hospital Colorado, Aurora, CO, (4)Neuroscience Department, Children’s Hospital Colorado, Aurora, CO, (5)University of Colorado Anschutz Medical Campus, Aurora, CO, (6)Pediatrics, University of Colorado School of Medicine, Aurora, CO

Background: Individuals with ASD frequently have behavioral issues and psychiatric comorbidities which can be difficult to manage and cause significant adaptive impairment. Currently, there are only two FDA approved medications for the treatment of irritability in ASD. Both medications have the potential for significant long-term side effects, including weight gain, tardive dyskinesia and elevated triglycerides. Caregivers often wish to avoid these medications, or look to alternative treatments when traditional medications are ineffective or intolerable. Preliminary studies suggest that cannabidiol (CBD), a non-psychoactive cannabinoid, may lead to improvements of behavioral symptoms in ASD including irritability, aggressive behaviors, and anxiety.

Objectives: To evaluate the efficacy of CBD for 12 weeks in patients 5 to 17 years of age on the primary outcome of irritability and aggressive behaviors, and secondary outcomes of anxiety, social communication, behavior, ASD symptoms, family stress, quality of life, and sleep disturbance in ASD compared to placebo.

Methods:

The CASCADE study is a randomized, double-blind, placebo-controlled study of oral CBD (100mg/mL; Jazz Pharmaceuticals) in children with ASD age 5-17 funded by the Colorado Department of Public Health & Environment, USA (clinicaltrials.gov nct04520685). The modified crossover trial includes 3 arms, including Arms A and B with traditional crossover design (with 3 week washout between drug and placebo period), and Arm C that receives CBD for the entire 27 weeks.

ASD diagnosis is confirmed at baseline by records review and ADOS-2 assessment by psychologist. At each study visit, the same caregiver completes a battery of questionnaires to assess their child’s irritability and aggressive behaviors (Aberrant Behavior Checklist—2nd Edition: ABC-2 Irritability subscale), anxiety (Anxiety, Depression, and Mood Scale; ADAMS), sleep (Sleep Clinical Global Impressions – Severity Scale, Sleep Clinical Global Impressions – Improvement Scale). The OACIS (Ohio Autism Clinical Impressions Scale) interview quantifies severity and improvement in all domains of ASD. Mixed effects general linear models, covarying for gender and age, will specify treatment group (CBD vs placebo), time, and group by time interaction. Efficacy will be determined by improvements in primary outcome (ABC-2 irritability subscale) and changes in scores on secondary outcome measures in the CBD treatment group versus the placebo group after 12 weeks.

Results: 68 participants have consented, including 11 screen fails, 18 active participants, 27 study completions, 11 early withdrawals, and 1 participant terminated by the PI. Of the 57 randomized to date, baseline characteristics include: mean age 10.6 (sd 3.02), 16% female/84% male, Race 84% Caucasian/16% other, Ethnicity 6% Hispanic, Stanford Binet IQ 79.8 (sd 24.7). Mean ABC-Irritability score on study entry was 23.2(sd 7.64). There have been no significant adverse events to date. Enrollment will be completed in early 2023, and cohort demographics, and adverse effects will be presented.

Conclusions: The use of CBD to treat behavioral symptoms of ASD is a promising innovative area of research. The present study will help answer important questions related to safety and efficacy of CBD for treatment of behavioral symptoms of ASD.

415.263 (Poster) Convergence of Two Clinician-Reported Global Impression Scales in Assessing Severity and Change of Autism Symptoms

S. Klupp, H. Staunton, T. Wiese, P. Schoenenberger, L. Murtagh, S. Schneider, S. Zhu and J. Tillmann, (1)Neuroscience & Rare Diseases, Pharma Research & Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche AG, Basel, Switzerland, (2)Roche Products Limited, Global Product Development Data Sciences, F. Hoffmann-La Roche AG, Welwyn Garden City, United Kingdom, (3)F. Hoffmann-La Roche Ltd, Basel, Switzerland, (4)Personalised healthcare (PHC), Product Development, F. Hoffmann-La Roche AG, Basel, Switzerland, (5)F. Hoffmann-La Roche Ltd, Welwyn Garden City, United Kingdom

Objectives: To evaluate the efficacy of CBD for 12 weeks in patients 5 to 17 years of age on the primary outcome of irritability and aggressive behaviors, and secondary outcomes of anxiety, social communication, behavior, ASD symptoms, family stress, quality of life, and sleep disturbance in ASD compared to placebo.

Methods:

The CASCADE study is a randomized, double-blind, placebo-controlled study of oral CBD (100mg/mL; Jazz Pharmaceuticals) in children with ASD age 5-17 funded by the Colorado Department of Public Health & Environment, USA (clinicaltrials.gov nct04520685). The modified crossover trial includes 3 arms, including Arms A and B with traditional crossover design (with 3 week washout between drug and placebo period), and Arm C that receives CBD for the entire 27 weeks.

Conclusions: The use of CBD to treat behavioral symptoms of ASD is a promising innovative area of research. The present study will help answer important questions related to safety and efficacy of CBD for treatment of behavioral symptoms of ASD.
Background: A key challenge in autism trials is a lack of sensitive clinical endpoints. Clinical Global Impression scales (CGI) are often used to measure symptom severity and improvement and as anchors to derive estimates of meaningful clinical change. While the CGI is a generic 1-item clinician's overall impression, the 10-item Ohio Autism Clinical Impression (OACIS) is autism symptom focused.

Objectives: Explore similarities and differences between two clinician-rated impression scales.

Methods: 339 autistic children between 5-17 years (M_{age}=12.2 years; SD_{age}=3.2 years; female=13%; clinicaltrials.gov identifier: NCT02901431) across placebo and treatment arms were assessed. Inclusion criteria included CGI-S score ≥4 at screening, indicating at least a moderate severity of autism. Severity (CGI-S & OACIS-S) and improvement (CGI-I & OACIS-I) clinician ratings of autism symptoms were obtained at multiple visits. We present frequency distributions, contingency tables to report the percentage of diagonal conformity (accordance on both scales), and Spearman correlational analyses at the 12 and 24 week time points (12W, 24W).

Results: At both follow-up visits, CGI-S and OACIS-S generic scores demonstrated a Gaussian distribution over the response options 2-6 (extreme anchors 1 and 7 with frequency=0), reflecting borderline/some symptoms to severe symptoms. The majority of subjects (~50%) rated with moderate severity. Contingency tables between the two generic scales revealed a diagonal conformity of 78% at 24W (74% at 12W). Correlation analyses confirmed this strong relationship (r_s=.79; p<.001). While some OACIS-S domains revealed a similar distribution as the generic score (e.g., social interaction), others showed a more uniform distribution towards milder severity. The differential score profile between the generic OACIS-S and domains was reflected by diagonal conformities ranging between 35-67% and weak-to-strong correlations (r_s=.29-.81; p<.001).

Generic change ratings showed a trend towards improvement similarly on both arms, with 33% on CGI-I (placebo=36%; trial=31%) and 26% on OACIS-I (placebo=31%; trial=23%) of individuals reporting much or very much improvement at 24W. OACIS-I domains of verbal communication and social interaction showed the largest improvements, which was less so for restricted and repetitive behaviors and other associated symptoms. CGI-I and OACIS-I ratings showed diagonal conformity in 76-81% of individuals across both visits. Correlation analyses confirmed this strong relationship at both time points (r_s=.79-.85; p<.001).

Improvements based on change in severity ratings were less frequently observed with cross-measure comparisons (deltaCGI-S/deltaOACIS-S=35-43% vs. CGI-I/OACIS-I=52-70%). Indicating that minor improvements on improvement scales are not necessarily in concordance with a minor improvement on the severity scales.

Conclusions: While we observed broad convergence in overall global impression scores both for severity and improvement ratings, individual domains reflected a more nuanced pattern of findings. Findings suggest that symptom domains may be weighted differently into a global score. Improvement trends are in accordance with ASD positive placebo response rates. Further, change ratings based on severity vs. improvement scales deviate from assessing minor improvement, questioning the use of CGI-I scales for anchor-based analyses. The results inform future research to develop condition-specific CGIs to assess the severity and improvement across specific autism symptom domains as well as the necessity to include functional impacts.

Keywords: clinician-reported; global impression scales; severity; improvement

415.264 (Poster) Effect of Gabapentin on Cortical Glutamate/Glutamine and Gamma-Aminobutyric Acid Levels, Potential Biomarkers of Social Cognition in Autism

Background: Magnetic resonance spectroscopy (MRS) suggests decreased gamma-aminobutyric acid (GABA) levels as a possible biomarker for social cognition deficits in autism. Gabapentin has been shown to increase GABA acutely in neurotypical individuals. Abnormalities in the anterior cingulate cortex (ACC) and anterior insula (AI) (components of the salience network) are associated with social cognition in autism.

Objectives: We sought to determine which clinical characteristics of autism were associated with glutamate/glutamine and GABA levels in the ACC and right AI, and whether an acute dose of gabapentin alters these levels.

Methods: We recruited 19 autistic adolescents ages 13-17 (17 M, 2 F). We used a Mesher-Garwood Point Resolved Spectroscopy Sequence (MEGA-PRESS) to measure Glx (combination of glutamate and glutamine) and GABA levels in two voxels: one covering the bilateral pregenual ACC and one centered on the right AI. We assessed correlation of Glx and GABA levels with multiple measures of social cognition: the Social Responsiveness Scale (SRS) total score, Reading the Mind in the Eyes Test (RMET) score, SRS subscale scores, and Autism Diagnostic Observation Scale (ADOS-2) scores. Finally, we administered a single dose of gabapentin to 18 of the 19 participants. We repeated the Glx and GABA MRS measurements 2 hours, 4 hours, and 6 hours after gabapentin dosing, and calculated the change in GABA and Glx from pre-dose to each of the individual time points. We used a generalized linear model to assess the relationship of change...
in GABA in the ACC and right AI to the weight-normalized dose of gabapentin (mg/kg), controlling for age, IQ, and baseline GABA/Glx level.

Results: GABA and Glx were correlated with different social cognition assessment scores in the two regions of the cortex. Greater impairment in social cognition was associated with lower levels of GABA and lower levels of Glx in the observed correlations. After gabapentin administration, GABA levels in the right AI rose sharply followed by a fall in levels over time; ACC GABA levels and ACC/right AI Glx levels did not have a robust response. At individual time points, a significant dose response of an increase in GABA in the ACC developed at 4 hours and became nonsignificant at 6 hours; GABA in the right AI demonstrated a statistically nonsignificant dose response of an increase in GABA at early time points that disappeared at 6 hours after the dose; Glx levels demonstrated much smaller (ACC) or absent (RAI) dose responses to gabapentin.

Conclusions: Glx and GABA levels are associated with social cognition measures, but in a region- and neurotransmitter-specific manner. A decrease in GABA levels with social cognition impairment remains the most consistent finding, and we demonstrate evidence that gabapentin may alter GABA/gluatamate imbalance. Implications on the potential clinical utility of gabapentin in autism will be discussed.

A. David, O. E. Stolar and E. Gal, (1)Occupational Therapy, University of Haifa, Haifa, Israel, (2)Autism Center, Tel Aviv University / Shamir (Assaf Harofeh) Medical Center, zefrin, Israel, (3)Department of Occupational Therapy, University of Haifa, Haifa, Israel

Background:

Due to the various behavioral and participation challenges of children with ASD, their parents are often required to use Family Accommodation (FA) to create and maintain a daily family routine. Although variety of treatments are available, medicine is still challenged to find intervention that alleviates the symptoms of children with ASD and improves family well-being. The effect of medical cannabis intervention for various conditions in children has raised the idea of examining its effect on children with ASD. This mixed-methods study is the first to examine the effect of medical cannabis, not only on child's presentation but also on parental well-being in general and on FA in particular.

Objectives:

the main goals of this study were (1) to examine the impact of medical cannabis intervention on parents reports on their family accommodation, and (2) to deepen the understanding of parent's perspectives on the changes in family accommodation following cannabis intervention.

Methods:

We utilized an explanatory sequential mixed methods design model, which included quantitative data collection followed by in-depth interviews to add deeper understanding and contextualization to the quantitative data.

In the quantitative study we analyzed data of 44 children (5–12 years old) who participated in an extensive research regarding the effect of medical cannabis on children with autism. Parents were asked to complete the Family Accommodation Scale for Restricted and Repetitive Behaviors (FAS-RRB) (Feldman et al., 2019), during three different times: (1) before cannabis intervention, (2) after three months of intervention and (3) after six months of intervention. After completing the intervention, 15 parents of children from the full sample participated in semi-structured in-depth interviews.

Results:

The results of the quantitative analysis indicate a significant decrease in FA after three months of intervention. Moreover, after six months of intervention, there was an additional moderate decrease, however, no longer significant. The decreased need for FA was followed by significant change in the child's short-term response if no parental accommodation has been made, and in the parental sense of distress, after three months of intervention. The following qualitative interviews indicated positive changes in the family’s routine and sense of their well-being as well as parents’ ability to engage in meaningful occupation, and experience enhanced interaction with family and friends due to the decreased FA and child's maladaptive behaviors following the intervention.

Conclusions:

Results support the effectiveness of medical cannabis intervention not only on child's presentation but also on parental well-being in general and on FA in particular. The decreased need for FA has a positive effect on the family's quality of life, parent's preoccupation, and
the interactions of the family members with their environment. Thus, it is important to include Family Accommodation as an additional outcome measure of intervention for children with ASD.

415.266  (Poster) Efficacy and Safety of Bumetanide: Results of a Child and Adolescent Spanish Sample with Autism
A. Blázquez, A. Tomás, A. Meseguer, M. L. Lazaro and R. Calvo Escalona, Hospital Clinic Barcelona, Barcelona, Spain

Background: The etiological heterogeneity in autism is considerable. At the molecular level, there has been increasing interest in the role played by glutamate, and several genetic studies support the involvement of the glutamate pathway in autism. Bumetanide, a diuretic agent that reduces intracellular chloride and thereby reinforces GABAergic inhibition, has been found to improve core autism symptoms in children in previous studies.

Objectives: Main: to demonstrate the superiority of bumetanide compared to placebo in the improvement of autism core symptoms, after 6 months of treatment in severely autistic children and adolescents (aged 7-18 years). Secondary: to analyze the adverse effects and safety of bumetanide.

Methods: A 6-month randomized, double-blind, placebo controlled multicentre parallel group study to evaluate efficacy and safety of bumetanide 0.5 mg twice a day followed by an open-label active 6-month treatment period with bumetanide and a 6-week discontinuation period after treatment discontinuation. In addition, the drug was provided to those wanting to pursue the treatment with bumetanide at the end of the main study periods. The study was conducted in autistic children and adolescents. A Data Monitoring Committee was set up and was responsible for periodic review of patient’s safety data throughout the study. This study was performed in strict accordance with Good Clinical Practice. The main criteria for inclusion were: Clinical Global Impression (CGI) – Severity (CGI-S) rating Score ≥ 4, CARS2 (Childhood Autism Rating Scale second edition) ≥ 34 and Social responsiveness Scale (SRS-2) ≥ 66 T-Score. Differences between placebo and bumetanide were analyzed by CARS2, SRS-2, CGI-I improvement and Vineland II Adaptive Behaviour Scale (VABS II). Safety and side effects were also collected. Statistical analyses were performed with SPSS 25.0. The significance statistical level was <0.05.

Results: 7 patients (6 males, 1 female) completed double-blind period (week 26) and 5 completed until 52 week. The 7 patients performed the wend visit. Mean age: 10.29 (SD=3.35). 3 patients were treated with placebo and 4 with bumetanide until week 26 (W026). At table 1 was collected the mean scores for different scales at baseline visit (W00) and at W026. At W026, SRS-2 has a trend to low punctuations in bumetanide group but it was not statically significant (p=0.07). The main side effects in bumetanide group were hypokalemia, polyuria and excessive thirst. Table 2 collects scales’ scores at 52 week (opened-label period) compared with W00. Statically significant differences were found in CGI (p=0.03) and CGI-improvement (p=0.02). After the 6-week discontinuation period, CGI punctuations were significantly worst (p=0.04). 4 of 5 families (80%) requested bumetanide for compassionate use.

Conclusions: Our study failed to demonstrate the superiority of bumetanide compared to placebo after 6 months of treatment in the CARS2 total score, SRS-2 and CGI-I expressed in terms of change from baseline to W026. However, the scales’ scores improved from W052 to W00. As expected, and in line with the known diuretic action and safety profile of the drug, hypokalemia, thirst and polyuria were the most common secondary effects reported on bumetanide group.

415.267  (Poster) High Throughput Virtual Screening of in-House Database Against mGluR5 in Preclinical Models of Autism
S. Dwivedi1, P. Chakraborty1, S. K. Vagolu1, Y. Perumal4 and P. Kulkarni5, (1)School of Health Sciences and Technology,, UPES, Dehradun, India, (2)Department of Pharmacy, Birla Institute of Technology and Sciences (BITS) Pilani Hyderabad Campus, Hyderabad, India, (3)Unit for Genome Dynamics, Department of Microbiology,, University of Oslo, Norway, Oslo, Norway, (4)Department of Pharmacy, Birla Institute of Technology and Sciences (BITS) Pilani Hyderabad Campus, Hyderabad, India, (5)Dr. Reddy’s Laboratory, Hyderabad, Hyderabad, India

Background:

Autism is a multifaceted neurodevelopmental infirmity, occurring at early childhood. The disorder is manifested by social, cognitive, and language impairment along with stereotypies. Pharmacological interventions for the overall treatment of autism do not exist. However, the medications currently available help only in symptomatic cure and disease management. Thus, the present scenario of drugs for autism urges for searching potential molecules with therapeutic value against autism. Pharmacological inhibition of metabotropic glutamate receptor 5 (mGluR5) is reported to rescue impaired social interaction and autistic and cognitive phenotypes in mouse models. Thus, has been explored in our study.

Objectives:

The present study involves the virtual screening of an in-house small molecule database against mGluR5 followed by a preclinical screening of the shortlisted molecules towards autism-like phenotypes in a cell-based study as well as a zebrafish model of valproic acid (VPA) toxicity.
Methods:

In this study, we have performed the virtual screening for the in-house BITS library, followed by investigating the selected in-house mGluR5 targeted molecules based on docking studies on in vitro and in vivo models. The selected compounds were screened against glutamate-induced excitotoxicity in differentiated Neuro-2a cells using an MTT assay. The promising compounds from the excitotoxicity assay were examined for VPA-induced toxicity in neurospheres. The neurospheres were co-treated for 7 days with VPA (1mM) along with the selected test compounds at different concentrations (0.1, 1, and 10µg/mL), and were investigated for cell proliferation and differentiation. Zebrafish larvae were exposed to VPA (75 µM) from 4 hours to 5 days post fertilization followed by treatment with selected test compounds from 5-7 days post fertilization. Seven days post fertilization battery of behaviour tests (for anxiety, attention deficit, and stereotypic behaviour) were performed followed by gene expression studies.

Results:

We have selected 20 compounds (SD-1 to SD-20) based on molecular interactions and docking scores to screen for inhibition of glutamate-induced excitotoxicity. Five out of 20 compounds were able to reduce excitotoxicity, and two of them had a significant effect. In neurosphere culture, chronic VPA treatment results in decreased proliferation followed by a disrupted differentiation pattern. Interestingly, the co-treatment with our lead molecules rescues VPA-induced neurotoxicity as evidenced by an increase in proliferation followed by differentiation and neurite outgrowth. The best compound (SD-9) was further investigated in the zebrafish larvae model for autism. The post-treatment with SD-9 was able to abrogate VPA-induced behavioural despairs in a dose-dependent manner observed with an open field test, inattentive behaviour test, and circling behaviour test. In addition, SD-9 rescues the effect of VPA on the expression level of autism-related genes.

Conclusions:

In conclusion, the compound SD-9 from BITS in-house database shows neuroprotective activity against VPA-induced toxicity when tested in vitro and in vivo. However, further exploration may be needed to validate the mechanistic aspects of molecules and their use as therapeutics in autism.

415.268 (Poster) How Learnings from Balovaptan Informed a New Drug Development Approach for the Alogabat Autism Program

Background:

Balovaptan, a selective V1a receptor antagonist, has been developed for use in autistic inviduals for treatment of social and communication symptoms. Based on the results of a phase 2 study in adult men with ASD (VANILLA) which demonstrated a positive, clinically meaningful effect on socialization and communication, a pediatric phase 2 trial (aV1ation) and an adult phase 3 study (V1aduct) were started. Both studies failed to show treatment benefits on the primary endpoint of social communication and interaction (Vineland II 2DC score) and no benefits were seen on the secondary endpoints.

This largest drug development program in autism generated a plethora of learnings in different areas of clinical development such as study design and conduct, choice of endpoints, quality monitoring, as well as participant population and insights into placebo response in autism. The Balovaptan learnings directly impacted the design and conduct of the Aurora Borealis trial. This ongoing phase 2 study investigating the efficacy, safety, tolerability, and pharmacokinetics of Alogabat (RO7017773), a GABA-A α5 receptor modulator, in autistic participants aged 15-45 years.

Objectives:

Share how Balovaptan learnings have informed the clinical trial design and conduct of the ongoing Aurora Borealis study.

Methods:

Data from the three Balovaptan clinical trials were analyzed with regard to critical clinical trial core components including participant eligibility and target population, endpoint strategy, site selection, rater selection and training, as well as the use of biomarkers to identify treatment-sensitive subgroups.

Results:

The Aurora Borealis phase 2 clinical trial (NCT04299464) has implemented several learnings, including the use of highly trained central raters and associated quality monitoring for the primary endpoint (live data monitoring, outlier threshold and erratic rating detection),
flexible remote assessment strategies to reduce subject burden while retaining quality of assessment, and placebo training for caregivers and clinicians. Further, a comprehensive biomarker battery was implemented to identify and further develop treatment-predictive and surrogate efficacy measures.

Conclusions:

Based on observations, analyses and overall learnings of several past studies testing balovaptan in participants in ASD, the Alogabat program was designed to start dissecting the phenotypic and biological heterogeneity of ASD in a clinical drug development program. The Aurora study serves as an efficacy and safety study piloting the use of EEG, neurobehavioral, and digital biomarkers for the further development of Alogabat. Furthermore, the study pioneers a set of measures to better standardize the participant population across geographic regions and to optimize endpoint strategy to ensure high-quality reporting and mitigate potential biases.

415.269 (Poster) In silico and in-Vitro Screening of a Dual Active Ligand That Inhibits HDAC2 and H3R to Rebuild Synaptic Circuitry in Autistic Patients

A. Raja, N. Shekhar, H. Singh and B. Medhi, (1)Pharmacogy, Post Graduation Institute of Medical Education and Research, Chandigarh, India, (2)Post Graduation Institute of Medical Education and Research, Chandigarh, India

Background:

Autism spectrum disorder (ASD) is a lifelong heterogeneous neurodevelopmental disease that can be diagnosed as early as two years old. In the autopsy of the autistic brain, decreased EAAT2 mRNA and protein levels were identified. The EAAT2 is a key astrocytic transmembrane protein to regulate the synaptic glutamate level. Further, HDAC2 is responsible for regulating EAAT2's mRNA and protein levels (1). Additionally, antagonizing the H3R (e.g., famotidine) has also been discovered to have a potential therapeutic role in the management of autistic-like symptoms (2). Because of the disease's mechanistic intricacy, dual molecular targeted therapy is needed. Hence, we identified H3R inhibitor ligands that are computationally effective at binding to the metal-coordinated binding site of HDAC2. In addition, we have also screened the lead molecule potency in invitro using primary astrocytic cell line.

Objectives:

In silico screening of a dual active ligand that inhibits HDAC2 and H3R to rebuild synaptic circuitry in autistic patients

Methods:

Following work-flow was followed:

Protein and ligand structure modeling- The protein crystal structure of HDAC2 was acquired from https://www.rcsb.org/ with the PDB id 5IX0. The receptor grid at the HDAC2 inhibition site was generated using GLIDE. The ligand molecules were acquired from Drugbank (FDA approved library) and individually from PubChem published bioassays of H3R inhibitors in sdf format.

Molecular docking and virtual screening

Final scoring of the virtual screening was achieved using the MM-GBSA binding free energies of the receptor-ligand complexes.

Pharmacokinetic assessment of the hits

The pharmacokinetic evaluations for the hits with high binding affinity were done using SwissADME, admetSAR and Qikprop tool from Schrodinger.

MD simulations and trajectory analysis

The full-scale molecular dynamics simulations were run on Desmond from Schrodinger.

Effect of lead on gene expression

In order to test the effect of lead molecules on EAAT2 expression, we have develop the primary astrocytic cell line from 3 day old pups brain and confirm using GFAP marker. Further, we have synthesized the lead molecules in collaboration with medicinal chemistry department. The gene expression of EAAT2 and HDAC2 were compared with treatment (24hr) and without treatment to primary cell culture using confocal technique.
Hypothesis- Presented in Fig. 1

Results:

The screened lead compounds with PubChem SIDs 103179850, 103185945, and 103362074 showed viable binding with HDAC2 in silico. The proposed H3R inhibitors 103179850, 103185945, and 103362074 were estimated as dual-active molecules to block the HDAC2-mediated deacetylation of the EAAT2 gene and H3R-mediated synaptic transmission irregularity. In addition, we have considered PubChem SIDs 103179850 for in-vitro studies because of its non-toxic and good pharmacokinetic profile. The lead treated cell group showed significant increase in EAAT2 and decrease in HDAC2 gene expression compared to untreated cell group.

Conclusions:

These lead compounds are expected to reduce HDAC2 mediated deacetylation of the EAAT2 gene and concomitantly inhibit H3R mediated detrimental genotypic and phenotypic effects in vitro and in vivo, indicating that they could be used as a therapeutic addition in ASD treatment.

415.270 (Poster) Influence of Repeated Intranasal Oxytocin Administration on Neural Activity during Face Processing in Children with Autism

Background: Rapidly and accurately processing faces and facial expressions is essential for the development of adequate social behaviour, which is often impaired in individuals with autism spectrum disorders (ASD). Intranasal administration of oxytocin (OT) is increasingly explored as a treatment for improving social behaviour, possibly by enhancing the salience of social cues or by reducing social stress and anxiety. However, mechanistic insight in the neural effects of OT, especially the impact of repeated multiple-dose OT treatment, remains largely unexplored.

Objectives: We implemented two complementary neuroimaging techniques (EEG and fMRI) in a multiple-dose OT clinical trial, in order to monitor the immediate and long-term neural effects of OT pharmacotherapy in ASD.

Methods: We performed a randomized double-blind placebo-controlled multiple-dose OT clinical trial (four weeks, 12 IU, twice daily) in 8-to-12-year-old boys and girls with ASD (n=29 OT, n=32 placebo), and assessed effects immediately post-treatment and after a four-week follow-up. Frequency-tagging EEG was used to robustly quantify neural sensitivity for subtle changes in happy and fearful facial expressions. A complementary fMRI face processing task was also administered to gain better understanding on the underlying neural mechanisms. Prior to the intervention we applied the frequency-tagging EEG and fMRI measures in neurotypical (NT) children (n=39), to compare the neural sensitivity of children with ASD with that of NT children.

Results: First, using the frequency-tagging EEG technique, we observed significantly reduced neural sensitivity towards emotional facial expressions in ASD compared to NT controls. Upon nasal spray administration, children with ASD displayed a significant increase in neural sensitivity at the post and follow-up sessions, but only in the placebo group, likely reflecting an implicit learning effect. Strikingly, in the OT group, neural sensitivity remained unaffected from the baseline to the post session, likely reflecting a dampening of an otherwise typically occurring implicit learning effect. At follow-up, four weeks after cessation of the OT treatment, we see an increase in neural sensitivity, comparable to the effect seen in the placebo group.

Secondly, the fMRI results revealed a different pattern of brain activity in ASD compared to NT controls. Children with ASD displayed significantly decreased activity in early visual brain areas and increased activity in the inferior frontal cortex and left amygdala compared to NT controls. Repeated oxytocin administration in ASD did not restore neural activity in these altered regions. However, evidence for an attenuating effect of oxytocin on superior temporal sulcus activity (a core facial expression processing brain region) was found.

Conclusions: First, these findings underline the robustness of frequency-tagging EEG to identify reduced neural sensitivity towards expressive faces in ASD. Secondly, contrary to the general hypothesis that OT may enhance social salience and heighten the reduced neural responses towards facial expressions in ASD, we see that repeated OT administration further attenuates these responses. Possibly, repeated OT administration without explicit social training or context may induce (social) stress reducing effects, thereby also reducing neural sensitivity for socio-communicative cues.

415.271 (Poster) Investigation of Serotonin-Stimulating Drugs Effects on Oxytocin Levels and Brain Activity in Zebrafish Larvae
D. Dreher Nabinger and L. Westberg, (1)Pharmacology, University of Gothenburg, Gothenburg, Sweden, (2)Department of Pharmacology, University of Gothenburg, Gothenburg, Sweden

Background:

Autism spectrum disorder (ASD) is characterized by deficits in social interactions. Although the condition severely affects 1% of the population worldwide, no pharmacological treatment is available yet. Oxytocin has been proposed to impact and facilitate social processing, and interventions increasing endogenous oxytocin seem to be an attractive alternative to diminish social deficiencies in ASD. Furthermore, serotonin-stimulating drugs have been suggested to decrease social deficits in animal models and in ASD patients – potentially by stimulation of oxytocin release.

Objectives: With the overall goal of developing treatment strategies for social deficits, this study aims to identify drugs that stimulate oxytocin neurons and to identify related neuronal circuits. Specifically, in this study, we investigated whether the serotonin-releasing drugs MDMA and fenfluramine as well as the serotonin receptor agonists buspirone, DMT, LSD and psilocybin stimulate activity of oxytocin neurons and overall brain activity in zebrafish larvae.

Methods: Five-day old transgenic zebrafish larvae, expressing fluorescent proteins in oxytocin-producing cells (oxtl:egfp) were exposed to different drugs shown to elevates human plasma levels of oxytocin. During 1 hour, zebrafish larvae were exposed to 0, 1, 10 or 100 µM of the following drugs: fenfluramine, buspirone, MDMA, DMT, LSD and psilocybin. After 1-hour exposure, fish were euthanized and the samples were prepared for whole mount immunohistochemistry approach using an antibody towards phosphorylated S6, an endogenous sensor of neuronal activation, and tyrosine hydroxylase (TH). The samples were analyzed by confocal microscopy (20X - LSM 710 NLO MP/Confocal, Carl Zeiss). Two brain regions were evaluated - subpallium and preoptic area – areas suggested to be implicated in oxytocin’s actions on social behaviors were evaluated. Imaging analysis was performed by ImageJ software.

Results: No activation of oxytocin cells was observed after drug treatments. However, the serotonin-releasing drugs MDMA and fenfluramine, and the agonists towards the serotonin receptor 2A (DMT, LSD and psilocybin), but not 1A (buspirone), significantly increased pS6 positive cells at subpallium and preoptic area of the zebrafish larval brain.

Conclusions: The results observed here suggest that our immunohistochemical approach using pS6 antibodies can be used to identify and characterize drug-activated neurons in zebrafish larvae. We provide evidence that drugs stimulating the release of serotonin or specifically the 2A receptor activates neurons of the pallium in zebrafish larva.

415.272 (Poster) Mediators of Placebo Response to Cannabinoid Treatment in Children with Autism Spectrum Disorder
A. Aran, M. Harel and D. Cayam-Rand, (1)Psychology Neuropediatric Unit, Shaare Zedek Medical Center, Jerusalem, Israel, (2)Shaare Zedek Medical Center, Jerusalem, Israel

Background: Placebo-response has a substantial impact on treatment outcome with important implications for clinical practice and trials. However, data regarding mediators of placebo-response in children with autism spectrum disorder (ASD) are sparse.

Objectives: To investigate possible mediators of placebo-response among participants of a placebo-controlled trial of Cannabinoid treatment for Behavioral problems in children with ASD (CBA trial).

Methods: We used a specifically designed questionnaire to explore possible mediators of placebo-response in 88 participants of the CBA trial who received placebo and had valid outcome scores. The questionnaire taps 8 domains: parental expectations, child's comprehension of the treatment purpose, previous positive experience with similar treatments (behavioral conditioning), parental locus of control, quality of the patient-physician relationships, recent aggravation of symptoms at baseline, recent fluctuations in symptom-severity at baseline, and adherence to study medications.

Results: Parents of 67 participants completed the questionnaire. Placebo-response was positively associated with the child's comprehension of the treatment purpose (p=0.037). There was also a trend for participants who had a relative aggravation of symptoms before treatment onset to improve following a placebo treatment (p=0.053). All other domains including parental expectations were not associated with placebo-response.

Conclusions: Placebo-response in children with ASD was associated with the child’s ability to understand the treatment purpose. This finding suggests that efforts to explain the treatment purpose to children with disabilities may enhance treatment efficacy in clinical practice and decrease differences in placebo-response between study arms. Contrary to our hypothesis, parental expectations regarding cannabinoid treatment were not associated with placebo-response.
**415.273 (Poster) Overcoming Barriers to Recruitment and Retention in a Placebo Controlled Randomised Controlled Trial of Medication Involving Autistic Adults**

A. X. Realpe, L. Beasant, A. Lorenc, J. E. Norris, S. Douglas, L. Kenny, D. Rai and N. Mills, (1)Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, United Kingdom, (2)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3)Bristol, United Kingdom, (4)NHS England, London, United Kingdom, (5)Population Health Sciences, Bristol Medical School, University of Bristol, UNITED KINGDOM, (6)Centre for Academic Mental Health, University of Bristol, Bristol, United Kingdom, (7)BASS Autism Services for Adults, Avon & Wiltshire Partnership NHS Trust, Bristol, United Kingdom

**Background:** Few large placebo randomised controlled trials (RCTs) for autistic adults have been conducted. They are considered challenging because they rely on uncertainty and blinding of treatments, aspects that can be particularly difficult for autistic people. The STRATA RCT, currently recruiting in UK and Western Australia, aims to assess whether sertraline is an effective and safe treatment for anxiety in adults with autism compared with a placebo. Anticipating recruitment and retention difficulties, we co-produced a programme of qualitative research, in collaboration with a long standing autistic advisory group to explore the views of autistic adults on being invited to an RCT to treat anxiety in both a hypothetical situation (APRiCoT study) and during a real RCT (STRATA).

**Objectives:** The objectives of this qualitative study were to:

- Use the results of a hypothetical study to refine optimal ways to present a real study and refine its protocol.
- Compare the views of those considering participating in a hypothetical RCT with those based on real experiences to investigate how well views align.
- Discuss what we can learn on trial design and conduct RCTs for an autistic population.

**Methods:** We thematically analysed data from in-depth interviews with 49 APRiCoT and 30 STRATA study participants. Interviews explored reasons for accepting or declining trial participation (real or hypothetical), views on the trial process, and experiences and acceptability of medication.

**Results:** We found a strong support for obtaining scientific evidence within the autistic community, especially for effective treatments for anxiety. We confirmed pre-trial hesitancy about taking trial medication because of experiences of autistic people developing atypical responses to commonly prescribed medications, reactions that may not be acknowledged or addressed by healthcare professionals. Design suggestions for RCTs included a bespoke safety check system to reassure individuals as well as a preference for online over face-to-face contact. Adjustments to the design of the RCT following feedback from participants in APRiCoT were recognised and appreciated by participants in STRATA. Length of blinding in the hypothetical trial produced divergent views amongst interviewees, yet retention in the real trial has been better than expected to date.

**Conclusions:** Whilst hypothetical studies are useful to understand views and possible actions in healthcare scenarios, continuing co-production with research partners provide anchorage when faced with real situations. This methodology will contribute to improving the conduct of ongoing and future RCTs so that they are more appropriate and inclusive, enabling robust treatment effectiveness in this under-served population to be determined.

**415.274 (Poster) Post-Treatment Gains in Social Gaze, Cognitive, and Behavioral Outcomes during a Combination Oxytocin-Social Skills Training Intervention**

L. V. Soorya, C. W. Brune, K. Nayar, E. V. Ocampo, E. F. Dillon, S. Licona, Z. E. Arnold and L. Hermle, (1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Department of Psychiatry, AARTS Center, Rush University Medical Center, Chicago, IL, (3)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (4)Center for Autism and Related Disorders, Autism Assessment, Research, Treatment, and Services (AARTS) Center at Rush, Baltimore, MD, (5)UCSB Koegel Autism Center, Santa Barbara, CA, (6)The University of Alabama at Birmingham, Birmingham, AL

**Background:** Social Skills Training (SST) groups are a widely used treatment modality with several randomized clinical trials (RCTs) showing improvements on social competence in autistic youth. Recently, studies of neural plasticity provide evidence that some SST groups have the potential to shift neural and gaze patterns to reflect those found in non-autistic youth. These findings reflect the significant neural restructuring that occurs starting around age 10 in non-autistic youth within brain networks supporting higher-order cognitive functions (e.g., attention and motivational processes critical to fostering peer social relationships). The current study seeks to extend the SST research on putative behavioral and cognitive mechanisms supporting neural plasticity in older autistic youth. Specifically, this study applies oxytocin augmentation of a SST group curriculum, which has been shown to increase recruitment of social-cognitive circuitry and improve proximal behavioral endpoints.

**Objectives:** The primary goal of this pilot RCT (Clinicaltrials.gov: NCT02918864) was to evaluate the potentiating effects off intranasal oxytocin (INOT) during a cognitive-behavioral group intervention targeting social-cognitive skills in school-aged children with autism.
Predictors of Placebo Response in Three Large Clinical Trials with the V1a Receptor Antagonist Balovaptan in Autism

(1)Nathan Kline Institute, Orangeburg, NY, (2)F. Hoffmann-La Roche Ltd, Welwyn Garden City, United Kingdom, (3)F. Hoffmann-La Roche Ltd, Basel, Switzerland, (4)New York State Psychiatric Institute, New York, NY, (5)Department of Psychiatry, Columbia University, New York, NY, (6)Department of Psychiatry and Behavioral Sciences and Albert Einstein College of Medicine, New York, NY

Background:

There are no approved pharmacotherapies for the core symptoms of autism. High rates of placebo response, which limit the statistical capacity to identify treatment differences, are increasingly implicated as a factor in failed autism clinical trials. However, there have been limited studies of the predictors of placebo response in autism.

Objectives:

To identify baseline predictors of placebo response and quantify their influence on clinical scales of interest for three, large, harmonised randomised clinical trials of balovaptan, a V1a receptor antagonist.

Methods:

Analyses comprised data from autistic children and adults assigned to placebo in three randomised controlled trials of balovaptan (VANILLA [NCT01474278], V1aduct [NCT03504917] and aV1ation [NCT02901431]). A two-step approach was used to identify predictors of placebo response on the Vineland-II two-domain composite (2DC; primary outcome in aV1ation and V1aduct and a caregiver measure) and Clinical Global Impression scales (CGI; secondary outcome and a clinician measure) at Week 12 and 24 separately. The candidate predictor set included baseline demographics (age, sex, IQ, body mass index [BMI]), baseline clinical scales (Social Responsiveness Score-2, CGI – Severity, Vineland-II socialisation and communication standard scores, Pediatric quality of life inventory™ family impact total score, RepetitiveBehavior Scale – Revised [RBS-R] subscale scores), concomitant medication and comorbidity. Site-specific factors such as commercial versus academic sites and number of participants enrolled were also considered. Step 1 identified influential predictors of placebo response using Least Absolute Shrinkage and Selection Operator (LASSO) regression while Step 2 quantified the influence of predictors via linear regression. Results were validated through statistical bootstrapping approaches with 500 replications of the analysis dataset.

Results:

The pooled participant-level dataset included individuals with autism aged 5–62 years (mean age 21 [SD 10]), among which 263 and 172 participants received placebo at Weeks 12 and 24, respectively. No influential predictors were identified for the CGI scale. At Week 12, increased placebo response on the Vineland-II scale was predicted by commercial versus academic sites (adjusted estimate 4.31; 95% CI
1.48, 7.13; p=0.003), higher dropout rate per site (8.95; 95% CI 0.55, 17.34; p=0.037), higher baseline RBS-R compulsive (0.58; 95% CI 0.05, 1.11; p=0.033), attention deficit hyperactivity disorder (3.71; 95% CI 0.51, 6.92; p=0.023) and depression (4.50; 95% CI 1.43, 7.57; p=0.004). At Week 24, increased placebo response was predicted by higher baseline RBS-R compulsive (0.78; 95% CI 0.17, 1.40; p=0.010) and higher RBS-R ritualistic (0.71; 95% CI 0.00, 1.42; p=0.050). In contrast, decreased placebo response at Week 12 and Week 24 was predicted by higher baseline Vineland-II 2DC (Week 12: –0.23; 95% CI –0.31, –0.14; p<0.001; Week 24: –0.32; 95% CI –0.44, –0.19; p<0.001). Additional factors associated with decreased placebo response at Week 24 included participants being recruited from EU versus US sites (–6.57; 95% CI –12.73, –0.42; p=0.040) and higher baseline BMI (–0.27; 95% CI –0.51, –0.03; p=0.020).

Conclusions:

Outside of meta-analyses, this study represents the largest initiative investigating placebo response in autism. Identification of these predictors of placebo response may help with anticipating and potentially mitigating placebo response in drug development efforts in autism.

**415.276 (Poster) Role of ORAL Probiotics in Children with Autism Spectrum Disorder: A Randomised Double Blind Placebo Controlled Trial**

**S. Gulati**, S. Grover, H. M. Rashmi, R. Chaudhry, S. Ojha, A. Chaudhary, K. Tabassum, G. Kamila, P. K. Panda, K. Parkayastha, P. Gupta, S. Khan, S. S. Kumaran, A. Upadhyay and G. Gulati. (1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (2)Dairy Microbiology Division, ICAR- National Dairy Research Institute., Karnal, Haryana, India, India, (3)Department of Microbiology, All India Institute of Medical Sciences, New Delhi, India, (4)All India Institute of Medical Sciences, New Delhi, India, (5)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (6)All India Institute of Medical Sciences, New Delhi, New Delhi, India, (7)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, Rishikesh, India, (8)Child Neurology Division, All India Institute of Medical Sciences, New Delhi, India, (9)Department of Pharmacology, All India Institute of Medical Sciences, New Delhi, India, (10)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (11)Department of NMR, All India Institute of Medical Sciences, New Delhi, India, (12)Department of Biostatistics, All India Institute of Medical Sciences, New Delhi, India

Background: Probiotics are live micro-organisms which can provide health benefits on the host when administered in adequate amounts. It has been proposed that probiotics may reduce the inflammatory state and modulate the gastrointestinal and behavioral symptoms in ASD via gut brain axis.

Objectives: To study the efficacy of add-on oral probiotics to standard treatment in improving core symptoms of Autism Spectrum Disorder(ASD)

Methods: In this ongoing randomised double-blind placebo-controlled trial, a total of 100 children(50-each group), age 2-18 years, fulfilling DSM V for ASD and on standard treatment for <12 weeks have been enrolled. Children with ASD suffering from chronic systemic illness, receiving standard treatment for ≥12 weeks, have received any alternate treatment in past 12 weeks or allergic to any known component of probiotics were excluded. *Lactobacillus rhamnosus*, *Lactobacillus plantarum and Bifidobacterium longus subsp infantis* in the dose of 1 billion CFU/g (Total=3*10⁹) as probiotic, was started along with standard treatment in the intervention group whereas control group received only standard care. Probiotics were given as 1 sachet/day, daily for 24 weeks. Outcome was assessed based on Childhood Autism Rating Scale (CARS), Autism Behaviour Checklist (ABC), Childhood Behaviour Checklist (CBCL), Development Profile 3 (DP3), Child Sleep Habit Questionnaire (CHSQ) and Sensory Profile 2; at 12 and 24 weeks in both the groups. fMRI Brain was done in a subset of patients in both the groups, and stools samples were collected and analysed for individual pathogenic and non-pathogenic microbial flora, along with fetal propionic acid.

Results: Out of the total 100 children enrolled, average age at enrolment was 5.4(2.6) years with an average age at diagnosis of 48 months(18-132 months). 25% of the children were receiving risperidone as a part of standard treatment whereas 63% were not on any medications. The mean CARS, ABC, CSHQ score at baseline was 36.69(+4.9), 73.7(+16.9), 33.1(+11.9) respectively. Sensory Profile scores were assessed under following domains: Seeking[61.6/95(+11.8)], avoiding[62.15/100(+10.2)], sensitivity[62.7/95(+11)], registration[57.5/110(+13.20)], auditory[25.8/40(+6.2)], visual[16.2/30(+4.6)], touch[32.5/55(+8.6)], movement[23.17/40(+5.7)], body position[16.9/40(+6.3)], oral[31.8/50(+8.9)], conduct[29.7/45(+6.9)], socioemotional[42.2/70(+7.4)] and attentional[36.3/50(+6.9)]. On CBCL, features of pervasive developmental disorder and being withdrawn were seen in all the children, associated inattention and hyperactivity was seen in 77% of them. 55.5% of the children were graded as mild- moderate ASD and 44.5% were severely autistic(CARS≥37). Most of the children had associated comorbidities, and on evaluation 97% of children had intellectual impairment, 98%-stereotypies, 46%-agression, 37%-constipation, 10%-epilepsy, 8%-feeding disorder, 7%-motor disorder, 3%-obesity, 1%-adolescent issues, 4%-anxiety disorder, 5%-mood disorder, 16%-ADHD, 12%-disruptive behaviour and 24% had OCD as associated co-morbidities. The average change in CARS and ABC at 12 and 24 weeks is 1.5 (0 - 9.5), 2 (0 - 9.5) and 2 (0 - 25), 3 (0 - 25) respectively. Significant reduction in complaints of constipation was seen in follow up at 24 weeks from 37% at baseline to 6%. One child had complaint of seizure while on therapy. No other side effects were noted.
Conclusions: Significance of change in scores and outcome will be assessed after the detailed analysis at the end of the study.

**415.277** (Poster) Testing a Mechanism-Based Treatment Candidate Using a Multiple n-of-1 Design: Bumetanide for Developmental Disorders (BUDDI) Trial

**H. Bruining, L. Geertjens, G. Cristian, J. J. Sprengers, E. Juarez, J. Ramautar, K. Linkenkaer-Hansen and G. J. van der Wilt**, (1) Child and Adolescent Psychiatry, Amsterdam University Medical Center, Amsterdam, Netherlands, (2) N=You Neurodevelopmental Precision Center, Amsterdam University Medical Center, Amsterdam Reproduction and Development, Amsterdam, Netherlands, (3) Child and Adolescent Psychiatry and Psychosocial Care, Amsterdam University Medical Center, Emma Children's Hospital, Amsterdam, Netherlands, (4) Brain Center Rudolf Magnus, Department of Psychiatry, UMC Utrecht, Utrecht, Netherlands, (5) CNCR, VU Medical Center, Amsterdam, Amsterdam, Netherlands, (6) Child and Adolescent Psychiatry and Psychosocial Care, Emma Children’s Hospital, Amsterdam UMC, Vrije Universiteit Amsterdam, Meibergdreef 5, 1105 AZ, Amsterdam, The Netherlands, Amsterdam, Netherlands, (7) Department of Integrative Neurophysiology, CNCR, VU University Amsterdam, Amsterdam, Netherlands, (8) RadboudUMC, Nijmegen, Netherlands

Background: Bumetanide is an example of a potential mechanism based treatment option for autism spectrum disorder that has been tested with mixed results in part due to multifaceted heterogeneity. We previously performed three trials in children using varying strategies to identify responsive subsets to bumetanide [1,2,3]. The completed trials indicated effectiveness of bumetanide in improving repetitive and irritable behavior in subsets of participants. Furthermore, we developed a strategy to identify responsive individuals using a combination of EEG biomarkers and behavioral measures [4]. Here, we present the first clinical results of an innovative trial multiple n-of-1 follow-up trial.

Objectives: To validate previous effects and improve clinical endpoints, we performed a series of single-case experimental designs (SCEDs) including physiological, cognitive and behavioral measurements.

Methods: A SCED is an N-of-1 design in which a baseline period is compared to an intervention period, evidence of treatment effect is based on demonstrating that the change in behavior only occurs during intervention versus a randomized baseline period. We performed SCEDs in participants aged 7-18 years with the ability to comply to trial procedures who received 6 months bumetanide treatment under repetitive evaluation of multiple endpoint domains using patient reported outcome measures (PROMs; weekly), conventional questionnaires (3 monthly), resting state EEG measurements (monthly) and an in house-designed battery of computerized tests to measure neurocognitive functions (3 monthly).

Results: In the first series of 40 completed SCEDs 82% of participants experienced a positive change during the treatment period. In all cases this improvement was substantiated by either behavioral, physiological or cognitive improvement. 30 participants showed a positive change in both conventional behavioral outcomes and PROMs, with the majority (80%) showing a change of more than 10 points on the ABC scale and 70% showing a change of more than 5 points on the RBS scale. Of the 33 participants able to perform the cognitive measurements 12 showed a significant change in one or more cognitive domains, of which 92% also experienced a clinical change.

Conclusions: In this first evaluation of the BUDDi trial n-of-1 trials we show applicability of PROMs as specific endpoints and replicate previous effects on repetitive and irritable behavior that seem associated with cognitive effects. Together, these results indicate utility for SCED based n-of-1 designs to test mechanism-based treatments in heterogeneous NDD populations.

**415.278** (Poster) The Efficacy of Vivomixx Probiotic for Autistic Children with Persistent Gastrointestinal Symptoms: A Randomised Placebo-Controlled Double-Blind Crossover Study

**S. D. Simmons and A. Emmanuel**, (1) GI Physiology, University College London, London, United Kingdom, (2) GI physiology, University College Hospital, London, London, United Kingdom

Background:
There is wealth of research demonstrating bidirectional communication between the human gut microbiota and the brain. There is a high prevalence of gastrointestinal (GI) symptoms in autistic children (47%) compared to not-autistic children and these symptoms persist for an extended period of time for a large proportion of autistic children. Research has indicated that the presence and severity of GI symptoms are related to the degree of autistic traits and the levels of anxiety and sensory over-responsivity. Evidence of benefit from the use of probiotics in autistic children is promising but limited: There have only been six studies of probiotics for autistic children and all suffer from methodological issues including small sample size and lack of blinding. However, overall the research is increasingly indicating that treating GI symptoms in autistic children should bring benefits beyond improvements in gastrointestinal symptoms.

Objectives: To assess the efficacy of Vivomixx probiotic on GI symptoms and global function in autistic children

Methods:

A randomised double-blind placebo-controlled crossover trial of Vivomixx probiotic was conducted for autistic children aged 3-14 years with at least one persistent gastrointestinal symptom. 69 participants were enrolled (57 boys) and each participant becomes their own control. All participants had a confirmed diagnosis of autism and the group included those with additional challenges including learning disability and minimal verbal communication. Participants were randomly assigned to either receive placebo for 12 weeks followed by Vivomixx for 12 weeks or vice versa, with a 4 week break in-between to eliminate any carry-over effect. Outcome measures included the Autism Treatment Evaluation Checklist, the Gastrointestinal History questionnaire and the Aberrant Behaviour Checklist and were collected at enrolment (T0), after the first 12-week treatment (T1) and after the second 12-week treatment (T2). The change in outcome measures from T0 after Vivomixx was compared to the change from T0 after placebo.

Results:

Vivomixx was not found to improve global function or reduce the frequency of gastrointestinal symptoms in this heterogeneous group. A subgroup of participants (n=22) displayed a notable improvement in global function following treatment with Vivomixx but post-hoc correlation analysis did not isolate any characteristics that identified these from the rest of the participants.

Conclusions:

The results of this clinical trial for autistic children with persistent gastrointestinal symptoms adds to the evidence regarding probiotic use in this group. As a crossover study with 69 enrolled participants, we believe it is the largest autism probiotic study yet reported. The results confirm the safety of Vivomixx in this patient group. As a randomised double-blind placebo-controlled trial, a significant treatment effect was not found in the group as a whole, which is contrary to published open studies and this highlights the importance of robust design for future studies. The identification of a subgroup that experienced a notable improvement in global function after Vivomixx treatment, suggests that further research with a more tightly defined subgroup may show positive results. Given the low risk of probiotic intervention and the high prevalence of gastrointestinal symptoms in autistic children, this warrants further research.

415.279 (Poster) Use of Medication in Persons with Autism Spectrum Disorder: First Results of a National Study

Background: In Italy, Autism spectrum disorder (ASD) prevalence data are based on regional information systems: in Emilia-Romagna and Piedmont, in the age group 0-17 years, the prevalence of ASD was estimated at 3.9 and 3.8 per thousand, respectively. There are currently no pharmacological treatments available for the 'core' symptoms of ASD but, in view of the presence of neurological and psychiatric co-occurring conditions in this population, the prescription of antidepressant and antipsychotic drugs is frequent.

Objectives: The National Institute of Health evaluated the use of drugs with particular regard to those for the Central Nervous System (CNS) in a cohort of subjects with ASD identified through current health sources.

Methods: The Emilia Romagna, Umbria, Abruzzo and Sardinia regions participated in the first phase of the project. The study population consisted of children born in the period 2000-2016 and ASD cases were defined on the basis of the first hospital admission with a principal or secondary diagnosis of ASD (International Classification of Diseases [ICD-9-CM] 299.x) and aged more than one year at the index event. A maximum of three controls were matched to each case by year of birth, sex and treating physician. For both ASD and controls, all pharmaceutical prescriptions paid for by the National Health Service dispensed in the 24 months following the index event were retrieved (for controls, the starting date of the observation period corresponds to the date of the index event of the relevant case). Analyses were conducted in terms of prevalence of use and quantity of drugs prescribed (number of prescriptions and packages) stratified by age group, therapeutic category, and active ingredient.
Results: 1,950 ASD and 5,827 controls aged between 1-17 years were included, with greater representation of males (80%) and the age group between 1-5 years (66%). The prevalence of drug use was 84.3% in ASD and 76.3% in controls, with a decreasing gradient by age: 86% between 1-5 years and 82% after 6 years for ASD and 80% between 1-5 years and about 68% after 6 years in controls. About one third of ASD and controls received >5 substances in the two years following the index date (definition of polypharmacy). CNS drugs account for 38% of the packages prescribed to ASD and only 6% in controls, reaching a maximum of 75% in ASD aged 12-17 years. As expected, the other categories with the highest use are antibacterial drugs (ASD: 32.3%, controls: 47.4%) and respiratory drugs (ASD: 13.8%, controls: 26.0%). Atypical antipsychotics (particularly risperidone and aripiprazole) and typical antipsychotics are the most prevalent psychotropic drugs in ASD (5.9% and 1.3% respectively), followed by 0.9% by SSRI antidepressants; in controls prevalence of these categories is less than 1%. 0.4% of ASD show symptoms attributable to ADHD treated with methylphenidate.

Conclusions: The present analyses characterized the prescribing pattern in individuals with ASD with particular regard to CNS pharmacological treatment. Pharmacological treatment must however be considered in a broader framework and seen as a possible component of a set of interventions that also includes non-pharmacological interventions.

415.280 (Poster) A Personalised Medicine Approach to Evaluating Therapies for Autistic Children: The Example of Oxytocin
A. J. Guastella, Brain and Mind Centre and Children's Hospital Westmead, Sydney, NSW, Australia

Background: There is growing interest in the use of personalised medicine to inform clinical trials for autism therapies. Despite this, personalised approaches in clinical trials remain in their infancy. Oxytocin is a hormone and neuropeptide that has been administered as a nasal spray to influence social cognition and behaviour. A series of administration studies have produced mixed findings to support use in autistic people. It is clear that a personalised medicine approach is now needed to understand whether there are therapeutic benefits of oxytocin to autistic people. The presenter has published a number of these studies that have produced mixed results. This includes a recent study that suggested that oxytocin may have benefits for younger autistic populations to social responsiveness.

Objectives: The presenter will provide an overview of personalised medicine approaches that can be used in autistic populations. The presenter will also present unpublished data utilising a personalised medicine approach to understand whether oxytocin can produce benefits for some autistic children.

Methods: 87 young autistic children completed a randomized controlled trial of oxytocin nasal spray with a placebo lead-in. They also completed a range of measures aimed at identifying objective markers of response to intervention. Data will be presented showing how clinical trial designs and new technology developed by this research team was used to enhance the evaluation of responses to intervention.

Results: The study showed that younger children showed improved social responsiveness following daily oxytocin nasal administration. A series of analyses are then conducted showing markers of response in sub-populations. This included the using a comprehensive range of technology-driven observational, physiological, biological and cognitive phenotypes to predict change. It is also clear that both modified trial designs and objective markers were needed to account for the placebo response. The results of this analysis will be presented at the time of presentation.

Conclusions: Autism is a heterogenous condition with a range of factors that impact presentation, with relevance for sub-typing response to intervention. Oxytocin has potential to improve social responsiveness, but targeted methods are needed to ensure those that receive the therapy will benefit. This study supports the potential of novel clinical trial designs and objective biomarkers to sub-type autistic individuals so that those who receive therapies are more likely to benefit.
individuals across a wide range of ages (2-21 years) with developmental disabilities, focusing on autism, with severely delayed to above average cognitive functioning. Speakers will present novel research exploring (1) advancements in assessments, prevalence estimates, and clinical predictors of aggressive behavior in early childhood; (2) psychiatric profiles of autistic school-aged youth with aggression; (3) interacting effects of risk factors in youth with genetic mutations related to autism; and (4) outcomes for a parent training intervention targeting challenging behaviors in a community setting. This panel presents a translational perspective on aggressive behavior in youth with developmental disabilities.

222.001 (Panel Discussion) Aggression and Its Relation to Emotional Reactivity in Preschoolers with and without Neurodevelopmental Delays

S. Sivathasan1, J. B. Northrup2, L. Wakschlag1 and C. A. Mazefsky3; (1)Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Department of Medical Social Sciences, Northwestern University, Chicago, IL

Background: Relative to the general population, children with developmental disabilities (DD) including autism spectrum disorder (ASD) display higher rates of emotion dysregulation (ED) challenges and aggression, placing them at an increased risk for psychiatric and behavioral problems. Yet, little is known about the relationship between ED and aggression in early childhood among children with ASD/DDS. Moreover, few standardized tools have been utilized to comprehensively assess the topography of aggressive behaviors in a large non-referred preschool-aged sample, which are critical to informing tailored targets for early intervention.

Objectives: To evaluate the prevalence of parent-reported aggressive behaviors in a large sample of preschool children with ASD/DDs relative to the general population, and to identify clinical predictors of aggression, including considering the contribution of emotional reactivity to aggression in this population.

Methods: Parents of 1068 children with ASD/DDs (“clinical sample”) and 690 children without DDs (“general sample”) between 2-5 years were recruited through the Simons Powering Autism Research (SPARK) registry and the local community. Parents completed the Aggression subscale of the Multidimensional Assessment of Preschool–Disruptive Behavior (MAP-DB), a caregiver-report measure that distinguishes developmentally appropriate from clinically significant challenging behaviors in the general population using an objective frequency scale, the Reactivity subscale of the Emotion Dysregulation Inventory-Young Child (EDI-YC), a newly-developed measure of ED severity validated for preschoolers with and without DDs, and the Social Communication Questionnaire (SCQ). Frequency of aggressive behaviors over the previous month were compared between groups using chi-square analyses and odds ratios. A hierarchical multiple regression was run to determine if the addition of autism traits and emotional reactivity improved the prediction of total aggression scores over and above group (clinical vs. general sample).

Results: Overall, parents of children in the clinical sample (74% with ASD; Table 1) endorsed significantly more frequent aggressive behaviors than those in the general sample on most MAP-DB-Aggression items, with frequent behaviors (defined as “most days”, “every day,” or “multiple times per day”) occurring in up to 18% of the clinical sample versus up to 7% of the general sample (Table 2). Notably, the general sample patterns were comparable to previous community samples, underscoring robustness of distinction from clinical patterns. Children with ASD/DDs were 6 times more likely than those without ASD/DDs to frequently hit, shove, kick, bite, or pinch when frustrated, angry, or upset” and “hit, shove, kick, bite, or pinch other adults.” The full regression model including group, autism traits, and reactivity predicting aggression scores was statistically significant, $R^2=.314$, $F(3, 1746) = 266.58$, $p<.0001$; adjusted $R^2= 313$. The addition of SCQ and reactivity led to significant increases in $R^2$ of .068 and .192, respectively, $ps<.0001$.

Conclusions: These findings suggest that children with ASD/DDs have greater difficulties with ED and aggression compared to children without DDs; however, this effect may be mediated by their greater emotional reactivity. These findings extend the literature on ED among older youth with ASD/DDs and may be indicative of atypical emotional development in early childhood, emphasizing a need for early emotion regulation interventions in preschoolers with ASD/DDs.

222.002 (Panel Discussion) Identification of Four Clusters with Distinct Emotional and Behavioral Presentations in a Large, Representative Sample of Autistic Youth: The Influence of Emotional Reactivity and Aggression

S. Eldeeb1, J. B. Northrup2, C. M. Conner3, H. Karim4, M. S. Siegel5 and C. A. Mazefsky6; (1)Electrical and Computer Engineering, University of Pittsburgh, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)University of Pittsburgh, Pittsburgh, PA, (4)Center for Clinical and Translational Science, MaineHealth, Portland, ME

Background:

Accumulating research suggests that autistic individuals are at high risk for emotion dysregulation, aggression, self-injurious behavior, depression, and anxiety. It is common for autistic individuals to present with multiple forms of emotional or behavioral difficulties, which can severely affect their daily life activities, decrease quality of life, and increase the use of restrictive interventions or hospitalization. Therefore, there is a growing interest in understanding how emotional and behavioral symptoms cluster together within individuals, a
critical gap given the marked heterogeneity within the autism spectrum in emotional and behavioral presentation. Identifying subgroups with similar presentations would be helpful for identifying underlying mechanisms and developing treatment approaches.

**Objectives:** The study aimed to: 1) utilize a machine learning clustering technique to identify subgroups of individuals within the autism spectrum with similar emotional and behavioral presentations and 2) determine which features most strongly inform clustering decisions.

**Methods:** The sample (total n = 1,609) included 558 psychiatrically hospitalized autistic youth from the Autism Inpatient Collection (age 12.7± 3.6), and 996 autistic youth from the Interactive Autism Network (IAN) autism research registry (age 11.9 ± 3). We applied a machine learning clustering technique to item-level parent report data from the Emotion Dysregulation Inventory (EDI) Reactivity (24 items) and Dysphoria (6 items) scales, three self-injurious behavior items from the Aberrant Behavior Checklist (ABC), and items from the Anxious/Depressed, Withdrawn/Depressed, and Aggression scales of the Child Behavior Checklist (CBCL; 39 items). Follow-up analyses were performed to identify significant differences between clusters as well as which scales and items were most informative for cluster membership.

**Results:** The clustering algorithm produced four distinct groups of individuals, as shown in Figure 1. A one-way ANOVA test showed that all pairwise comparisons of the four clusters have significant mean differences. As seen in Figure 1, the EDI Reactivity and CBCL Aggression scales are directly proportional. Furthermore, although the fourth group shows moderate levels across all scales, the first and second groups show higher levels of EDI Dysphoria, CBCL Anxiety and Withdrawn scales than the EDI Reactivity and CBCL Aggression scales. The third group shows the opposite pattern: higher levels of EDI Reactivity and CBCL Aggression scales than the other scales. We ran a feature importance test to assess the importance of each scale and each item within the scale. The results showed that both EDI Reactivity and CBCL Aggression items contributed most to the clustering decision, followed by EDI Dysphoria; an item level feature importance test resulted in similar conclusions.

**Conclusions:** This study provides insights into the underlying similarities between autistic youth based on parent report data related to emotional and behavioral presentation to aid in identifying underlying mechanisms and developing treatment approaches. Results suggest that presence of emotion dysregulation and aggression contribute significantly in determining the cluster membership and the pattern between the emotional and behavioral presentation across these clusters. Next steps will include the identification of non-clustering variables that explain variance in cluster membership.

**222.003 (Panel Discussion)** Interacting Risk Factors for Aggression in Individuals with Rare Variants in ASD-Associated Genes

**H. Reu,** E. Neuhaus†, E. C. Kurtz-Nelson†, R. K. Earl†, R. A. Bernier†, E. E. Eichler†, C. M. Hudac* and S. J. Webb*, (1)Center for Human Development and Disability, University of Washington Psychiatry and Behavioral Sciences, Seattle, WA, (2)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Indiana University School of Medicine, Indianapolis, IN, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)Department of Genome Sciences, University of Washington, Seattle, WA, (6)Department of Psychology; Carolina Autism and Neurodevelopment (CAN) Research Center, University of South Carolina, Columbia, SC

**Background:** IQ, ASD traits, and executive functioning (EF) have been separately linked to aggression in autistic youth. However, we know little about the interaction of risk factors for aggression, particularly in individuals with high-confidence ASD genes with a range of cognitive functioning. Understanding the development of aggression can inform clinical practice and research on mechanisms of change in those interventions.

**Objectives:** We evaluate executive functioning as a moderator in the relation among Verbal IQ (VIQ), Nonverbal IQ (NVIQ), and ASD traits with aggressive behavior in youth with high-confidence ASD genes and in youth and in autistic youth without known genetic mutations.

**Methods:** Enrollment is ongoing for families with rare pathogenic variants associated with ASD (current n=92) and families with ASD without rare variants (current n=61) completed extensive clinical phenotyping through in-person, in-home, and/or virtual methods. All children had diagnoses of ASD and 46.2% had intellectual disability. The majority of the sample were male (76.8%) and ages ranged from 4 to 21.67 years (M=11.69, SD=3.81). IQ was assessed using the Differential Abilities Scale, 2nd Edition, autism traits were assessed using the Social Responsiveness Scale, 2nd Edition, EF was assessed using the Behavior Rating Inventory of Executive Functioning Global Executive Functioning index, and aggression was assessed using the Aberrant Behavior Checklist Irritability Subscale. Group was analyzed as a covariate but not significant and not included for parsimony.

**Results:** Individuals with and without identified rare genes did not differ on severity of aggression (t(166)=-.51, p=.609). Clinically significant levels of aggression were present in 13.7% of the sample. There were main effects of VIQ (B=.05, SE=.02, p=.040) and EF (B=.13, SE=.04, p=.001) on aggression, but these factors did not interact. Similarly, EF did not moderate the relation among NVIQ and aggression, despite significant main effects of NVIQ (B=.06, SE=.02, p=.010) and EF (B=.13, SE=.04, p=.001). Again, while there were main effects, EF also did not moderate the relation among restricted repetitive behaviors with aggression (B=.005, SE=.004, p=.190) or among social-communication skills and aggression (B=.005, SE=.004, p=.182). As only main effects were identified, exploratory multiple

**Conclusions:** The study aimed to: 1) utilize a machine learning clustering technique to identify subgroups of individuals within the autism spectrum with similar emotional and behavioral presentations and 2) determine which features most strongly inform clustering decisions.

**Methods:** The sample (total n = 1,609) included 558 psychiatrically hospitalized autistic youth from the Autism Inpatient Collection (age 12.7± 3.6), and 996 autistic youth from the Interactive Autism Network (IAN) autism research registry (age 11.9 ± 3). We applied a machine learning clustering technique to item-level parent report data from the Emotion Dysregulation Inventory (EDI) Reactivity (24 items) and Dysphoria (6 items) scales, three self-injurious behavior items from the Aberrant Behavior Checklist (ABC), and items from the Anxious/Depressed, Withdrawn/Depressed, and Aggression scales of the Child Behavior Checklist (CBCL; 39 items). Follow-up analyses were performed to identify significant differences between clusters as well as which scales and items were most informative for cluster membership.

We ran a feature importance test to assess the importance of each scale and each item within the scale. The results showed that both EDI Reactivity and CBCL Aggression items contributed most to the clustering decision, followed by EDI Dysphoria; an item level feature importance test resulted in similar conclusions.

**Conclusions:** This study provides insights into the underlying similarities between autistic youth based on parent report data related to emotional and behavioral presentation to aid in identifying underlying mechanisms and developing treatment approaches. Results suggest that presence of emotion dysregulation and aggression contribute significantly in determining the cluster membership and the pattern between the emotional and behavioral presentation across these clusters. Next steps will include the identification of non-clustering variables that explain variance in cluster membership.
Background:

Up to half of autistic children exhibit challenging behaviors, including tantrums, defiance, and aggression (Brown et al., 2019). Without intervention, these behaviors interfere with child and family quality of life, including child academic, adaptive, and social functioning, as well as parent stress and community engagement (Mazurek et al., 2013). Research Units in Behavioral Interventions (RUBI) is a low-intensity, manualized intervention for parents of children with ASD and co-occurring challenging behavior. Although the results of three large scale trials have shown that RUBI significantly decreases child challenging behavior, RUBI has yet to be implemented and tested in community settings (Bears et al., 2015). Additionally, although moderators of treatment response have been tested in previous trials of RUBI, they have not been examined in a community context (Lecavalier et al., 2017). The identification of moderators may provide insight on subgroups that may be more or less likely to respond to an efficacious treatment delivered in a real-world setting.

Objectives:

The aims of the current study were to: (1) evaluate the effectiveness of RUBI on challenging behaviors in autistic youth in a community setting; and (2) examine baseline moderators of treatment response in this sample.

Methods:

Participants were 189 autistic children (ages 2-13), who were referred for treatment for challenging behaviors, and their caregivers. Sessions took place at two large community-based autism centers. Participants in this sample were more demographically diverse than in previous RUBI trials (e.g., 15% Hispanic, IQ 45-136). Parents received twelve sessions of RUBI on average, which were delivered by both doctoral-level and graduate student clinicians. Challenging behaviors were measured via the Aberrant Behavior Checklist Irritability Subscale (ABC-I) and the Home Situations Questionnaire (HSQ) at pre-, mid-, and post-treatment, and again at a one-month follow-up. Our team selected a priori demographic and clinical variables as moderators that could have a prognostic influence on outcomes: parenting stress (measured by the Parenting Stress Index (PSI)), IQ (measured by the Stanford-Binet 5 (SB-5)), and child anxiety (measured by the Multidimensional Anxiety Scale for Children 2 (MASC-2)).

Results:

The first aim was investigated using multi-level modeling to fit data to specific models to test distinct growth trajectories from pre- to post-intervention (Hox, 2010). There were significant decreases in ABC-I scores from pre- to mid-intervention ($\beta=5.32$, $p<.001$), post-intervention ($\beta=8.82$, $p<.001$), and follow-up ($\beta=9.10$, $p<.001$). There were also significant decreases in HSQ scores from pre- to mid-intervention ($\beta=0.77$, $p<.001$), post-intervention ($\beta=1.43$, $p<.001$), and follow-up ($\beta=1.76$, $p<.001$). Moderators (parenting stress, IQ, and child anxiety) were then added to the models and main effects and interactions were examined. Moderation analyses were not significant.

Conclusions:

Results from this study support the effectiveness of the RUBI parent training program for children with autism and challenging behaviors in community-based clinical practice. Key baseline characteristics did not moderate treatment outcomes, suggesting that RUBI is likely to benefit a wide range of children with autism and disruptive behavior. Further examination of the purposeful implementation and sustainment of RUBI in broader and more geographically diverse community settings is indicated.
Autism co-occurs with various neuro-psychiatric conditions. Over the last few years, the co-occurrence of autism with post-traumatic stress disorder (PTSD) has gained more research attention. Studies have shown that PTSD is much more common in autism than in typical development, and that it is often associated with adverse social experiences. The current panel brings together an international collection of researchers to advance our understanding of the triggers, the clinical manifestation, and the mechanisms underlying autism-PTSD co-occurrence. Connor Kerns will present findings on the Childhood Adversity and Social Stress questionnaire, which was especially designed to examine trauma triggers and traumatic symptoms in autistic children and youth. Arvid Kildahl will present findings on the clinical and behavioral characteristics of autistic adults with intellectual disabilities, and how despite these features, PTSD is underdiagnosed by mental health professionals. Freya Rumball will present results of an international longitudinal study which examined traumatic experiences of autistic vs. non-autistic adults resulting from the COVID-19 pandemic. Finally, Danny Horesh will offer a fresh look on social cognition as a mechanism underlying autism-PTSD co-occurrence, and on how being more aware of social cues could actually expose autistic individuals to more traumatic stress.

**229.001 (Panel Discussion) Psychometric Properties of the Childhood Adversity and Social Stress (CASS) Questionnaire, Parent Report Version: A Trauma Measure Tailored for Autistic Youth**

_C. M. Kerns_1, A. Zaidman-Zaït_2, D. L. Robins_3, C. J. Newschaffer_4, C. A. Mazefsky_5 and S. J. Berkowitz_6, (1)University of British Columbia, Vancouver, BC, Canada, (2)Tel-Aviv University, Tel-Aviv, ISRAEL, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)College of Health and Human Development, Pennsylvania State University, University Park, PA, (5)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (6)psychiatry, UC School of Medicine, Denver, CO

Background: Research suggests autistic youth are more likely than non-autistic youth to experience childhood adversity and traumatic reactions. However, studies have relied on measures neither designed nor validated for autistic populations, a limitation given evidence of distinct sources and expressions of trauma in this group. To address this, we used a mixed-method approach to develop an autism-tailored tool, the Childhood Adversity and Social Stress (CASS) questionnaire, with self and parent-report versions. An extensive literature review, qualitative interviews with autistic adults and caregivers and Delphi poll of experts in autism and childhood trauma generated and refined CASS items. The measure included traditional (e.g., maltreatment) and autism-related adversities (e.g., stigma, sensory-related distress) as well as symptoms identified as “important indicators” of trauma in autistic youth (with varied language) by expert consensus. Notably, symptoms are only queried if a traumatic event (TE) is reported (i.e., parent endorses ≥1 past adversity that (a) upset the child for more than a few weeks and (b) still upsets them currently).

Objectives: To assess the psychometric properties of the parent-report CASS.

Methods: Parents of 749 autistic children ages 8–17 years old (80.1% male; Mage(SD)=13.09(2.69); 85.1% White) with communicative phrase speech were recruited via the Interactive Autism Network. They completed the CASS along with sociodemographic questions, a parent-reported Child PTSD Symptom Scale (CPSS) and Short Sensory Profile (SSP) online. Data analysis included: descriptive statistics of the CPSS items, confirmatory factor analysis and exploratory structural equation modeling (ESEM; which allows cross-loading of items) of the CASS symptoms with 4-factor (DSM-based) versus 5-factor (Dysphoric Arousal) PTSD models. Last, we examined correlations between the CASS, CPSS and SSP total scores and compared PTE types and totals in those endorsing v. not endorsing a TE (as defined above).

Results: Endorsement of adversities ranged from 2.4% (sexual abuse) to 64.0% (sensory distress). Stigma, death of a loved one, bullying, changes in routine, and chronic social confusion were also common (see Table 1). These items were also the most common in participants with a TE (n=298), who had approximately twice as many total adversities, M(SD)=6.37(3.26) as those without a TE, (M(SD)=3.42, (2.33), t(489)=13.55, p<.001. Significant correlations between the CPSS and CASS adversity subscales (R=.63, p<.001) and CPSS and CASS symptom subscales (R=.63, p<.001) supported convergent validity. CASS symptoms were also significantly associated with the SSP total (R=.403, p<.001), but this relationship was significantly weaker than that between CASS and CPSS symptoms (Z=–3.65, p<.001), supporting discriminant validity. We found the PTSD dysphoric arousal five-factor ESEM model had the best fit, X(148) = 242.97, CFI=.98, TLI=.97, RGMMA=.046 (CFI: .036 - .057), SRMR=.03.
Conclusions: Results suggest the parent-report CASS is a valid measure of adversities and traumatic reactions in autistic youth. Further, we found the latent structure of symptoms was consistent with a 5-factor dysphoric arousal model of PTSD. Further research is needed to extend these findings in samples with enhanced gender and racial diversity, and to evaluate the self-report CASS, as multi-informant accounts will likely enhance sensitivity.

229.002 (Panel Discussion) Posttraumatic Stress Disorder in Autistic Adults with Intellectual Disabilities: Under-Recognized and Underdiagnosed?
A. N. Kildahl and S. B. Helverschou, (1)Norwegian Advisory Unit for Mental Health in Intellectual Disabilities, Oslo University Hospital, Oslo, Norway, (2)NevSom, NevSom, Oslo University Hospital, Oslo, Norway

Background: Autistic people with intellectual disabilities (ID) are at increased risk of potentially traumatic experiences, including violence or sexual abuse, but the prevalence of posttraumatic stress disorder (PTSD) in this population is unclear. Furthermore, previous research suggests that symptoms of PTSD may be misinterpreted as anxiety, depression, or “challenging” behaviours in these individuals. Such misinterpretations seem particularly likely if the traumatic experience is not known by, or reported to, mental health professionals. However, even when traumatic experience is reported, it is unclear how such reports inform diagnostic decision-making in mental health services for this population.

Objectives: To explore the clinical and behavioural characteristics, including final diagnoses, of autistic individuals with intellectual disabilities who have experienced violence and sexual abuse, in a clinical sample of autistic adults with intellectual disabilities referred for general mental health assessment.

Methods: Autistic adults/older adolescents with ID (n=89; age M(SD)=27.5(10.76); 29.2% female; 83.1% mild/moderate ID, 16.9% severe/profound ID) were recruited from specialist mental health services for adults with ID. Frequency analyses were conducted for final diagnoses among participants having experienced violence/sexual abuse. Associations with scores on the Psychopathology in Autism Checklist (PAC) and the Aberrant Behavior Checklist (ABC) were investigated for violence and sexual abuse using hierarchical regression (ENTER model), controlling for age, gender, level of intellectual disability, verbal language skills, and autism-related characteristics.

Results: Violence was reported for 30 (33.7%) participants (in males 36.5%, females 26.9%; mild/moderate ID 31.1%, severe/profound ID 46.7%) and included institutional abuse, caregiver/domestic violence and random assaults. Sexual abuse was reported for 15 (16.9%) participants (in males 15.9%, females 19.2%; mild/moderate ID 16.2%, severe/profound ID 20.0%). Sexual abuse had been perpetrated by family members, service providers or peers. For six participants (3 females, 5 mild/moderate ID) co-occurring violence and sexual abuse was reported. Final diagnoses for participants having experienced violence included anxiety disorders (46.7%), affective disorders (33.3%), psychosis (30%), personality disorders (10%), obsessive-compulsive disorders (6.7%), and PTSD (6.7%). For sexual abuse, final diagnoses included anxiety disorders (53.3%), affective disorders (46.7%), personality disorders (26.7%), PTSD (13.3%), and psychosis (6.7%). For behavioural measures, associations were found for these experiences on two of the subscales on the ABC: irritability/agitation/crying and hyperactivity/noncompliance. PAC scores over cutoff were common on the anxiety, depression, and general adjustment difficulties scales for both experiences, as well as on the psychosis scale for violence.

Conclusions: In this sample, despite evidence of high prevalence of traumatic experiences, only three participants were diagnosed with PTSD: one had experienced violence, one had experienced sexual abuse, and one had experienced both. PTSD diagnoses were rare even if clinicians had access to reports of violence and sexual abuse, and these reports were associated with behavioural measures previously found to be associated with PTSD. This indicates that PTSD may be an underutilized diagnosis in services for this population, and that emotional and behavioural changes associated with traumatic experience are unlikely to be reflected in clinical diagnoses in mental health services for this population.

229.003 (Panel Discussion) Subjective Trauma and PTSD Symptomatology across the COVID-19 Pandemic in Autistic and Non-Autistic Adults

Background: Autistic individuals appear to develop post-traumatic stress disorder (PTSD) following a wide range of adverse life events and have higher rates of probable PTSD compared with non-autistic individuals. The COVID-19 pandemic has been universally challenging, particularly for autistic individuals for whom uncertainty and change can be particularly distressing.

Objectives: This study aimed to investigate the impact of the COVID-19 pandemic on autistic and non-autistic adults, by comparing types and rates of trauma exposure and subsequent PTSD symptomatology longitudinally across the pandemic.
Methods: A longitudinal design was used to compare trauma and PTSD symptom levels between autistic (N=148) and non-autistic (N=137) adults across four timepoints of the pandemic. Participants were recruited from Belgium, the Netherlands and the United Kingdom and included a mixed gender sample (N=218 female, N=57 male, N=10 other). Trauma was defined according to participants own subjective interpretations of experiences.

Results: Experience of trauma across the pandemic was not the norm, no trauma was reported by 45-59% of autistic adults and 57-67% of non-autistic adults. Rates of trauma exposure were higher for autistic adults than non-autistic adults at two time points, the middle and end of the restrictions. Both autistic and non-autistic adults reported some traumas which would not meet the DSM-5 A1 definition of trauma, but were subjectively perceived as traumatic, for example difficulties with relationships, employment and daily living. Traumas reported more commonly by autistic adults included, for example, others not following lockdown restrictions, mental and physical health difficulties, and emotional abuse during the pandemic. Multilevel modelling revealed consistently higher PTSD symptom severity for autistic adults compared to non-autistic adults in response to these covid-traumas, but PTSD severity did not fluctuate across the pandemic.

Conclusions: Findings illustrate that a range of life events were interpreted as traumatic by autistic and non-autistic adults across the COVID-19 pandemic. Traumatic events occurring across the pandemic were linked to more severe PTSD symptomatology for autistic than non-autistic adults, necessitating the provision of sufficient support for this population.

Objectives: The present study aimed to explore the role of SC in autism-PTSD co-morbidity. Specifically, we examined the following questions: 1. Do autistic, compared to TD, individuals face an increased risk for PTSD? 2. Is impaired SC associated with increased PTSD symptoms among autistic individuals? 3. Does SC moderate the association between autism and post traumatic symptoms?

Methods: 101 adults, 51 with ASD and 50 TD controls, participated in this study (mean age=23.78, SD=4.95; 55.4% males, 44.6% females). Groups were comparable on age, education, family status and employment status. Inclusion criterion for participation in the autism group was an official diagnosis by a clinical psychologist or psychiatrist, without intellectual impairment. Participants completed self-report questionnaires assessing sociodemographic variables, PTSD (PCL-5), and stressful life events (LEC-5). SC was assessed using the ‘Reading the Mind in the Eyes’ Test (Baron-Cohen et al., 2001), which examines a participant’s ability to identify others’ complex emotional and mental states.

Results: Autistic individuals reported a significantly higher rate (43%) of probable PTSD (based on PCL-5 cutoff) compared to TD controls (22%), as well as higher scores on total PTSD symptoms and all PTSD symptom clusters, except for avoidance. SC was positively associated with PTSD severity in the autism group only (with PTSD total score, r=.328, p<.05; with intrusion, r=.328, p<.05; with hyperarousal, r=.336, p<.05). Finally, SC was found to moderate the association between autism and PTSD symptoms. Thus, autism was associated with PTSD intrusion symptoms when social cognition scores were high (t=-3.11, p<.01; t=-2.28, p<.05 for males and females, respectively), but not when they were low.

Conclusions: Autistic individuals may be particularly vulnerable to the negative effects of traumatic exposure. Previous studies from both our team and others have shown that social stressors (e.g., ostracizing, bullying) may be particularly distressful for autistic individuals. Interestingly, our findings show that a more accurate perception of interpersonal and social cues may be associated with higher levels of PTSD among autistics. This may be attributed to the fact that one’s understanding of social adversity and victimization may increase one’s sense of perceived threat, subsequently leading to elevated levels of post-traumatic distress. Mental health professionals are encouraged to take into account autistic individuals’ perception and interpretation of social aspects, in order to more accurately tailor trauma-focused interventions to meet the unique needs of this population.
Background: Co-occurring mental health conditions are higher in autism than the general population. Rates of these conditions increase during adolescence and into early adulthood. Sex/gender-specific patterns of mental health conditions have been observed, however little is known about how anxiety and depression symptoms may develop across the lifespan in autistic males and females. Social communication difficulties, which form a continuum across the population including those with formal autism diagnoses, have also been associated with mental health issues.

Objectives: To compare rates of depression and anxiety amongst males and females with/without an autism diagnosis or social communication difficulties.

Methods: Participants were obtained from the Avon Longitudinal Study of Parents and Children (ALSPAC), a population-based cohort study following over 14,000 children from birth up to adulthood. Information on autism diagnosis (male N = 119, female N = 28) and social communication difficulties (SC; Social Communication Disorder Checklist) were obtained in childhood. Participants were split into high SC (top decile; male N = 155, female N = 140) and low SC (lowest 9 deciles; male N = 1438, female N = 2176) groups within each sex. Symptoms of depression (Short Moods & Feelings Questionnaire) and anxiety (General Anxiety subscale of the Development and Wellbeing Assessment) were measured at multiple timepoints from age 10 to 16 years (anxiety) or 10 to 28 years (depression). Clinical diagnoses of depression were recorded at 18 and 24 years, and of anxiety at 24 years, with odds of diagnosis calculated within each sex for diagnostic and SC groups. Trajectories of predicted mean scores for anxiety/depression were compared between autistic/high-SC and non-autistic/low-SC participants within each sex, using mixed-effect linear growth models and controlling for relevant covariates.

Results: Trajectories for males and females are presented in the attached figures. Autistic males had higher symptoms of depression and anxiety than non-autistic males in early adolescence, but were no more likely to have a diagnosis of anxiety (Adj OR = 1.67, 95% CI = 0.34 – 8.22) or depression (Adj OR = 0.87, 95% CI = 0.12 – 5.77) in adulthood. In contrast, no differences were observed between autistic and non-autistic females; however females with high SC were more likely to receive a diagnosis of depression (Adj OR = 1.93, 95% CI = 1.21-3.08) or anxiety (Adj OR = 1.84, 95% CI = 1.12 – 3.02) at 24 years compared to females with low SC.

Conclusions: Autism diagnosis and high autistic traits predict higher levels of anxiety and depression for males in adolescence, although there is less evidence into adulthood. In contrast, there is more evidence for females’ anxiety and depression being driven by social communication difficulties specifically across adolescence and early adulthood. Interventions to address mental health issues in autism should consider both sex and age, and that females with social communication difficulties (whether or not they have a diagnosis of autism) should be considered particularly at risk for anxiety and depression. However, results may be biased by missing data, particularly for the small sample of diagnosed autistic females.

Background: Anxiety disorders commonly co-occur with autism and occur more frequently in females in the general population. However, sex-specific prevalence rates of co-occurring anxiety in autism remain understudied. In addition, there is increasing recognition that autistic individuals may have unspecified, or distinct, presentations of anxiety in addition to traditional DSM-specified anxiety disorders. Again, sex differences in the presentation of distinct and DSM-specified anxieties have not yet been examined.

Objectives: 1) To evaluate sex differences in the rates of distinct and DSM-specified anxieties 2) To examine the development of the amygdala and 32 monosynaptically connected regions across childhood in a large, longitudinal cohort of autistic children.

Methods: Autistic participants were enrolled at 2-3.5 years of age (n = 112, 89 assigned male at birth, 23 assigned female at birth) and assessed longitudinally at three additional time points across childhood. MRI scans were acquired at each time point and anatomically-based parcellations were conducted using MRICloud. At Time 4, when children were 9-11 years old, the Anxiety Disorders Interview
Schedule-IV-Parent Interview (ADIS) and Autism Spectrum Addendum (ASA) were administered. The ADIS-ASA is a semi-structured diagnostic interview that differentiates between anxiety and autism symptoms and captures distinct expressions of anxiety in autistic youth. DSM-specified anxieties included specific phobia, separation, social and generalized anxiety disorders. Forms of anxieties distinctly related to autism included idiosyncratic fears, fear relating to social confusion, special interest fears, and fears of change. Clinician severity ratings > 4 were utilized as a diagnostic cutoff for each anxiety disorder. The proportion of males and females endorsing DSM and distinct anxieties was compared using chi-square tests. Descriptive post-hoc sex comparisons for each form of anxiety were conducted. Analyses were repeated excluding children who only endorsed specific phobia.

Results: Autistic children with distinct anxieties exhibited slower amygdala growth resulting in smaller amygdala volumes at T4, but the opposite pattern (larger right amygdala) was observed in children with DSM-specified anxiety. Sex differences in the development of the amygdala network were also observed. At T4, a higher proportion of autistic females had distinct anxiety presentations than autistic males (65% vs 31%, p = .003), driven by a higher proportion of autistic females with fear of change (43% of females, 17% of males). If individuals with specific phobias only were excluded (17 male, 1 female), rates of DSM-anxieties also trended higher in females (55% vs 37%, p = .10). Autistic females had higher rates of social anxiety (17% vs 4%), generalized anxiety (28% vs 17%), and separation anxiety (17% vs 7%).

Conclusions: During middle childhood, autistic females have higher rates of clinical anxiety than autistic males, particularly in presentations that are distinct to autism. Distinct presentations of anxiety are not as easily recognized and may have different risk factors and etiologies than DSM anxieties. If distinct anxieties are more common in autistic girls, this implies the need for more careful assessment of anxiety as well as treatment selections. Future studies will evaluate sex differences in early childhood behavioral and neural predictors of these different forms of anxiety.

318.003 (Oral) Exploring Diagnostic Bias: Sex Differences in Psychiatric Diagnoses Preceding and Following a Diagnosis of Autism, and Their Association with Age of Autism Diagnosis

M. Martini, R. Kuja-Halkola; A. Butwicka; F. Happe, P. Lichtenstein; H. Larsson; and M. Taylor. (1)Medical Epidemiology and Biostatistics, Karolinska Institute, Stockholm, Sweden, (2)Department of Medical Epidemiology and Biostatistics, Karolinska Institute, Stockholm, Sweden, (3)Medical Epidemiology and Biostatistics, Karolinska Institute, Stockholm, Sweden, (4)Child and Adolescent Psychiatry Stockholm, Stockholm Health Care Services, Region Stockholm, Sweden, Stockholm, Sweden, (5)Department of Child Psychiatry, Medical University of Warsaw, Warsaw, Poland, (6)Department of Biostatistics and Translational Medicine, Medical University of Lodz, Lodz, Poland, (7)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, UNITED KINGDOM

Background: While both autistic males and females are at increased risk of psychiatric diagnoses compared to non-autistic young people, autistic females are at particularly elevated risk. Sex differences in the identification and diagnosis of autism might be relevant: autistic traits might more likely be misdiagnosed as psychiatric conditions in autistic females, delaying autism diagnosis. This is reflected in autistic females often receiving psychiatric diagnoses (e.g., anxiety and depression) prior to their autism diagnosis, which sometimes are no longer present after receiving a diagnosis of autism. It is important to clarify whether increased diagnoses of mental health problems in autistic females reflect true co-occurrence or result from diagnostic bias.

Objectives: To investigate sex differences in psychiatric diagnoses received prior to being diagnosed as autistic, their stability over 5 years following autism diagnosis, and to what extent they are associated with age of autism diagnosis.

Methods: Using a population-based cohort design, we identified all individuals born in Sweden between 1990 and 2008 with a clinical autism diagnosis (19,223 males, 7,881 females). Linking different national registers, we identified outpatient and inpatient diagnoses of 12 different psychiatric diagnoses received prior to and following an autism diagnosis from the National Patient Register. We compared prior diagnoses and their stability over time (being re-diagnosed with the psychiatric disorder) between autistic males (reference) and females using logistic regression analyses. We further used generalized estimating equations, to examine the association of a prior psychiatric diagnosis with age of autism diagnosis, and how this differed by sex.

Results: Mean age of autism diagnosis was 11.33 (SD=4.95) for autistic males and 13.06 (SD=5.09) for autistic females (t=25.694, p<.001). Odds ratios (OR), comparing autistic males and females, indicated higher odds among autistic females for all psychiatric disorders (ORrange=1.40[1.05,1.87]-20.38[9.37,44.31], Figure 1) except substance use disorders (OR=1.04[.76,1.41]). Autistic females were further more likely than autistic males to retain their diagnosis in the 5 years after autism diagnosis, indicating their stability over time (Figure 2). This was the case for 11 out of 12 disorders (ORrange=1.48[1.16,1.90]-29.82[9.27,95.95]; ORsubstance-use disorders=.99[.60,1.63]). A psychiatric diagnosis received prior to an autism diagnosis was associated with a later age of autism diagnosis (2.72 years [2.62,2.81]). The interaction with sex was not statistically significant (β=.06[-.10,.21]), indicating that prior diagnoses delay autism diagnosis for both, autistic females and males with psychiatric diagnoses.

Conclusions: Autistic females, who remain underrepresented in research and clinical practice, are more likely to receive psychiatric diagnoses prior to their autism diagnosis and are also more likely to keep their psychiatric diagnosis after being diagnosed as autistic compared to autistic males. This suggests that increased mental health problems in autistic females reflect true comorbidity rather than...
diagnostic bias, highlighting the need to increase early mental health services. Our findings indicate that the presence of prior psychiatric diagnoses might overshadow autistic traits and thus delay autism diagnosis for both autistic females and males, and to a similar extent. Consequently, increased research and clinical efforts in differentiating autism from psychiatric conditions with overlapping symptoms are required to ensure timely diagnosis.

318.004 (Oral) Autism Severity, Cognitive Impairment, and Sex As Predictors of Anxiety and Depression Among Youth with ASD
E. E. Long, M. Johnson and L. Carpenter, Medical University of South Carolina, Charleston, SC

Background: Youth with autism spectrum disorder (ASD) are at elevated risk for experiencing depression and anxiety. However, the characteristics of youth with ASD who may be at increased risk for internalizing problems are not well understood. Researchers have postulated that youth with higher cognitive abilities and poorer social communication skills may be particularly at risk, as they may have greater insight into their social difficulties. Additionally, given evidence that typically-developing girls are at increased risk for internalizing problems, particularly depression, girls with ASD may also be at heightened risk relative to boys. However, correlates of internalizing outcomes among ASD and potential moderators of those associations are poorly understood.

Objectives: We investigated whether autism severity interacts with cognitive impairment or sex to predict anxiety and/or depression symptoms among youth with ASD.

Methods: Participants comprised 7996 children ages 6-17 (M=10.77, SD=3.31; 77% boys) with ASD from the Simons Foundation Powering Autism Research for Knowledge (SPARK) registry. Autism severity was assessed via caregiver report on the Social Communication Questionnaire. Symptoms of anxiety and depression were assessed via caregiver report on the Child Behavior Checklist. Presence or absence of cognitive impairment was a derived variable that was calculated based on all available clinical signs of possible intellectual disability (e.g., IQ scores, reported delays, Vineland scores).

Results: Complete results are reported in Table 1. Autism severity (β=.12) and cognitive impairment (β=.05) both predicted anxiety (p<.001). Greater autism severity was associated with higher levels of anxiety, while presence of cognitive impairment was associated with lower levels of anxiety. Autism severity and cognitive impairment did not interact to predict anxiety symptoms (β=.05, p=.41). Autism severity predicted depression, such that greater autism severity was associated with higher levels of depression (β=.17, p<.001). However, presence of cognitive impairment was not associated with symptoms of depression (β=.01, p=.47). Autism severity and cognitive impairment did not interact to predict depression (β=.01, p=.68).

Autism severity interacted with child’s sex to predict anxiety (β=.04, p=.002), such that the association between autism severity and anxiety was stronger for boys than for girls (Figure 1). Autism severity (β=.18) and sex (β=.08) both predicted depression (p<.001); greater autism severity and female sex were associated with higher levels of depression. However, autism severity did not interact with sex to predict depression (β=.02, p=.18).

Conclusions: Youth with greater autism severity experienced more symptoms of anxiety and depression. Importantly, associations between cognitive impairment and internalizing outcomes differed across symptom domains. Cognitive impairment was related to anxiety, but not depression; youth with cognitive impairment had lower levels of anxiety relative to their peers without cognitive impairment. Findings support the hypothesis that youth with ASD without cognitive impairment may be uniquely vulnerable to experiencing anxiety. Alternatively, barriers to the accurate measurement of anxiety in youth with ASD who have cognitive impairment (e.g., expressive language limitations) may contribute to lower caregiver-reported symptom levels. Autism severity interacted with sex to predict anxiety, but not depression; the association between autism severity and anxiety was stronger for boys than for girls.

416 - Medical and Psychiatric Comorbidity II

416.281 (Poster) Gender Identity of Adolescents on the Autism Spectrum with Co-Occurring Psychiatric Disorders
I. Łucka, M. Jurczyk, A. Rynkiewicz, G. Klecha, J. Nawrocka and R. A. Vasa, (1)Department of Developmental Psychiatry, Psychotic and Geriatric Disorders, Medical University of Gdansk, Gdansk, Poland, (2)Institute of Pedagogy, University of Gdansk, Gdansk, Poland, (3)Department of Psychiatry, College of Medical Sciences, University of Rzeszow, Rzeszow, POLAND, (4)Center for Diagnosis, Therapy and Education SPECTRUM ASC-MED, Gdansk, Poland, (5)Clinical Hospital № 2 Rzeszow, Rzeszow, Poland, (6)Students Research Club, Department of Psychiatry, College of Medical Sciences, University of Rzeszow, Rzeszow, Poland, (7)Kennedy Krieger Institute/Johns Hopkins University, Baltimore, MD, (8)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD

Background: The prevalence of autism spectrum disorders (ASD) in individuals attending specialized clinics for those experiencing gender dysphoria ranges from 5.5 to 26% (Pasterski et al. 2014; Kaltiala Heino et al. 2015), which is well above the 1% prevalence of ASD.
in the general population (e.g., Baird et al. 2006). Research on the psychological experiences of those who belong to both groups is therefore critical to develop strategies that can improve psychological well-being and reduce risk of adverse mental health outcomes.

Objectives: This is a retrospective study that aimed to compare the experiences of gender between adolescents with and without ASD who presented to an inpatient psychiatric unit in Gdansk, Poland.

Methods: Data on 34 adolescents. 16 with ASD and 18 without ASD, who were admitted to an adolescent psychiatric unit due to life-threatening behaviors from January to October 2022 were analyzed. The methods used to understand their psychological experience included clinical interviewing and observation, mental state examination, and consultation with an expert in sex and gender orientation. Both adolescents with and without ASD reported discomfort with their biological sex. Major themes in psychological functioning were analyzed including a sense of belonging and gender dysphoria, among others.

Results: The 16 adolescents with ASD reported experiencing minority stress, lack of support, feelings of alienation and "otherness", lack of a sense of group belonging and lack of a sense of identity, more often than symptoms fulfilling diagnostic criteria for gender dysphoria. In adolescents without a diagnosis of ASD, no identical statistically significant conclusions were found.

Conclusions: Findings from this study emphasize the necessity of providing timely diagnosis and treatment planning for those with ASD and gender diversity who present to acute care settings. These interventions, which include both treatment of core psychiatric problems and addressing psychosocial support factors, are crucial in reducing suicide risk and rehospitalization, while also helping adolescents navigate the tasks of adolescence, which may be particularly difficult for those with ASD.

416.282 (Poster) Examining Gender Differences and Interrater Agreement for Internalising Symptoms in Young Autistic People
N. C. Freeman, A. N. Giavara, M. L. Scott and N. Abramowitz, School of Educational Psychology & Counselling, Faculty of Education, Monash University, Melbourne, VIC, Australia

Background: Anxiety and depression are the most common co-occurring conditions among young autistic people. Previous studies examining internalising symptoms in this group, however, have generally used predominantly male samples that have precluded firm conclusions about their prevalence and severity in females. Further, many studies have compared young autistic people with neurotypical community samples, rather than a clinical group who may have a higher prevalence of co-occurring mental health challenges.

Objectives: The first aim was to ascertain whether there were differences in anxiety and depression symptoms in a clinical sample of young people, based on gender and diagnostic status (autistic or non-autistic). The second aim was to determine the inter-rater reliability across young people, parents and teachers.

Methods: Participants were children and adolescents referred to a University clinic in Melbourne, Australia for a clinical assessment. The sample comprised 146 young people aged 6 – 18 years (73 autistic; 92 males and 54 females) matched on gender, age and socioeconomic status, as well as 146 parents and teachers. Parent, teacher and self-report of anxiety and depression symptoms were examined using the Behavior Assessment System for Children - Third edition.

Results: When controlling for age and FSIQ, significantly higher anxiety and depression was reported for young autistic people compared with the non-autistic clinical group based on parent report (scores fell within the ‘at risk’ range), but no gender or interaction effects. No group differences were found based on teacher report. Significantly higher anxiety and depression were self-reported by autistic young people compared with the non-autistic clinical group (although scores fell within the average range), but no gender or interaction effects. Inter-rater reliability was poor to moderate for parent-teacher ratings and very poor for self-teacher ratings across both the autistic and non-
autistic young people. Inter-rater reliability was poor for parent-self ratings with the exception of depression in the autistic group, which was poor to moderate.

Conclusions: The absence of interaction effects in the present study suggests that autistic males and females may be equally susceptible to elevated anxiety and depression, contrary to the double-hit hypothesis proposed for autistic females related to internalising conditions. Only parents, however, reported higher internalising symptoms in autistic young people. Autistic young people rated themselves as having average anxiety and depression, which may relate to the items being insufficiently sensitive to situations that evoke anxious or depressed feelings in these young people or that they have less insight into their symptoms. The poor inter-rater reliability, particularly when teachers and parents were compared with self-ratings, suggests that use of a broad-band behaviour measure may result in young people under-reporting their anxiety and depression symptoms (irrespective of whether they are autistic or have other clinical conditions). Alternative measures developed specifically for autistic people should be considered in clinic settings, particularly when the clinician seeks to understand internalising symptoms from the perspective of the young person.

416.283 (Poster) What Predicts My Personality Profile: Autism, Alexithymia or Both?

L. Albantakis¹, L. Weindel¹, M. L. Brandi², L. Henco¹, I. C. Zillekens¹, H. E. Thaler³ and L. Schilbach⁴, (1)Independent Max Planck Research Group for Social Neuroscience, Max Planck Institute of Psychiatry, Munich, Germany, (2)Department of Psychiatry and Psychotherapy, Ludwig-Maximilian-University Munich, Munich, Germany, (3)Department of Psychiatry and Psychotherapy, Medical Faculty, LMU Munich, Munich, Germany, (4)Kliniken der Heinrich-Heine-Universitaet, LVR-Klinikum Duesseldorf, Duesseldorf, Germany

Background:

Autism spectrum disorder (ASD) and personality disorders (PD) are often considered as differential diagnoses. However, in the diagnostic process they are often difficult to distinguish especially in late adolescence and adulthood. A possible reason for this difficulty may be alexithymia (i.e. the inability to identify and describe emotions in oneself and others), which is frequently found in both disorders. Recent research indicates that individuals with ASD can develop certain personality traits in addition to their autism. Comorbid alexithymia could be an influential factor in the complexity of these disorders of social interaction.

Objectives:

In this study, we investigated whether the degree of autistic and alexithymic traits can explain the co-occurrence of specific personality traits (namely schizoid, Borderline, narcissistic, avoidant and obsessive-compulsive PD). Autistic and alexithymic traits are dimensional constructs and present in both clinical and non-clinical populations. Thus, we extended the investigation beyond ASD and included other patients with social interaction difficulties other than autism as well as the general population.

Methods:

We included 89 individuals with confirmed ASD diagnosis (ASD group; 62 males; mean age: 34.8 ± 10.6 years), 51 individuals with a psychiatric diagnosis other than autism (Non-ASD group; 30 males; mean age: 34.8 ± 12.4 years) and 84 individuals without any psychiatric diagnosis considered as neurotypicals (NT group; 32 males; mean age: 25.8 ± 6.3 years). Autistic traits were measured by the Autism Quotient (AQ) test. Levels of alexithymia were assessed by the Toronto Alexithymia Scale with 20 items (TAS-20) and personality traits were obtained by the Assessment of DSM-IV Personality Disorders (ADP-IV). Data processing and statistical analyses were performed in MATLAB (R2010a, The MathWorks, Inc., Natick, MA, USA) and IBM SPSS 27.0 including the bootstrapping tool (IBM Corp., 2020). For each model and diagnostic group, we performed a three-step, forced entry hierarchical regression analysis with changed entry orders of the independent variables (AQ and TAS-20 scores). The five personality PDs served as dependent variables. It was controlled for age, sex, depressive and social anxious symptoms.

Results:

Alexithymia (TAS-20 scores ≥ 61) was found in 58.4 % of the ASD group, 49.0 % of the Non-ASD group and 6.0 % of the NT group. Schizoid traits were predicted by AQ scores in the ASD sample (b=0.22, p=.018), and by TAS-20 scores in the NT sample (b=0.17, p=.027). Borderline traits were predicted by TAS-20 scores only in the NT group (b=0.25, p=.022). No significant models could be established for narcissistic or avoidant PD in any diagnostic sample. Obsessive-compulsive traits were predicted by AQ scores in all three diagnostic groups (ASD: b=0.30, p=.016); Non-ASD: (b=0.27, p=.046); NT: (b=0.44, p=.018)

Conclusions:

In contrast to the high comorbidity rate, alexithymia did not represent a risk factor for any of the five selected PDs neither in the ASD nor in the Non-ASD group. However, autistic traits were identified as predictors of obsessive-compulsive traits in all three diagnostic groups.
416.284 (Poster) Impact of Covid-19 Crisis on the Behavioural and Emotional Adjustment of Children with ASD and Their Families: A National Study

Background:
Children with autism spectrum disorders (ASD) experienced a variety of behavioural challenges during the COVID-19 pandemic and its associated lockdown. It is not known whether the nature or severity of those challenges differed from those experienced by children with intellectual disabilities ID that are not associated with ASD. To address this question, we surveyed participants in the IMAGINE-ID national UK study of children with Intellectual Disabilities (IDs) of known genetic origin.

Objectives:
We aimed to identify the range and severity of behavioural and emotional reactions to lockdown in children with ASD during the period when the Covid-19 pandemic impacted children’s ability to access in-person educational provisions for several months. We compared reported difficulties to those experienced by children whose ID was not associated with ASD. We tested the hypothesis that parents of children with ASD would report more severe emotional and behavioural responses to lockdown than those with children whose ID was not associated with ASD traits.

Methods:
1063 caregivers completed the Coronavirus Health and Impact Survey (CRISIS) between May-December 2021. The CRISIS questionnaire enquired about the following areas of concern: overall parental stress; whether their child shielded; the biggest challenges faced by the family; changes in the child’s emotional adjustment and behaviour during this critical period of the pandemic. Positive changes were defined as children becoming happier, more relaxed, and more confident, whilst negative changes were defined as becoming more irritable, less energetic, and more restless.

Results:
Data were obtained on 1063 participants (7 to 27 years, M=14.9, SD=4.4), of whom 55% were male. Overall, 40.5% had ASD; the remainder had ID of genetic aetiology that was not associated with ASD traits. Caregivers of children with ASD reported a greater level of CRISIS-measured familial stress compared to families whose child did not have ASD traits (p<0.001). Overall, most families (84.5%) reported facing challenges to their children’s mental health due to the pandemic and its associated temporary shielding requirement. Overall, IMAGINE-ID children had increased anxiety (21.5%), loneliness (13.7%) and low mood (6.7%), but there were significant differences in both the nature and the severity of Covid-related problems between subgroups. The biggest challenge for those with ASD was anxiety (29% vs 16%) but the restrictions imposed by social distancing were less impactful on them (21% vs 26%). Overall, negative behavioural reactions to lockdown (42%) were greater than positive reactions (16%).

Conclusions:
During the peak of the Covid-19 pandemic, children with ASD had more severe and wide-ranging emotional and behavioural reactions to lockdown, and lack of access in-person education, than children with ID that was not associated with ASD.

416.285 (Poster) Increased Multimorbidity across Organ Systems Among Autistic Versus Non-Autistic People
J. H. Ward, E. M. Weir, S. Baron-Cohen and C. Allison, (1)Royal Devon and Exeter NHS Foundation Trust, Provo, UT, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, Autism Research Centre - University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom

Background: There is growing evidence of poorer physical health and associated outcomes of morbidity and mortality in autistic people. Whilst studies have examined the prevalence of health conditions in autistic people, there are so far no studies examining physical multimorbidity in autistic adults without intellectual disability. In this context, multimorbidity refers to chronic health conditions affecting multiple organ systems (at least two) and does not include autism.

Objectives: to compare rates of multimorbidity between autistic and non-autistic people.

Methods: We administered an anonymous, cross-sectional, self-report survey using a convenience sampling design to autistic (n = 1129) and non-autistic (n = 1176) adults (mean age 41.3, 65.9% female, 86% White, 66.9% UK Based). This anonymous online survey inquired...
about demographics, lifestyle behaviours, personal medical history, and family medical history. A variable was then created totalling the possible organ systems implicated (with each chronic condition only counting towards one organ system) across the following categories: respiratory, cardiovascular, gastrointestinal, endocrine, neurological, bone and joint, visual, ear/nose/throat, liver and kidneys, haematological, skin, and diabetic/prediabetic conditions. We utilised R version 4.2.1, package CrossTable for chi-squared tests and glm to conduct unadjusted and adjusted regression analyses covarying for age, sex, ethnicity, country of residence, education level and lifestyle behaviours (i.e. smoking, alcohol, BMI) to assess differences in rates of multimorbidity among autistic and non-autistic individuals. We used the Benjamini-Hochberg procedure for multiple comparison correction.

**Results:** The distributions of the data are presented in figure 1. A Kolmogorov-Smirnov test demonstrated that the data were non-normally distributed ($p<0.0001$). A two sample Anderson-Darling Test demonstrated that the distributions of the autistic/non-autistic samples were significantly different ($p<0.001$). We compared the levels of multimorbidity between autistic and non-autistic samples, which showed a significant difference (67.4% versus 53.4% respectively, $p<0.0001$).

An initial unadjusted Poisson regression demonstrated significance at the $p<0.0001$ level (relative risk (RR) 1.43, 95% CI 1.40-1.47). When factoring in basic demographic factors (age, sex, ethnicity, country of residence, education level), the relative risk increased to 1.54 (95% CI 1.45-1.64, $p<2.2e-16$). When accounting for lifestyle factors, the relative risk was 1.51 (95% CI 1.41-1.61, $p<2.2e-16$). There was a non-significant interaction of sex and autism in this model.

We then re-examined these models with an age x autism interaction term. This was significant in the unadjusted model ($p<0.0001$). However, in the demographic and the lifestyle adjusted models, the variable became non-significant ($p=0.26$ and $p=0.27$ respectively).

**Conclusions:** Our data provide preliminary evidence that autistic people are likely to have illnesses affecting 1.5 times more organ systems than others, even after accounting for age, sex, ethnicity, country of residence, and lifestyle behaviours. However, these analyses should be confirmed using population-based data, given our sample’s bias towards white, female, university educated UK adults. To our knowledge, this is the largest analysis of multimorbidity among autistic adults to date.

**416.286 (Poster) Intolerance of Uncertainty Is Associated with Irritability in School-Age Autistic Children**

**J. Zhong,** C. Calvini; M. Rutter; J. Snyder; J. Hinton; and D. G. Sukhodolsky; (1)Yale Child Study Center, Yale University, New Haven, CT, (2)Child Study Center, Yale University, New Haven, CT, (3)Child Study Center, Yale School of Medicine, New Haven, CT, (4)Yale Child Study Center, New Haven, CT

Background: Intolerance of Uncertainty (IoU), a dispositional tendency towards thinking and responding to uncertain situations in daily life in a negative or maladaptive way, is associated with anxiety in autism (Jenkinson et al., 2020). In addition, IoU is considered one of the key processes in autistic cognition (Stark et al., 2021) that contributes to anxiety and other co-occurring internalizing and externalizing behavioral problems in autism (Ozsivadjian et al., 2021). Irritability, which encompasses a variety of behavioral problems including anger outbursts, is a common and impairing set of externalizing behaviors in ASD. Although IoU and anxiety in autism has been well documented, no studies to date have examined the potential contribution of IoU to irritability in autism.

**Objectives:** To examine the associations between intolerance of uncertainty and irritability in children with ASD with co-occurring anxiety disorders.

**Methods:** Subjects included 75 children with ASD and 26 age- and sex-matched typically developing (TD) controls, aged 8-15 (M=11.8, SD=1.80; 28.7% female). ASD diagnosis was confirmed with the ADOS-2 and ADI-R, conducted by a research reliable clinical psychologist; a clinical interview; and a review by an expert clinician. Parents completed the 27-item Intolerance of Uncertainty Scale for children (IUS) (Comer et al., 2009), the Multidimensional Anxiety Scale Second Edition (MASC-2) (March, 2013), and the Affective Reactivity Index (ARI) (Stringaris et al., 2012). Analyses were conducted in SPSS. Independent sample t-tests were used to assess group differences between ASD and TD samples, and bivariate correlations and hierarchical linear regressions were used to test associations of IoU with anxiety and irritability.

**Results:** First, autistic children had significantly higher scores on IoU, anxiety, and irritability measures relative to TD controls. Second, within the autism group, IoU was found to be significantly correlated with both anxiety ($r_{75}=0.24$, $p=0.038$) and irritability ($r_{75}=0.36$, $p=0.002$). Lastly, hierarchical regression analyses revealed that after accounting for age, IQ, and anxiety entered as the first block, there was a significant effect of IoU on irritability (Model $R=0.422$, $R^2$ change=0.087, $F_{1,67}$change=6.659, $p=0.012$) (Figure 1).

**Conclusions:** These findings demonstrate that, even after statistically controlling for the presence of anxiety, Intolerance of Uncertainty was associated with irritability in autistic children. IoU may reflect a cognitive process that contributes to negative affectivity in general, thus impacting both anxiety and irritability. Given that irritability is a common and impairing problem that affects approximately 40% of autistic children, IoU could be tested as a possible moderator of behavioral and cognitive-behavioral interventions for irritability in autism or as a potential target for intervention for irritability in autism.
Background: Social anxiety is highly prevalent in the autistic community (White et al., 2014), but it is currently unclear to what extent this overlaps with social desire. In the general population, individuals with social anxiety disorder tend to be socially motivated (Lee & Jang, 2019). Within the autism spectrum, individual variability in social motivation has been documented in general, with empirical findings suggesting a developmental trend toward increased social motivation with age among autistic people (Deckers et al., 2017). Despite the lack of research on this topic, many hypothesize that autistic individuals who experience social anxiety tend to be socially motivated (White & Roberson-Nay, 2009).

Objectives: Using data from an ongoing study of emotional health in autistic adults, we aimed to investigate the overlap between self-reported social anxiety and social motivation. We hypothesized that greater social anxiety would be associated with higher levels of social motivation in both autistic and non-autistic cohorts.

Methods: We compared adult samples of N=77 autistic adults (Age M=26.43, SD=6.948; n=29 men, n=39 women, n=9 nonbinary/other) and N=41 non-autistic, non-depressed adults (Age M=26.37, SD=7.599; n=16 men, n=24 women, n=1 nonbinary/other). The Brief Fear of Negative Evaluation (BFNE; Leary, 1983) was used to operationalize social anxiety, and the Anticipatory and Consummatory Interpersonal Pleasure Scale (ACIPS; Gooding & Pfum, 2014), indexed capacity for social pleasure/social motivation. We assessed this relationship using a regression model controlling for chronological age and gender.

Results: Social motivation and social anxiety were not correlated among either autistic participants (β=.015, t(130), p=.897) or non-autistic, non-depressed comparisons (β=.117, t(.721), p=.476), in models controlling for age and gender. Visualizing our data by gender groups showed -- in the context of minimal correlation in any gender grouping -- that non-autistic participants followed the expected positive trend (see Figure 1), while autistic women in particular displayed a nonsignificant negative relationship between social motivation and social anxiety (see Figure 2), relative to autistic men and nonbinary individuals who showed almost zero, though positive, association between these variables.

Conclusions: Our findings did not support our hypothesis that greater social anxiety would be associated with greater levels of social motivation across neurotypes. In fact, negligible correlation between social motivation and social anxiety was observed in our sample. Null findings could represent measurement effects, in which social anxiety may cause individuals to be less likely to endorse “wanting” the type of social interactions described on the ACIPS measure, regardless of their true degree of inherent social motivation. A unique, though nonsignificant, negative relation between these variables in autistic women compared to other genders suggests that this research question should be studied in larger samples with robust numbers across gender groupings.

416.288 (Poster) Latent Brain States during Sleep in Rett Syndrome Deviate from the Traditional Sleep Stages

C. Huang1, A. Mahat1, D. G. Glaze2, M. Maletic-Savatic3, A. Buckley3 and M. McGinley6, (1)Neuroscience, Baylor College of Medicine, Houston, TX, (2)Jan and Dan Duncan Neurological Research Institute, Texas Children’s Hospital, Houston, TX, (3)Children’s Mercy Hospital, Kansas, MO, (4)Neurology, Texas Children’s Hospital, Houston, TX, (5)Pediatrics-Neurology, Baylor College of Medicine, Houston, TX, (6)National Institute of Mental Health, Bethesda, MD, (7)Electrical and Computer Engineering, Rice University, Houston, TX

Background:

Traditionally, quantitatively describing sleep relies on manual scoring of the sleep polysomnography (PSG) into 5 stages: Wake, rapid eye movement (REM), and Non-REM 1-3. However, sleep brain state dynamics may be so significantly altered in developmental brain disorders such as Rett syndrome, that the conventional PSG approach be incomplete, or even inaccurate.

Objectives:

Here we used a Hidden Markov Model (HMM) approach to describe brain activity during sleep as continuous transitions between quasi-stable brain states. We compared the latent states’ structure with traditional PSG scoring, as well as between healthy subjects and the states from Rett syndrome patients, in order to objectively describe the changes in brain state dynamics.

Methods:

Two age groups of healthy children of both sexes (34 subjects, 5.5±2.1 years old and 17 subjects age 14.0±3.2 years) and girls diagnosed with Rett syndrome (age 11.6±5.4 years) participated in the study. As the model input (feature set), we extracted power spectrum from eight frequency bands spanning 0.5 to 20 Hz, as well as the root mean squared (RMS), and entropy of electroencephalogram (EEG),
recorded using a 10-20 EEG system, as well as chin electromyography (EMG) and electrooculogram (EOG). We then fitted multivariate Gaussian HMM to infer the latent brain states, including initial states probability, the mean activity and covariance matrix, and states transition probabilities. In parallel, the sleep data was staged by a sleep technician.

Results:

The HMM states could be well-fitted to the two neurotypical and Rett-syndrome groups. The number of the inferred states that well-explained the variance of the inputted feature set varies across the 3 groups, indicating differing dimensionality to the brain state space in Rett Syndrome. In each group, some states were highly specific to a PSG stage, whereas some states appeared to reflect within-stage microstructure and others reflected novel cross-stage states not captured by conventional PSG staging. More specifically, for the Rett group, no states were highly specific (< 40%) to the REM stage, indicating highly nonstandard REM-related architecture. States exhibiting high sigma power, which reflects spindles, were found in both two control groups, as expected, but were not found in the Rett group. A modularity analysis of the state transition matrix also revealed a high transition probability between states that occurred during NREM3 and REM stages in Rett girls; yet rarely happened in either control group.

Conclusions:

Latent brain states dynamics, as revealed by our HMM framework, perform better in revealing brain state pathology in Rett syndrome, compared with traditional sleep scoring. Our approach holds promise for diagnosis as well as evaluation of treatment efficacy, particularly when treatments aim to alter early developmental neuromodulatory brain state aberrancies in developmental brain disorders.

416.289 (Poster) Longitudinal Evaluation of Gastrointestinal Symptoms in Children with Autism

Background: 1 in 44 children in the US meet criteria for autism. Frequently, co-existing medical issues, such as gastrointestinal (GI) symptoms, can further affect their behavior, daily functioning, and wellbeing. Children with autism have been found to experience more GI symptoms compared to typically developing children. However, it is not well known how these symptoms persist over childhood.

Objectives: To determine the frequency and persistence of GI symptoms across childhood in children with autism in a longitudinal sample.

Methods: 383 children with autism spectrum disorder (ASD) and 166 age-matched typically developing (TD) children were enrolled at 2-3.5 years of age and assessed for GI symptoms at 3 time points: baseline, two years later (4-6 years), and during middle childhood (9-12 years). Diagnostic confirmation of ASD was conducted at each time point using the Autism Diagnostic Observation Scale administered by a licensed clinical psychologist. GI symptoms, including abdominal pain, bloating, constipation, diarrhea, and sensitivity to foods, were assessed using a parent-report obtained via interview by a physician. Frequency of symptoms was rated on a 5-point scale. Children with at least one symptom in the ‘frequently’ or ‘always’ range were categorized as having GI symptoms. The number of concurrent GI symptoms experienced was also assessed.

Results: GI symptoms were reported in 47% of children with ASD compared to 30% in the TD group at baseline (chi square p < .001). Across the three time points, 40% of children with ASD experienced GI symptoms at two time points compared to 15% of TD participants. Children with ASD continued to report more GI symptoms and they were more likely to experience several symptoms at each time point. Moreover, 30% of children with ASD experienced GI symptoms at all three time points, compared to 7% of the TD group. The relative risk (RR) of GI symptoms in ASD relative to TD children is 2.04 [1.62, 2.57] (p < .001), and on average, children with ASD reported 2.4 [1.9, 3.1] more GI symptoms than TD (p < .001). Across both groups, the estimated risk of GI symptoms trended towards higher in females than males (RR = 1.15 [0.98, 1.36]) (p = .07) and females averaged 1.4 [1.1, 1.7] more GI symptoms than boys (p < .01).

Conclusions: Children with autism presented with more frequent and more significant GI symptoms which tended to persist over time. The presence of multiple GI symptoms was found to be associated with diagnosis of ASD and female sex. Future analyses will assess the impact of GI symptoms on behavioral and mental health issues.
Background: Though anxiety is a common psychiatric comorbidity in autism spectrum disorder (ASD), the developmental emergence and trajectory of anxiety in ASD remains poorly understood, particularly early in childhood and in children with intellectual disability (ID). Furthermore, despite the mechanistic role of physiological regulation in anxiety, associations between physiological indices and anxiety symptoms across early development have not been studied in ASD. A better understanding of the relationship between anxiety and physiological regulation across early development in ASD can inform early interventions, which are known to mitigate long-term impacts of anxiety in neurotypical (NT) children.

Objectives: This study aimed to characterize development trajectories of anxiety symptoms and physiological regulation and investigates the relationship between anxiety and physiological regulation across early childhood in ASD.

Methods: Participants included 86 children (ASD: n=49; TD n=37) tested multiple times from 3-7 years of age (256 observations). The mean age of first timepoint was 3.64(0.73) years and was similar between groups (ASD: 3.63(0.55); NT: 3.65(0.94)). Of the children in with ASD, 75.5% had IQs <70. Parent-reported anxiety symptoms were measured by the Anxiety Depression and Mood Scale (ADAMS) total score. Directly observed anxiety symptoms were measured by the Modified Anxiety Dimensional Observation Schedule (M-Anx-DOS) total score. Physiological regulation was measured by heart activity (respiratory sinus arrhythmia [RSA] and heart rate [HR; beats per minute]) during a baseline period. To analyze developmental change, multi-level models were employed, with age, group, and age-by-group interaction entered as predictors. Concurrent correlations between anxiety and physiological regulation were measured via Pearson correlations.

Results: For parent-reported anxiety symptoms, there was a main effect of group, $F(1, 84.7)=63.99, p<.0001$, with ASD exhibiting more symptoms across age, but no effect of age and no age-by-group interaction, $p=.281$. For observed anxiety symptoms, there were main effects of age, $F(1, 196)=7.22$, and group, $F(1, 85.9)=17.41$, and an age-by-group interaction $F(1, 196)=13.13, p<.008$, such that M-Anx-DOS scores increased slightly across age in ASD, while decreasing dramatically in NT controls (Figure 1). For both RSA and HR, there were main effects of age, $p<.001$, and group, $p<.003$, with ASD exhibiting lower RSA and faster HR across early childhood, but no age-by-group interaction, $p>.458$. HR was correlated with observed anxiety symptoms in the NT group, $r=.25, p=.025$ and parent-reported anxiety symptoms in the ASD group, $r=.26, p=.014$ (Figure 2).

Conclusions: To our knowledge, this is the first study to longitudinally examine anxiety as measured by direct observation alongside physiological indices in autistic children with ID. Findings suggest that anxiety symptoms emerge early and remain elevated across early childhood in ASD, while decreasing in NT controls. Physiological regulation was also consistently atypical in ASD (lower RSA, higher HR), but changed across development at a rate similar to NT controls. Heart rate, an indicator of arousal controlled by sympathetic and parasympathetic function, was correlated with anxiety symptoms in both groups, whereas RSA, an indicator of parasympathetic regulation, was not. These findings suggest that hyperarousal, as opposed to physiological regulation, contributes to anxiety in both ASD and NT development.

416.291 (Poster) Vulnerability to Stress in Youth with ASD: Associations with Mental Health and Emotion Regulation

Background:

Previous research shows that individuals with autism spectrum disorder (ASD) experience increased levels of stress, including peer victimization. Repeated exposure to stress could lead to heightened emotional reactivity to minor stressors, which is known to be a vulnerability factor for the development of mental health issues, and which was recently reported in adults with ASD. A mechanism that may contribute to increased stress reactivity and mental health symptoms is a dysregulation of the hypothalamic-pituitary-adrenal (HPA)-axis. Indeed, previous studies have observed altered cortisol levels in individuals with ASD, indicating alterations in the HPA-axis functioning that could partially explain the vulnerability to mental health issues in ASD. Moreover, emotion regulation (ER) difficulties have been reported in individuals with ASD, which could contribute to increased stress responses. However, to date, the effect of stress reactivity or cortisol dysregulation on mental health has been little investigated in ASD, especially during adolescence and emerging adulthood.

Objectives:

The aim was to investigate possible alterations in stress reactivity and daily cortisol rhythm in a sample of verbally fluent adolescents and young adults with ASD, and to examine whether they are associated with mental health symptoms. The role of ER in the vulnerability to stress was also investigated.
Methods:

Adolescents and young adults aged between 12 and 30 years with ASD as well as with typical development (TD) participated in two studies. In the first study, Ecological Momentary Assessment (EMA) was used to investigate perceived stress and negative affects (NA) in daily life in 39 verbally fluent participants with ASD and 55 TD participants. Affective reactivity to daily stress was measured as an increase in NA in response to stressors. In the second study, 46 participants with ASD and 54 TD participants collected salivary cortisol at home several times per day for two days. For the second study, data collection is currently being finalized, and data analyses will be conducted after co-registration of the study. In both studies, psychopathology and ER strategies were assessed with questionnaires and clinical interviews. Multilevel regression models were used to analyze the data.

Results:

Results show higher levels of perceived stress as well as an increased affective reactivity to stress related to daily activities in youth with ASD compared to TD. Moreover, we observed that a more frequent use of maladaptive ER strategies (e.g., rumination) in youth with ASD increased their affective response to stress, and was associated with more severe mental health difficulties. In light of the findings of the first study, we hypothesize that youth with ASD show alterations in daily cortisol that are associated with mental health symptoms. We expect alterations in cortisol to be stronger in individuals who have previously been exposed to higher levels of stress, including bullying.

Conclusions:

The current findings provide insight into the mechanisms that link stress exposure to mental health problems in autism. They highlight the importance of effective stress management and reduction of maladaptive ER to prevent the negative effects of stress in youth with ASD.

416.292  (Poster) Understanding Relationships between Restricted Repetitive Behaviours and Depression, Anxiety and Stress in Autistic Adults without Intellectual Disability

N. B. Hernandez Mancilla, C. Ashwin and H. Went, (1)Department for Health, University of Bath - Centre for Applied Autism Research (CAAR), Bath, United Kingdom, (2)Department of Psychology, Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3)Devon Adult Autism and ADHD service, Devon Partnership Trust, Exeter, United Kingdom

Background: Restricted repetitive behaviours (RRBs) are key diagnostic criteria in autism involving stereotyped or repetitive movements, insistence on sameness including adherence to routines, and restricted and overly-intense interests. RRBs in autistic people are associated with developing depressive (Simonoff et al., 2008; Ghaziuddin et al., 2002) and anxiety conditions (Jenkinson et al., 2020; van Steensel et al., 2011). However, there is scarce literature focusing on RRBs and mental health in autistic adults, particularly about the subtype of special interests.

Objectives: The present study aimed to explore differences in the three RRB subtypes of special interests, repetitive sensory-motor behaviours (RSMBs) and insistence on sameness (IS), and the three mental health subtypes of depression, anxiety and stress in autistic compared to non-autistic adults, as well as the relationship between RRBs and mental health between the groups. It was expected the autistic group would have higher RRBs and mental health scores than the non-autistic group, and that there would be a stronger relationship between RRBs and mental health measures for the autistic versus the non-autistic group.

Methods: The study was co-designed with autistic and non-autistic individuals from different countries. A total of 120 autistic adults (Mage=33.58, SDage=11.67; 56M/56F/8Other) and 126 non-autistic adults (Mage=32.99, SDage=11.16; 56M/64F/6Other) were recruited, and all participants completed the Adult Behaviour Questionnaire-2 (RBQ-2A; subscales RSMBs and IS), and the University of Bath Interests Scale (UBIS; subscales degree of interest, time engaging in interests, interference and distress), and the Depression Anxiety and Stress Scale (DASS21) to measure mental health. ANOVAs were used for group comparisons and hierarchical regressions were used to explore relationships between RRBs and depression, anxiety and stress.

Results: ANOVA results showed higher depression, anxiety and stress scores as well as greater repetitive sensory-motor behaviours and IS in the autistic versus the non-autistic adults. Autistic adults also showed reduced interests and higher distress and interference in everyday life when unable to engage in their interests, than the non-autistic adults (Figure 1). Regression results showed a stronger negative relationship for the autistic group between time engaging in interests and both depression and anxiety scores, and a stronger positive relationship between the degree of interests and both depression and anxiety scores, compared to the non-autistic group. There was a stronger positive relationship for the autistic group between RSMBs and anxiety compared to the non-autistic group (Figure 2).

Conclusions: The greater scores in RRBs, depression, anxiety and stress scores in autistic versus non-autistic adults are consistent with previous research showing an association between autism and poorer mental health, and with diagnostic criteria demonstrating repetitive behaviours and reduced interests. A higher degree of interest in autistic participants related to poorer mental health, which may reflect the effects of overly-intense interests. Reduced time spent on interests was associated with poorer mental health in autistic adults than non-autistic adults, perhaps reflecting the importance of time engaging in specialised interests for autistic wellbeing. These findings help to
inform interventions and future research exploring the effects of RRBs, specifically of interests on mental health in autism.

416.293 *(Poster)* Using Neurophysiological Sleep Signatures to Evaluate Developmental Trajectories in Toddlers at Risk for ASD

**X. Hong. National Institutes of Health, Bethesda, MD**

**Background:** Sleep electroencephalogram (EEG) is a highly advantageous modality for exploring early abnormalities in neurodevelopmental trajectories due to lack of signal noise from external waking stimuli. Certain features of sleep EEG have been found to be atypical in autism spectrum disorders (ASD), including sleep spindle properties and EEG coherence, a measure of functional connectivity. However, few studies have investigated longitudinal changes of these markers in early development when neural circuits are undergoing rapid maturation.

**Objectives:** To evaluate between-group and within-person differences in a) EEG coherence and b) sleep spindle properties in typically developing (TD) toddlers and toddlers with language delay (LD) at risk for ASD at 12-18 months and 36 months.

**Methods:** Participants consisted of 39 TD toddlers and 16 LD toddlers seen at the NIH Clinical Center in Bethesda, MD. Participants entered the study at 12 or 18 months of age, with follow-up at 36 months. At baseline and follow-up, participants underwent an overnight sleep study and a neurodevelopmental assessment consisting of the Mullen Scales of Early Learning (MSEL) and the Vineland Adaptive Behavior Scales. Participants with receptive and language scores in the very low range (T scores ≤ 30 on the MSEL) were placed in the LD group. EEG recordings were collected during awake, drowsy, and sleep states using the 10-20 system of electrode placement.

Spindle data were analyzed using Luna software to determine differences in density, amplitude, duration, frequency, and chirp. Coherence values were analyzed masked to participant group using Neuroguide. Values were subsequently subjected to Fisher transformation and the effects of group and age were evaluated using linear mixed model. Exploratory analyses were conducted separately for coherence and spindles to evaluate associations with verbal developmental quotient (VDQ), non-verbal developmental quotient (NVDQ) and socialization.

**Results:** Increased coherence was observed for LD relative to TD, with differences most prominent in slow-wave sleep (SWS) and few differences detected in the awake state (p<.01). Within the LD group, lower VDQ scores were associated with higher coherence in REM, mainly within 18-25 Hz (Alpha); within the TD group, lower VDQ scores were associated with higher coherence in SWS across multiple frequency bands (p<.01).

Density of 9 Hz spindles decreased at follow-up in central and temporal channels; density of 11 Hz spindles increased in frontal channels (p<.01). Duration and frequency increased for 11 Hz spindles and decreased for 15 Hz spindles. For all parameters, the LD group demonstrated a smaller magnitude of change from baseline to follow-up compared to the TD group.

**Conclusions:** Early detection and diagnosis of autism spectrum disorders (ASD) is crucial to optimal developmental outcomes. Our results indicate that abnormalities in sleep electrophysiological features can be detected as early as 18 - 36 months in children with language delay who are at-risk for ASD, before most other overt symptoms are evident. Additionally, alpha oscillations and sleep spindles are both generated by thalamocortical interactions, an area which has also been implicated in sleep disruptions in ASD. As such, these results provide additional insight underlying the developmental pathophysiology of ASD.

416.294 *(Poster)* Perinatal Risk Factors for Gastrointestinal Symptoms in 2 to 5-Year-Old Children with Autism Spectrum Disorder, Developmental Delay, and from the General Population

**A. M. Reynolds, L. Silveira, K. Hightshoe, T. Kral and S. E. Levy, (1)University of Colorado School of Medicine, Aurora, CO, (2)University of Colorado Anschutz Medical Campus, Aurora, CO, (3)University of Pennsylvania School of Nursing, Philadelphia, PA, (4)Division of Developmental and Behavioral Pediatrics, Center for Autism Research, Children's Hospital of Philadelphia; Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA**

**Background:** Gastrointestinal symptoms (GIS) are common in children with autism spectrum disorder (ASD) and developmental delays (DD). The gut microbiome has been implicated in gastrointestinal dysfunction and in ASD. Elevated maternal pre-pregnancy BMI (PP-BMI), prematurity birth, and cesarean delivery interfere with typical gut colonization.

**Objectives:** Evaluate associations between GIS at 2 to 5-years and perinatal risk factors in children with ASD, DD, and children in the general population (POP).

**Methods:** The Study to Explore Early Development (SEED) is a multi-site, community based, case-control study of ASD risk factors and health problems. The study includes 2,243 2 to 5-year-old children in 3 groups: 840 with ASD and DD with ASD features (DDw/ASD), 602 with DD without ASD features (DDw/oASD), and 801 POP children randomly recruited through birth certificates. Mode of delivery
(MOD), gestational age, PP-BMI, breastfeeding, and maternal race and education were collected from caregiver interview and/or abstracted from prenatal, delivery, and neonatal medical records. Child cognitive score and research diagnostic classification were determined using the Mullen Scales of Early Learning, Autism Diagnostic Observation Schedule, and Autism Diagnostic Interview, Revised. Children with a history of ASD, screen positive for ASD with the Social Communication Questionnaire, or behaviors concerning for ASD during cognitive testing that did not meet strict research criteria for ASD were categorized as DDw/ASD. Within each group, univariate logistic regression models were developed to evaluate associations between having GI problems and the characteristics of interest: MOD, gestational age, PP-BMI, and breastfeeding. Analyses also adjusted for: site; maternal race and education; and child age, sex, and cognitive score. All variables that were significant ≥0.15 in the univariate analysis were dropped. From there the least significant variable ≥0.15 was removed and the multivariate analysis redone until all variables were significant at the <0.15 level.

Results: Associations with GIS at 2 to 5 years in children with ASD and DDw/ASD: male sex aOR 0.64(0.44-0.93) p=0.020, child age 0.97(0.95-0.99) p=0.006, gestational age 0.98(0.95-0.99) p<0.001, black race 0.53(0.41-0.71) p<0.001, other race 0.47(0.30-0.75) p=0.001. Associations with GIS in DDw/oASD: breast feeding <26 months aOR 1.63(1.30-2.04) p<0.001. Associations with GIS in POP: gestational age aOR 0.93(0.88-0.99) p=0.028, black race 0.56(0.36-0.89) p=0.015, and breastfeeding <26 weeks aOR 1.48(1.28-1.73) p<0.0001.

Conclusions: In this cross-sectional study of preschool children using retrospective perinatal history, MOD and PP-BMI were not associated with GIS in any group. Children breastfed <26 weeks were more likely to have GIS in the DDw/oASD and POP groups. Breast feeding was not associated with GIS in ASD and DDw/ASD group. POP children with older gestational age and black race were less likely to have GIS. Children with ASD and DDw/ASD were less likely to have GIS if they were male, older at study enrollment, older gestational age, and not Caucasian. Limitations include: no clinical diagnosis of GIS, no evaluation of microbiome, cross sectional data, lack of information about exclusivity of breastfeeding. Further study is needed to evaluate potential causes for the difference in association with breastfeeding in the ASD and DDw/ASD group compared to DDw/oASD and POP.

416.295 (Poster) Pilot Study Shows Blue Food Coloring in Muffins Provides a Non-Invasive, Objective Measure of Gastrointestinal Function in People across the Autism Spectrum

Background:

Autism-linked gastrointestinal (GI) distress, involving severe constipation, reflux, bloating, and pain are common and yet objective GI assessments for people across the autism spectrum are currently lacking. Moreover, because people with profound autism may be non-verbal or otherwise unable to communicate their symptoms, gastrointestinal symptoms remain under-reported with negative impacts on quality of life for these individuals and their caregivers.

Objectives:

Our goal was to run a small pilot study of a non-invasive, home-based objective measure of whole gut transit time and lag phase, two measures relevant to gut motility/function. To quantify whole-gut-transit-time and other, co-occurring symptoms prospectively, we developed a web application, ‘Stripes Symptom Tracker’ based on a caregiver-assisted questionnaire (Margolis et al. 2019). Stripes Symptom Tracker works on an account system, allowing multiple caregivers to log symptoms.

Methods:

Participants were recruited through the Phelan-McDermid Syndrome Foundation patient advocacy group. There were eleven participants: seven patients and four sibling controls across seven households. Blue muffins were prepared by a professional baker and shipped to consented families. Telemedicine appointments were arranged for each household at the start of their day so that participants would consume the blue muffins after an overnight fast with a doctor present on the call in case of complications. Caregivers were then asked to track four broad categories of symptoms: bowel movements (checking for blue or blue green color in stools), reflux, pain, and neurological symptoms including sleep quality and irritability/aggression for a month using Stripes Symptom Tracker.

Results:

All participants, ranging in age from 8-33 years, ate the blue muffins. Caregivers were able to detect blue dye in subsequent bowel movements in ten of eleven cases, even when whole gut transit (time to first blue bowel movement) and lag phase (time from first to last blue bowel movement) were prolonged, taking 3+ days for transit and six days for lag phase. For one household account creation in Stripes Symptom Tracker was problematic and therefore, detailed prospective symptom data are lacking for one patient and one sibling control. Of the remaining nine participants, four tracked symptoms for a week+, three tracked symptoms for one month, and two tracked symptoms for
Prevalence and Odds of Diabetes Mellitus Among Autistic Adults in the United States

D. Gilmore and B. N. Hand, (1)The Ohio State University, Columbus, OH, (2)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH

Background: Diabetes mellitus is a challenging chronic health condition at the forefront of attention of the healthcare system in the United States. Diabetes results in high healthcare costs and is burdensome for patients and families. While important estimates quantifying how diabetes prevalence varies by age exist for the general population, these estimates are poorly characterized among autistic adults. Most estimates for autistic adults have stemmed from relatively small-scale studies or used pediatric samples. Thus, there is a critical gap in understanding the prevalence of diabetes among autistic adults, emphasizing the need for large, adult-focused analyses with greater generalizability to inform the development of autism-specialized diabetes support services.

Objectives: To compare the prevalence of diabetes among autistic adults in the United States to non-autistic adults as a function of age.

Methods: We did a cross-sectional analysis of inpatient and outpatient IBM MarketScan health claims data from 2019-2020 to estimate diabetes prevalence among privately insured autistic adults (N = 54,500) and age and sex-matched non-autistic adults (N = 109,000) in the United States. Autistic adults were included if they were 18-64 years old and had at least 1 inpatient or outpatient encounter with an International Classification of Diseases, 10th edition (ICD-10) code for autism (F84.0, F84.1, F84.5 F84.9). Beneficiaries without an autism ICD-10 code were considered non-autistic adults. Diabetes among autistic and non-autistic adults was identified via ICD-10 codes (E08.xx-E13.xx) corresponding to diabetes due to underlying condition, drug or chemical induced diabetes, type 1 diabetes, type II diabetes, and other specified diabetes. Using logistic regression, we estimated autistic adults’ odds of diabetes relative to non-autistic adults throughout adulthood at five-year age intervals (e.g., 18-22, 23-27), while controlling for demographic factors.

Results: 76% of included beneficiaries were between 18-27 years old, and approximately 73% of beneficiaries were male. Less than 1% of non-autistic adults, and 7.15% of autistic adults, had an intellectual disability. Most beneficiaries lived in the South or North-Central United States, and approximately 20% of beneficiaries lived in a rural residence. 5.15% of autistic adults and 3.07% of non-autistic adults in our sample had diabetes. Odds of diabetes increased monotonically at each five-year age interval for autistic adults (Figure 1). Autistic adults had a higher likelihood of diabetes than non-autistic adults at most five-year age intervals, with the greatest difference at ages 23-37 (OR = 2.67; 95% CI = 2.33-3.06) (Table 1).

Conclusions: Our results provide more generalizable estimates of diabetes prevalence for autistic adults than estimates that are currently available. Our findings suggest that autistic adults may be more likely than non-autistic adults to experience diabetes in adulthood. Thus, development of diabetes support services and programs that accommodate autistic adults’ individualized needs are important for future study to promote optimal diabetes outcomes for this population.

Prevalence of Autism Spectrum Disorder in Patients with Congenital Heart Defects

S. M. Wilson, E. G. Shah, P. A. Filipek and A. F. Corno, (1)Pediatric Neurology, University of Texas Health Science Center at Houston, Houston, TX, (2)Pediatric Neurology, Washington University in St. Louis, St. Louis, MO, (3)Cardiovascular Surgery, University of Texas Health Science Center at Houston, Houston, TX

Background: Congenital heart defects (CHD) are the most common birth defect in the United States. With recent advances in medical and surgical care, there has been a decrease in overall mortality, and consequently, a growing focus has been placed on these patients’ subsequent quality of life, including neurodevelopmental outcomes. Risk stratification has not been fully understood, however, a direct correlation between type of CHD and underlying genetic complexity, and severity of neurodevelopmental outcomes, has been established. Per the Centers for Disease Control and Prevention (CDC), the most recent prevalence estimate of autism spectrum disorder (ASD) in the United States among children 3-17 years of age is 2.5%. ASD has gained specific attention in children with CHD, with an odds ratio of 1.33 identified. The Modified Checklist for Autism in Toddlers (M-CHAT) is an ASD screening tool, with screenings at the age of 18 and 24 months recommended by the American Academy of Pediatrics to evaluate the risk of ASD in well children visits.

Conclusions:

Pilot data indicate that blue dye in muffins is a feasible way to detect delayed transit as well as altered lag phase dynamics. The Stripes Symptom Tracker facilitates prospective collection of symptoms in real time and reveals dynamics of how symptoms cluster with each other and change over time. Based on these pilot data, we next plan to validate these measures in a larger population of people across the autism spectrum to better understand autism-linked GI distress and provide tools for identifying helpful interventions.
Objectives: The goal of this retrospective observational study was to determine the prevalence of ASD in children with CHD with heart surgery performed in the first 3 months of life between September 2017 and December 2020.

Methods: Approval for this study was obtained from the Institutional Review Board. After reviewing the local electronic medical records of the Society of Thoracic Surgeons Congenital Heart Surgery Database, 94 patients met the inclusion criteria. Data pertaining to an M-CHAT at 18 and/or 24 months of age and the presence or absence of ASD diagnosis were documented.

Results: Of the 94 patients that met entry criteria for the study:

- 40/94 (42.5%) had at least one M-CHAT
  - 6/40 (15%) had 18 month M-CHAT only
  - 12/40 (30%) had 24 month M-CHAT only
  - 22/40 (55%) had 18 and 24 month M-CHAT
- 24/40 (60%) had M-CHAT scores in the elevated risk range
- 9/24 (37.5%) were referred for ASD evaluation
- 6/24 (25%) had documented diagnosis of ASD
  - Of patients diagnosed with ASD, on the 18 month M-CHAT, 3/6 (50%) had an elevated risk M-CHAT
  - Of patients diagnosed with ASD, on the 24 month M-CHAT, 4/6 (66.7%) had an elevated risk M-CHAT

Conclusions: Of the 94 CHD children evaluated in this study, 40 children (42.5%) had at least one M-CHAT; 24/40 children (60%) had an elevated risk on the 18 month and/or 24 month M-CHAT, while 6/40 children (15%) were diagnosed with ASD. The discrepancy in our observations raises the concern that the prevalence of ASD in this patient population might be underrepresented. It is important to perform screenings for developmental delays and to identify subjects with ASD to ensure these children are provided with access to developmental therapies, proper resources, and close follow-up.

416.298 (Poster) Primary Anxiety Diagnoses in a Clinical Sample of Autistic Teens with Intellectual Disability

A. Blakeley-Smith, A. T. Meyer, L. Olson, T. Abu-Ramadan, L. Hayutin, C. Middleton and J. Reaven, (1)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (3)Joint Doctoral Program in Clinical Psychology, SDSU/ UC San Diego, San Diego, CA, (4)University of Wyoming, Laramie, WY, (5)University of Colorado Anschutz Medical Campus, Aurora, CO, (6)University of Colorado School of Medicine, Aurora, CO

Background: Significant efforts have been made to understand the rates of anxiety symptoms in autistic youth with average cognitive abilities (van Steensel et al., 2017), however, less is known about the nature of anxiety symptoms in autistic youth with intellectual disability (ID). Autistic youth with ID are a complex and underserved population who have historically been excluded from anxiety research. Further, behavior and communication differences can make anxiety assessment particularly challenging in this population (Jennett & Hagopian, 2008). As such, very few studies have employed gold standard assessments to examine anxiety in this population. One study that did use a standardized assessment for autistic youth with ID (age 9-13) identified Specific Phobia as the most common diagnosis in this age group, followed by Social Phobia, and GAD (Kerns et al, 2020). It is unclear to what extent this pattern would change in adolescence. Knowledge of how anxiety manifests in adolescents with co-occurring ASD/ID is critical to informing care in this underserved population.

Objectives: The purpose of this study is to characterize patterns of anxiety, and identify rates of primary anxiety diagnoses among autistic teens.

Methods: Twenty-nine autistic teens with ID, ages 12-18 (and their parents), participated in a Facing Your Fears (FYF) anxiety treatment study which has been adapted for teens with ID (FYF: IDD). ASD diagnoses were ascertained using gold-standard diagnostic tools (ADOS-2; Lord et al., 2012). See Table 1 for participant characteristics. Parents were administered the ADIS: Autism Spectrum Addendum (ADIS:ASA, Kerns et al, 2017). Primary anxiety diagnosis was determined based on the highest Clinician Severity Rating (CSR, range=0-7) which incorporates parent reported levels of interference and disruption to daily life.

Results: While many teens met criteria for multiple diagnoses, the top two primary diagnoses based on the ADIS:ASA were Social Phobia (48%) and Generalized Anxiety Disorder (GAD, 29%). The other 23% of participants had either specific phobia, separation anxiety disorder, OCD, fear of change, or unspecified anxiety as a primary diagnosis (See Figure 1).

Conclusions: Autistic teens with ID are a markedly understudied group yet a critical population to serve given their mental health needs (Kucharchzket al., 2015). Results of the present study indicate that Social Phobia and GAD were the most common parent-reported primary anxiety diagnoses. Similarly, these were also identified as the top two primary anxiety diagnoses in autistic teens without ID (Reaven et al.,
2011). The pattern of increased social/generalized worries as youth enter adolescence is in line with a developmental progression of anxiety and has important implications for anxiety treatment. In addition, parents reporting GAD as a top priority in their teens with ID points to the potential value of CBT treatment that addresses broader anxiety symptoms. This is a departure from more common treatment approaches (i.e., behavioral analytic) used with autistic youth with ID, particularly those with specific phobias (Rosen, Connell, & Kerns, 2016). Limitations include a small sample size and the clinical nature of this trial (i.e., all families were actively seeking CBT treatment, potentially limiting a wider range of participants).

416.299 (Poster) Challenges in Understanding GI Dysfunction in Neurodevelopmental Disorders

Background:

There is a high prevalence of gastrointestinal (GI) problems in individuals with neurodevelopmental disorders (NDDs). However, type, frequency and impact of these problems has been variable and difficult to ascertain across individuals with rare genetic disorders and NDDs and those with idiopathic NDDs. While there are variabilities in symptom presentation between different forms of NDDs, there are also differences across different subtypes. In addition, it is unclear if individuals who are either non-speaking or cognitively disabled have the ability to express the source of their GI distress or are able access or tolerate appropriate diagnostic evaluations and treatments.

Objectives:

In order to better understand the prevalence in type of GI symptoms across those with different forms of NDDs, The Consortium for Neurodevelopmental Disorders and Digestive Diseases (CANDID) (www.candidgi.com) was formed in 2022. The goal of the collaboration was to better understand and help those with co-morbid GI problems and NDDs across the spectrum with different abilities and disabilities.

Methods:

A quantitative survey including the PedsQL and PROMIS for GI symptoms and Quality of Life (QOL) was administered to 717 caregivers with minor or adult children with either syndromic or idiopathic forms of autism spectrum disorder. This was done to determine prevalence and type of GI problems in children and the impact on families. Recruitment was conducted through patient advocacy groups and through autism organizations.

Results:

Constipation was the most common (p<0.05) disorder among respondents of the PedsQL, but other symptoms including nausea/vomiting, reflux, abdominal pain, diarrhea, dysfunctional swallowing, and bloating were also present at equal frequencies. Many of these children have sensory function impairment as well as medical complexities making sequelae difficult to document. A statistically significant (p<0.05) decrease in quality of life associated with GI disorders was identified in the adult population compared with other age groups, suggesting that as children age, QoL decreases. Constipation and abdominal pain worsened QOL scores by at least 1 SD. Unfortunately, the survey questions received qualitative feedback from respondents expressing that there were too many questions and that they could not adequately assess the GI dysfunction or pain in their non-speaking or cognitively disabled child, or the questions did not reflect the day-to-day realities of those families experiencing these problems.

Conclusions:

Constipation is the highest reported, but not only, GI problem experienced across those with NDDs. In order to better determine the source of GI distress, better subjective and objective measures need to be developed, especially for those who are non-speaking or have limited cognitive ability. This group is particularly vulnerable to the invasive testing required to properly diagnose some of these GI issues. This group (CANDID) represents a newly developed consortium of stakeholders dedicated to improving the detection and management of GI disorders in those with NDDs. Other needs identified include training of pediatric gastroenterologists and building repository data to share clinical results across researchers and clinicians.

416.300 (Poster) Repetitive Negative Thinking As a Prospective Predictor of Depression and Anxiety Symptoms in Autistic and Non-Autistic Incoming College Students
Background: Improving the understanding and treatment of mental health concerns, including depression and anxiety, are significant priorities for autistic adults (Benevides et al., 2020; Crane et al., 2019; Pellicano et al., 2014). While several theories have been proposed to explain the high prevalence of internalizing symptoms in autistic people, little longitudinal research has been done to investigate potential causal mechanisms. One potentially fruitful area of investigation is to explore how well-known contributors to depression/anxiety in the general population predict and/or moderate the development of internalizing symptoms in autistic individuals.

Objectives: The current study investigates the relation of one established risk factor from the general population, repetitive negative thinking (RNT), to internalizing symptoms over the course of college students’ first semester. We will also examine whether this association is moderated by a measure of autistic traits (Social Responsiveness Scale, Second Edition; SRS-2; Constantino & Gruber, 2012) and self-described autism status.

Methods: Students were recruited from four northeastern United States universities prior to their first semester at their university (in Fall 2020, Fall 2021, and Fall 2022). Our sample (N=263 total) includes 105 students who either reported a formal autism diagnosis (n=30) or endorsed a history of self and/or others thinking that they may be autistic (n=75), as well as 158 students with no history of autism. Participants completed a baseline survey battery within their first two weeks of starting college, a brief biweekly survey throughout their first semester (up to 24 times across 12 weeks), and an endpoint packet. Cross-sectional and longitudinal relationships of interest were assessed using general linear models and generalized least squares (GLS) regression (Pinheiro & Bates, 2000) with a first-order autoregressive correlation structure (AR1), respectively.

Results: Cross-sectional analyses on the full dataset (N=263) indicate that autistic (self-identified or clinically diagnosed) students tended to report greater repetitive negative thinking (F(1,252)=42.40, p<.001, d=0.83), as well as higher depression (F(1,257)=25.20, p<.001, d=0.64) and anxiety (F(1, 256)=26.49, p<.001, d=0.65) symptoms at baseline (see Table 1). Longitudinal analyses on the Fall 2020 and 2021 cohorts (n=144) demonstrated that elevated trait-like RNT at baseline prospectively predicted biweekly ratings of sadness (b=0.04, CI95%; 0.03, 0.05, f2 =0.11), anhedonia (b=0.04, CI95%; 0.03, 0.05, f2 =0.12), and anxiety (b=0.04, CI95%; 0.03, 0.05, f2 =0.11) symptoms across the semester, when controlling for SRS-2 scores and time trend (see Figure 1). A third wave of data will be added in January 2023 to supplement these longitudinal analyses.

Conclusions: These preliminary findings highlight RNT as a specific predictor of depression/anxiety that extends across neurotypes but may be especially prevalent in autistic adults. If causality continues to be supported, then RNT may be an important intervention target toward reducing the elevated depression and anxiety rates within the autistic community. Furthermore, understanding common factors in depression and anxiety treatment across populations may assist in increasing clinician confidence and competence in treating the underserved population of autistic adults with mood disorders (Maddock et al., 2020).

---

416.301 (Poster) Results from the Specifying and Treating Anxiety in Autism (STAAR) Trial
M. Solomon1, M. E. Tudor1, B. Winder-Patel1, B. Heath1, E. S. Bickel1, S. Bothra1, G. S. Young1, S. Park1, M. C. Hunsche1, C. M. Kerns1, D. Hess1, D. G. Amaral2, C. W. Nordahl2 and J. J. Wood1, (1)Department of Psychiatry and Behavioral Sciences, University of California Davis, MIND Institute., Sacramento, CA, (2)UC David MIND Institute, Davis, CA, (3)MIND Institute, MIND Institute, UC Davis Medical Center, Sacramento, CA, (4)UC Davis MIND Institute, Sacramento, CA, (5)MIND Institute, UC Davis, Sacramento, CA, (6)Psychiatry and Behavioral Sciences; MIND Institute, University of California, Davis, Sacramento, CA, (7)UC Davis MIND, Sacramento, CA, (8)University of British Columbia, Vancouver, BC, Canada, (9)Department of Psychiatry & Behavioral Sciences, MIND Institute, UC Davis, Sacramento, CA, (10)Department of Psychiatry and Behavioral Sciences, UC Davis The M.I.N.D. Institute, Sacramento, CA, (11)Department of Psychiatry and Behavioral Sciences, UC Davis, Sacramento, CA, (12)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA

Background: Approximately 40%-80% of autistic children and adolescents exhibit clinically significant anxiety symptoms. These symptoms are associated with increased social deficits, depression, irritability, and stereotyped and self-injurious behaviors. Furthermore, youth with anxiety frequently avoid potentially stressful situations, missing opportunities to learn important skills. Multiple small trials provide promising evidence that selective serotonin reuptake inhibitors and cognitive behavior therapy (CBT) might reduce anxiety in autistic persons. However, there remains a need for a large, rigorously designed clinical trial that validates and compares the effectiveness of medication and CBT for treating anxiety in autistic youth. The COVID-19 pandemic also raised provocative questions about the relative efficacy of in-person versus online treatments.

Objectives: 1) To conduct the first 16-week randomized, placebo-controlled, comparative treatment trial to test the relative efficacy of a CBT called Behavioral Intervention for Anxiety in Children with Autism (BIACA), compared to sertraline and pill placebo; 2) To examine the efficacy of in-person versus online therapy.
Methods: The current sample consists of 56 of 60 expected participants ages 8-14 years and their parents who received hybrid (68%) versus fully online therapy (32%). They were qualified into the study using gold standard autism diagnostic (ADOS-2) and anxiety measurements (ADIS/ASA). They also were administered the Pediatric Anxiety Rating Scale (PARS), a brief clinician-rated semi-structured interview, which was used as the primary outcome measure, and will be reported here. They also were administered other secondary measures of anxiety, problem behaviors, and family adaptation. They were randomly assigned to receive CBT, sertraline, or pill placebo in a 1:1:1 allocation (n’s of 19, 19, and 18, respectively), with age and IQ used to stratify the sample. After randomization, participants received 16 weeks of CBT, sertraline, or pill placebo treatment. They then completed the post-treatment and 3-month follow-up assessments. The pill placebo group was then offered either medication or CBT treatment. All analyses were conducted in R using lme4 for fitting random effect models. Age at baseline was included as a covariate in all models. Higher order interactions with online status were also examined.

Results: A random effects growth model revealed a significant treatment by time interaction effect (F=3.96, p<.05). Simple effect comparisons revealed that PARS scores for the CBT group decreased (improved) over time significantly more than the placebo group (t=2.82, p<.01), and the Sertraline group decreased marginally more than the Placebo group (t=1.51, p=.13). There was no main effect or higher order interactions with online status.

Conclusions: Both CBT and sertraline resulted in decreased report of anxiety symptoms compared to the Placebo group, although results were only significantly better for the CBT group. Interestingly, the online rather than in person receipt of treatment did not appear to affect these results. Low hanging fruits for future work include studies of combination therapy, secondary outcome variables, and more rigorously controlled trials of online versus in-person therapy. All of these hold the potential to advance the treatment armamentarium for this debilitating problem in autistic youth and offer greater access to care.

416.302 (Poster) Sex Differences in Aggression and Anxiety in Adolescents and Young Adults, As Related to Autism
G. P. Pierce, M. Santhosh, H. Rea, K. Pelphrey and S. J. Webb, (1)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Center for Human Development and Disability, University of Washington Psychiatry and Behavioral Sciences, Seattle, WA, (4)Autism and Neurodevelopment Disorders Institute, University of Virginia School of Medicine, Washington, DC, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

Background:
Anxiety commonly co-occurs with Autism Spectrum Disorder (ASD), with approximately 40% of autistic individuals experiencing a social, specific, generalized, or other anxiety disorder (Zaboski & Storch, 2018). High anxiety in autistic individuals is correlated with increased aggression, rule-breaking, and obsessive-compulsive behaviors (Panju et al., 2015). Additionally, in neurotypical individuals, physical aggression is more prevalent in males (Lansford et al., 2012).

Objectives:
This project investigated the relationship between self-reported anxiety and aggression in youth with ASD as compared to non-autistic youth. In this study, we (1) examined sex differences in aggression and anxiety in youth ages 12-26 years with and without ASD, and (2) investigated whether this relationship differs in autistic females compared to autistic males.

Methods:
Data were collected from an NIH-funded study on sex and gender differences in ASD. The sample comprised of 30 autistic females, 45 autistic males, 43 neurotypical females, and 45 neurotypical males. This study included 3 gender-diverse individuals. All individuals were ages 12-26. ASD diagnosis was confirmed via the ADOS-2. Anxiety and aggression were assessed via CBCL-YSR and ABCL-ASR.

Results:
The full sample (neurotypical and autistic, n=163) showed a positive relation between anxiety and aggression (r=.58, p<.001); greater anxiety was related to greater aggression. This relationship was present in the autistic youth when analyzed separately (r=.42, p<.001); however, it was significant in autistic females (r=.47, p<.01) but not autistic males (r=.27, p=.08). The difference between the relationship in autistic females compared to autistic males was not significant (z=.95, p=.34).

Conclusions:
This study replicated findings by Panju et al.’s 2015 study of the relationship between anxiety and aggression in autistic individuals. We extended this finding to youth and young adult self-reported behavior. Our preliminary analyses suggest that the relationship may differ in autistic youth, based on their sex-assigned-at-birth. Follow-up analyses will examine additional individual characteristics in autistic individuals (e.g. parent report scores, family income) that may affect the relationship between anxiety and aggression.

416.303 (Poster) Sex Differences in Anxiety Symptoms and Eye-Blink Rates in Children with Autism: Results from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)

Background: Children with autism spectrum disorder (ASD) experience higher rates of anxiety disorders than typically developing peers with a prevalence rate of roughly 40% (Mingins et al., 2021; van Steensel et al., 2011). Spontaneous eye-blinking is an autonomic process, and rates are affected by emotional states, such as stress or anxiety. Spontaneous eye-blink rates (EBRs) predict abnormal dopamine activity, and dopamine plays a role in anxiety modulation (Jongkees & Colzato, 2016; de la Mora et al., 2010). Previous research has found that EBRs increase significantly during stressful situations or while watching stressful videos (Giannakakis et al., 2017; Korda et al., 2021). EBRs in relation to anxiety symptoms in autistic children has yet to be explored.

Objectives: The current study examined the relationship between EBRs and anxiety symptoms (AS) in autistic children. It was predicted that higher AS would be associated with increased EBRs. Exploratory analyses were conducted to examine sex differences in EBRs and AS.

Methods: Participants in this study included 211 autistic children (female=45, mean age=8.61±1.66 years) from the Autism Biomarkers Consortium for Clinical Trials. ASD diagnoses were confirmed with the Autism Diagnostic Observation Schedule, Autism Diagnostic Interview-Revised, and clinician endorsement of DSM-5 criteria for ASD. Parent-reported AS were assessed via the Child and Adolescent Symptom Inventory-5. ET data was recorded at 500 Hz using the SR Eyelink 1000+. ET data was collected while participants viewed 5 paradigms: activity monitoring (AM), biological motion (BM), interactive social task (SI), static scenes (SS), and visual search (VS). EBRs were calculated as number of spontaneous eye-blinks per paradigm and across the overall experiment. EBRs were normalized with a log base 10 transformation. T-tests were performed to compare AS and EBRs between groups and linear regression models were performed to test the relationship between AS, EBRs, and sex.

Results: Females had significantly higher AS than males (t(58)=2.6, p=.011), but significantly lower EBRs during the entire experiment (t(65)=2.1, p=.031) and SS (t(70)=2.07, p=.048). AS were not significantly related to EBRs across all paradigms. When sex was added to the regression model, there was a significant AS-by-sex interaction effect across the entire experiment (ß=.006, t=2.18, p=.029). The model was also statistically significant for SI (R²=.05, F(3,207)=4.28, p=.005). AS (ß~.007, t=2.492, p=.013), sex (ß~.07, t=2.648, p=.008), and the AS-by-sex interaction (ß=.01, t=3.178, p=.001) was significantly related to EBRs. Higher AS were only associated with increased EBRs for males (ß=.003, t=1.984, p=.049; Fig. 1).

Conclusions: Consistent with our hypothesis, results indicated higher AS were associated with increased EBRs, however, this effect was only seen in autistic males. This partially replicates findings in other populations. One potential explanation for this effect being unobserved in autistic females might be that, consistent with social camouflaging, females may be attempting to suppress physical expressions of their anxiety, resulting in lower EBRs and increased AS. This study also reports a novel finding that autistic females have lower EBRs than autistic males. Results suggest it is important to consider sex and co-occurring psychiatric conditions when studying EBRs in autistic populations.

416.304 (Poster) Sex Differences in Predictors of Mental Health Symptoms Level and Growth across Childhood in Autism

Background: More males than females receive an autism diagnosis, and females who are diagnosed show greater etiologic risk factors (e.g., a greater genetic mutational load)[1]. Also, higher levels of co-occurring intellectual disability or emotional and behavioural problems predict autism diagnosis in girls (given equal autism symptoms).[2] Consistent with this, we have shown in this sample that girls with autism show substantially higher rates of disruptive behavioural, anxious-depressed and attention problems relative to their same-sex typically developing peers. No previous study has examined whether risk factors for mental health symptoms show a greater association with mental health symptoms in girls than boys.

Objectives: To identify possible sex differences in predictors of level and growth of mental health symptom across childhood in autistic children

Methods: The Canadian Pathways in ASD study enrolled children with ASD (n=398; 63 girls) who were assessed eight times from the time of diagnosis (age 2-4 years) to age 10.5 years. Mental health problems were assessed using the parent-report Child Behaviour Checklist [4,5] aggression, attention problems and anxiety-depression syndrome scales. Predictors of these symptoms included socio-demographic risk (indexed by family income), autism symptom severity (ADOS social affect and repetitive and restricted behaviour [RRB] [5]), and IQ assessed using the Weschler Intelligence Scales for Children[6]. Growth curve models were fitted with a scaling factor to accommodate the change from the preschool to school age questionnaires.

Results: A significant sex difference was found in prediction from income to all three mental health dimensions. Lower income was more strongly associated with higher levels of disruptive behaviour and anxious-depressed symptoms, and with higher growth in rates of disruptive behaviour, anxious-depressed and attention problem symptoms over childhood, in girls compared to boys. A significant sex difference was seen in prediction from ADOS social affect problems to growth of aggression and anxious-depressed symptoms, with opposite effects in boys and girls. That is, social affect problems were associated with improving symptoms over childhood in girls and worsening symptoms over childhood in boys. No sex differences obtained in IQ; lower IQ predicted increased behavioural problems and attention problems similarly in both sexes. RRB problems also showed no sex differences and were not significantly associated with mental health symptoms.

Conclusions: Lower income showed a stronger association with levels and growth of mental health symptoms in autistic girls than in boys. Given a consistent association between lower income and mental health in typical development in both sexes, this may suggest distinct aetiologies for co-occurring mental health symptoms in autistic boys. The finding may also be consistent with females requiring more risks factors to receive an autism diagnosis, given that diagnosis is more likely with accompanying mental health symptoms. Social affect problems were a risk for mental health symptoms in boys, but surprisingly appeared to be protective for growth in symptoms over time in girls. Examining why increased social difficulties would lead to reducing mental health symptoms in girls who receive an early diagnosis of autism is an important topic for future research.

416.305 (Poster) Shared Pathways to Anxiety in Individuals with Moderate-Profound Intellectual Disability: The Role of Characteristics Associated with Autism across Diagnostic Groups

G. Edwards, J. Tarver, E. Pearson, C. Oliver and J. Waite, (1)Aston University, Birmingham, United Kingdom, (2)University of Birmingham, Birmingham, United Kingdom

Background: Anxiety is common in autistic individuals with intellectual disability (ID) and some genetic syndromes associated with both autism and ID. Correlates of anxiety in autism that inform models of possible causal pathways to anxiety include sensory processing differences, repetitive behaviour, health conditions and intolerance of uncertainty. However, a paucity of research examines correlates of anxiety that cut across diagnostic groups associated with ID, while controlling for autism characteristics. Identifying common correlates of anxiety across groups will inform models of anxiety, determine the possible role of autistic characteristics and contribute to the development of transdiagnostic interventions.

Objectives: To determine the associations between anxiety, repetitive behaviour, sensory processing differences, health conditions and intolerance of uncertainty, across diagnostic groups associated with moderate-profound ID, while controlling for autism characteristics.

Methods: Parents/carers completed an online questionnaire battery including the Wessex Questionnaire (a proxy measure of adaptive ability), the Social Communication Questionnaire (SCQ), Repetitive Behaviour Questionnaire-2 (RBQ-2), Health Questionnaire, subscales
from the Sensory Profile-II, the Responses to Uncertainty and Low Environmental Structure (RULES) Questionnaire and the Anxiety, Depression and Mood Scale (ADAMS).

Results: Parents/carers of 165 individuals with ID participated (55.8% male; $M_{age}=20.9$ years ($SD=11.1$), range: 4-63). Diagnoses included autism ($n=38$), autism with a diagnosis of a genetic syndrome ($n=34$) and a diagnosis of a genetic syndrome or ID alone ($n=93$). Diagnosis, autism characteristics, age, gender, ability level, and verbal ability were entered as potential covariates in hierarchical regression analyses. There were group differences based on diagnosis, whereby individuals with Cornelia de Lange and Fragile X syndromes appeared to have similar anxiety scores to autistic individuals, whilst those with Angelman syndrome and heterogeneous diagnosis had significantly lower scores. All other covariates did not significantly predict anxiety. Diagnosis was no longer significant when the variables of interest were entered into the model; higher frequency of health conditions and intolerance of uncertainty predicted higher levels of anxiety ($p=.002$; $p<.001$ respectively) with a trend towards significance for auditory sensory processing differences ($p=.012$). This model explained 61.9% of the variance in anxiety scores. Visual and tactile sensory processing differences and repetitive behaviour were not significant predictors of anxiety.

Conclusions: Health conditions and intolerance of uncertainty are associated with anxiety in both autistic and non-autistic individuals with moderate-profound ID of heterogeneous aetiology. Auditory hyperreactivity may play an important role in the experience of anxiety rather than auditory hyporeactivity or sensory seeking; although further exploration of these relationships are needed in this group. These correlates cut across groups, demonstrating shared correlates associated with moderate-profound ID that underpin anxiety risk. This is crucial considering individuals with varying diagnoses will present to the same clinical services. Identifying potential pathways between health conditions, intolerance of uncertainty and anxiety informs models of the development and maintenance of anxiety, and indicates targets for the development of tailored anxiety interventions.

416.306 (Poster) Sleep Characteristics of Infants with Down Syndrome, High Familial Likelihood of Autism, and Low Familial Likelihood of Autism

Background: Typically developing (TD) infants sleep 12-16 hours in the first year of life. Sleep challenges for school-age children with Down Syndrome (DS) and autism have been previously described; however, there are few studies on sleep in infants with DS or high likelihood of autism (HL). Infants with DS may sleep 1 hour less per night than TD infants (Yau et al., 2019) and infants later diagnosed with autism may show increased sleep onset latency in the first year of life (MacDuffie et al., 2020). Identifying differences in sleep characteristics across infants with DS, HL, and low familial likelihood of autism (LL) could lead to targeted sleep interventions to support healthier outcomes.

Objectives: We aimed to identify differences in quantitative and qualitative sleep characteristics in three age-matched groups (DS; HL; LL) at 6 and 12 months of age.

Methods: Participants were part of the multi-site Infant Brain Imaging Study (IBIS). Sleep in 159 infants at 6 months (DS=35, HL=81, LL=43) and 111 at 12 months (DS=34, HL=57, LL=20) was assessed by parent-report on the Brief Infant Sleep Questionnaire (BISQ), yielding hours of night sleep, daytime sleep, sleep onset latency, and night wakefulness. An analysis of variance was conducted with post hoc pairwise comparisons. Qualitative information on concern about infants' sleep, home sleeping arrangements, method used for falling asleep, and sleep position was obtained.

Results: The DS group had significantly fewer parent-reported hours of night wakefulness compared to the LL and HL groups at 6-months (fig. 1). There were no significant differences across groups for total hours slept during the night, hours slept during the day, or sleep onset latency. DS group parents reported significantly less concern about their child’s sleep than LL and HL at 6-months (Fisher exact test, $p=0.023$). Parent concerns increased from 6 to 12 months for the DS and HL groups, but not the LL group; however, there were no significant group differences in parent concerns at 12 months. Sleeping arrangements at 6 months were infant 1) in parent’s room/crib (DS 53%, HL 43%, LL 23%), 2) in separate room (DS 35%, HL 33%, LL 54%), and 3) in parent's bed (DS 60%, HL 17%, LL 09%). At 12-months, sleeping arrangements were infant 1) in parent’s room/crib (DS 31%, HL 18%, LL 14%), 2) in separate room (DS 63%, HL 58%, LL 72%) and 3) in parent's bed (DS 60%, HL 14%, LL 14%).

Conclusions: Parents of DS infants have less concern and report less time awake at night compared to HL and LL infants at 6 months of age. Objective measures are needed to determine whether this reflects differences in sleep or in other domains (temperament or motor).
Parent sleep concerns increase notably for the DS and HL groups from 6 to 12 months of age. Sleeping arrangements appear to vary by group in the first year of life. Future research is needed to understand whether neurobiological differences might be associated with parent-reported sleep concerns and what may be driving parent choices about infant sleeping arrangements.

**416.308 (Poster)** Sleep Disturbance in Autistic Children and Adults in the EU-AIMS LEAP Cohort: A Follow up Study

\(^8\)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK, London, United Kingdom

**Background:** High rates of sleep disturbances in autistic individuals are common, and remain throughout development. Given the negative impact of sleep disturbances in the manifestation of autism characteristics, or vice versa, it is a must to understand factors (e.g., sensory, mental health, etc.) which may be contributing to long-term sleep disturbances in autism. To date, most longitudinal sleep studies have focused on children, and little emphasis has been placed on autistic individuals beyond childhood.

**Objectives:** To investigate the type of sleep problems in autistic and non-autistic individuals that are maintained through development; To study mid-term predictors of continued sleep disturbances in autism across ages.

**Methods:** A very well-characterized cohort of autistic and non-autistic individuals between 6 and 30 years of age were assessed as part of the multi-centre EU-AIMS Longitudinal European Autism Project (Charman et al., 2017; Loth et al., 2017) during baseline, T1, and 18-24 months later, T2. Sleep disturbances were studied with the Child Sleep Habits Questionnaire (parent report version for 6-11 years-olds) or the self-report adolescent version (for over 11 years of age). Individuals with completed sleep questionnaires at both time points by the same reporter were selected for this study. This resulted on 33 autistic (mean age at T2 =17.19(3.89)), and 39 neurotypical (mean age=17.86(4.27)) adolescents/adults, and 34 autistic (mean age=8.96(0.93) and 17 neurotypical (mean age= 9.04(1.24)) children, none with intellectual disability. At both time points, autistic symptomatology was characterized with the ADOS, Social Responsiveness Scale (SRS), Short Sensory Profile (SSP), and Repetitive Behaviours Scale (RBS). Comorbidities were characterized using the ADHD DSM-5 checklist, and Beck questionnaires for Anxiety and Depression.

**Results:** The rate of disturbances at T2 were not, on average, significantly different to those at T1 in any of the groups (i.e., autism vs non-autism) or ages (i.e., children or adolescents/adults). However, autistic adolescents/adults presented more bedtime resistant behaviours than non-autistics (p=.016), and sleeping times, on average, were significantly longer for autistic individuals (p=.018). Autistic children, and similar to baseline, scored significantly higher (more disturbed) than non-autistic in all subscales (all p<.039), except for disordered breathing. SSP, SRS, RBS and the ADOS collected at T1 were used as predictors for total sleep disturbance in T2. All four factors together contributed to predict the rate of sleep disturbances in children (R=.37,F\(_{3,49}=6.84\), p<.001), but none of them were significant for adolescents/adults (p=.113). Anxiety, depression and ADHD symptomatology from T1 were entered in a different model to study possible mental health conditions to affect long term sleep disturbance. Depressive symptomatology at T1 predicted disrupted sleep in children at T2 (R=.43, F\(_{3,47}=11.81\), p<.001), but ADHD and depression in adolescents/adults (R=.13, F\(_{2,69}=5.09\), p=.009).

**Conclusions:** Sleep problems persist throughout development in autism, and the rate continues to be greater than in non-autistics. Autism core characteristics seem to predict long term sleep problems in children but not in adolescents/adults. Depression at earlier ages predict later sleep problems. Treating some of these conditions at early ages may help improving later sleep disturbances and overall quality of life of those living with poor sleepers.

**416.309 (Poster)** Sleep Problems in Autistic Youth and Maternal Mental Health

*B. J. Taylor*, W. R. Strathmann\(^3\), C. B. Peura\(^1\), C. A. Mazejsky\(^1\) and M. S. Siegel\(^1\),

\(^1\)Center for Clinical and Translational Science, MaineHealth, Portland, ME, 
\(^2\)Psychology, The Roux Institute at Northeastern University, Portland, ME, 
\(^3\)The Glickman Lauder Center of Excellence in Autism and Developmental Disorders, Portland, ME, 
\(^4\)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, 
\(^5\)Psychiatry, Tufts School of Medicine, Boston, ME

**Background:** Sleep problems are common in autistic youth and have been linked with mental health problems in parents. Understanding this relationship could reveal modifiable mechanisms and support the development of family system interventions. This study advances the literature by utilizing a large inpatient sample enriched for psychiatric and behavioral problems, which are known correlates of both sleep problems in autistic youth and poor mental health in parents.

**Objectives:** To evaluate interconnections between child sleep problems and maternal mental health problems.
Methods: Participants were 356 youth with ADOS and clinically confirmed autism and their biological mothers. Participants were enrolled at the time of hospital admission to a participating site of the Autism Inpatient Collection. Mothers completed questionnaires about the presence and nature of their child’s sleep problems prior to admission and family psychiatric history. Binary logistic regressions evaluated if sleep problems in autistic youth predicted self-reported maternal diagnoses of depression and/or anxiety controlling for demographic characteristics, level of impairment, (i.e., autism severity, non-verbal IQ, and verbal ability), and externalizing/internalizing symptoms (as measured by the Child Behavior Checklist) in children. Parenting stress was also evaluated as a mediator and/or moderator of associations between children’s sleep problems and maternal mental health in a subset of 231 participants who completed the Parenting Stress Index. Exploratory analyses evaluated the moderating effect of covariates on outcomes.

Results: Child participants were 12.0±3.3 years old, 82.6% male, 93.3% white, 37.4% minimally verbal, and 36.5% with comorbid intellectual disability. Biological mothers were 42.3±8.1 years old, 64% were married or living with a partner, 79% had at least some college education, and 52.2% had an annual household income greater than $50k. Of the 356 child participants, 45.2% had difficulty falling asleep, 44.7% had frequent nighttime awakenings, and 12.1% had early morning awakenings and the inability to return to sleep. Of the 356 maternal participants, 47.2% reported depression diagnoses and 53.1% reported anxiety diagnoses. In fully adjusted models, biological mothers of children with difficulty falling asleep were 79% more likely to report depression (OR: 1.79, 95% CI: 1.1-3.0) and those of children with frequent nighttime awakening were 75% more likely to report anxiety (OR: 1.75, 95% CI: 1.0-3.0). There was no main effect of early morning awakening on maternal mental health; however, moderation analyses revealed that early morning awakening increased risk for maternal depression in mothers of school aged children (X²=4.9, p=0.03) but not pre-teens or adolescents. Parenting stress did not mediate or moderate associations between sleep and maternal mental health.

Conclusions: Sleep problems in autistic youth may increase risk for self-reported depression and anxiety in biological mothers. Alternatively, because directionality cannot be determined with this data, it is possible that depression or anxiety in mothers may increase sensitivity to sleep problems in autistic youth. Future studies should seek to identify mechanisms linking sleep problems in autistic youth and maternal mental health problems and evaluate if interventions to improve sleep problems in autistic children have collateral benefits for maternal mental health and the factors that moderate intervention success.

416.310 (Poster) Sleepy Tots: Contributors to Sleep Disturbance in Young Children with and without Autism
A. G. Hartman, J. B. Northrup, K. T. Mackenzie, A. Soehner and C. A. Mazefsky, (1) University of Pittsburgh, Pittsburgh, PA, (2) Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3) Department of Psychiatry, University of Pittsburgh Department of Medicine, Pittsburgh, PA

Background: Sleep health has been directly linked to critical health outcomes like cognitive and physical development, emotional regulation, and mental health (Matricciani et al., 2019). Insufficient sleep in young children can lead to downstream health effects if left untreated. While high rates of sleep disturbances has been demonstrated for autistic children (6-12) (van der Heijden et al., 2018) and young adults (ages 18+) (Jovevska et al., 2020), research characterizing sleep in young autistic children (ages 2-5) is limited. Further, it is unclear whether depressive or anxiety characteristics to sleep problems at this young age. Understanding these relationships directly inform intervention choices and lead to more effective and targeted care.

Objectives: We aimed to (i) examine differences in parent-reported sleep for young children (ages 2-5) with and without autism and (ii) understand Whether parent-reported child depressive and anxiety characteristics account for sleep differences within groups.

Methods: Participants were drawn from a larger protocol adapting the Emotion Dysregulation Inventory (Mazefsky et al., 2018) for young children (Day et al., 2022). Participants with complete data were divided into two groups for this secondary data analysis: those with a parent-reported autism diagnosis (ASD) and those without (NON). Three PROMIS Early Childhood Measures were completed: Sleep Problems 8-item short form (Lai et al., 2022), Depressive Symptoms 10 item short form (Sherlock et al., 2022), and Anxiety 8 item short form (Sherlock et al., 2022). A stepped multivariable linear regression assessed the differences between groups and the contribution of child depressive and anxiety characteristics on sleep disturbances after controlling for age, sex, parent education, and total score of the Social Communication Questionnaire (Rutter et al., 2003), a measure of autism features.

Results: A total of 1,766 parents completed the sleep, anxiety, and depression PROMIS measures (nASD=1,077, nNON=689). Relative to children without autism, autistic children experienced significantly greater sleep disturbance (Table 1). Specifically, 58% of parents of autistic children and 28% of parents of children without autism endorsed sometimes for at least 1 item. Twenty-seven percent of parents of autistic children and 9% of parents of children without autism endorsed “almost always” on at least 1 sleep item.

In the final adjusted regression model (Model 4, Table 2), group differences in sleep disturbances were sustained (F=99.17, p<.001, R²=0.37). When depression and anxiety were included as covariates, depressive characteristics accounted for an additional 15% of variance in sleep (change in R²). Anxiety characteristics accounted for an additional 4% of variance when added to the model (change in R²).

Conclusions: Sleep impairment is evident even in young age for autistic children. Further, when accounting for depression and anxiety characteristics, sleep problems persist. These findings suggest that sleep problems must be addressed independently from, but perhaps in
tandem to, mental health interventions for depression or anxiety.

416.311 (Poster) Static and Dynamic Measures of Sleep and Self-Injury in Autistic Children with Intellectual Disability.
C. Richards1, C. Laverty1, A. Bagshaw1, R. Devine1, F. J. Symons1 and G. Agar, (1)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (2)University of Birmingham, Birmingham, United Kingdom, (3)University of Minnesota, Minneapolis, MN, (4)Aston University, Birmingham, United Kingdom

Background: Persistent poor sleep is commonly reported by parents of autistic individuals (Richdale & Schreck, 2009) with reduction in total sleep time noted for autistic individuals with intellectual disability (ID; Elrod & Hood, 2015). Self-injury is also reported at high rates in autistic individuals with co-occurring ID (Richards et al., 2012; Steenfeldt-Kristensen et al., 2020). Some studies have demonstrated a relationship between sleep problems and self-injury (Brylewski & Wiggs, 2004; DeLeon et al., 2004) with the suggestion that poor sleep leads to tiredness which acts as a setting event for self-injury (Carr & Smith, 1995). However, these studies are limited by their reliance on informant-report measures of sleep, which prevents evaluation of the relationship between self-injury and specific sleep parameters.

Objectives: To use overnight actigraphy to study objective habitual sleep parameters, and their relationship with self-injury, in the home environment.

Methods: Caregivers of 95 autistic children with ID (M age [SD] =10.52 years [2.60]; N males =70) completed questionnaire measures about their child’s sleep, using the Child Sleep Habits Questionnaire (CSHQ, Owens et al., 2000) and self-injury, using the Challenging Behaviour Questionnaire (CBQ, Hyman et al., 2002). Of these, 32 children who showed self-injury on a weekly basis were invited to take part in a 10 day at home assessment of sleep and behaviour using the CamnTech MotionWatch 8. Caregivers completed a diary about their child’s sleep and recorded whether or not self-injury occurred in continuous 2-hour periods throughout the assessment period. Teachers completed behaviour diaries to record occurrences of self-injury at school. Of this sample, 28 children were able to tolerate the actigraphy assessment for at least 5 nights (M age [SD] =10.43 years [2.99]; N males =21).

Results: Sleep problems and self-injury were commonly reported in the sample of 95 children, with 60 participants reported to show self-injury on at least a daily basis and 93 scoring above the clinical cut-off for sleep problems on the CSHQ (Owens et al., 2000). There was no significant correlation between self-injury severity according to the CBQ and the total or subscale scores of the CSHQ in the wider sample. For the 28 children who took part in the actigraphy assessment, sleep parameters were objectively poor with difficulties with sleep onset latency (M=37 minutes, range <1 minute – 3 hours 56 minutes), night waking (M=65 minutes, range 26 minutes – 2 hours 10 minutes) and sleep efficiency (M=82.93%, range 57.60-92.20%). The number of time periods in which self-injury was recorded across the assessment period was significantly correlated with the mean sleep efficiency at group level (r [26] =-.343, p =.037).

Conclusions: This study provides further evidence of objective and subjective sleep disturbance in a large sample of autistic children with ID. Preliminary results indicate that number of time periods in which self-injury occurred has a negative relationship with sleep efficiency, highlighting the importance of using dynamic measures of sleep and behaviour, as part of an at-home extended assessment, rather than relying on static informant-report measures.

416.312 (Poster) Testing the Stability of Co-Occurring Mental Health Difficulties in a Longitudinal Cohort Study of Autistic Youth
E. Roberts1, N. Wright1, V. Courchesne1, A. Zaidman-Zaït1, C. M. Kerns1, E. Duke1, S. Georgiades1, I. M. Smith1, L. Zwaigenbaum1, P. Szatmari1, T. Bennett1, T. Vaillancourt1, W. J. Ungar1, A. E. Richard1, T. Bennett1, R. Bedford1 and M. Elsabbagh1, (1)University of Bath, Bath, (2)Department of Psychology, Manchester Metropolitan University, Manchester, United Kingdom, (3)Centre for Addiction & Mental Health (CAMH), Montréal, QC, Canada, (4)Tel-Aviv University, Tel-Aviv, ISRAEL, (5)University of British Columbia, Vancouver, BC, Canada, (6)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (7)Dalhousie University / IWK Health Centre, Halifax, Canada, (8)Autism Research Centre, University of Alberta, Edmonton, AB, Canada, (9)Department of Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (10)University of Ottawa, Ottawa, ON, Canada, (11)The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (12)Autism Research Centre, IWK, Halifax, NS, Canada, (13)Hamilton Health Sciences, Hamilton, ON, Canada, (14)University of Bath, Bath, United Kingdom, (15)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada

Background: Experiencing a particular mental health difficulty is a strong predictor of experiencing the same difficulty later in life, a phenomenon known as homotypic continuity. However, the experience of particular early psychological difficulties also predicts different difficulties later on, a phenomenon known as heterotypic continuity. While both continuities have been well-established in neurotypical samples, there is limited evidence examining the trajectory of homo- or heterotypic continuity of mental health difficulties in young people with autism. The small number of existing studies have failed to adjust for possible confounders or only examined individuals at two developmental timepoints, possibly masking more complex fluctuations over time.

Objectives:
To clarify the trajectory of homo- or heterotypic continuity in autistic youth by using a prospective cohort study to examine the association between mental health syndrome scales, measured at three different timepoints through childhood and adolescence.

Methods:

Participants were prospectively measured as part of the Pathways in ASD study, a large Canadian cohort study of autistic youth (n = 421, 85% male). Mental health data were collected using the Child Behaviour Checklist (CBCL) at multiple timepoints through childhood. We used CBCL data collected at 2-4 (Time 1), 7-8.5 (Time 2), and 10-12 years of age (Time 3). Analyses used the Anxious/Depressed, Aggressive Behaviour and Attention Problems subscales. Associations between the subscales at the three timepoints were examined using regression analyses. Hypothesised confounding variables (sex, IQ, autism symptom severity, social economic status, parental mental health, and recruitment site) were included in analyses.

Results:

Subscale scores at earlier timepoints were associated with their equivalents at later timepoints – evidence of homotypic continuity. Scores at Time 1 were associated with the same scores at Time 2 (Anxious/Depressed β = .32, p = .001; Aggressive Behaviour β = .34, p < .001; Attention Problems β = .27, p = .001) and Time 3 (Anxious/Depressed β = .15, p = .041; Aggressive Behaviour β = .30, p = .002; Attention Problems β = .16, p = .013). Evidence for heterotypic continuity was limited to one cross-subscale association – Aggressive Behaviour scores at Time 1 were negatively associated with Anxious/Depressed scores at Time 3 (β = -.22, p = .017).

Conclusions:

Mental health symptoms are consistent across childhood development for autistic youth. These results demonstrate the importance of the early identification of, and intervention for, mental health difficulties. There is less evidence for heterotypic continuity in this population, which suggests that a single p factor may not underlie multiple conditions, and that the increased prevalence of different psychological disorders among autistic populations may each require their own explanatory framework. It may be the case that pathways of developmental change are fundamentally different in autistic populations compared to typically developing populations; further research is required to adequately answer this question.

416.313 (Poster) The Association between Emotion Regulation, Autism Traits, Borderline Personality Traits and Childhood Trauma: A Comparison between Adults with ASD and Adults with BPD.

(1)Psychiatry, Hospital Universitari Vall d’Hebron, Barcelona, Spain, (2)Hospital Universitari Vall d’Hebron, Barcelona, Spain, (3)University of Salamanca, Salamanca, Spain, (4)Instituto Universitario de Integración a la Comunidad INICO-InFoAutismo, Universidad de Salamanca, Salamanca, Spain

Background: Difficulties in emotional regulation are considered a transdiagnostic condition that affects a large number of diagnostic categories. Two of these are Autism Spectrum Disorder (ASD) and Borderline Personality Disorder (BPD). There is evidence of overlapping in some characteristics of both disorders (e.g., cognitive inflexibility), however the evidence on the relationship of clinically relevant variables with difficulties in emotional regulation in these two populations is scarce.

Objectives: The objective of the present study is to compare the scores on measures of autism, borderline personality, and childhood maltreatment in two groups of people with ASD and BPD, as well as to study the relationship of these variables with difficulties in emotional regulation.

Methods: Two groups of adult participants were recruited from the ASD (n = 53) and BPD (n = 44) specialized outpatient programs of a Tertiary Hospital. Exclusion criteria were established as a full-scale IQ of less than 70 in the participant with ASD and language and cognitive barriers in the respondents, as determined by clinical judgment. Assessment instruments included self-reported measures of autism (Autism Quotient Short-Form, AQ-Short), borderline personality (BPD Checklist, BPD-CL), childhood maltreatment (Childhood Trauma Questionnaire, CTQ), and emotional regulation (Difficulties in Emotion Regulation Scale, DERS). A set of independent t-tests were conducted comparing the two clinical groups on the study variables. Correlation analyses were performed using Pearson’s r in order to assess the association between the dependent (emotion regulation) and independent (sex, age, autism traits, borderline personality features, and childhood maltreatment) variables. Finally, two set of regression analyses using the stepwise method were carried out for each clinical group with the emotion regulation score (DERS Total) as an outcome and those variables whose correlations showed statistical significance (p < 0.05) as predictors. Only subscale scores were taken into account for the regression analyses.

Results: Compared with the ASD group, participants with BPD showed significantly more self-reported emotional regulation difficulties and reported a significantly higher prevalence of childhood sexual abuse. Within participants with ASD, emotion regulation difficulties was associated with all core features of the AQ-Short, but the strongest association was with switching subscale. Also in this group, all the BPD-CL subscales and the total score moderately correlated with difficulties in emotional regulation, even more than in the BPD group.
Only the emotional and physical neglect subscales were significantly associated with difficulties in emotional regulation in BPD participants. Regression analysis for ASD found BPD-CL affective instability, AQ-Short switching, female sex, and BPD-CL impulsivity to positively predict difficulties in emotional regulation. These variables explained 67% of the variance in emotional regulation difficulties. Transient paranoid/dissociative BPD-CL, AQ-Short switching, and female sex positively predicted difficulties in emotional regulation in the BPD group, with this model accounting for 42% of the variance.

Conclusions: The results suggest variables specifically related to difficulties in emotional regulation that could be considered when dealing with differential diagnosis between ASD and BPD adults. The small sample size and the lack of objective measures compromise the generalizability of the results. Future research on the present topics are warranted.

416.314 (Poster) The Longitudinal Relationship between Social Motivation and Depressive Symptoms in Autistic Adults

R. H. Himelstein, G. T. Han, Z. J. Williams and K. O. Gotham, (1)Psychology, Rowan University, Glassboro, NJ, (2)Anesthesiology, Vanderbilt University School of Medicine, Nashville, TN, (3)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN

Background: Autistic adults as a group have high mental health needs, with depression being one of the most common and clinically significant outcomes among this population. Identifying pathways to depressed mood in autistic adults may help to build resources for this underserved community, as causal contributors may translate to treatment targets around which to improve intervention efficacy. Smith and White’s (2020) social motivation model suggests that when there is a discrepancy between desire and opportunity for social connectedness, autistic adults become lonely, which then leads to depression; they postulate that, when desire and opportunity for social connectedness are both low, this lack of a discrepancy protects against loneliness and depression. In contrast to this model, empirical findings suggest that low desire for social interaction still correlates with loneliness and subsequently depressive symptoms (Han et al., 2019).

Objectives: We aim to test if social motivation moderates the relationship between social success and loneliness, such that individuals with greater social motivation and lower reported social connectedness will report higher levels of loneliness than participants with low social motivation. We further hypothesize that loneliness will prospectively predict growth in depressive symptoms over time in autistic adults.

Methods: Sample 1 includes autistic adults (AUT; N=49), non-autistic depressed adults (DEP; N=30), and non-autistic, non-depressed controls (CON; N=28) recruited locally for an in-person study. Measures included the Social Responsiveness Scale (SRS-2) as a proxy for social impairment, Loneliness in Context Questionnaire (LiCQ), and the Beck Depression Inventory-II (BDI-II). Sample 2 includes autistic adults (N=300) recruited through the SPARK online registry and surveyed three times within six months. Here, the PROMIS Emotional Support items and Satisfaction with Participation in Discretionary Social Activities items were used as an index of social connectedness, and the Overall Depression Severity and Impairment Scale (ODSIS) measured depressive symptoms. In both samples, the Anticipatory and Consummatory Interpersonal Pleasure Scale (ACIPS) indexed social motivation.

Results: Across diagnostic cohorts in Sample 1, the ACIPS (t(96) =2.52, p =0.01) significantly moderated the relationship between SRS-2 scores and loneliness (i.e., adults who reported high social motivation but also high social impairment were more likely to endorse loneliness). Further, loneliness (LiCQ) was the strongest predictor of depressive symptoms in the transdiagnostic sample (t(94)=8.02, p<0.001, adjusted R2 =.49) and AUT cohort alone (t(41)=3.41, p=0.001, adjusted R2=.33). Importantly, by the INSAR 2023 conference, we will have all three follow-up longitudinal waves collected to test if these patterns hold longitudinally, and with a more purposeful marker of social connectedness.

Conclusions: For socially motivated autistic individuals, the discrepancy between desire and opportunity for social interaction may lead to higher levels of loneliness, which then contributes to depression. These findings stand to enhance our understanding of social reward processes as a potential contributor to depression among autistic adults, with the ultimate goal of improving our ability to predict and intervene in those at risk for mood disorders.

416.315 (Poster) The Moderating Role of Reward Activation on the Link between Rumination and Withdrawn/Depressive Symptoms in Autistic Adolescents

L. Antezana, G. J. Siegle, T. N. Day, A. Collier and C. A. Mazeysky, Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA

Background: A meta-analysis has demonstrated that as compared to neurotypical people, autistic people demonstrate differences in brain reward network activation (processes as reward and punishment) in response to both external social (i.e., smiling faces) and monetary feedback (Clements et al., 2018). Given findings of altered reward activation in depressed adolescents (Forbes et al., 2006) and its associations with depressive symptomatology in neurotypical individuals, but not autistic individuals (e.g., Schalbroeck et al, 2021), we were interested in what individual differences might impact these associations. Rumination, a response style in which one repetitively focuses on negative mood or thoughts, has been theorized to potentiate withdrawn/depressed symptoms, such that it may provide an evidence-base that justifies withdrawal and this cycle of rumination and withdrawal can be reinforced as it reduces exposure to aversive situations (Nolen-Hoeksema et al., 2008). Greater rumination has been found in autistic vs. neurotypical samples. Considering the
relatively high rates of depressive symptoms in autism, we were interested in whether rumination, reward function, or their relationship could help to explain withdrawn/depressed symptoms in autistic adolescents.

**Objectives:** We aimed to (1) examine reward network activation during a loss condition in response to monetary reward in autistic vs. neurotypical adolescents, and (2) examine the role of reward mechanisms on the link between rumination and withdrawn/depressed symptoms in autistic adolescents.

**Methods:** Data were collected on 25 autistic (M(SD) age = 14.95(2.47) years) and 23 neurotypical adolescents (M(SD) age=15.5(2.76) years). Participants completed a coin toss task while undergoing a functional MRI scan. During the task participants were instructed to predict the result of a coin toss (heads/tails) with blocks characterized by winning or losing. A Region of interest (ROI) anatomical mask was derived from the Harvard-Oxford subcortical parcellation for dorsal striatum (caudate, putamen). Group differences for loss blocks were analyzed using AFNI 3dtest++ at p<.005, with an empirical contiguity threshold of 16 voxels within the ROI. Average beta weights were extracted for each participant for moderation analysis. Moderation was used to examine levels of reward activation on the link between rumination (Response to Stress Questionnaire) and withdrawn/depressed symptoms (Child Behavior Checklist) using SPSS PROCESS.

**Results:** The autistic group demonstrated diminished activation in an 18-voxel sub-region of the dorsal striatum, compared to the neurotypical group (Talairachx<sub>1</sub>=-14, 21, 38; Figure 1). Within the autistic group, dorsal striatal activation moderated the relationship between rumination and withdrawn/depressed symptoms (B=-.16, SE=.062, p<.05, ΔR<sup>2</sup>=.23), such that at lower dorsal striatal activation, greater rumination predicted greater withdrawn/depressed symptoms, while at higher levels of dorsal striatal activation greater rumination predicted lower withdrawn/depressed symptoms (Figure 2).

**Conclusions:** Consistent with previous work examining neural differences in response to reward, the autistic group demonstrated decreased dorsal striatal reactivity to loss compared to neurotypical adolescents. Dorsal striatal activation moderated the role of rumination on withdrawn/depressed symptoms in autism. These results suggest that for those who are less affected by external feedback, rumination is associated with depression. Yet for those who are more affected by external feedback, having the ability to ruminate might buffer against depression symptoms.

### 416.316 (Poster) The Relationship between Anxiety Symptoms and Adaptive and Social Functioning in Children with Autism Spectrum Disorder

**S. Terrosa**, G. L. Fjermedal¹, D. G. Sukhodolsky² and P. E. Ventola³, (1)Child Study Center, Yale University, New Haven, CT, (2)Ventola Lab, New Haven, CT, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT

Background: Anxiety is one of the most diagnosed comorbidities in children with ASD, occurring in about 40% of all cases (van Steensel et al., 2011). While deficits in social communication skills and adaptive behavior are considered core features of ASD, few studies have examined the relationship between these features and anxiety symptoms. Understanding the relationship between ASD and comorbid anxiety symptoms is an imperative first step in developing and delivering effective treatment and support.

**Objectives:** This project had two objectives. First, we examined the relationship between anxiety symptoms and adaptive and social functioning in children with ASD. Secondly, we examined the difference in social and adaptive skills of children with and without anxiety.

**Methods:** The study included 43 children aged 4-9 years old (M = 6.58 years, SD = 1.35). All children had an ASD diagnosis as confirmed by the Autism Diagnostic Observation Schedule (ADOS). Anxiety symptoms were assessed using the CBCL (1.5-5 (n = 21), 6-18 (n = 22). Parents also completed an assessment capturing their child’s adaptive behavior (VABS-3) as well as an assessment measuring their child’s social functioning (SRS-2).

**Results:** 1) CBCL anxiety subscale scores were negatively correlated with the VABS-3 Daily Living Skills domain (r(41) = -.37, p = .014). CBCL anxiety subscale scores were also negatively correlated with the VABS-3 Interpersonal Relationships subdomain (r(41) = -.30, p = .048). CBCL anxiety subscale scores were positively correlated with the SRS-2 Total Score, (r(41) = .48, p = .001; SRS-2 Social Cognition, r(41) = .42, p = .005; SRS-2 Social Communication r(41) = .42, p = .005; SRS-2 Social Motivation, r(41) = .38, p = .012, and SRS-2 RRIs, r(41) = .49, p < .001. 2) Participants who scored in the borderline or clinically significant range on the CBCL anxiety subscale (n = 16) had significantly lower adaptive and social skills than participants who scored below the clinical threshold (n = 27) on the VABS-3 Daily Living Skills, t(41) = -2.1, p = .041; VABS-3 Interpersonal subdomain, t(41) = -2.6, p = .014; SRS-2 Total Score, t(41) = 2.5, p = .018; SRS-2 Social Cognition domain t(41) = 2.1, p = .040; SRS-2 Social Communication domain t(41) = 2.1, p = .042; and SRS-2 Restricted Interests and Repetitive Behavior domain t(41) = 2.7, p = .010.

**Conclusions:** Higher anxiety symptoms were significantly related to greater impairment in adaptive daily living and interpersonal relationship skills. Additionally, elevated anxiety symptoms were also significantly related to higher core social impairment. These findings support the idea that anxiety may further impact existing social difficulties, highlighting the need to target and treat anxiety in addition to core symptoms of ASD. Further, participants who scored in the Borderline/Clinically Significant range on the CBCL anxiety subscale had...
significantly lower adaptive skills and social functioning than participants who scored below the threshold. This finding supports the idea that clinically significant anxiety is linked to increased deficits in adaptive and social functioning beyond the core autism symptoms and requires targeted treatment.

416.317 (Poster) Timing and Risk Factors for Depression Among Autistic Children and Adolescents: Key Findings to Inform Depression Prevention Efforts

**J. L. Kuhn**, H. Cabral, R. C. Sheldrick and E. Feinberg; (1)Pediatrics, Boston Medical Center, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)Brown University School of Public Health, Providence, RI

**Background:**

Research evidence suggests that autistic people have a uniquely high lifetime prevalence of depression, with recent estimates suggesting rates between 29% and 50%. This rate is three-to-five-times that of the general population. While these concerning findings should inspire depression prevention efforts that focus on autistic people, little is known about the timing and specific risk factors for developing depression within this heterogeneous population. Such information is needed to inform efforts to prevent depression among autistic people.

**Objectives:**

With a goal to inform prevention efforts during childhood and adolescence, we sought to answer the following research questions:

- What are key risk factors of developing depression among autistic children and adolescents?
- As children and adolescents age, how does the prevalence or predicted probability of current depression differ for those with versus without autism?

**Methods:**

We used data collected between June 2020 and January 2021 for the US Census Bureau’s 2020 National Survey of Children’s Health, a nationally representative survey of households with children ages 0-17 years in the United States (n = 42,777; see Table 1 sociodemographic characteristics). To achieve correct weighted population sizes and variances, survey weights were applied. First, we built a best-fit model of predictors for currently having depression within the subpopulation of autistic individuals. Then, with the full dataset, we used logistic regression to estimate the interaction between age and autism status when predicting current depression diagnosis, controlling for other pertinent predictors. Last, to illustrate changes in prevalence rates and predicted probability of current depression across age stratified by autism diagnostic status, we generated a weighted unadjusted plot and a weighted adjusted plot based on the logistic regression model.

**Results:**

Holding the adequacy of the child’s health insurance coverage constant, our best-fit model (McFadden Pseudo-R-squared = 0.402, indicating excellent fit) suggests the following as statistically significant predictors of depression within autistic children and adolescents: female gender, a higher number of adverse childhood experiences, a higher frequency of being bullied in the past year, higher intellectual ability, higher severity of anxiety symptoms, and older age. Full model results including odds ratios and confidence intervals are reported in Table 2.

In a separate logistic regression model predicting current depression incidence among the full weighted sample, we found that while autism (aOR = 2.49; CI = 1.59 to 3.89), age (aOR = 1.34; CI = 1.28 to 1.41), and other relevant covariates significantly predicted currently having depression, a significant interaction exists between autism diagnostic status and age (p < 0.05). The prevalence and predicted probabilities of current depression among those with and without autism are presented in Figures 1 and 2.

**Conclusions:**

Depression prevention efforts targeting the needs of autistic children and adolescents are likely to be most impactful if geared toward those whose identities, life experiences, intellectual abilities, and anxiety symptoms put them at a higher risk for developing depression. Furthermore, compared to the general population, autistic children display depression at an earlier age, with a steady increase through adolescence.

416.318 (Poster) Transdiagnostic Pathways to Understanding Anxiety and Depression in Autistic Adolescents and Adults

**L. P. Lawson**, A. L. Richdale, A. Chalmers, M. Ujarevic, E. Morris, S. Arnold and J. N. Trollor; (1)Department of Psychology, Counselling & Therapy, La Trobe University, Melbourne, VIC, AUSTRALIA, (2)Cooperative Research Centre for Living with Autism
**Background:** Anxiety and depression frequently co-occur among autistic individuals and exceed prevalence rates reported in non-autistic populations. These co-occurring conditions have been linked to poorer employment outcomes and reduced quality of life for autistic adults. Developing our understanding of how anxiety and depression develop and are maintained by examining transdiagnostic factors is essential to creating effective support options. Several transdiagnostic factors have been implicated in the development and maintenance of anxiety and depression in autistic adults, including insomnia, autistic traits, intolerance of uncertainty, sensory sensitivity, and autonomic symptoms. However, to date no work has used a singular model to examine the relationships between all these constructs.

**Objectives:** To explore relationships between transdiagnostic factors, autistic traits, insomnia, anxiety, and depression in sample of autistic adolescents and adults.

**Methods:** Participants were drawn from the Study of Australian School Leavers with Autism (SASLA) and Australian Longitudinal Study of Autistic Adults (ALSAA) baseline surveys. The sample for this study consisted of 183 autistic people aged 15-80 years (55.2% female), with no co-occurring intellectual disability. Using path analysis, we tested four hypothesis driven models examining inter-relationships between intolerance of uncertainty (IU-12), sensory sensitivity (GSQ), autonomic symptoms (COMPASS-31), autistic traits (AQ-short), insomnia (PSQI), anxiety (DSM-GAD), and depression (PHQ-9).

**Results:** For the four models, analyses were initially conducted using a fully saturated model (df=0), where non-significant pathways and paths with coefficients <.10 were removed. Bootstrapping was performed with 1,000 resamples and 95% confidence intervals were determined. Model 1 provided the best fit to the data, explaining 50% of variance in depression, 37% of variance in anxiety, and 29% of variance in insomnia. Autistic traits, intolerance of uncertainty, and insomnia were directly associated with anxiety and indirectly associated with depression through anxiety. Anxiety, insomnia, sensory sensitivity, autonomic arousal, and intolerance of uncertainty were all directly associated with depression; autonomic arousal and sensory sensitivity were also indirectly associated with depression through insomnia.

**Conclusions:** The results highlight that multiple transdiagnostic factors contribute to anxiety and depression symptoms among autistic individuals. These include not only known pathways such as insomnia and intolerance of uncertainty, but also somatic symptoms and sensory sensitivity. The model did not support a direct relationship between intolerance of uncertainty and insomnia, which could indicate that for autistic people cognitive arousal (e.g., intolerance of uncertainty) is not as salient as physiological arousal (e.g., sensory sensitivity and autonomic symptoms) with respect to insomnia. This pattern of results does not align with the non-autistic literature. The data illustrate the need for careful clinical evaluation and individualised support plans for autistic adults presenting with anxiety or depression difficulties. Results highlight the need to not rely on relationships established in non-autistic populations to drive clinical decision making for autistic people.

416.319 (Poster) Discrimination Against Autistic Adults in Kidney Transplantation: Comparing Transplant Rates and Outcomes Among Autistic and Non-Autistic Adults with End-Stage Renal Disease

**B. N. Hand**, J. M. Hyer, A. Schenk, A. Coyne, D. Gilmore, L. Wang and A. Ejaz, (1)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, (2)The Ohio State University, Columbus, OH, (3)University of Cincinnati, Cincinnati, OH

Background: Equity in organ transplantation for people with autism and other developmental disabilities is a topic of social discourse in US media and legislation. This topic was highlighted at the 2022 American Medical Association conference and the US Department of Health and Human Services is currently seeking public comments on how to improve equity and reduce disparities in organ transplantation. At the congressional level, a new House bill is under consideration that would prohibit denying access to organ transplants on the basis of disability. This proposed federal legislation has launched the topic of equity in organ transplantation into US mainstream media and social dialogue. However, studies examining disparities in transplant rates and outcomes among autistic adults to inform evidence-based policymaking initiatives are lacking.

**Objectives**: Compare odds of kidney transplantation and transplant-specific outcomes between propensity-score matched groups of adults with end-stage renal disease (ESRD) with and without co-occurring autism.

**Methods**: As all people with ESRD are eligible for Medicare in the US, we performed a retrospective study using 100% Medicare inpatient and outpatient standard analytical files from 2013-2020. Autistic adults were included if they were aged 18 years or older and had at least one encounter with a diagnosis of ESRD. Propensity-score matching was used to identify a comparison group of non-autistic adults with ESRD who were well-balanced with the autistic adult sample based on age, sex, race, and Charlson Comorbidity Index. The matched cohorts consisted of 2074 adults with ESRD (n=1037 autistic adults) and 344 kidney transplant recipients (n=139 autistic adults). Our outcome measures were: (1) evaluation for kidney transplantation, (2) kidney transplantation, (3) peri-operative complications, and (4) 90-
day readmissions. We used logistic regression to compare autistic and non-autistic adults on the odds of each outcome, controlling for sex, age, and Charlson Comorbidity Index.

Results: Table 1 provides the matched cohort characteristics. Relative to matched peers, autistic adults had 39% lower odds of being evaluated for transplantation (OR=0.61; 95%CI=0.50-0.75; p<0.0001). Among those who were evaluated, autistic adults had 29% lower odds of receiving a kidney transplant (OR=0.71; 95%CI=0.51-0.99; p=0.04). Among matched cohorts of kidney transplant recipients, odds of peri-operative complications and 90-day readmissions were similar for autistic and non-autistic adults (all p>0.05).

Conclusions: Using a large, US national cohort of autistic adults with ESRD, we found rates of evaluation and transplantation were lower for autistic adults than non-autistic peers. Yet, among transplant recipients, peri-operative and 90-day outcomes were similar for autistic and non-autistic adults. This study adds to a growing US national discourse around equal access to organ transplantation for people with disabilities. We recognize that organ transplantation is a lifelong care-intensive undertaking and that, like non-autistic peers, some autistic adults may not be strong candidates for transplantation. However, autistic adults deserve (and legally have a right to) equal access to evaluation and full, holistic consideration as to whether they would be good transplant candidates. Ultimately, our results bolster the body of evidence supporting full consideration of autistic adults for kidney transplantation and the urgent need for anti-discrimination initiatives.

416.320  (Poster) United States National Update of Health Condition Prevalence Among Privately-Insured Autistic Adults
A. Longo, D. Radford and B. N. Hand, (1)The Ohio State University, Columbus, OH, (2)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH

Background: An increasing amount of literature shows autistic adults are more likely to experience many mental and physical health conditions than the general population. Estimates of physical and mental health condition prevalence among autistic adults can help inform healthcare providers, health promotion initiatives, and healthcare policies aiming to better meet autistic adults’ needs. Prior studies on the prevalence of health conditions among autistic adults using healthcare claims data laid important groundwork for the field but used local or regional data from 2008-2015, which may or may not be consistent current United States (US) national prevalence estimates. We will build on this important work by providing updated prevalence estimates using US national data from 2019-2020 to provide a current, comprehensive picture of the health of autistic adults to inform healthcare, health promotion, and policy initiatives.

Objectives: Compare odds of mental and physical health conditions among autistic adults to age and sex-matched peers.

Methods: We analyzed IBM Marketscan data from 2019-2020, containing inpatient and outpatient healthcare claims from privately uninsured people across the US. Autistic adults (n=30,258) were included if they were aged 18-65 years and had one inpatient or two outpatient encounters with an autism diagnosis. We also identified a population comparison (PC) group of age and sex-matched adults without autism diagnoses (n=60,516). We identified mental and physical health conditions from healthcare claims using the Healthcare Cost and Utilization Project Beta Multilevel Clinical Classification Software for ICD-10, which groups codes in healthcare claims into a smaller number of clinically relevant categories. We used logistic regression models to compare autistic and non-autistic adults on the odds of each mental and physical health condition, controlling for sex, age, and rural residence.

Results: Table 1 provides sample characteristics. Autistic adults had significantly greater odds of all physical health conditions except multiple sclerosis, respiratory infections, arthritis, back conditions, and fractures (Table 2). The largest between-group differences in physical health conditions were epilepsy (OR=8.1, 95%CI=7.6-8.8), osteoporosis (OR=2.9, 95%CI=2.2-3.8), and obesity (OR=2.6, 95%CI=2.5-2.7). Autistic adults also had significantly greater odds of all mental health conditions except substance use disorders. The largest between-group differences for mental health conditions were schizophrenia and psychotic disorders (OR=8.5, 95%CI=7.7-9.3), attention deficit disorders (OR=6.6, 95%CI=6.3-6.8), and personality disorders (OR=6.5, 95%CI=5.7-7.4).

Conclusions: Using the largest US-based sample to-date to provide current, comprehensive estimates of health condition prevalence among privately insured autistic adults. To our knowledge, this study is also the first to estimate the prevalence of health conditions among autistic adults using a US national sample. Consistent with prior studies, we found that autistic adults had significantly greater odds of most physical and mental health conditions. These findings alert healthcare providers and policymakers to health conditions most common among autistic adults to improve screening and management of these conditions, inform initiatives to improve access to healthcare, and guide future funding priorities. Ultimately, this work supports prioritization of innovative, comprehensive person-centered healthcare approaches to evaluate and address specific mental and physical healthcare needs of autistic adults.

416.321  (Poster) Mechanisms Underlying Suicidality in Autistic People with Attention Deficit and Hyperactivity Disorder (ADHD): Testing Hypotheses from the Interpersonal Theory of Suicide
R. Moseley, N. J. Gregory', P. Smith', C. Allison', S. A. Cassidy' and S. Baron-Cohen', (1)Department of Psychology, Bournemouth University, Poole, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (4)School of Psychology, University of Nottingham, Nottingham, UNITED KINGDOM

Results: Table 1 provides the matched cohort characteristics. Background:

While suicidality is especially common within the autistic population, certain individuals seem to be at particularly high risk. Autistic people with co-occurring ADHD appear to be one such group, but the reason for their heightened risk is unknown. Over and above identifying risk factors, understanding why they increase suicide risk is important to develop targeted interventions or strategies for support and prevention. Here, two explanatory mechanisms from the interpersonal theory of suicide (ITS) might be especially pertinent. Firstly, autistic people with co-occurring ADHD are at even greater risk of academic underachievement, unemployment, financial distress, and psychiatric illness, all factors associated with two cognitive-affective states, thwarted belongingness and perceived burdensomeness, which evoke suicidal feelings. The ITS suggests that for people to act on suicidal feelings, they must have acquired ‘capability’ for suicide, which occurs when individuals are habituated to pain and to thoughts of death. The model suggests this typically happens through exposure to traumatic (‘painful and provocative’) events, which, through increasing pain tolerance and eroding fear of pain and death, increase suicide risk through their impact on suicide capability. Given the association between hyperactive/impulsive features and violent and/or traumatic life events, autistic people with co-occurring ADHD may be more likely to acquire capability to enact suicidal thoughts.

Objectives:

We examined two causal pathways to explain heightened suicide risk in autistic people with co-occurring ADHD: firstly, through greater likelihood of thwarted belongingness and perceived burdensomeness; and secondly, that hyperactive/impulsive features might particularly increase risk of painful and provocative events, and through these acquired capability for suicide.

Methods:

Autistic adults (n = 314) completed an online survey including measures of four ITS constructs (thwarted belongingness, burdensomeness, painful and provocative events, and acquired capability) and the Connors Adult ADHD Rating Scale. First, we examined associations between co-occurring ADHD, past-year suicide ideation and lifetime suicide attempts via the parallel mediators of thwarted belongingness, burdensomeness, and anxiety and depression. In several models, we then examined hyperactive, impulsive and inattentive features as predictors of exposure to painful and provocative events and subsequent capability for suicide, and examined whether these two variables, sequentially or individually, mediated an association with lifetime suicide attempts.

Results:

ADHD co-occurrence was associated with past-year ideation via greater feelings of depression and burdensomeness, which also mediated its association with more lifetime suicide attempts. Hyperactive and impulsive features were associated with greater exposure to painful and provocative events, through this greater suicide capability, and henceforth more numerous lifetime suicide events. An additional pathway between both feature-types and lifetime suicide attempts was seen via painful and provocative events alone, suggesting that these events increased suicide risk irrespective of their effect on suicide capability.

Conclusions:

These data suggest that elevated suicidality in autistic people with co-occurring ADHD may be partially related to burdensomeness and to acquired suicide capability following exposure to painful and provocative events. However, as we observed a pathway to suicidality associated with painful and provocative events alone, it is likely that there are other mechanisms through which trauma heightens suicide risk.

Non-Suicidal Self-Injury and Its Relation to Suicide in Autistic People: A Test of Acquired Capability for Suicide As a Causal Mechanism

R. Moseley, N. J. Gregory, P. Smith, C. Allison, S. A. Cassidy and S. Baron-Cohen, (1)Department of Psychology, Bournemouth University, Poole, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (4)School of Psychology, University of Nottingham, Nottingham, UNITED KINGDOM

Background:

Non-suicidal self-injury (NSSI) is more common in autistic than non-autistic people and serves a range of intrapersonal and interpersonal functions; its defining feature is that it occurs in the absence of suicidal intent. While some autistic people perceive their NSSI as a benign or even positive coping strategy, a worrying relationship between NSSI and increased likelihood of future suicide attempts has been observed in both autistic and non-autistic populations. By way of explaining how non-suicidal behaviour might increase future suicide risk, psychological theory suggests that NSSI might confer capability for suicide through means of increasing pain tolerance, eroding fear of pain and death, and mental rehearsal of suicide. From this perspective, more numerous and more painful/graphic forms of NSSI are especially potent with regards to acquiring suicide capability, such that individuals would later be able to act on suicide ideation if it
occurred. This mechanism for explaining the link between NSSI and later suicidal behaviour has not been examined in autistic people; nor do we know whether certain NSSI behaviours might warrant particular concern.

Objectives:

We aimed to explore acquired capability as the mediator of increased suicide risk associated with NSSI in autistic and non-autistic adults, examining moderating effects of diagnosis on these relationships. Second, we explored whether particular forms and characteristics of NSSI might be especially associated with capability and suicide.

Methods:

Autistic and non-autistic adults (n=314, n=312) completed an online survey exploring lifetime suicide attempts, experience with NSSI, and acquired capability for suicide. We explored relationships between lifetime incidence of NSSI and lifetime suicide attempts via three facets of capability (pain tolerance, reduced fear of death, mental rehearsal of suicide). In self-harming participants (224 autistic and 156 non-autistic), we explored whether capability mediated associations between suicide attempts and four NSSI-related predictors: engagement in scratching, cutting and self-hitting as forms of NSSI, and greater number of different NSSI behaviours.

Results:

While higher frequency of NSSI was associated with all three facets of acquired capability in both groups, only reduced fear of death and mental rehearsal of suicide mediated an indirect relationship between NSSI and lifetime suicide attempts. More NSSI also directly predicted more numerous suicide attempts. Autistic people tended towards reduced fear of death and mental suicide rehearsal regardless of NSSI status. Among self-harming autistic and non-autistic participants, cutting and increased number of NSSI behaviours were particularly strongly associated with lifetime suicide attempts, with acquired capability only partially mediating these relationships. Acquired capability did, however, fully explain an association between self-hitting and lifetime suicide attempts in both groups.

Conclusions:

Our data suggest that acquired capability only partly explains the association between NSSI and suicide risk. This relationship (especially pertaining to certain forms of NSSI, like cutting) might be partly explained by a third variable common to both, such as the presence of mental illness. A broader conceptualization of suicide capability, with innate and acquired factors of varying stability, may also offer greater explanatory power as regards understanding relationships between NSSI and other life events and suicidality.

POSTER SESSION — MEDICAL AND PSYCHIATRIC COMORBIDITY

424 - Medical and Psychiatric Comorbidity I

424.246 (Poster) Aggression: Comparisons in Autistic and Neurotypical Youth across Childhood

Background: Approximately half of autistic youth experience issues with aggression. Aggression can exacerbate the problems autistic youth often already experience with peers, and it can be a precipitating factor in inpatient hospitalizations, referral to longer-term residential programs, and expulsion from school. Unfortunately, the prevalence and characterization of aggressive behaviors across development in this population remains poorly understood. Furthermore, the literature infrequently explores similarities or differences in aggression for autistic versus neurotypical youths.

Objectives: The current study attempted to better characterize aggression in autistic youth, building on extant literature in several ways: 1) data was collected from large samples of autistic youth and age-matched neurotypical youth (ages 3-17 years), 2) multiple measures of aggressive behavior and related constructs (i.e., anger, disruptive behavior) were used for a comprehensive assessment of youth functioning, and 3) qualitative descriptions were also collected to understand parental concerns.

Methods: Caregivers of autistic children were recruited from the Simon Foundation’s Powering Autism Research (SPARK) database. Caregivers of neurotypical children were recruited online through a digital software company (i.e., Cint). Families of children (<6, 6-12, 13-17 years) with autism (N = 450) and neurotypical children (N = 432) completed multiple measures of aggressive behavior. Families completing the assessments included mostly mothers (82.2%) who were married (78.0%) with at least a bachelor’s degree (59.6%). Children were largely male (79.0%) averaging 9.70 years; were White, non-Latinx (83.1%) followed by Latinx (16.6%) and then Black (8.6%). Child demographic variables did not differ between groups.
Background:

Anxiety disorders are the most prevalent co-occurring mental health problem in autism spectrum disorder, impacting negatively numerous life domains. Accurately measuring anxiety in autism has proven challenging and fraught with complexities. Despite anxiety symptoms being divided into different anxiety disorders, these are frequently associated, resulting in an individual experiencing symptom from several seemingly distinct diagnostic categories. Moreover, symptoms of anxiety and autism are often difficult to disentangle, and the large heterogeneity in autism symptoms and other individual characteristics, may also affect the presentation of anxiety symptoms. These unresolved complexities, emphasize the need to further study the phenomenology of anxiety symptoms in autism. Network theory has the potential to do just this. According to network theory, interactions between the symptoms themselves is constitutive of the disorder. In network theory, mental disorders are seen as complex dynamic system of interacting symptoms that influence each other, with some individual symptoms playing a unique and central role in relation to other symptoms.

Objectives:

To examine the network structure of anxiety symptoms in a large sample of autistic children and adolescents. Specifically, to investigate the interconnection among anxiety symptoms across various anxiety disorders and to determine which symptoms form distinct communities. Furthermore, to examine whether anxiety symptoms exhibit differential relationships with clinically relevant variables such as autism features.

Methods:

We utilized a large, pooled sample of 1133 of autistic children and adolescents (M age = 11.25 years, SD age = 2.54; 149 females) and analyzed their caregivers’ report on anxiety symptoms using the Spence Children’s Anxiety Scale-Parent Version. We estimated Gaussian Graphical Model network, a regularized partial correlation network model. The graphical lasso was used to ensure estimation of spurious edges. To estimate the structural importance of individual symptoms, we examined node strength centrality (i.e., the number and strength of connections a node has with other nodes), theoretically proposed to denote the importance and clinical relevance of symptom within a network. To identify which symptoms, tend to cluster together we performed community detection analyses using the Louvain algorithm. Last, we carried out state-of-the-art stability and accuracy analyses.
Results:

The anxiety network featured a highly inter-connected structure; all domains correlated but to varying degrees. Figure 1 presents the network structure with symptoms colored according to the communities identified by the Louvain community detection algorithm. Positive edges are found among nodes belonging to the same community as well as among nodes belonging to different communities. Social anxiety and generalized anxiety symptoms were strongly connected and tend to cluster together. Symptoms of generalized anxiety had the highest strength centrality (e.g., worries about things). Results in relation to autism features will also be discussed.

Conclusions:

Findings demonstrate the interconnected nature of anxiety disorders, manifests along multiple, inter-connected symptom domains. Findings revealing high connectivity of generalized anxiety symptoms suggests that worry shared across other more specific domains. Findings attest to the potential value of applying the network approach for a more detailed and nuanced description of the structure of anxiety symptoms in autism.

424.248 (Poster) Anxiety and Depression Mediated the Relationship between Autistic Traits and Eating Disorder Psychopathology

L. S. Iao and C. Hyland, (1)Nottingham Trent University, Nottingham, UNITED KINGDOM, (2)Nottingham Trent University, Nottingham, United Kingdom

Background:

Autistic individuals often do not only experience the core symptoms of Autism Spectrum Disorder (ASD; e.g., difficulties in social communication) but also co-occurring mental health issues (e.g., anxiety, depression and eating disorders; Brede et al., 2020; Hollocks et al., 2019). ASD can manifest in individuals in a variety of severity levels (Gotham et al., 2009), representing one end of a continuum. In this continuum, traits associated with ASD are higher in autistic individuals, intermediate in first degree relatives of autistic individuals, and lower in neurotypical individuals (e.g., Wheelwright et al., 2010). These autistic traits are positively associated with symptoms of anxiety, depression and eating disorders in both autistic and non-autistic individuals (e.g., Coombs et al., 2011; Kanne et al. 2009). However, the nature of these associations remains unclear.

Similar to autistic individuals, individuals with Anorexia Nervosa (AN) also often experience co-occurring mental health issues, particularly anxiety and depression (e.g., Riquin et al., 2021). Although this co-occurrence may be explained by neuroendocrinological imbalances induced by starvation, there are evidence suggesting that individuals with AN have pre-existing anxiety and depression (Johnson et al., 2002; for a review, see O’Brien & Vincent, 2003) which could be related to higher autistic traits.

Objectives:

Study 1 studied the relationships between autistic traits, anxiety, depression and eating psychopathology in a non-clinical sample. Study 2 replicated and furthered Study 1 by having a larger sample, using shorter measures as well as controlling for alexithymia which is a difficulty in identifying emotions and another common co-occurrence in ASD and eating disorders (e.g., Kinnaird et al., 2019; Westwood et al., 2017).

Methods:

In Study 1, 178 adults (136 females, 32 males, 10 non-binary; mean age = 27.61, SD = 11.33, age range = 18-64) participated in an online survey measuring depression (the Patient Health Questionnaire; Kroenke & Spitzer, 2002), anxiety (the Beck Anxiety Inventory; Beck et al., 1988), autistic traits (the Autism-Spectrum Quotient; Baron-Cohen et al., 2001) and eating psychopathology (the Eating Attitudes Test; Garner et al., 1982). Four hundred and fifty-four adults (365 females, 66 males, 18 non-binary, 4 prefer not to say; mean age = 23.16, SD = 6.73, age range = 18-72) participated in Study 2 which used the short Depression Anxiety Stress Scales (Henry & Crawford, 2005) for anxiety, the short Autism-Spectrum Quotient (Booth et al., 2013) and the short Eating Disorder Examination Questionnaire (Gideon et al., 2016) instead, plus the short Toronto Alexithymia Scale (Williams & Gotham, 2021) and the Patient Health Questionnaire.

Results:

Results from both studies showed that anxiety and depression mediated the relationship between autistic traits and eating psychopathology. Results in Study 2 further revealed that these were indirect-only mediations while controlling for alexithymia.

Conclusions:
These findings suggested that individuals with higher autistic traits are more likely to experience symptoms of anxiety and depression which in turn increasing the likelihood of experiencing symptoms of eating disorders. However, cautions would need to be made in concluding any causality of these relationships given that the data was cross-sectional.

424.249 (Poster) Anxiety and Depressive Symptoms in Autistic Adolescents and Youths: Investigating Risk and Protective Factors
R. Cardillo and I. C. Mammarella, Department of Developmental and Social Psychology, University of Padova (IT), Padova, Italy

Background: Anxiety and depression appear to be among the most common comorbid conditions in children and youths with autism spectrum disorders (ASD) conferring unique impairments in their quality of life (White et al., 2018). Different factors were found to be involved in the regulation (adaptive emotion regulation strategies, social support) and maintenance (maladaptive emotion regulation strategies, worry, rumination) of these psychiatric symptoms in the general population (Scardera et al., 2020; Schäfer et al., 2017; Young & Dietrich, 2015). However, few studies have investigated anxiety and depressive symptoms in autistic adolescents considering different risk and protective factors (Yarger & Redcay, 2020) and none have analyzed together the role of cognitive processes such as worry and rumination, emotion regulation strategies and perceived social support.

Objectives: The aim of the present study was to explore the level of comorbid symptoms of anxiety and depression in autistic adolescents and youths, comparing them with a matched group of non-diagnosed (ND) peers. The role of risk (repetitive negative thoughts, maladaptive emotion regulation strategies) and protective (perceived social support, adaptive emotion regulation strategies) factors contributing to these comorbid anxiety and depression symptoms was also considered.

Methods: A total of 124 Italian adolescents and youths (ASD group with no intellectual disability=41 (35 M); matched ND group = 83 (71 M); aged 13-20 years; mean age=16.75 years, SD=1.69 years; no difference between groups in the Full Scale Intelligence Quotient (F(1, 122)=1.72, p=.19)) were recruited. Self-reports assessing anxiety, depression, repetitive negative thoughts (i.e. worry and rumination), emotion regulation strategies, and perceived social support were administered. First, a series of univariate ANOVA were performed in order to highlight similarities and differences between groups. Second, regression analyses were conducted to investigate the associations among the dependent variables (anxiety and depression) and the hypothesized risk and protective factors.

Results: Higher levels of anxiety $[F(1, 122)=37.69, p<.001]$ and depression $[F(1, 122)=6.56, p=.01]$ were found for the ASD group as compared to the ND group. The significant contribution of similar factors emerged in association to the two groups’ anxiety symptoms: higher levels of worry $[B=-.46, p<.001]$ and maladaptive emotion regulation strategies $[B=.27, p=.04]$ corresponded to higher anxiety, while higher perceived social support $[B=-.27, p=.008]$ corresponded to lower anxiety. Concerning depression, the significant effect of similar risk factors emerged for the two groups (i.e. rumination $[B=.40, p=.02]$ and maladaptive emotion regulation strategies $[B=.36, p=.03]$), while the effect of different protective factors emerged: higher levels of adaptive emotion regulation strategies for the ASD group $[B=.25, p=.05]$ and higher perceived social support for the ND group $[B=.27, p=.03]$ were significantly associated with lower depression.

Conclusions: Overall, our findings showed higher anxiety and depressive symptoms in autistic adolescents and youths as compared to the ND group. The significant role of similar risk factors, in explaining anxiety and depression symptoms of both groups emerged. However, different protective factors seem to contribute to their depressive symptoms, revealing that support different abilities might be relevant to reduce these symptoms in each group. The clinical and preventive implications of these findings are discussed.

424.250 (Poster) Anxiety, Depression, and Well-Being in Autistic Adults: A Longitudinal Cross-Lagged Analysis
H. K. Schiltz; K. Sterrett; H. Singer; and C. Lord; (1)UCLA, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)UCLA CART (Center for Autism Research and Treatment), Los Angeles, CA, (4)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

Background: Autistic people are at high likelihood for anxiety and depression, which can negatively affect a host of outcomes. Although we have a growing understanding of internal and external factors that might place an autistic person at greater risk for these mental health concerns, there is limited research on the temporal links between anxiety and depression over time, and how this interplay might impact specific aspects of positive subjective well-being.

Objectives: First, we aimed to better understand the temporal associations between anxious and depressive symptoms in autistic adults by testing cross-lagged models. Second, we sought to understand how and if anxiety and depression explain unique variance in specific dimensions of well-being in autistic adults.

Methods: A sample of 131 autistic adults were drawn from an ongoing longitudinal study at two time points (Time 1 (T1): ages 18 – 26, M = 20.15, SD = 1.68; Time 2 (T2): ages 26 and older, M = 26.67, SD = 1.75). Depressive symptoms were measured at T1 and T2 with the Beck Depression Inventory- II (Beck et al., 1996) and scored using an IRT-based program developed for autistic adults (Williams et al., 2021). Anxious symptoms were measured at T1 and T2 with the Adult Manifest Anxiety Scale (AMAS; Reynolds et al., 2003). Wellbeing was measured at TP2 with the Scales of Psychological Well-Being (SPWB; Ryff, 1989) and included three subscales (purpose in life, self-acceptance, personal growth). All three measures were completed by caregivers in order to include participants of varying ability levels in
INSAR 2023 ANNUAL MEETING ABSTRACTS

the sample; a subsample \((n = 76)\) also provided self-report. Developmentally appropriate standardized IQ measures indexed cognitive ability and the Autism Diagnostic Observation Schedule Calibrated Severity Score (ADOS-CSS) measured autism features; both IQ and ADOS-CSS were included as covariates in all models. A cross-lagged panel analysis was run with caregiver-reported data, and given the smaller sample size, regressions were utilized with self-report.

**Results:** There were significant autoregressive effects for anxiety symptoms and depressive symptoms based on both caregiver-report (Figure 1) and self-report (Table 1). Based on caregiver-report, anxiety symptoms predicted later depressive symptoms, but depressive symptoms did not predict later anxiety (Figure 1). The opposite pattern was identified for self-report as depressive symptoms predicted later anxiety, but anxiety not predict later depression (Table 1). Anxiety was related to self-acceptance based on both self- and caregiver-report (Figure 1; Table 1). Depression was related to all three dimensions of well-being according to caregiver-report and only related to purpose in life via self-report (Figure 1; Table 1).

**Conclusions:** Results revealed that, although the pattern of findings differed across reporter, there was evidence for cross-lagged links between anxiety and depression over time among autistic adults. Additionally, aspects of positive well-being (purpose in life, self-acceptance, personal growth) demonstrated differential links with anxiety and depression. These findings highlight the potential utility of a transdiagnostic approach to mental health services for autistic adults, and the need to carefully monitor for anxious or depressive symptoms in autistic adults presenting with depression or anxiety, respectively.

424.251  (*Poster*) Assessment of Anxiety and Behavioral Disorders Among Children with Autism Spectrum Disorder and Other Neurodevelopmental Disorders

**M. B. Halvorsen**, E. R. Heiervang, B. Mathiassen, S. Kaiser and S. B. Helverschou, (1)Department of Pediatric Rehabilitation, University Hospital of North Norway, Tromsø, Norway, (2)University of Oslo, Oslo, Norway, (3)University Hospital of North Norway, Tromsø, Norway, (4)UiT The Arctic University of Norway, Tromsø, Norway, (5)NevSom, NevSom, Oslo University Hospital, Oslo, Norway

**Background:**

There is a strong clinical need for valid and standardized measures of mental health disorders in children and youths with autism spectrum disorder (ASD) and other neurodevelopmental disorders (OND).

**Objectives:**

We here assessed associations between three ASD and OND mental health symptom measures and general child mental health diagnostic interview.

**Methods:**

We included children referred for ASD or OND assessment at a neuro-pediatric outpatient clinic at a university hospital in Norway in February 2020 to June 2021. Ratings on the Developmental Behavior Checklist (DBC-P), the Aberrant Behavior Checklist (ABC), and the Psychopathology in Autism Checklist (PAC) were compared with emotional and behavioral diagnoses derived from the Developmental Well-Being Assessment (DAWBA) diagnostic interview, completed online by parents, teachers and self-report (from age 11).

**Results:**

Participants were 2 to 17 years of age \((M = 8.3, \ SD = 4.1; 87 \text{ boys and 34 girls}; Table 1)\). The majority of children lived with parents (97.3%). More than half of the parents had college or university degrees (63.6%). DAWBA expert raters were blind to ratings on the DBC-P, ABC and PAC. As shown in Table 1, DSM-IV diagnoses included anxiety disorders (20.6%), depression (3.3%) and behavioral disorders (primarily oppositional defiant disorder (ODD; 19%). Correspondence between measures was adequate for: i) DAWBA anxiety disorders and DBC-P anxiety, ii) DAWBA ODD and DBC disruptive and ABC irritability, and good for iii) DAWBA anxiety disorders and PAC anxiety (Table 2).

**Conclusions:**

Although “gold standard” measures for co-occurring mental health disorders in children with ASD and ND are lacking, the current study indicates adequate to good correspondence between measures designed for the ASD/OND population and anxiety and ODD diagnoses.

424.252  (*Poster*) Associations between the Pupillary Light Reflex and Anxiety Symptoms, ADHD Symptoms, and Sensory Behaviors in Autistic Children: Results from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)
Background: Autistic children exhibit characteristics of autonomic nervous system (ANS) dysfunction including differences in the pupillary light reflex (PLR), the natural constriction and redilation of the pupil in response to light, compared to typically developing (TD) children (Daluwatte et al., 2013). Anxiety, ADHD, and sensory sensitivities, which commonly co-occur with autism, are also related to ANS dysfunction (Daluwatte et al., 2015; Hamrakova et al., 2020; Sharma et al., 2011). Although PLR may serve as an objective index of these shared clinical characteristics, few studies have examined how PLR may differ across autistic children based on these co-occurring clinical features. Work in this area may illuminate physiological mechanisms related to the overlapping presentations of these conditions.

Objectives: This study explored how anxiety symptoms, ADHD symptoms, and sensory behaviors relate to the PLR in autistic children.

Methods: As part of the Autism Biomarkers Consortium for Clinical Trials (ABC-CT), 207 children with autism diagnoses (74% male, 68% white), ages 6-11 (M=8.42±1.65), viewed nine flashes of light on a dark screen during an eye-tracking experiment. PLR was measured at 500 Hz with an SR Eyelink-1000+ binocular remote camera system. Mean constriction time (duration), latency (onset) to constriction, and relative constriction (change in pupil diameter) were calculated. Mean latency was log transformed. One extreme constriction time outlier was removed after conducting Rosner’s test. Parents reported on participants’ autism characteristics using the Social Responsiveness Scale, 2nd edition (SRS-2; Constantino, 2012), ADHD and generalized anxiety symptoms using the Child and Adolescent Symptom Inventory, 5th edition (CASI-5; Gadow & Sprafkin, 2013), and sensory behaviors using the Pervasive Developmental Disorder Behavior Inventory (PDDBI; Cohen & Sudhalter, 1999). Table 1 provides descriptive statistics for scores on these measures. Separate linear regressions explored relationships between each clinical variable and each PLR measure while controlling for ambient light and autism characteristics.

Results: Greater sensory sensitivities (B=−.86, SE=.41, p=.04), generalized anxiety symptoms (B=−.59, SE=.24, p=.02), ADHD hyperactive/impulsive symptoms (B=−.55, SE=.26, p=.03), and ADHD combined symptoms (B=−.66, SE=.30, p=.03) each significantly predicted faster pupil constriction times. The models predicting latency to constriction and relative constriction were not significant (p>.05).

Conclusions: This is the first study to examine the association between pupil constriction time and co-occurring sensory, anxiety, and ADHD symptoms in autistic youth. Faster constriction time was associated with increased symptoms whereas no associations were found with latency to constriction and relative constriction. Results suggest that autistic children with greater ADHD, anxiety, or sensory symptoms may experience greater ANS reactivity than those without these co-occurring symptoms. Given high rates of co-occurring symptoms in autism (Lai et al., 2019), future studies should continue to parse the relationship between these symptoms and PLR in autistic children. Additionally, studies examining PLR differences in autistic children, relative to TD children, should control for co-occurring symptoms. Results highlight PLR constriction time as a tool for understanding neural correlates of individual differences in autism. Future research examining longitudinal relationships between PLR and clinical features may further clarify the utility of PLR as a marker of clinical change.

M. Siracusano†, R. Campanile†, A. Riccioni†, L. Emberti Gialloreti†, R. Moavero† and L. Mazzone†*, (1)Biomedicine and Prevention, POLICLINICO TOR VERGATA, University of Rome Tor Vergata, Rome, Italy, (2)Child and Adolescence Psychiatry Unit, Policlinico Tor Vergata Hospital, Rome, Italy, (3)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy, (4)Neuroscience and Neurorehabilitation Department, Child Neurology Unit, Bambino Gesù Children’s Hospital, Rome, Italy, (5)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy, (6)System Medicine, Division of Child Psychiatry, University of Catania, Italy, Rome, ITALY

Background: Suicidality in Autism Spectrum Disorder (ASD) is a field full of unanswered questions but compelling needs especially in youth. Firstly, specific autism risk and protective factors for suicide ideation and attempt have not been clearly delineated. Secondly, a well-defined clinical picture -unique to autism - predictive of suicide is not known; in addition a distinctive tool for the assessment of suicidality in autism is still lacking. Finally, even if co-occurring disorders have been associated to suicidality (mood disorders, anxiety), enough research attention has not been given to comorbid medical condition such as sleep disturbances.

Objectives:
1. To characterize suicidality (ideation and attempt) and to investigate possible behavioral clinical predictors of suicidality within a population of young individuals with ASD in comparison to a group of peers without diagnosis of ASD.
2. To evaluate if the presence of a sleep disorder and specific sleep parameters (total sleep time, sleep onset latency) are related to suicidality.

**Methods:** Adolescents with an IQ >70 referring to our clinical unit for suspected suicidality from September 2021 to October 2022 were evaluated for the presence of suicide ideation and attempt (The Columbia Suicide Severity Rating Scale C-SSRS), self-cutting (Repetitive Nonsuicidal Self-Injury Questionnaire, R-NSSI-Q), depressive symptoms (CDI2, BDI II), anxiety (MASC2), and social-communicative difficulties (Social Responsiveness Scale SRS). Sleep disorder was evaluated for all individuals using subjective (Sleep Disturbance Scale for Children SDSC) and objective measures (Polysomnography PSG).

**Results:** A preliminary sample of 20 individuals (age M: 15±SD 2.2; IQ 109±17.4) was enrolled: 8 ASD, 12 No-ASD (age t = 0.11 p = 0.90; IQ t = 0.47 p = 0.63). 50% of ASD and 66.7% of No-ASD presented suicide ideation. Suicide attempt was not found within ASD sample. ASD individuals with suicide ideation were characterized by a lower level of autism symptoms (ADOS-2 CSS: 4.6) in comparison to participants without suicide ideation (CSS: 6.79). All participants with suicide ideation presented a severe impairment of social-communication skills measured by SRS. Sleep disorder (according to SDSC cut-offs) was present in 16/20 participants of the total sample and 5/8 ASD. Most of individuals with sleep disorder had suicidal ideation (3/5 ASD; 8/11 No-ASD). PSG revealed that all participants with suicide ideation showed reduced total sleep time in comparison to individuals without suicide ideation (t = 2.3 p = 0.048) and alterations of all the other parameters (prolonged sleep onset latency, reduced sleep efficiency, prolonged after sleep onset, reduced total REM). This sleep pattern, even if no significant, was also found in the ASD subgroup with suicidal ideation (Figure).

**Conclusions:** Given the small sample size, this very preliminary report doesn’t permit to lead to any conclusion on suicidality and autism. Of particular interest, it is the finding that a lower level of autism symptoms and the presence of a reduced total sleep time - suggestive of a sleep disorder - characterizes ASD individuals with suicide ideation. As a whole, our results show that suicide ideation is a promising topic in autism which need to be further investigated.

**Background:** Research suggest that a dual diagnosis of autism spectrum disorder (ASD) and substance use disorder (SUD) is uncommon (Işık et al., 2020; Brugha et al., 2011). On one hand, studies indicates the prevalence of SUD in adults with ASD is as high as 83%, with alcohol abuse/dependence disorder being the most prevalent in adults with ASD (Lugo et al., 2019). On the other hand, when addressing the prevalence of ASD in SUD, only one study has examined this prevalence (see Ståhlberg et al. 2010) in which 14% of individuals with SUD had ASD. Even though it seems that ASD + SUD are infrequent, growing evidence indicates that autistic traits (ATs) are more prevalent for those with a SUD (Stickley et al., 2022). ATs represent problems or peculiarities in the development of social interaction, communication, or the presence of restricted behaviors or interests relative to the severity of symptoms and distribution of traits that by themselves fall short of meeting criteria for a clinical diagnosis of ASD (Constantino et al., 2004; Constantino & Todd, 2003; Lai et al., 2013).

**Objectives:** Our aim was to assess autistic traits/dimensions covered by the Autism Quotient-Short (AQ-S): Imagination, Social Skills, Switching, Numbers and Patterns and Routines in a group of individuals with a diagnosis of SUD, other with ASD, and a non-clinical group to explore whether there is a pattern of behaviors between these groups.

**Methods:** So far 117 participants took part of this study. The control group consisted of 45 participants, the ASD group of 45 and the SUD consisted of 27 participants. We ran a Kruskal-Wallis H-Test as well as a post-hoc test, to study group differences between the groups. As the study of Işık et al. (2020) suggested, we expected to find higher scores on the AQ-S on the dimensions of Imagination and Numbers and Patterns.

**Results:** As expected, our results showed the distributions on the Imagination and Numbers and Patterns dimensions from the ASD and SUD groups differed from the scores of the Control group (X(3) = 47.670, p = .001) and (X(3) = 31.151, p = .001), respectively, in which both ASD and SUD participants scored higher than the Control group. Also, our study shows that the two clinical groups, scored higher with a similar distribution in the Social Skills domain X(3) = 53.144, p = .001.
Conclusions: Throughout this study the two main autistic traits previously identified as problematic in the ASD and SUD groups (Imagination and Numbers and Patterns), continued to display the same pattern in the present study. Nonetheless, this study provides new insights between common ATs between the two clinical groups. As the participants with SUD obtained higher scores associated with difficulties in the Social Skills dimension. This new finding indicates that individuals with SUD have similar difficulties in the same extent as those difficulties reported by individuals with ASD.

424.255  (Poster) Autism Spectrum and Hikikomori
M. Yamada1, H. Ohta1, N. Kato2 and A. Iwanami3. (1)Showa University Department of Psychiatry, Tokyo, Japan, (2)Showa University, Tokyo, JAPAN, (3)Medical Institute of Developmental Disabilities Research, Showa University, Tokyo, Japan, (4)Showa University, Setagayaku, Japan

Background: The ‘Hikikomori’ syndrome (HS) is a form of prolonged and severe social withdrawal or social isolation which continues for more than 6 months. In prior research examining hikikomori, various psychiatric disorders have been suggested to comorbid hikikomori, such as anxiety disorder, Schizophrenia, and autism spectrum disorder (ASD). However, little research has been conducted to elucidate the biopsychosocial basis of hikikomori and ASD.

Objectives: We aimed to clarify the common and different bases of hikikomori (social withdrawal) and ASD

Methods: Recruitment was conducted through the outpatient department of the Developmental Disorder Research Center in Showa University Hospital. Patients were limited to males and age limitation was set to above 18 years old. Recruited patients had been diagnosed as ASD by medical interview, AQ, WAIS-III, and ADOS I or II. Patients were subjected to a structured interview regarding social withdrawal, various psychological tests, and blood tests. Through structured interviews, patients were divided into two groups: the hikikomori group and the non-hikikomori group. Assessment was conducted by T test and Mann Whitney U test.

Results: 46 clinical patients whose living conditions and social withdrawal status were evaluable; 17 cases of ASD clinical patients with co-occurring social withdrawal (hikikomori) and 29 controls of ASD clinical patients without co-occurring social withdrawal. No significant differences were found in age, marital status, final education, or household income, and no clear association with withdrawal was found in WAIS scores and AQ-J. In terms of discrepancy, hikikomori cases had an inverse correlation with higher hikikomori scores. In blood tests, uric acid levels were significantly lower in the hikikomori group (p=0.006). The HQ-25, TACS22, PHQ-9, and TCI140 were significantly higher in the hikikomori group, indicating higher tendency toward withdrawal, social anxiety, depression, and avoidance. The adult sensory profile also showed stronger sensory hypersensitivity and sensory avoidance in the hikikomori group. (p<0.009, p<0.01) Atopic dermatitis was a significant comorbidity for hikikomori cases. (p<0.006) 70% of the patients participating in the study had either a past of hikikomori, or was in the state of hikikomori.

Conclusions: Through this study, we have revealed several possible factors of ASD and cases with hikikomori. ASD itself may be stated to be a possible risk factor of hikikomori. ASD cases with higher sensory sensitivity, discrepancy, lower uric acid levels, coexistence of atopic dermatitis, higher depression level and social phobia showed to be possible risk factors of hikikomori. Although having these characteristics may lead to the withdrawal of social activity, by receiving appropriate support from doctors and regional resources, patients with hikikomori may have a good chance from withdrawing from hikikomori. Furthermore, these results may work as predictive factors for psychiatrists examining ASD patients in the future.

424.256  (Poster) Autistic Children Have Elevated Clinical Symptoms When Compared to Non-Autistic Peers

Background: Autistic people often display comorbidities with other psychological conditions, such as ADHD, depression, and anxiety (Mafevsky et al., 2011; Mannion & Leader, 2013). The Child Behavior Checklist 6-18 (CBCL) is a screening tool that aims to detect underlying clinical symptoms within the age group of 6–18-year-olds, and many have used the CBCL to find a common “autistic profile” when compared to non-autistics (Hoffman et al., 2016; Katsuki et al., 2020). However, published work examining differing profiles within autistic samples is sparse.

Objectives: To compare the overall levels of clinical symptoms of school-age autistic children with non-autistic children and to examine whether there were differing profiles of clinical symptoms within the school-age autistic group.
Methods: The children in this study (aged 6-14 years) either had a high or low likelihood of developing autism based on family history (e.g., presence of autism in an older sibling) and were evaluated for ASD at multiple time-points. Thus, participants make up three groups: high-likelihood for autism and autistic (HL-ASD, \( n = 44 \)), high-likelihood for autism but not autistic (HL-Neg, \( n = 127 \)), and low-likelihood for autism and not autistic (LL-Neg, \( n = 100 \)). Group differences in CBCL \( t \)-scores were evaluated for two domain scores: internalizing and externalizing, and eight syndrome scales: anxious/depressed, withdrawn/depressed, somatic complaints, social problems, thought problems, attention problems, rule-breaking behavior, and aggressive behavior. A latent class analysis within the HL-ASD group was used to find differing clinical profiles across all eight syndrome scales based on cut off scores of 65 (i.e., borderline or clinical scores). A four-class solution was selected based on log-likelihood values.

Results: The HL-ASD group had significantly higher \( t \)-scores on both the externalizing and internalizing scales when compared to HL-Neg and LL-Neg groups (Table 1). Additionally, the HL-ASD group had significantly higher rates than the LL-Neg group on all eight syndrome scales. The HL-ASD group had significantly higher \( t \)-scores than the HL-Neg group on all syndrome scales except for the somatic complaints scale. The HL-Neg group had significantly higher rates than the LL-Neg group on the attentional problems syndrome scale. The latent class analysis revealed four distinct profiles within the HL-ASD group (Figure 1). The first class (\( n = 4 \)) displayed elevated (i.e., over 50% of class) rates of anxious/depressed behaviors, social problems, rule-breaking behaviors and attentional problems. The second class (\( n = 12 \)) displayed elevated rates of anxious/depressed behaviors, withdrawn/depressed behaviors, and somatic complaints. The third class (\( n = 23 \)) displayed extremely low rates of borderline-clinical/clinical levels on all syndrome scales. The fourth class (\( n = 5 \)) displayed elevated rates of depressed behaviors, thought problems, attention problems, and aggressive behavior.

Conclusions: The group comparisons revealed significant elevations in clinical symptoms for the HL-ASD group when compared to both the HL-Neg and LL-Neg groups. These results highlight the need to provide school age autistic children with comprehensive mental health support. Further research should be done to examine how clinical profiles can be used to better craft interventions and supports for children with clinical symptoms.

Background: Younger siblings of children with autism spectrum disorder (ASD) display higher rates of negative emotions and lower rates of positive emotions on parent-reported questionnaires. An under-explored area in younger siblings is behavioral and physiological measurement during emotion-eliciting tasks (e.g., bubbles). Because physiological indices of arousal can register differences in early-developing processes, they may be informative for mechanisms underlying emotional development and ASD symptom emergence.

Objectives: To examine behavioral and physiological responses during an emotion-evoking task in infants who are increased likelihood for ASD (younger siblings; IL) and low likelihood for ASD (no family history of ASD; LL). A secondary objective was to explore relationships between behavioural and physiological indices and internalizing and externalizing behaviours.

Methods: Participants: IL (\( n = 125 \)) and LL (\( n = 61 \)) infants assessed at 6, 12, 18, and 24 months of age.

Emotion-evoking Task: Activities designed to elicit positive and negative emotions (bubbles, toy play, toy removal, and negative task phases; Sacrey et al., 2021) to measure (1) percent of time looking at the task object (gaze); (2) behavioral affect, coded for valence and intensity; and (3) heart rate, calculated as a change from baseline.

ASD Symptom Expression: The Autism Diagnostic Observation Schedule 2nd Edition Toddler Module was used to measure ASD symptoms and classify participants into three groups: LL (\( n = 61 \)), IL not classified with ASD (IL non-ASD; \( n = 96 \)), and IL classified with ASD (IL-ASD; \( n = 29 \)) at 24 months.

Internalizing and Externalizing Behaviours: Parents completed the Child Behaviour Checklist 1.5-5 years when their child was 3 years old.

Analytic Approach: A a series of linear mixed models with group (IL-ASD, IL-non-ASD, LL) and age (6, 12, 18) as the independent variables and scores on each phase of the EE-Task for heart rate, affect, and gaze as the dependent variables were run. Relationships between behavioural-physiological indices and internalizing and externalizing \( T \)-scores were also examined.

Results: The IL-ASD group displayed higher levels of negative affect during toy removal (\( p = .008, \ d = .36 \)) and negative tasks (\( p = .013, \ d = .36 \)) compared to the other two groups. Further, the IL-ASD group showed a greater increase in heart rate from baseline during the toy removal (\( p = .005, \ d = .38 \)) and negative tasks (\( p < .001, \ d = .42 \)) compared to the LL group. For the associations with the CBCL, there were no relationships at 6 months, but at 12 months, internalizing and/or externalizing behaviours were associated with heart rate during toy removal and negative tasks, affect during toy removal, and gaze during bubbles, toy play, toy removal, and negative tasks (\( p \)’s < .05). At 18
Background: Autistic adults are often camouflaging, which refers to using (un)conscious strategies to present oneself as neurotypical. Since autistic adults reported camouflaging as a cause of their mental health difficulties, several studies tested whether such a relationship exists. It indeed seems to be the case that camouflaging is associated with mental health difficulties. However, these studies were all cross-sectional and therefore, conclusions about causality cannot yet be drawn.

Objectives: In the present study, we use longitudinal data to investigate whether 1) camouflaging predicts the change in mental health difficulties and whether 2) mental health difficulties predict the change in camouflaging behavior.

Methods: In this preregistered (Aspredicted # 89077) study, 334 autistic adults aged 30 to 86 years filled in the Dutch Camouflaging Autistic Traits Questionnaire (CAT-Q-NL), the Symptom Checklist-90 Revised (SCL-90-R) and the Autism Quotient (AQ) on two timepoints, with a time interval ranging from 1.3 to 3.3 years. Using multilevel models we analyzed whether 1) camouflaging at T1 predicted the change in mental health difficulties between T1 and T2 and whether 2) mental health difficulties at T1 predicted the change in camouflaging behavior between T1 and T2. In all analyses we controlled for age, biological sex, and autism traits at T1.

Results: Preliminary analyses showed that mental health difficulties increased over time (β = 11.99, p = .004). Also, there was a significant interaction between time and camouflaging behavior on T1 (β = -.14, p = .001). The negative β indicates that a higher camouflaging score on T1 predicts a decrease in mental health difficulties.

Furthermore, camouflaging did not significantly change over time (β = .53, p = .747). Also, there was no interaction between time and mental health difficulties on T1 (β = -.01, p = .343). This means that any change in camouflaging did not depend on someone’s mental health difficulties at T1. Before INSAR 2023, we will conduct the final analyses in order to present the definite findings at the conference.

Conclusions: Based on these preliminary analyses, we conclude that 1) mental health difficulties increased over time, 2) for people with higher camouflaging scores, mental health difficulties decreased over time and 3) camouflaging seems to be a stable trait that is not influenced by mental health difficulties. These results suggest that more camouflaging would result in less mental health difficulties, which is in sharp contrast to what was hypothesized based on reports of autistic adults and clinical impressions. Further analyses are necessary to test whether these preliminary conclusions are indeed valid and to gain deeper understanding of these findings.

Conclusions: These results suggest that IL children classified as ASD show differences in affect, gaze, and heart rate during an emotion-evoking task, which are associated with internalizing and externalizing behaviours at age 3. As such, behavioral and physiological reactivity during emotionally-evocative tasks may inform early intervention approaches for infants who show early signs of ASD, with potential implications for understanding mechanisms related to emerging ASD.

Background: The connection between autism spectrum disorder (ASD) and schizophrenia is complicated. Autism spectrum disorder and childhood schizophrenia were once considered the same disorder, but during the 1970s, these conditions were differentiated on the basis of age of onset and symptoms. Clinicians continue to report difficulty with the differential diagnosis of these conditions, partly due to apparent similarities in social communication, negative symptoms, and neurocognitive impairments (Jutla, Foss-Feig, & Veenstra-Vanderweele, 2022). To fill this gap, we present two case studies involving deep clinical phenotyping of individuals with an early diagnostic history of ASD and current symptoms of schizophrenia.

Objectives: This detailed case study series of comorbid schizophrenia and ASD, compared with age-matched individuals with ASD only, aims to characterize the overlapping and distinguishing characteristics of schizophrenia and ASD.

Methods: Participants were two young adults with ASD+schizophrenia and 11 young adults with ASD only; Table 1. Current symptoms of ASD were assessed using the ADOS-2, Module 4 in an online protocol (Eigsti et al., 2022) or in-person (Lord et al., 2012). Early ASD symptoms were assessed via parent interview, with the ADI-R (Lord, Rutter, & Le Couteur, 1994). The Vineland Adaptive Behavior Scales-3 (VABS-3) provided a measure of social and adaptive functioning. Schizophrenia symptoms were assessed with the Structured
Clinical spectrum disorder (ASD) is characterized by difficulties in social communication and interaction as well as repetitive behaviors and/or restricted interests. In addition to these core symptoms, children and adolescents with ASD often exhibit comorbid emotional and behavioral difficulties, which in turn negatively affect socioemotional development and life outcomes (Rosen et al., 2018; Guerrera et al., 2019). While numerous studies have examined factors associated with emotional and behavioral difficulties in ASD, they have predominantly focused on child-level characteristics (see Yarger & Redcay, 2020 for review). Consequently, there is limited understanding of the full range of factors that predict emotional and behavioral difficulties, particularly whether and to what extent parental-level factors are associated with such difficulties.

**Objectives:**

The present study aimed to (1) characterize emotional and behavioral difficulties in children and adolescents with ASD in South Korea and (2) investigate whether and to what extent a parental environmental factor (namely, maternal depressive symptoms) is related with emotional and behavioral difficulties in ASD. We also examined the role of potential moderators such as age, sex, and cognitive ability.

**Methods:**

Data were drawn from 112 children and adolescents diagnosed with ASD and their parents. The mean age of the children was 5.25 years (SD=2.69, Range=2-18). There were 88 boys and 24 girls. Children’s emotional and behavioral difficulties were assessed using the Child Behavior Checklist (CBCL), and three domain scores (Total Problems, Internalizing Problems, and Externalizing Problems) were used. The cutoff score (≥ 60) was used to determine the children with clinically significant or subclinical levels of problem behaviors. Cognitive ability was measured using the FSIQ obtained from the K-Leiter-R, K-WPPSI-IV, K-WISC-IV, or K-WAIS-IV. Mothers’ depressive symptoms were self-reported using the Beck Depression Inventory.

**Results:**

(1) Approximately a half of the ASD children and adolescents (51%) had scores indicating clinically significant or subclinical levels of Total Problems. Regarding Internalizing Problems and Externalizing Problems, respectively, 41% and 36% of the participants had a score indicating borderline to clinical levels.

(2) Maternal depressive symptoms significantly, positively correlated with children’s Total Problems, Internalizing Problems, and Externalizing Problems (rs > .33, ps < .001), suggesting mothers with higher depressive symptoms had children with more emotional and behavioral difficulties (Figure 1). In addition, age significantly, positively correlated with Total Problems and Internalizing Problems (rs > .20, ps < .05), suggesting that older ASD children tended to have more emotional and behavioral problems. FSIQ negatively correlated
with Total Problems, indicating that children with higher IQ tended to have less overall extent of emotional and behavioral difficulties ($r = -0.18, p = .07$). No effects of sex were detected.

Conclusions:

A high proportion of ASD children and adolescents showed borderline or clinically significant levels of emotional and behavioral difficulties, suggesting the importance of routine screening and support services for this population. Mothers' depressive symptoms, as well as child age and IQ, were related to emotional and behavioral problems in ASD, indicating that the multiple levels of analysis at child- and parent-levels are needed to understand psychiatric comorbidity in ASD.

424.261 (Poster) Characterization and Association of Temperament Subgroups with Social-Emotional Functioning across the Early Developmental Period

**L. Chetcuti**, M. Uljarevic**, K. J. Varcin**, M. Boutrus**, S. Dimov**, J. Barbaro**, C. Disanayake**, J. Green**, A. J. Whitehouse**, K. Hudry** and S. Pillar**, (1)La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)Melbourne School of Psychological Sciences, Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Parkville, VIC, (4)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (5)Telethon Kids Institute, University of Western Australia, Perth, Australia, (6)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (7)La Trobe University, Melbourne, Australia, (8)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (9)Cooperative Research Centre for Living with Autism (Autism CRC), The University of Queensland, Indooroopilly, QLD, Australia, (10)Olga Tennison Autism Research Centre, School of Psychology and Public Health, La Trobe University, Melbourne, VIC, Australia, (11)University of Manchester, Manchester, United Kingdom, (12)Telethon Kids Institute, Perth, Western Australia, AUSTRALIA, (13)La Trobe University, Melbourne, VIC, AUSTRALIA, (14)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia

Background: Links between temperament and social–emotional difficulties are well-established in the general population but remain poorly characterized in autism, particularly during early development when autism and co-occurring symptoms first emerge. Extant studies of autism provide evidence that individual traits predict variability in concurrent internalizing and externalizing symptoms in middle childhood, and the emergence of mental health conditions in later life. However, because multiple temperament traits act in concert and influence on another, a person-centred approach to the study of temperament and its influence could be more informative. This approach conceptualizes temperament as the combination of multiple traits within each person, as opposed to individual traits, and seeks to identify homogeneous subgroups within a heterogeneous population with distinct multi-trait profiles.

Objectives: To characterize temperament subgroups and their association with social-emotional difficulties across the infant and toddler periods.

Methods: 103 infants (68% male) showing signs of emerging autism were referred to the study by community healthcare professionals and seen for assessments when aged around 12-months (Time 1), 18-months (Time 2), and 24-months (Time 3). Latent profile analysis was applied at each timepoint to caregiver-report data on the Infant Behavior Questionnaire-Revised (IBQ-R; Time 1) and Early Childhood Behavior Questionnaire (ECBQ; Times 2 and 3). Next, analysis of variance were performed at each timepoint to explore subgroup differences in concurrent internalizing and externalizing symptoms on the caregiver-reported Infant-Toddler Social and Emotional Assessment (ITSEA), while controlling for autism level on the Autism Diagnostic Observation Schedule-2nd Edition. Validation of subgrouping results was established through examination of (i) the replicability of subgroup configurational structures across timepoints, (ii) the intra-individual consistency of subgroup classification across adjacent timepoints, and (iii) consistency of subgroup associations with internalizing and externalizing symptoms over time.

Results: Subgroups labelled inhibited/low positive, active/negative reactive, and sociable/well-regulated were identified at each timepoint, and an additional reactive/regulated subgroup was identified uniquely at Time 3. Inhibited/low positive and active/negative reactive children had the highest reported internalizing and/or externalizing symptoms at each timepoint, whereas sociable/well-regulated children had the lowest reported symptoms. Subgroups did not differ in terms of child age, sex, or cognitive/developmental level. There was a significant likelihood of children having a recurrent subgroup classification from one timepoint to the next, and no apparent patterns to the movement of children who did change from one subgroup to another over time.

Conclusions: Young children with signs of emerging autism can be divided into temperament subgroups – characterized by varying configurations of multiple traits – that meaningfully map onto variation in internalizing and externalizing symptoms. Temperament subgroup classifications might represent a reliable and very early indicator of social-emotional functioning in the context of emerging autism.

424.262 (Poster) Child Cognition As a Moderator of the Relation between ASD Severity and Anxiety Symptoms

**Background:** Previous research suggests that children with autism spectrum disorder (ASD) receive significantly higher ratings anxiety than non-ASD children (e.g., van Steensel et al., 2011). Studies examining anxiety among youth with ASD have identified autism severity and verbal IQ as predictors (Mayes et al., 2011). However, little research exists on how these three variables relate to one another. For example, some have found that high intelligence is not related to anxiety (Eussen et al., 2012), whereas others propose that it predicts anxiety (Mayes et al., 2011).

**Objectives:** The present study aims to better understand the relation between ASD severity and anxiety by examining demographic variables and parent-rated cognition of the child to bolster evidence of the nature of the relation.

**Methods:** Participants were 115 caregivers with one child with ASD. Caregivers completed questionnaires measuring child anxiety symptoms (BASC-3), ASD severity (CSBQ), and overall cognitive functioning (using a 5-point Likert scale ranging from ‘Well Below Average’ to ‘Well Above Average’).

**Results:** Correlations between demographic variables (child gender, age, and ethnicity) and the variables of interest showed that child age significantly, positively related to ASD symptoms and anxiety symptoms, \( r = .20, p = .01 \) and \( r = .22, p = .02 \), respectively, indicating that older children had higher ratings of both ASD symptoms and anxiety symptoms. Therefore, child age was used as a covariate. There also was a significant positive correlation between ASD severity and anxiety symptoms, \( r = .38, p < .001 \), indicating children with higher levels of ASD symptoms had higher ratings of anxiety.

A moderated multiple regression analysis (Table 1) with age (covariate), ASD severity (predictor), and parent-rated cognition (moderator) predicting anxiety symptoms (criterion) demonstrated that age was a significant predictor in the covariate model (\( p = .02 \)) and that child age and ASD severity were significant predictors in the main effects model (\( p = .02 \) and \( p < .001 \), respectively). Although the cognition main effect was not significant (\( p = .36 \), the interaction between ASD severity and cognition in the final model predicted unique variance in anxiety symptoms (\( p = .04 \)). A post-hoc plot (Figure 1) demonstrated that higher levels of cognition exacerbated the relation between ASD severity and anxiety (\( p < .001 \)), whereas lower cognition attenuated the relation (\( p = .08 \)).

**Conclusions:** Findings suggest elevated social difficulties, in combination with high intellect, put youth at higher risk for anxiety symptoms. They may be more cognizant of their social differences (thereby exacerbating anxiety), whereas those with lower cognitive functioning may be less aware of their social challenges (thereby attenuating anxiety). Some studies have found that anxiety tends to be higher among youth with higher ASD severity (e.g., Baribeau et al., 2020; Mayes et al., 2011; Ozsizadjian et al., 2014), whereas others have found the inverse relation (e.g., Eussen et al., 2012; Gadow et al., 2005), suggesting other factors may moderate this relation. Future studies considering how factors, like cognition, relate to ASD severity and anxiety may further elucidate the nature of the relationship.

---

**K. Ohashi and J. Hayano,** (1)Department of Neonatology and Pediatrics, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, (2)Heart Beat Science Lab, Sendai, Japan

**Background:** Many of the clinical symptoms of autism spectrum disorder (ASD) such as orthostatic dysregulation, bowel movement disorder, and circadian rhythm disorder suggest autonomic nerve disorders. Although autonomic nerve function in children with ASD has been assessed using a variety of methods, a unified view has yet not been reached.

**Objectives:** This study aimed to characterize autonomic nerve function in children with ASD.

**Methods:** Children without congenital heart disease or arrhythmia, who belonged to a regular class without special support for studying, were evaluated for autonomic function using 24-hour electrocardiography (ECG). High frequency power (HF) as an index of parasympathetic function, low frequency power (LF) / HF as an index of sympathetic function, and standard deviation (SD) of each as an index of their respective variability were calculated. Indexes of autonomic nerve function were calculated for two time periods: all day (24 h) and during sleep (1-3 am). They were also assessed for developmental characteristics using the Social Responsiveness Scale Second Edition (SRS-2) and Autism-Spectrum Quotient Test for child (AQ child). We examined the correlation between the index of autonomic nerve function calculated by 24-h ECG and strength of developmental disorder characteristics.

**Results:** Seventeen children (Male 6, Female 11; median age, 10.0) were analyzed. Their median T score and interquartile range (IQR) of total SRS-2, SRS-2 social communication impairment (SCI), SRS-2 repetitive/restrictive behavior (RRB), and total score of AQ child were as follow: 63.4 (IQR 53-76), 62.0 (IQR 53-73), 61.4 (IQR 48-70), and 25.6 (18-31), respectively. In the indexes of autonomic nerve function, only SD of LF/HF during sleep (1-3 am) were significantly correlated with T score of total SRS-2 (\( p=0.016, r=0.574 \)), T score of SRS-2 SCI (\( p=0.018, r=0.567 \)), total score of AQ child (\( p=0.025, r=0.540 \)).

**Conclusions:** Although difference in overall autonomic nerve function was absent, it can be concluded that the stronger the ASD characteristics, the stronger the variability of sympathetic fluctuation during sleep.
Background: The exact mechanisms and clinical characteristics of comorbid tic disorders in individuals with ASD remain unclear.

Objectives: The primary aim of this study is to investigate the prevalence of comorbid tic disorders in individuals with ASD using standardized assessment methods. Secondly, we aimed to explore differences in ASD symptom severity, other comorbidities, such as OCD symptoms and externalizing/internalizing behaviors, and baseline functioning through verbal/non-verbal IQ or adaptive behaviors.

Methods: We included individuals diagnosed with ASD (n = 679) aged 4 to 18 years who completed the Yale Global Tic Severity Scale (YGtSS) questionnaire. Based on the YGtSS score, the included individuals were divided into two groups: ASD only (n = 554) and ASD with tics (n = 125). Individuals were assessed using the verbal and non-verbal intelligence quotient (IQ), Vineland Adaptive Behavior Scale (VABS-2), Social Responsiveness Scale-2 (SRS-2), Child Behavior Checklists for Ages 6-18 (CBCL), and Yale-Brown Obsessive-Compulsive Scale (YBOCS), followed by between-group comparisons. All tests were conducted using the Statistical Package for the Social Sciences (SPSS) version 26.

Results: Regarding the type of tics, both motor and vocal tics affected the majority of individuals (n = 40, 40.0%). The ASD with tics group had a significantly higher average age and full-scale IQ score than the ASD only group. Regarding clinical characteristics, the ASD with tics group showed significantly higher SRS-2, CBCL, and YBOCS subdomain scores after adjusting for age. Furthermore, all variables except the non-verbal IQ and VABS-2 scores were positively correlated with the YGtSS total score. Individuals with a higher IQ (IQ ≥70) showed a significantly greater proportion of tic symptoms.

Conclusions: A higher IQ is associated with a greater proportion of tic symptoms in individuals with ASD. Moreover, the severity of ASD core and comorbid symptoms is associated with tic disorders and tic severity among affected individuals. Accordingly, there is a need for proper surveillance and clinical interventions for individuals with ASD.

Background: Autism spectrum disorder (ASD) with co-occurring sensorineural hearing loss is established (Beers et al., 2014). However, only one report of ASD co-occurring with auditory neuropathy spectrum disorder has been reported (ANSD; Plyer et al., 2005). ANSD is a disorder with abnormal/absent neural responses—auditory brainstem response (ABR) and presence of pre-neural responses—otoacoustic emissions (OAEs) or cochlear microphonics (Starr et al, 1996). This creates challenges in auditory processing, speech discrimination and delayed language development (Breneman et al., 2012).

Objectives: The primary aim of this study is to investigate the prevalence of comorbid tic disorders in individuals with ASD using standardized assessment methods. Secondly, we aimed to explore differences in ASD symptom severity, other comorbidities, such as OCD symptoms and externalizing/internalizing behaviors, and baseline functioning through verbal/non-verbal IQ or adaptive behaviors.

Methods: This case report is of a 40-month-old, male child presenting with concerns of inconsistent response to name call, soft and loud sounds, atypical and reduced communication, and poor social interaction. A multidisciplinary team (MDT) of audiologists, speech-language pathologists, and a child psychiatrist assessed the child. Audiological evaluation consisted of immittance audiometry, distortion product OAEs (DPOAEs), and ABR. Detailed history was collected from parents and assessments were conducted over four sessions. Developmental and behavioural assessments (e.g., ComDEALL Developmental Checklist, CSBS-DP) were conducted using parent report and direct observation measures. Although diagnostic measures like ADOS-2 could not be administered due to prohibitive costs for training in LMICs, a 30-minute semi-structured play session with a clinician was video recorded and coded for behaviours under domains of social communication, play skills and Restricted Repetitive Behaviours (RRBs). A clinical best estimate (CBE) diagnosis was made using DSM 5.

Results: Audiological evaluation revealed normal middle ear function, bilateral absent reflexes and bilateral DPOAEs present (Fig 1a) indicative of normal outer-hair cell functioning. ABR revealed bilateral absent peaks at 90 dB nHL and clear pattern of cochlear microphonics (Fig 1b). These results confirmed bilateral ANSD. The child demonstrated delay across multiple domains (Fig 2) with larger delays in communication, social, and cognition domains. Play session observations included reduced use of gestures, poor joint attention and verbal/nonverbal imitation, limited social overtures, poor social engagement and sharing of interests, atypical nonverbal communication, challenges in transitions, presence of repetitive play and restricted interests (e.g., banging of objects, vocal stimulating, hand flapping) – patterns not seen in ANSD. Infact, non-verbal communication and imitation are strengths for children with ANSD (Stredler-
Brown, 2002). Further probing of RRB’s indicated presence of behaviours like adherence to play routine, preference to certain food consistencies, challenges with haircutting and nail clipping, and increased threshold of pain – profiles not commonly seen in ANSD. Based on clinical history, parent interview and observation, a CBE diagnosis of ASD was made.

Conclusions: Reduced gesture use, atypical non-verbal communication, poor joint attention, and imitation were amongst the most important clinical features that prompted us to look for concerns beyond ANSD. Detailed history, good clinical observations, and an eye for differential diagnosis by an MDT is crucial for distinguishing and reporting co-occurring diagnoses such as these. Early identification and diagnosis of such comorbid disorders can guide tailored interventions focusing on providing amplification devices, auditory training, promoting multimodal communication, enhancing social-communication, reciprocity, and engagement with appropriate family support.

424.266 (Poster) Cognitive Disengagement Syndrome in Young Autistic Children with and without Co-Occurring ADHD: Clinical and Neurobiological Correlates

Background: Cognitive Disengagement Syndrome (CDS; previously called Sluggish Cognitive Tempo), refers to a constellation of cognitive and motor behaviors characterized by a propensity for mind wandering and slowness in behavior. CDS has predominantly been studied in individuals with Attention-Deficit/Hyperactivity Disorder (ADHD) and is associated with greater social difficulties, more internalizing symptoms, different sensory responses, and increased academic difficulties. CDS is estimated to occur in 30-49% of autistic individuals, yet less is known about its clinical presentation or neurobiological correlates, particularly in young autistic children. However, early evidence suggests that CDS is associated with similar difficulties when co-occurring with autism as when co-occurring with ADHD.

Objectives: Explore the clinical and neurobiological correlates of CDS in autistic children with and without co-occurring ADHD and children with only ADHD.

Methods: Participants were 196 3-8 year old children from three groups: Autistic (N=55), Autistic+ADHD (N=46), ADHD (N=51), and neurotypical (N=44). CDS was assessed with 8 questions from the Child and Adolescent Disruptive Behavior Inventory. Social skills, sensory processing, and internalizing symptoms were assessed via parent report using the Social Responsiveness Scale, Sensory Experiences Questionnaire, and Child Behavior Checklist, respectively. Neurobiological correlates were assessed using resting state EEG (rsEEG) in 138 participants (DVs: absolute theta [4-8Hz], absolute beta [16-30Hz], and theta/beta ratio at frontal-central channels). Associations between CDS and clinical and neurobiological outcomes were tested across the three clinical groups using general linear models with age, sex, and developmental quotient included as covariates.

Results: While all three clinical groups had significantly elevated CDS scores compared to neurotypical children, CDS scores were similar among Autistic, ADHD, and Autistic+ADHD children. Autistic and Autistic+ADHD children had greater social difficulties (F(1)=40.2, p<.0001) and sensory hypersensitivity (F(1)=3.0, P=.05) compared to children with ADHD alone. However, regardless of diagnostic classification, higher CDS scores were associated with greater social difficulties (F(1)=12.8, p<.0001) and hypersensitivity (F(1)=29.4, p<.0001) across groups. Higher CDS score were also associated with greater sensory hypersensitivity (F(1)=40.4, p<.0001) and greater internalizing symptoms (F(1)=30.3, p=.0001) for all groups. Analyses of EEG revealed that rsEEG theta absolute power (F(1)=8.5, p<.01) and group (F(2)=3.8, p<.05) individually predicted higher CDS scores. Furthermore, there was a significant group-by-theta interaction (F(2)=3.3, p<.05); lower frontal-central rsEEG theta power was associated with higher CDS scores for the Autistic+ADHD group (F(1)=11.6, p<.01) but not other groups. There were no significant associations between CDS score and either rsEEG beta power or theta/beta ratio.

Conclusions: Our results revealed similar elevated CDS scores for children diagnosed with autism, ADHD, and autism+ADHD. Furthermore, higher CDS scores were associated with greater social difficulties, internalizing symptoms, and sensory differences regardless of diagnostic group. Lower rsEEG frontal-central theta power was associated with higher CDS scores for young Autistic+ADHD children, but not children with either disorder alone. Some previous evidence suggests theta power may be increased in autistic and ADHD children, but decreased in children with co-occurring autism+ADHD. As such, associations between decreased theta and higher CDS in our Autistic+ADHD group suggests that elevated CDS may explain, in part, prior findings of decreased theta in autism+ADHD.

424.267 (Poster) Comprehension of Death and Suicide in Youth with Autism and Other Neurodevelopmental Disorders

P. H. Lipkin1,2, M. R. Ngur1, P. C. Ryan1, S. Rybczynski1, A. Thurm1, L. M. Horowitz1, C. Lopez-Arvizu1, S. Jadhav1, K. McCalla1, M. Bay1 and C. Lenz2, (1)Neurology and Developmental Medicine, Kennedy Krieger Institute, Baltimore, MD, (2)Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, (4)Office

Conclusions: Reduced gesture use, atypical non-verbal communication, poor joint attention, and imitation were amongst the most important clinical features that prompted us to look for concerns beyond ANSD. Detailed history, good clinical observations, and an eye for differential diagnosis by an MDT is crucial for distinguishing and reporting co-occurring diagnoses such as these. Early identification and diagnosis of such comorbid disorders can guide tailored interventions focusing on providing amplification devices, auditory training, promoting multimodal communication, enhancing social-communication, reciprocity, and engagement with appropriate family support.

424.266 (Poster) Cognitive Disengagement Syndrome in Young Autistic Children with and without Co-Occurring ADHD: Clinical and Neurobiological Correlates

Background: Cognitive Disengagement Syndrome (CDS; previously called Sluggish Cognitive Tempo), refers to a constellation of cognitive and motor behaviors characterized by a propensity for mind wandering and slowness in behavior. CDS has predominantly been studied in individuals with Attention-Deficit/Hyperactivity Disorder (ADHD) and is associated with greater social difficulties, more internalizing symptoms, different sensory responses, and increased academic difficulties. CDS is estimated to occur in 30-49% of autistic individuals, yet less is known about its clinical presentation or neurobiological correlates, particularly in young autistic children. However, early evidence suggests that CDS is associated with similar difficulties when co-occurring with autism as when co-occurring with ADHD.

However, regardless of diagnostic classification, higher CDS scores were associated with greater social difficulties (F(1)=12.8, p<.0001) and hypersensitivity (F(1)=29.4, p<.0001) across groups. Higher CDS score were also associated with greater sensory hypersensitivity (F(1)=40.4, p<.0001) and greater internalizing symptoms (F(1)=30.3, p=.0001) for all groups. Analyses of EEG revealed that rsEEG theta absolute power (F(1)=8.5, p<.01) and group (F(2)=3.8, p<.05) individually predicted higher CDS scores. Furthermore, there was a significant group-by-theta interaction (F(2)=3.3, p<.05); lower frontal-central rsEEG theta power was associated with higher CDS scores for the Autistic+ADHD group (F(1)=11.6, p<.01) but not other groups. There were no significant associations between CDS score and either rsEEG beta power or theta/beta ratio.

Conclusions: Our results revealed similar elevated CDS scores for children diagnosed with autism, ADHD, and autism+ADHD. Furthermore, higher CDS scores were associated with greater social difficulties, internalizing symptoms, and sensory differences regardless of diagnostic group. Lower rsEEG frontal-central theta power was associated with higher CDS scores for young Autistic+ADHD children, but not children with either disorder alone. Some previous evidence suggests theta power may be increased in autistic and ADHD children, but decreased in children with co-occurring autism+ADHD. As such, associations between decreased theta and higher CDS in our Autistic+ADHD group suggests that elevated CDS may explain, in part, prior findings of decreased theta in autism+ADHD.
Background: Youth with autism and other neurodevelopmental disorders (ASD/NDD) are at greater risk for dying by suicide. Suicide risk screening is an early detection strategy aimed at prevention. The age in which children understand death and its finality vary depending on age and developmental trajectory. There is limited research describing how youth with NDD conceptualize and understand death compared with neurotypical peers. As clinicians screen youth with NDD for suicide risk, it is important to evaluate their understanding of suicide and its finality.

Objectives: To describe the relationship between understanding death and suicide risk among youth with ASD and NDD more broadly.

Methods: Children with either ASD or other NDD aged 8-17 years, English-speaking, and verbally fluent were recruited for participation in an ongoing suicide risk screening instrument validation study across 4 medical clinics. Research staff administered an understanding death assessment developed for youth with ASD/NDD (e.g., “If you died, would you wake up the next day?”) along with measures of suicide risk (including the Ask Suicide-Screening Questions [ASQ], a brief 4-item validated tool as well as 10 candidate items developed specifically for ASD/NDD youth). The data collector and each participant’s parent/guardian also evaluated the participant’s perceived level of understanding. Response categories included: “completely understood,” “somewhat understood,” and “did not understand.” Parent and child acceptability of suicide risk screening are also reported.

Results: Of 269 eligible participants to date, 57.0% (n=153) children were enrolled and screened (73.9% male, 56.2% White, 33.3% Black, mean age: 12.4 [SD 2.6]). Approximately one-fifth, 20.3% (n=31), of participants screened positive on the ASQ. 84.3% (n=129) of all participants reported having heard the word “suicide” previously though responses of its definition were mixed, and 9.8% (n=15) reported knowing someone who died by suicide. 90.1% (n=138) of participants understood the finality of death (i.e., indicating that those who die do not wake up the next day). The majority of both youth (63.7%, n=86/135) and parents/guardians (85.2%, n=115/135) indicated children should be screened for suicide risk in the medical setting. Further statistics describing how participants’ understanding of death and suicide differed by ASQ outcome, mental health diagnosis, and age will be presented.

Conclusions: As suicide continues to be a pressing public health problem for youth with ASD and other NDD, evaluating their understanding of death and suicide can inform prevention strategies. Nearly one out of ten youth with NDD in this sample did not understand the finality of death, underscoring the need to tailor prevention strategies to accommodate youth with NDD.

424.268 (Poster) Coping with COVID-19: Neurodivergent Mental Health Differences of Young Adults in the Wake of a Pandemic

Y. H. Chou, C. T. Moody, J. E. Lerner, C. Keyler and E. A. Laugeson; (1)UCLA Semel Institute for Neuroscience and Human Behavior, UCLA PEERS® Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, University of California Los Angeles, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience and Human Behavior, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA

Background: Neurodivergent individuals, including those on the autism spectrum (ASD) or with attention-deficit/hyperactivity disorder (ADHD), often experience higher rates of co-occurring mental health disorders than neurotypical peers (Pehlivanidis et al., 2020), a trend which some studies show has been exacerbated since the pandemic (Oomen et al., 2021; Sibley et al., 2021). Although research on both autistic and ADHD populations during COVID-19 show common themes (e.g., social isolation), there appears to be population-specific impacts too (e.g., chronic boredom in ADHD; stress from routine disruption in autism). Yet, other research indicates the pandemic has also had positive impacts for neurodivergent individuals (e.g., increased time to complete schoolwork for those with ADHD; reduced sensory overload for autistic individuals; Mumbardó-Adam et al., 2021; Oomen et al., 2021; Behrmann et al., 2022). Given mixed findings, it is important to further clarify impacts of the COVID-19 pandemic on neurodivergent populations. Further, few studies have compared impact across neurodivergent groups or among individuals with co-occurring presentations (e.g., ADHD and autism), who generally show greater impairments and needs (Zablotsky et al., 2020).

Objectives: This study explores differences in mental health symptoms of adults on the autism spectrum and/or with ADHD prior to and during COVID.
Methods: Participants included 164 young adults (72.6% male; $M_{age}=22.1$, $SD=4.5$) previously diagnosed with ASD ($n=94$), ADHD ($n=33$), or ASD+ADHD ($n=37$) who presented for treatment at the UCLA PEERS® Clinic prior to COVID (2017-2019; $n=70$) and during COVID (2020-2022; $n=94$). Depression and loneliness were assessed via self-report on the Major Depressive Inventory (MDI; Bech et al., 2001) and Social and Emotional Loneliness Scale for Adults (SELSA; DiTommaso & Spinner, 1993), respectively. Social anxiety was assessed using caregiver- and self-report on the Social Anxiety Scale (SAS; La Greca, 1988).

Results: A MANOVA revealed a significant interaction between diagnosis and COVID presence, $F(8, 252)=2.02$, $p=.045$, suggesting COVID impacted mental health symptomatology differently across neurodivergent groups. Probing this through univariate ANOVAs, the models including depression and social anxiety were nonsignificant. However, a significant interaction emerged in the model including loneliness, as measured by the SELSA, $F(2,139)=5.33$, $p=.006$. Specifically, the ADHD group demonstrated significant increases in loneliness during COVID, $t(26)=-2.77$, $p=.010$, while there were no significant changes in loneliness in the ASD, $t(82)=1.05$, $p=.296$, or ASD+ADHD, $t(31)=-.90$, $p=.378$, groups after the onset of the pandemic. Although autistic adults had significantly higher levels of loneliness pre-pandemic than adults with ADHD, $p=.005$, these differences diminished during COVID due to increased loneliness in adults with ADHD, $p=.452$.

Conclusions: These findings demonstrate similar degrees of depression and social anxiety prior to and during COVID for young adults across neurodivergent diagnostic groups. However, results suggest that the pandemic disproportionately impacted adults diagnosed with ADHD without co-occurring autism with respect to loneliness. Co-occurring autism may have mitigated feelings of loneliness during the pandemic for those with both diagnoses, perhaps due to simultaneous feelings of relief from social stress reported by autistic people (Mumbardó-Adam et al., 2021). Further research investigating the evolution of mental health functioning over time in the COVID-19 pandemic is also warranted.

424.269  (Poster) Depression and Anxiety in Girls with and without Autism Spectrum Disorder, Considering Pubertal Timing
S. Bansal, M. Santhosh, K. Pelphrey and S. J. Webb, (1)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Autism and Neurodevelopment Disorders Institute, University of Virginia School of Medicine, Washington, DC, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by social communicative impairments and sensory sensitivities. In addition, the physical and social changes that occur with puberty may be a turbulent time for adolescents. Earlier pubertal timing has been correlated with higher internalizing mental health symptoms for neurotypical girls. Specifically, earlier onset of menarche in females has been tied to higher rates of depression that persist into adulthood (Hoyt, 2020). Less longitudinal research has been done on the effects of differential pubertal timing on autistic girls, with one study demonstrating early onset of puberty for only females (Corbett, 2020) and another study finding no early puberty onset (May, 2017).

Objectives: To investigate the relation between pubertal timing and internalizing mental health problems for both autistic and non-autistic adolescents in a longitudinal study.

Methods: 23 female ASD participants (ages 8 to 17 at the 1st time point) and 42 female TD participants (ages 8 to 17 at the 1st time point) from the ACE GENDAAR network, a five-site NIH-funded project investigating sex and gender differences in individuals with autism, will be included in the study. Participant data was collected at two time points 3 to 8 years apart. ASD diagnosis was confirmed via gold-standard diagnostic measures. Data on pubertal development was collected using the Pubertal Development Scale, a parent or self-report measure of physical development. Depression and anxiety were assessed via the Child Behavior Checklist (CBCL) at the first time point, a parent-report behavioral checklist of comorbid mental health symptoms, and via the Adult-Self Report (ASR) or the Youth Self-Report (YSR), self-report analogues to the CBCL, at the second time point.

Results: Residuals of a pubertal maturation by time regression were calculated for each participant to approximate pubertal timing variation. For both the autistic and the non-autistic group, no significant correlations ($r = -0.292$ to $0.111$) were found between pubertal timing and depression and anxiety data at both timepoints.

Conclusions: Initial correlations have not shown that pubertal maturity at younger ages is related to variability in mental health problems. Future analyses will include a multiple regression model to examine longitudinal effects considering symptoms at and pubertal timing at the first timepoint predicting depression and anxiety at the second timepoint.

424.270  (Poster) Diagnosis of Autism Spectrum Disorder in Donnai-Barrow Syndrome: A Case Study
D. Swaminathan, S. Srikumar, S. Sayed, M. Srikar, P. Jacob and S. S. Meerar, (1)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, Bangalore, India, (2)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, (3)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, India, (4)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, INDIA
Background: Donnai-Barrow syndrome (DBS) is a rare autosomal recessive condition caused by LRP2 gene mutation. The prevalence reported is <1/100,000. DBS is characterized by multiple atypical craniofacial features, ophthalmologic abnormalities, corpus callosum agenesis, sensorineural hearing loss, intellectual disability, and global developmental delay (GDD) (Longoni., et al, 2018). Autism spectrum disorder (ASD) diagnosis in DBS is even rarer and has not been reported previously.

Objectives: To highlight the process of ASD diagnosis in a child with DBS

Methods: This case report is of a 6-year-old female child, diagnosed with DBS confirmed by genetic testing at birth. The child was fitted with cochlear implants bilaterally at 13 months of age and has been attending auditory-verbal therapy (AVT) since then. Her ocular difficulties (myopia) were corrected using prescription spectacles. Parental concerns of limited improvement in language and social communication, reduced social interaction and poor outcomes with AVT suggested a need for detailed assessments to rule out presence of other neuro developmental disorders. Although parents were concerned earlier (by 4 years), they had not brought her for an evaluation due to the pandemic. A team of speech language pathologists, child psychologist and psychiatrist assessed the child. Detailed history was collected from parents following which formal behavioural and developmental assessments (e.g., ComDEALL Developmental Checklist) were administered. Although diagnostic measures like ADOS-2 could not be administered due to prohibitive costs for training in LMICs, a 30-minute semi-structured play session with the clinician was video recorded and coded for behaviours under the domains of social communication, play skills and restricted repetitive behaviors (RRBs). A clinical best estimate (CBE) diagnosis was made based on DSM-5.

Results: History from parents revealed that the child largely used previously heard lines from stories or poems during interactions (indicative of gestalt processing of language), had poor communication intent and RRBs/sensory patterns like smelling pungent odours, playing with shadows/reflecting surfaces, touching different surfaces, hypersensitivity to light. Formal assessments showed delay across all developmental domains, with longest delay in social skills (Fig 1). Play observation revealed inconsistent joint attention, poor verbal/nonverbal imitation, limited use of gestures, poor social engagement and reciprocity, reduced sharing of interests, insufficient pretend play, a preference for solo play, smelling toys and preoccupation with specific parts of objects. Motor, language, social communication delay, and RRBs can be present in children with autism, hearing impairment (HI), and severe GDD. The challenge was with diagnosing ASD in the presence of GDD and HI although the child was fitted with CI bilaterally at young age. A recommendation for tailored intervention with focus on sensory integration and social communication was made.

Conclusions: Diagnosing ASD in presence of multiple disabilities is challenging. Was the delay in receiving diagnosis of ASD due to delay in reaching out for assessments due to the pandemic or due to the nature of diagnostic overshadowing cannot be commented upon. Awareness of occurrence of ASD in DBS, timely diagnosis, and initiation of intervention are key for good outcomes.

424.271 (Poster) Does Cognitive-Behavioral Therapy Treatment of Anxiety Improve Sleep in Autistic Children?

H. Harris, M. Kook; A. Guzick; A. M. Lyons-Warren; Y. W. Wan; R. P. Goin-Kochel; L. N. Berry; C. N. Murali; R. G. Voigt; A. C. Ramirez; S. Olsen; and E. A. Storch, (1)Pediatrics, Developmental Behavioral Pediatrics, Meyer Center for Developmental Pediatrics, Texas Childrens Hospital, Baylor College of Medicine, Houston, TX; (2)BAYLOR COLLEGE OF MEDICINE, Houston, TX; (3)Baylor College of Medicine, Houston, TX; (4)Pediatrics, Baylor College of Medicine, Houston, TX; (5)Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; (6)Baylor College of Medicine, Houston, TX; (7)Department of Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

Background: Sufficient quality and duration of sleep are necessary for optimal neurobehavioral functioning in all individuals. Sleep problems occur frequently in autistic children and persist from childhood into adolescence. Prior work suggests that co-occurring anxiety correlates with sleep disturbance in autistic children. However, the literature does not clarify the directionality of this relationship or whether treating anxiety might improve sleep in autistic children.

Objectives: This study examined (a) the correlation between baseline sleep problems and anxiety severity in autistic children, and (b) how sleep problems change with anxiety treatment.

Methods: Ninety-six autistic children, ages 4 to 14 years, were enrolled in an anxiety-focused treatment study utilizing a stepped-care cognitive-behavioral therapy approach. Measures of anxiety and sleep were collected pre-treatment, mid-treatment and immediately post-treatment. Measures included a clinician-rated measure of severity of anxiety symptoms - the Pediatric Anxiety Rating Scale (PARS) and a parent-rated measure of sleep behaviors - the Children's Sleep Habits Questionnaire, Short Form/Abbreviated (CSHQ-SF). Higher PARS scores are indicative of higher severity of anxiety symptoms and higher CSHQ-SF scores indicate more frequent occurrence of sleep problems. Correlation between baseline PARS total severity scores and CSHQ-SF total scores were calculated using Pearson correlations. Paired t-tests were used to compare CSHQ-SF total scores at each time point to determine if there were significant changes in sleep habits as a function of anxiety treatment. For the 43 individuals who had CSHQ-SF assessments at all three time points, a repeated measures ANOVA was performed to compare the effect of treatment on total CSHQ scores.
Results: Of the 93 children who completed baseline assessments, 57 had mid-point assessment data and 48 had post-treatment assessment data. Baseline elevated PARS scores were positively correlated with baseline elevated CSHQ-SF scores (Pearson's correlation: $0.31$, $p = 0.003$). Via paired t-tests, there was a significant reduction in CSHQ-SF total scores from baseline to mid-treatment ($p <=0.001$) and again from mid-treatment to post-treatment ($p=0.021$). For participants with data at all time points, there was a statistically significant improvement (reduction) in CSHQ-SF scores over the course of treatment $[F(2) = 17.13, p <=0.001]$. 

Conclusions: Clinician-rated anxiety symptom severity in autistic children is positively correlated with parent-reported sleep problems. Cognitive-behavioral therapy for anxiety symptoms was associated with improvements in parent-reported sleep habits among autistic children.

424.272 (Poster) Effortful Control and Emotional Reactivity at Age 2 Predict Internalizing and Externalizing Symptoms at Age 3 in Toddlers with and without Autism

S. Macari $^1$, K. All $^1$, E. Diamond $^2$, K. K. Powell $^1$, A. Vernetti $^3$ and K. Chawarska $^4$; (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Yale University, New Haven, CT, (3)Child Study Center, Yale Child Study Center, Yale School of Medicine, New Haven, CT, (4)Child Study Center, Yale School of Medicine, New Haven, CT

Background:

Internalizing (e.g., anxiety) and externalizing (e.g., aggression) symptoms occur in many children with autism (Vaillancourt et al., 2017). Models of their emergence stress the roles of early negative and positive emotions (Behrendt et al., 2020; Putnam & Stifter, 2005) and self-regulation. Self-regulation can both moderate early emotional reactivity and serve as a direct predictor of later internalizing/externalizing problems (An & Kochanska, 2020; Lonigan et al., 2009). Research on predictors of internalizing/externalizing symptoms in children with autism is limited.

Objectives:

Determine if 1) 3-year-olds with autism differ from peers on I/E symptoms; 2) Time 1 (age 2) emotional reactivity (joy, frustration) during standardized induction tasks predicts I/E symptoms at Time 2; and 3) Time 1 (age 2) self-regulation, alone or in combination with emotional reactivity, predicts I/E symptoms at Time 2.

Methods:

Participants included age-matched toddlers with autism (n=67; 81% male) and without autism (n=81; 58% male, including siblings of children with autism (SIB; n=26), toddlers with typical development (TD; n=24) or with atypical development (ATP; n=31)). At Time1 ($M_{age}=21.35m, SD=3.38$), children underwent six Laboratory Temperament Assessment Battery (LabTAB)-based tasks (Goldsmith & Rothbart, 1999) eliciting mild frustration and joy. Peak reactivity for joy (LabTAB-Joy) and frustration (LabTAB-Frustration) was coded off-line and averaged across facial, bodily, and vocal channels. At Time1, parents completed the Early Childhood Behavior Questionnaire (ECBQ; Putnam et al., 2006), yielding Effortful Control (ECBQ-EC) scores, and at Time2 ($M_{age}=39.16m, SD=3.67$), the Early Childhood Inventory-5 (ECI-5; Sprafkin & Gadow, 2014), yielding Internalizing and Externalizing composites. Group (4) x sex (2) general linear models examined differences in Internalizing and Externalizing scores with NVDQ and sex as covariates; multiple linear regressions tested contributions of Time1 LabTAB-Joy, LabTAB-Frustration, ECBQ-EC, ADOS-SA, sex, and NVDQ to Time2 Internalizing or Externalizing scores.

Results:

There were significant effects of group for Internalizing ($p<.01$) but not for Externalizing ($p=0.638$) scores; Neither sex ($p=.694$) nor NVDQ ($ps=.413$) contributed to the model. Planned contrasts indicated toddlers with autism had significantly higher Internalizing symptoms than ATP ($p<.002, d=72$), SIB ($p<.001, d=1.48$), and TD ($p<0.001, d=1.38$). The regression predicting Time 2 Internalizing scores was significant (adj $R^2=0.258, F(8,131)=8.891, p<.001$); Time 1 ADOS-SA ($\beta=.310, p=.002$) and ECBQ-EC ($\beta=-.297, p=.003$) were significant predictors. For Time 2 Externalizing, significant predictors of the regression (adj $R^2=0.091, F(8,131)= 3.13, p=.005$) included ECBQ-EC ($\beta=-.482, p<.001$) and the interaction between EC and LabTAB-Joy ($\beta=.290, p=0.009$), such that the negative association between EC and Externalizing was strongest at low levels of LabTAB-Joy.

Conclusions:

Internalizing (but not externalizing) symptoms were elevated in 3-year-olds with autism compared to toddlers with neurodiverse developmental profiles, controlling for sex and NVDQ. Severity of internalizing symptoms at age 3 was predicted by autism severity and self-regulation assessed one year earlier. 2-year predictors of externalizing problems at 3 years included self-regulation as well as the interaction between observed joy and self-regulation; higher levels of joy weakened the relationship between poor self-regulation and later
externalizing symptoms, suggesting a possible protective effect of positive reactivity. Targeting self-regulation in intervention programs may help ameliorate future emotional and behavioral challenges.

424.273 (Poster) Emotion Dysregulation in Autistic Individuals: A Meta-Analysis
R. G. McDonald, M. I. Cargill, S. Khawar and E. Kang, Department of Psychology, Montclair State University, Montclair, NJ

Background: As psychiatric disorders frequently co-occur in autistic individuals (Simonoff et al., 2008), it is important to identify underlying mechanisms that may relate to the development of these symptoms in autistic individuals, as they may contribute to difficulties across the lifespan and reduced quality of life (Connor et al., 2020; Hollocks et al., 2019). Emotion dysregulation (ED) is a deficit in executive functioning defined as the reduced ability to effectively regulate emotional experiences and expressions when presented with changing environmental stimuli (Gross, 2007). ED is experienced at a higher rate in autistic compared to typically-developing (TD) people, and has been proposed to underlie both internalizing and behavioral disorders in autism spectrum disorder (ASD; Conner et al., 2021; Uhl et al., 2019). Despite the higher rates of ED in autistic people, there has been no quantitative synthesis of the literature of ED severity compared to other populations, which is important in order to reveal patterns and contributing factors of ED severity across multiple studies that may be otherwise obscured.

Objectives: This project sought to synthesize the body of literature to date on ED in autism by conducting a meta-analysis 1) to assess the magnitude of difference in ED severity between autistic populations compared to TD and/or OC (e.g., anxiety) groups, and 2) to explore the role of potential moderators (e.g., sex composition, mean age) that may contribute to the heightened risk of ED in ASD.

Methods: Following a literature search of PubMed, PsycINFO, MEDLINE, and PsycArticles, adhering to the PRISMA guidelines, twenty studies were included in the analyses (Total \( N = 8,778 \) [4,287 ASD, 2,881 TD, 1,609 OC]; see Table 1). Meta-analyses were used to examine the effect size (Hedge’s \( g \)) of differences in ED severity between groups. Additional analyses examined potential moderators (sex composition, mean age) via meta-regression, and publication bias.

Results: Overall, the autistic group had significantly higher ED relative to the comparison groups (\( g = 1.03, k = 20, 95\% \) confidence interval \([0.68-1.38]\), \( p < .001 \); Figure 1), indicating a large effect (Cohen, 1982). Subgroup analyses indicated a large effect when compared to TD group (\( g = 1.71, k = 14, 95\% \) CI[1.32–2.11], \( p < .001 \)) and a small-to-medium effect compared to OC groups (\( g = 0.44, k = 11, 95\% \) CI[0.09–0.80], \( p = .02 \)). Moderator analyses revealed more pronounced differences between autistic versus overall comparisons groups in samples with higher percentage of males (\( b = 1.56, p = .01 \)). No evidence of publication bias was found.

Conclusions: Our findings insinuate that autistic individuals experience significantly higher ED severity compared to TD and their OC counterparts. Sex composition was a significant moderator, underscoring the importance of directly examining gender differences in ED severity in autistic individuals in future investigations of ED in autism. Given that autistic individuals may be at heightened risk for experiencing a myriad of difficulties associated with ED, future studies should seek to better understand factors associated with the expression of ED (e.g., neural processes; Dennis et al., 2010), as well as to examine effects of intervention that includes emotion regulation as a target of treatment (Beck et al., 2020).

424.274 (Poster) Emotion Regulation in Children and Adolescents with Autism Spectrum Disorder: A Systematic Review and Meta-Analysis
J. Lugo Marin, D. Restoy Serrano, M. Oriol Escude, I. Setien, M. Magan Maganto, E. Diez Villoria, R. Canal-Bedia, J. A. Ramos-Quirorga and L. Gisbert, (1)Psychiatry, Hospital Universitari Vall d’Hebron, Barcelona, Spain, (2)Hospital Universitari Vall d’Hebron, Barcelona, Spain, (3)UNIVERSITY OF SALAMANCA, Salamanca, SPAIN, (4)University of Salamanca, Salamanca, Spain, (5)Instituto Universitario de Integración a la Comunidad INICO-InFoAutismo., Universidad de Salamanca, Salamanca, Spain

Background: Children and adolescents with Autism Spectrum Disorder (ASD) usually present difficulties in emotion regulation (ER) that interfere with their adaptive functioning. These difficulties can trigger episodes of disruptive behavior that cause significant discomfort both in the person with ASD and in their family environment. Although there is evidence of the high prevalence of these difficulties in children and adolescents with ASD, the frequency compared to the general population, as well as the relationship with clinically significant variables (e.g., internalizing symptomatology) have not been yet explored exhaustively.

Objectives: The objective of this study was to systematically review the evidence on ER in children and adolescents with ASD and its relationship with the following variables: internalizing and externalizing symptoms, intellectual functioning and social skills.

Methods: An electronic search of four databases (PsycINFO, PubMed, Scopus, Web of Science) was conducted to identify potential studies. The manual search consisted in the screening of the reference list of related articles and contacting corresponding authors of topic-related studies in order to request unpublished data. Only peer-reviewed English-written articles addressing emotion regulation in children and/or adolescents were included. Non-empirical sutdies (e.g. review articles) and studies with less than 10 participants with ASD were excluded.
Results: A total of 59 studies were included in the systematic review. A set of meta-analyses were conducted in order to compare ASD participants with non-ASD participants in subjective and objective measures of ER. Statistical significant between-group differences was found for both subjective (Cohen’s d = -1.61, 95% CI [-1.9, -.132], p < .001) and objective measures of ER (Respiratory Sinus Arrhythmia: Cohen’s d = -.28, 95% CI [-.46, -.173], p = .002; Heart rate: Cohen’s d = .69, 95% CI [.46, .92], p < .001), suggesting lower ER skills in the ASD group. Also, statistical significant differences were found for the use of adaptive (Cohen’s d = -.16, 95% CI [-.30, -.017], p = .03) and maladaptive strategies of ER (Cohen’s d = .41, 95% CI [.22, .603], p < .001), with the ASD group showing more frequently maladaptive ER strategies than the non-ASD participants. Significant associations were found for subjective ER measures and ASD severity (Cohen’s d = -.19, 95% CI [-.29, -.089], p < .001), and social skills (Cohen’s d = .62, 95% CI [.45, .74], p < .001), with participants with greater ER difficulties showing more severe ASD and poorer social skills. Finally, internalizing symptomatology was significantly correlated with both adaptive (Cohen’s d = -.27, 95% CI [-.34, -.21], p < .001) and maladaptive ER strategies (Cohen’s d = .29, 95% CI [.19, .39], p < .001), pointing at the use of maladaptive ER strategies being associated with higher prevalence of internalizing symptoms. No significant association was found between ER measures and intellectual functioning.

Conclusions: ER skills are significantly impaired in children and adolescents with ASD compared to their peers without ASD. The severity of ASD and difficulties in social skills are significantly related to difficulties in ER. Physiological measures could capture ER difficulties in this group.

424.275 (Poster) Emotional and Behavioral Problems in a Group of Brazilian Adults with Autism Spectrum Disorder
T. P. Mecca, D. Scharlau, C. Oliveira, D. P. L. Lourenço, I. C. A. Braga, R. Lowenthal and M. C. Teixeira, (1)Mental Health Department, Santa Casa de São Paulo School of Medical Sciences, São Paulo, Brazil, (2)Santa Casa School of Medical Sciences, São Paulo, Brazil, (3)Mackenzie Presbiterian University, Sao Paulo, Brazil, (4)Mental Health, Santa Casa de São Paulo School of Medical Sciences, Sao Paulo, Brazil, (5)Developmental Disorder Program, Mackenzie Presbiterian University, Sao Paulo, Brazil

Background: Previous studies show a high prevalence of emotional symptoms (internalizing) and behavioral problems (externalizing) in adults with autism spectrum disorder (ASD) when compared to the general population. Due to the difficulty in accessing health services in low- and middle-income countries, this prevalence is unknown, impacting the lack of adequate mental health care for this population. In Brazil there are few studies identifying psychopathologies in adults with ASD.

Objectives: To examine the prevalence of internalizing and externalizing problems in a group of Brazilian adults with ASD.

Methods: This is a cross-sectional quantitative study with no probabilistic sample of eighty-three individuals aged 18-58 years (mean=34.00; SD=10.08), 53 of whom were women (63.9%), diagnosed by a specialist physician. Behavioral and emotional problems were assessed by Adult Self-Report (ASR/18-59), considering empirically based scales, DSM-oriented scales and the three higher-order factor scales of internalizing, externalizing and total problems.

Results: Descriptive statistics for T-scores showed clinical classification of the individuals in the empirically based scales anxiety/depression, withdrawn, somatic complaints and in the internalizing higher-order factor scales. Clinical classification was verified also in problems with thoughts and inattention problems. In the aggressive and rule-breaking scales, they are found in the borderline range, as well as for the total score in externalizing problems. While on the intrusiveness scale, the observed average is within the expected range for the age. In the DSM-oriented scales, the group is in the clinical range for the anxiety, depression, somatic problems, avoidant disorder and ADHD problems scales. Only on the Antisocial scale did the mean scores indicate a borderline range. Significantly greater impairments in women were observed in somatic, attention, and internalizing problems, as well as in DSM-oriented scales that indicate anxiety, somatic, and ADHD problems. On the DSM-oriented scales, the group was classified in the clinical range for anxiety disorders, depression, somatic problems, avoidant personality, and ADHD problems. Only on the antisocial scale the mean scores indicate a borderline range. Significantly greater impairments in women were observed in somatic complaints, attention, and total internalizing problems, as well as in DSM-oriented scales that indicate anxiety disorders, somatic complaints, and ADHD problems. There was a high percentage (≥70%) of individuals with clinical range on the following empirically based scales: withdrawn, thought problems, and total internalizing problems. In the DSM-oriented scales, only in the avoidant personality problems scale a higher percentage of individuals with a clinical range was observed (86.74%). Between 60 and 69% of the group was classified in clinical range for: anxiety/depression on the syndrome scale and total behavior problems. On the DSM-oriented scales, this percentage was observed in depression, anxiety and ADHD problems. There was a positive, low, but significant correlation between total problems and age (r=0.31; p=0.005).

Conclusions: Although with a small sample, this was the first study to raise emotional and behavioral problems in a sample of autistic adults in Brazil, indicating high rates of clinical profiles mainly for internalizing symptoms.

424.276 (Poster) Epilepsy in Autism: Prevalence and Associated Factors in a Large Inpatient Psychiatric Sample
K. Kidity, K. Luo, M. S. Siegel, and C. A. Mazefsky, (1)UPMC Children’s Hospital of Pittsburgh, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Center for Clinical and Translational Science, MaineHealth, Portland, ME

Conclusions: ER skills are significantly impaired in children and adolescents with ASD compared to their peers without ASD. The severity of ASD and difficulties in social skills are significantly related to difficulties in ER. Physiological measures could capture ER difficulties in this group.

424.275 (Poster) Emotional and Behavioral Problems in a Group of Brazilian Adults with Autism Spectrum Disorder
T. P. Mecca, D. Scharlau, C. Oliveira, D. P. L. Lourenço, I. C. A. Braga, R. Lowenthal and M. C. Teixeira, (1)Mental Health Department, Santa Casa de São Paulo School of Medical Sciences, São Paulo, Brazil, (2)Santa Casa School of Medical Sciences, São Paulo, Brazil, (3)Mackenzie Presbiterian University, Sao Paulo, Brazil, (4)Mental Health, Santa Casa de São Paulo School of Medical Sciences, Sao Paulo, Brazil, (5)Developmental Disorder Program, Mackenzie Presbiterian University, Sao Paulo, Brazil

Background: Previous studies show a high prevalence of emotional symptoms (internalizing) and behavioral problems (externalizing) in adults with autism spectrum disorder (ASD) when compared to the general population. Due to the difficulty in accessing health services in low- and middle-income countries, this prevalence is unknown, impacting the lack of adequate mental health care for this population. In Brazil there are few studies identifying psychopathologies in adults with ASD.

Objectives: To examine the prevalence of internalizing and externalizing problems in a group of Brazilian adults with ASD.

Methods: This is a cross-sectional quantitative study with no probabilistic sample of eighty-three individuals aged 18-58 years (mean=34.00; SD=10.08), 53 of whom were women (63.9%), diagnosed by a specialist physician. Behavioral and emotional problems were assessed by Adult Self-Report (ASR/18-59), considering empirically based scales, DSM-oriented scales and the three higher-order factor scales of internalizing, externalizing and total problems.

Results: Descriptive statistics for T-scores showed clinical classification of the individuals in the empirically based scales anxiety/depression, withdrawn, somatic complaints and in the internalizing higher-order factor scales. Clinical classification was verified also in problems with thoughts and inattention problems. In the aggressive and rule-breaking scales, they are found in the borderline range, as well as for the total score in externalizing problems. While on the intrusiveness scale, the observed average is within the expected range for the age. In the DSM-oriented scales, the group is in the clinical range for the anxiety, depression, somatic problems, avoidant disorder and ADHD problems scales. Only on the Antisocial scale did the mean scores indicate a borderline range. Significantly greater impairments in women were observed in somatic, attention, and internalizing problems, as well as in DSM-oriented scales that indicate anxiety, somatic, and ADHD problems. On the DSM-oriented scales, the group was classified in the clinical range for anxiety disorders, depression, somatic problems, avoidant personality, and ADHD problems. Only on the antisocial scale the mean scores indicate a borderline range. Significantly greater impairments in women were observed in somatic complaints, attention, and total internalizing problems, as well as in DSM-oriented scales that indicate anxiety disorders, somatic complaints, and ADHD problems. There was a high percentage (≥70%) of individuals with clinical range on the following empirically based scales: withdrawn, thought problems, and total internalizing problems. In the DSM-oriented scales, only in the avoidant personality problems scale a higher percentage of individuals with a clinical range was observed (86.74%). Between 60 and 69% of the group was classified in clinical range for: anxiety/depression on the syndrome scale and total behavior problems. On the DSM-oriented scales, this percentage was observed in depression, anxiety and ADHD problems. There was a positive, low, but significant correlation between total problems and age (r=0.31; p=0.005).

Conclusions: Although with a small sample, this was the first study to raise emotional and behavioral problems in a sample of autistic adults in Brazil, indicating high rates of clinical profiles mainly for internalizing symptoms.

424.276 (Poster) Epilepsy in Autism: Prevalence and Associated Factors in a Large Inpatient Psychiatric Sample
K. Kidity, K. Luo, M. S. Siegel, and C. A. Mazefsky, (1)UPMC Children’s Hospital of Pittsburgh, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Center for Clinical and Translational Science, MaineHealth, Portland, ME
Background: Recent systematic reviews and meta-analyses reveal that anxiety disorders are highly prevalent in youth with Autism Spectrum Disorder (ASD). Given the high prevalence of anxiety among this population, recent research has focused on investigating potential mechanisms underpinning anxiety.

Objectives: The purpose of the current study was to examine the relationship between anxiety and social functioning in youth with ASD in a large heterogeneous dataset as well as the moderating influence of sex, age, and IQ on the relationship between overall social functioning and anxiety symptoms.

Methods: The current study involved secondary data analysis, using data from the Simons Foundation for Autism Research Initiative. The sample included 2745 individuals aged 4 to 18 and was well-characterized and heterogeneous in IQ. Parent- and teacher-report of anxiety symptoms and social functioning were included in the analyses.

Results: Based on both parent and teacher data, the social functioning domains (social awareness, social cognition, social communication, social motivation, and restricted interests and repetitive behaviours) accounted for a substantial portion of the variance in anxiety, controlling for age, sex, and IQ (24% for parent report and 27% for teacher report). All five social functioning domains were significant predictors of anxiety. For parent data, IQ was found to moderate the relationship between anxiety and social functioning, suggesting that when social functioning is low, youth without intellectual disability show higher anxiety than youth with intellectual disability.

Conclusions: The results indicate that social functioning is a significant predictor of anxiety. The knowledge that social functioning accounts for a large percentage of the variance in anxiety in this population will help inform behavioural mental health interventions. Interventions that target social functioning (e.g., social skills training programs) may enhance the effectiveness of treatment for youth with ASD. In addition, the results of the present study would assist in identifying at-risk youth (i.e., those with low social functioning) and developing preventive therapeutic and school-based interventions with the goal of improving youth’s social functioning and social experiences.
424.278 (Poster) Examining the Relationship between Autistic and Neurotypical Children’s Sleep and Adaptive Behavior
N. E. Fears* and H. L. Miller*, (1)School of Kinesiology, Louisiana State University, Ann Arbor, MI, (2)School of Kinesiology, University of Michigan, Ann Arbor, Ann Arbor, MI

Background: Many autistic children have poor sleep quality including difficulties falling asleep and staying asleep through the night. Many autistic children also have difficulties with adaptive behaviors, such as communication and daily living skills. Previous research has indicated a strong relationship between sleep and adaptive behavior in neurotypical children, but less is known about this relationship in autistic children and adolescents.

Objectives: The current study aimed to determine the relationship between autistic children’s sleep (e.g., daytime sleepiness, insomnia) and their adaptive behavior (e.g., communication skills, daily living skills, social skills).

Methods: We tested 45 autistic (Male=37, Female=8; Mage=13.7 years, SEage=2.96, Rangeage=7.81-17.80) and 63 neurotypical (Male=43, Female=20; Mage=12.9 years, SEage=3.06, Rangeage=7.37-18.2) children and adolescents. Participants reported their sleep on the Pediatric Daytime Sleepiness Scale (PDSS) and Women’s Health Initiative Insomnia Rating Scale (WHIIRS). Participants’ guardians reported the participants’ adaptive behavior abilities on the Vineland-3.

Results: Daytime Sleepiness

Examining reports of daytime sleepiness on the PDSS, autistic and neurotypical children were similar overall, but there were significant differences on two items. Autistic children (M=1.2, SD=0.76) reported feeling less alert most of the day compared to neurotypical children (M=0.84, SD=0.83, Welch’s t=2.34, p=.022). Autistic children (M=1.8, SD=1.42) also reported having to be awoken in the morning by someone more often than neurotypical children (M=1.19, SD=1.31, Welch’s t=2.27, p=.026).

Insomnia Symptoms

Examining reports of insomnia symptoms on the WHIIRS, autistic and neurotypical children were similar overall, but autistic children (M=0.98, SD=1.18) reported that their sleep difficulty was more likely to interfere with their daily functioning compared to neurotypical children (M=0.48, SD=0.83, Welch’s t=2.35, p=.022).

Relationship between Adaptive Behavior and Sleep scores

Due to autistic children reporting that their sleep was more likely to interfere with their daily functioning, we examined the relationships between autistic children’s adaptive behavior scores on the Vineland-3 and their sleep scores on the PDSS and WHIIRS. We found a significant negative relationship between autistic children’s feelings of being alert throughout their caregivers’ ratings of their overall adaptive behavior (Pearson’s r=-0.376, p=.031). More specifically, this appears to be due to the relationship between autistic children’s feelings of alertness and their daily living skills scores (Pearson’s r=-0.475, p=.005), but not their social or communication skills (ps>.05).

We also found significant relationships between autistic children’s reports of waking up too early and being unable to fall back asleep (Pearson’s r=-0.370, p=.037) and their overall insomnia symptoms (Pearson’s r=-0.407, p=.021) with their caregivers’ ratings of their social skills.

Conclusions: Overall, autistic children reported their symptoms of daytime sleepiness and insomnia at similar rates of neurotypical children. Despite these similarities there were some key differences. Autistic children reported being less alert throughout the day and that their sleepiness was more likely to impact their daily functioning. Notably, autistic children’s sleep ratings correlated with their caregivers’ ratings of their daily living skills and social skills. These results indicate that sleep quality and feelings of alertness likely affect autistic children’s daily functioning and thus warrant further research to improve their quality of life.

424.279 (Poster) Exploring Social and Sensory Differences in Autistic and Non-Autistic Individuals with Anorexia Nervosa and Their Parents.
E. J. Nimbley, K. Gillespie-Smith†, F. Duffy†, H. Sharpe† and E. Maloney†, (1)School of Health in Social Science, University of Edinburgh, Edinburgh, United Kingdom, (2)Department of Clinical Psychology, University of Edinburgh, Edinburgh, United Kingdom, (3)University of Edinburgh, Edinburgh, United Kingdom

Background:

Accumulating research evidence has established an overlap between autism and eating disorders, particularly anorexia nervosa (AN), and subsequent qualitative studies suggest that current treatments fail to meet their unique set of needs. As a result, research has begun to explore possible underlying mechanisms, with a broad range of factors implicated for autistic individuals including social and sensory
differences. There remains scope, however, to explore and compare these factors across autistic and non-autistic adults with anorexia in an effort to untangle common and condition-specific factors. Furthermore, parenting an individual with autism or anorexia has been found to be associated with multi-dimensional challenges, and it is important this broader social context is included in our understandings.

Objectives:

The current study will therefore focus on exploring social and sensory differences in both autistic and non-autistic individuals with anorexia in an attempt to untangle common and autism-specific mechanisms in acute and recovered stages of anorexia.

Methods:

Autistic and non-autistic individuals (18+ years) were interviewed online with a parent/primary caregiver. While previous studies have encouragingly adopted a multi-perspective approach, to date no study has explored these perspectives as dyads. Dyadic interviews not only provide multiple perspectives but also allows for interaction of perspectives. Interviews are being analysed using Interpretative Phenomenological Analysis. An autistic co-researcher and expert by experience of anorexia has assisted in the development of the interview schedule, as well as in the development of the themes.

Results:

14 dyads took part in the study. Preliminary findings suggest both common and autism-specific factors. Difficulties with social relationships, social isolation and socio-emotional processing and communication were common across both autistic and non-autistic participants. Social comparisons appear to play more of a role for non-autistic individuals, while only autistic participants reflected that they sometimes perceived their interactions to be more different than in deficit. Differences in interoception (the awareness and identification of internal bodily signals) were reported across both groups, and smell and taste sensitivities appeared to be more pronounced for both groups during the acute stages of anorexia. Autistic participants displayed more pronounced and consistent sensory sensitivities across all senses, including proprioception (perception of the position and movement of the body), and these sensitivities appear to be integrally linked with emotion and stress responses.

Conclusions:

There appears to be both common and condition-specific factors involved in the development, maintenance and recovery from anorexia. The personal and clinical significance of identifying possible common and autism-specific differences in social and sensory processing will be discussed, and the importance of involving autistic and neurodiverse perspectives in the broader field of eating disorders will be emphasised.

424.280 **(Poster)** Exploring the Association between Social Skills and Social Communication Impairments and Depression in Youth with Autism Spectrum Disorder

**L. de la Roche, K. Forbes, M. Pascoe, B. Derby, E. Psaradellis, E. Aragonostou, R. Nicolson, S. Georgiades and E. Kelley**, (1)Developmental Psychology, Queen’s University, Kingston, ON, Canada, (2)Queen’s University, Kingston, ON, Canada, (3)Autism Research Centre, Bloorview Research Institute, University of Toronto, Toronto, ON, Canada, (4)Department of Psychiatry, University of Western Ontario, London, ON, Canada, (5)Oppford Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (6)Department of Psychology, Queen’s University, Kingston, ON, Canada

**Background:** High comorbidity rates of depression are common in autistic individuals (Ghazuddin et al., 2002), and critical to investigate due to their associations with numerous negative factors, including suicidality and other self-injury behaviours. To date, there are mixed findings when investigating the associations between depression and social communication difficulties (Greenlee et al., 2020; Vikerstaff et al., 2007) and little on the association between social skills and depression (Bauminger & Kasari, 2000).

**Objectives:** The current study aimed to further understand the association between social (dis)abilities and depressive symptoms in autistic youth. We developed two primary objectives: the first being to determine if social skills predict depressive symptoms, and the second to investigate the inverse – if higher social communication difficulties predict higher depressive symptoms.

**Methods:** Data for both studies was obtained from the Province of Ontario Neurodevelopmental Network (POND) which is a research network that includes five hospitals and universities across Ontario. Study 1 included 542 autistic youth (mean age=11.82 SD=2.67, 420 males), and study 2 included 453 autistic youth (mean age=11.80 years, SD=2.69, 353 males, with 429 overlapping participants between the two studies). All youth had received a diagnosis of ASD from a medical professional prior to participation in the data collection, and diagnosis was confirmed using the ADOS (Lord et al., 2001; Lord et al., 2012), and the ADI - R (Le Couteur et al., 2003). Study 1 used the Revised Children Anxiety and Depression Scale (RCADS-P; Chorpita et al., 2000) and The Adaptive Behavior Assessment System 2nd Edition (ABAS-II; Harrison & Oakland, 2003) to assess depression, anxiety and behaviour in the autistic youth, and study 2 used the RCADS-P and the ADOS 1-4 (participants assigned according to recommendations from Lord et al (2012)) to assess depression and
symptom severity. Specifically, study 2 combined social communication algorithm scores, with higher scores indicating greater difficulties (Lord et al., 2012).

Results: In study 1 we conducted a hierarchical multiple regression; after controlling for age, gender and IQ, results indicate that social communication difficulties did not significantly predict depressive symptoms, and depressive symptoms did not significantly predict social communication difficulties. A hierarchical regression was also run for study 2 to evaluate how social skills might predict depressive symptoms in autistic youth. After controlling for age, gender and IQ, lower social skills predicted higher depressive symptoms, and higher depressive symptoms predicted lower social skills.

Conclusions: The results from study 1 extend the limited available literature investigating the relationship between social communication difficulties and depressive symptomatology. Findings from study 2 aligned with our hypothesis and current available literature (e.g., Duan et al., 2022). The difference in our findings between studies may be partially explained through the different measures used (ABAS-II vs. ADOS) wherein one is parent-report while the other is observer-report. The focus on the association between definitive autism symptoms and depression highlighted the association between social skills and depressive symptoms in autistic youth. Results from our study emphasize the necessity for social skills training and support for autistic youth.

424.281 (Poster) Exploring the Effects of Co-Occurring ADHD and Anxiety on Sensory Processing Differences and Repetitive Behaviours in Autistic Children

N. Khalil†, A. Deronda†, E. Wodka, S. H. Mostofsky† and N. A. Puts†, (1)South London and Maudsley NHS Foundation Trust and Institute of Psychiatry, Psychology and Neurosciences, King's College London, London, United Kingdom, (2)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger, Baltimore, MD, (3)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD, (4)Johns Hopkins School of Medicine, Kennedy Krieger Institute, Baltimore, MD, (5)Russell H. Morgan Department of Radiology and Radiological Science, Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK, Baltimore, MD, United Kingdom

Background:

Autistic individuals are at higher risk of developing co-occurring psychiatric conditions, including ADHD and anxiety disorders, compared to the general population. Having a co-occurring condition is associated with wider range of functional impairment and higher needs for more support. Little is known about how co-occurring psychiatric disorders interact with core autism traits. In this study, we focus on the impact of co-occurring ADHD and anxiety on sensory processing differences and repetitive behaviours in a group of autistic children with and without ADHD, and those with only ADHD.

Objectives:

1. To assess sensory processing differences and repetitive behaviours in autistic children with and without ADHD, and children with ADHD.
2. To assess the effect of anxiety symptoms on sensory processing and repetitive behaviours in these groups.
3. To examine whether the presence of co-occurring ADHD may influence the relationship between sensory domains and subtypes of repetitive behaviours.

Methods:

Participants: We recruited 18 children with ASD only (14M, 4F), 54 children with ASD+ADHD (47M, 7F) and 69 children with ADHD only (49M, 20F). Age (between 8-13 years old) and IQ were matched.

Clinical measures: Sensory Processing Measure (SPM), The Repetitive Behaviour Scale (RBS), Screen for Child Anxiety Related Disorders (SCARED).

Analyses: A 1-way ANOVA was used to compare the mean scores for sensory processing, anxiety, and repetitive behaviours between the 3 groups. Then, we used mediation analyses to determine how anxiety, sensory processing and repetitive behaviours may be interrelated. Finally, we used Pearson’s correlation to assess the correlation between sensory domains and subtypes of repetitive behaviours between autistic children with and without ADHD. We plan additional moderation analyses of the association between anxiety, sensory differences and repetitive behaviours in the three groups.

Results:

There were significant group effects on sensory processing (p < 0.001), repetitive behaviours (p < 0.001), and anxiety (p < 0.001) with autistic children with co-occurring ADHD being most affected, followed by autism alone (Figure 1ABC). Across all groups, we found that anxiety, sensory processing differences and repetitive behaviours were positively intercorrelated. Anxiety partially mediates the
relationship between sensory processing differences and repetitive behaviours (Figure 1D). Effects of having ADHD and ASD on the relationship between sensory domains and subtypes of repetitive behaviours are shown in Table 1.

Conclusions:

Our results suggest that having co-occurring ADHD leads to high sensory processing difficulties and repetitive behaviours in autistic individuals. Moreover, anxiety has a partial mediation effect on the association between sensory differences and repetitive behaviours in ASD. In those with co-occurring ADHD, ADHD may lead to a broader range of repetitive behaviours including increased self-harm. This might be explained by wider affection of sensorimotor brain circuits in those individuals or may be related to higher anxiety levels which increase repetitive behaviours in an attempt to regulate emotions. The findings suggest that simultaneous consideration of sensory processing and co-occurring mental health issues can help address the heterogeneity of autism, improving targeted intervention and tailored care.

424.282 (Poster) GI Wanna Talk about Autism: A Qualitative, Participatory Study of Gastrointestinal Symptoms in Autistic Adults

C. B. Holingue, M. Johnson, K. Almendinger, K. Daley, F. DiJulia, Z. J. Williams, L. G. Kalb, S. N. Brasher and E. Pellicano,
(1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Emory University Nell Hodgson Woodruff School of Nursing, Atlanta, GA, (3)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Kennedy Krieger Institute, Baltimore, MD, (5)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (6)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)School of Nursing, Emory University, Atlanta, GA, (8)Macquarie School of Education, University College London, Sydney, NSW, United Kingdom

Background:

Gastrointestinal (GI) symptoms are common among autistic people and can be distressing and disabling. However, the lived experiences, needs, and priorities of autistic adults with GI symptoms have not been examined.

Objectives:

The goal of this study was to gain an understanding of the experiences, needs, and priorities of autistic adults with a range of support needs, as they pertain to GI health through qualitative interviews.

Methods:

This study adopted a participatory approach in which a 26-member Community Board of autistic and non-autistic adults with diverse professional and lived experiences contributed to the study design. Four researchers, including two autistic adults, conducted in-depth, semi-structured interviews with 27 participants: 21 autistic adults, four mothers of autistic adults, and one mother with their autistic adult child. Of the 21 autistic adults who participated on their own, ten were women and seven were men (14 cisgender; 3 transgender), and four were non-binary or gender non-conforming. All interviews took place via Zoom in video or audio format and were transcribed verbatim. Transcripts were reviewed by participants for accuracy and approval then analyzed using Interpretative Phenomenological Analysis. A five-person team (the four interviewers and an additional autistic researcher) used inductive coding to identify patterns of meaning in personal lived experiences. A final codebook was generated through an iterative process of individual transcript coding and group consolidation and refinement of codes.

Results:

Our analysis demonstrates that in many instances, GI symptoms have profound and extensive negative impacts on all areas of life (“...I don’t know if I’ll be able to hold down a full-time job or not...Will I ever be able to date or do anything?”). Autistic adults described the effort, time, planning, and other resources used to prevent or manage GI symptoms. Common triggers of GI issues include stress, sensory overwhelm, and changes in routine and food, though triggers were not always apparent. Unfortunately, most autistic adults and their parents described primarily frustrating and unhelpful healthcare interactions. They found the system difficult, unpleasant, and expensive to navigate and felt healthcare providers were often dismissive and did not offer useful diagnoses or advice (“They weren’t concerned at all.”). Autistic adults relied on medications, extensive planning and preparation, avoidance of triggers, and positive supports such as family or friends to help prevent and manage their symptoms.

Conclusions:

This study reveals the frequency, magnitude, and ways in which GI symptoms shape the experiences and opportunities of autistic adults. It also captures the many and varied ways individuals manage their symptoms to carry out their lives as best they can. These results, with input from our Community Board, will serve to inform the next phase of this study in developing recommendations for potential services,
Background: Prevalence estimates of co-occurring neurological, psychiatric, and medical conditions have yet to be firmly established in autistic children and adults. Having reliable estimates of co-occurring conditions improves their recognition and treatment, improving the quality of life of autistic persons and their caregivers.

Objectives: The present study aims to determine the best estimates of neurological, psychiatric, and medical co-occurring conditions in children and adults with Autism Spectrum Disorder (ASD).

Methods: The research question progressed within the development of the Italian Guideline for the diagnosis and management of children, adolescents, and adults with ASD. The protocol was registered within the PROSPERO database (CRD42019132347) and reported following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols (PRISMA-P) statement. The co-occurring conditions listed in the search strategy were reviewed by the Italian Guidelines Panel members, including 36 professionals, carers, and persons with ASD, and integrated by the stakeholder’s suggestion collected over a four-week period. A systematic search strategy of articles indexed from the inception to May 2022 using PubMed and PsycINFO bibliographic databases was performed. Six blinded authors screened records for inclusion/exclusion criteria and extracted the data. The risk of bias was evaluated using the quality assessment checklist for prevalence studies (Hoy et al., 2012). Criticisms were debated by the review team and content experts. Pooled prevalence estimates for different co-occurring conditions in ASD were determined using random effects models. Heterogeneity was investigated using random-effects meta-regression models.

Results: Of 19,535 studies, 341 publications were included for systematic review and meta-analysis. Meta-analyses of 23 co-occurring conditions with at least 15 studies included were performed. 40% of the included studies were conducted in the US, and 75% were clinical sample-based studies. Among the point prevalence, feeding disorder, 53% (95%CI 43%-64%), sleep-wake problems, 45%, (35-55%), gastrointestinal problems, 40% (34-46%), ADHD, 38% (33-44%), anxiety disorder, 37% (33-44%), overweight/obesity, 35% (29-42%), elimination disorder, 32% (21-43%), sleep-wake disorder, 30% (19-41%), disruptive behavior, 29% (24-34%), were the most frequent co-occurring conditions analyzed. On one hand, studies investigating ADHD (45 vs 24%, p<0.0001), anxiety disorder (43 vs 29%, p=0.033), and sleep-wake problem (46 vs 16%, p=0.0001) prevalence in children<18 years old showed higher prevalence compared to those including adults. Depressive disorder (15 vs 36%, p<0.0001), epilepsy (15 vs 23%, p=0.0001), and gastrointestinal disorder (15 vs 37%, p=0.005) were found to be prevalent in studies including adults compared to those with children. Estimates in clinical sample-based studies were generally higher than in population/registry-based studies. Gender and intellectual disability were associated with heterogeneity across studies (gender for tic disorder, depressive disorder, epilepsy, sleep-wake problem, affective disorder, gastrointestinal disorder, Down Syndrome; intellectual disabilities for schizophrenia).

Conclusions: Co-occurring conditions worsen the quality of life of autistic individuals and their carers. Notably, the awareness of the presence of specific co-occurring conditions associated with autism allows for targeted interventions and better outcomes.
predictors of GI symptoms: sensory over-responsivity, anxiety, and neuroticism. Participants were divided into a high autistic traits group (AQ+, n = 72) and a low autistic traits group (AQ-, n = 83) using an Autistic Quotient cut-off score of 32. Fisher’s Exact Test and independent samples t-tests were used to compare AQ+ and AQ- groups for GI symptom severity and GI symptom predictors. A hierarchical multiple regression analysis and mediation analyses were conducted to analyse the predictive and mediatary effects of autistic traits, sensory-over-responsivity, anxiety, and neuroticism on GI symptom severity.

Results: Compared to the AQ- group, the AQ+ group were more likely to have at least one GI symptom (p = .001), and had more severe GI symptoms overall (t(153) = -3.51, p < .001, d = 0.57). The AQ+ group also had higher levels of all GI symptom predictors: sensory-over responsibility (t(153) = -10.65, p < .001, d = 1.72), anxiety (t(153) = -4.75, p < .001, d = 0.77), and neuroticism (t(153) = -3.98, p < .001, d = 0.64). A hierarchical multiple regression analysis found that autistic traits were a significant predictor of GI symptom severity, but this relationship was not significant following the inclusion of the other predictors. The final model explained 49% of the variance in GI symptoms severity. Anxiety emerged as the only independent predictor of GI symptoms severity (β = .28, t(146) = 3.49, p < .001). The relationship between autistic traits and GI symptom severity was fully mediated by anxiety in the whole sample.

Conclusions: The prevalence and severity of GI symptoms in autistic adults is attributable to higher levels of anxiety. Future research should investigate the effect of reducing anxiety in order to treat GI symptoms in autistic adults.

424.285 (Poster) Gastrointestinal Symptoms in Autistic Children and Their Relationship Maternal Mental Health
H. Aslan Genç, M. Güldan, J. Osmanlı, P. Arıkan, E. Özdoğan and Ç. Arıkan, (1)School of Medicine, Psychiatry Department, Koç University, Istanbul, Turkey, (2)Koç University School of Medicine, Istanbul, Turkey, (3)Koç University College for Social Sciences and Humanities, Istanbul, Turkey, (4)Pediatric Gastroenterology and Hepatology, Koç University School of Medicine, Istanbul, Turkey

Background: Autistic children suffer from comorbid somatic or psychiatric disorders. FGIDs are a group of disorders characterized by symptoms such as abdominal discomfort, dysphagia, epigastric pain, constipation without any pathological findings on testing and are associated with low quality of life (QoL) and comorbid psychopathologies such as depression and anxiety. Functional gastrointestinal disorders (FGID) are more common in autistic children than their peers in the general population, however studies examining FGIDs with reliable and valid tools and investigating maternal QoL, depression and anxiety are limited.

Objectives: We aimed to describe the FGID symptoms in autistic children, compare the maternal QoL, depression and anxiety scores in autistic children, children with FGIDs and healthy controls.

Methods: In this cross-sectional study, the participants were recruited from child psychiatry outpatient unit and Turkish Autism Society for autism group (n=82), from pediatric gastroenterology outpatient units for FGID group (n=30). The control group (n=38) was recruited via snowballing. The autism severity was assessed via Childhood Autism Rating Scale, the FGID symptoms via ROME III criteria, maternal QoL, depression and anxiety symptoms via Quality of Life in Autism Questionnaire-parent version, Beck Depression and Beck Anxiety Inventory, respectively. Group comparisons were made via ANOVA and post-hoc tests were conducted for normally distributed data on SPSS version 26. A probability level lower than 0.05 was set as statistical significance.

Results: Demographic variables such as age, parental education and socioeconomic status were similar between groups (p>0.05). Seventy percent of the autistic children met criteria for at least one FGID, and 52 % met criteria for at least two or more. The autism group had a higher M:F ratio than FGID and control groups (p=0.04). Functional constipation (56 %), functional dyspepsia (50 %) and abdominal pain (33 %) were the most prevalent FGIDS in autistic children. FGID symptoms did not differ according to age (p>0.05) or sex (p>0.05) in autistic children. The maternal QoL was lower (p<0.001) and depression and anxiety scores were higher (p=0.012 and p=0.001, respectively) in autism group compared to FGID and healthy control groups (Table 1). Maternal quality of life in autism group was strongly correlated with depression (rho=0.781, p<0.001) and anxiety scores (rho=0.591, p=0.001), and these correlations remained significant in linear regression analyses (p<0.001 and p=0.16).

Conclusions: Majority of autistic children in our sample had one or more FGIDs without prior referral to gastrointestinal units. Mothers of autistic children needed support for quality of life, depression, and anxiety. Early recognition and treatment of gastrointestinal disorders may help both individual and maternal well-being regarding reciprocal relationship between maternal mental health and behavioral difficulties seen in autistic children.

424.286 (Poster) Gastrointestinal and Behavioral Symptoms in Typically Developing Children and Children with Autism Spectrum Disorder
Background:
Up to 91% of children with autism spectrum disorder (ASD) experience gastrointestinal (GI) symptoms. The most common GI symptoms include abdominal pain with or without diarrhea, and chronic constipation with or without encopresis. GI symptoms have been associated with an increase in self-injurious behaviors, hyperactivity, irritability, and inhibition in individuals with ASD. In addition, anxiety is thought to play a role in GI symptoms in children with ASD. Studies have shown that children with ASD and GI symptoms scored higher on anxiety scales compared to typically developing (TD) peers.

Objectives:
The objective of this analysis is to compare GI and behavioral symptoms in TD children and those with ASD who present for an evaluation of clinically significant GI symptoms at specialized GI clinics.

Methods:
Children with GI symptoms warranting a colonoscopy and/or endoscopy were recruited to participate. Study procedures included a chart review to extract demographics, suspected food allergies, and medical diagnoses. Pediatric Quality of Life Inventory (PedsQL) Gastrointestinal Symptoms Module, Questionnaire on Pediatric Gastrointestinal Symptoms—Rome III Version (QPGS-RIII), cognitive assessments including IQ, autism diagnostic assessment, and behaviors using the Behavior Assessment System for Children, 3rd Edition (BASC-3) and Repetitive Behavior Scale – Revised (RBS-R) were obtained. Eligibility criteria for the TD group included Social Communication Questionnaire (SCQ) score <15 and ASD group with ADOS score above ASD cutoff.

Results:
51 participants ages 3-17 years were enrolled in the study. 7 TD participants were excluded from analysis due to inflammatory bowel diseases identified during GI workup (n=4), inflammatory musculoskeletal disease (n=1), developmental delay (n=1), and elevated SCQ score without ASD diagnosis (n=1). 3 ASD participants were excluded due to known genetic variants (n=2) and incomplete assessments (n=1). 41 children were included in the data analysis of which 34 were TD (17 M, 17 F) and 7 had ASD (5 M, 2 F). Based on the QPGS-RIII, fewer TD participants (47%) than in the ASD group (71%) met criteria for irritable bowel syndrome (IBS). Twice as many ASD participants (29%) than TD participants (12%) met criteria for functional constipation. The mean health-related quality of life (HRQoL) scores on the PedsQL for abdominal pain were impaired in both groups (42.97±19.52 in TD and 41.57±11.03 in ASD, p=0.82). Children in the ASD group had a trend for worse HRQoL score for constipation (65.36±18.58 vs 39.71±29.95, p=0.065). The mean anxiety scores on the BASC-3 were largely in the typical range, 53.03±11.47 in the TD group and 53.71±13.59 in the ASD group (p=0.904). Lastly, scores on the RBS-EC were significantly higher in the ASD group (4.15±8.02 vs. 46.29±18.09; p<0.001).

Conclusions:
IBS and constipation were more common in children with ASD. However, HRQoL scores were not a good differentiator between the TD and ASD groups; this may be due to small sample size. Lastly, these findings are consistent with previous studies showing that children with ASD exhibit more restricted and repetitive behaviors than TD peers. Future analyses include histological and immune analysis of biopsy samples to investigate possible underlying mechanisms for these differences.

424.287 (Poster) Gastrointestinal Issues in Autism Spectrum Disorders: Lack of Evidence for Specificity
J. Wolstencroft, 1. D. Imagine and D. H. Skuse, (1)UCL GOS Institute of Child Health, London, United Kingdom, (2)UCL GOS Institute of Child Health, UCL, London, United Kingdom, (3)Institute of Child Health, London, United Kingdom

Background:
For many years the possibility that there is a gut-brain connection in ASD has been proposed, based largely on reports that many children with ASD have chronic constipation, diarrhoea and abdominal pain. There are also cases of gastroesophageal reflux and unusual gastroenterological reactions to some foods. Although there is an assumption that gastrointestinal abnormalities could be causally linked to ASD features in some children, the hypothesis that GI dysfunction might be similar in children with intellectual disabilities of genetic aetiology, irrespective of associated ASD, has never before been tested.

Objectives:
We aimed to identify the range of co-occurring gastrointestinal symptoms in a national UK sample of children with pathogenic CNVs or SNVs that were associated with ASD and to compare those comorbidities with children whose ID was not associated with ASD. We also tested the hypothesis that children who had gastrointestinal symptoms would experience a range of emotional and/or behavioural problems that were more extensive and more severe than those did not have such symptoms, irrespective of the severity of their intellectual disability or ASD characteristics.

Methods:

1282 children and young people, aged between 5-19 years (M=9.1, SD=3.9) were recruited via UK National Health Services and patient support groups. Of these, 34.3% (n=440) participants met criteria for an ASD. Participants were 54.7% male and 45.3% female. A standardised psychiatric interview was completed online (the Development and Wellbeing Assessment (DAWBA), as well as the Strengths and Difficulties Questionnaire (SDQ). Participant families also completed the Social Aptitude Scale and an account was obtained concerning gastrointestinal symptoms among other aspects of the child’s medical history.

Results:

GI problems affected a substantial proportion of participants overall (40.8%). The most common gastrointestinal symptoms were severe constipation (58.3%) and gastroesophageal reflux (51.8%). There was no significant difference ($\chi^2=3.9, p>.05$) when we compared the proportion of participants reporting GI problems in those with ASD (44.4%) with those whose ID was not associated with ASD (38.6%). Within the ASD sample there were no differences in symptomatology between those with and without reported GI problems on the SAS, which evaluates social understanding and behaviour (p= .17). Overall, SDQ rated emotional difficulties were significantly higher in those with GI symptoms than those without (p<.05), but there were no significant differences in the severity of conduct problems, hyperactivity or peer difficulties.

Conclusions:

Our study found no difference in the nature of GI symptoms when we compared children ASD of genetic aetiology with children whose ID was not associated with ASD traits. Although it had previously been assumed that the high prevalence of GI disorders in children with ASD could be linked causally to the condition, through increased intestinal permeability for example, it seems there is no specificity in that association.

J. Wolstencroft, H. Housby; I. D. Imagine and D. H. Skuse; (1)UCL GOS Institute of Child Health, London, United Kingdom, (2)Great Ormond Street Institute of Child Health, UCL, London, United Kingdom, (3)UCL GOS Institute of Child Health, UCL, London, United Kingdom, (4)Institute of Child Health, London, United Kingdom

Background:

Little is known about the developmental trajectory of autistic children with intellectual disabilities (ID) of genetic aetiology in childhood. Longitudinal studies of affected children are rare and have been constrained by a focus on specific genetic anomalies, and small unrepresentative samples. The IMAGINE-ID research program had the opportunity to follow-up a nationally representative sample of children such children over a 5-year period, and to evaluate changes in behavioural phenotype from middle childhood to adolescence.

Objectives:

Our main aim was to measure behavioural changes in a diverse sample of children who had been ascertained with IDD of identified genetic aetiology. Using standardized annual assessments, we aimed to compare the trajectories of those affected by autism with IDD that is not associated with autistic traits.

Methods:

IMAGINE-ID participants (4-22years: M=9.3, SD=4.2) were initially recruited from UK NHS Genetic Services between 2015-2020. Of these, 41.4% reported their child had been diagnosed with ASD. Caregivers completed the Strengths and Difficulties Questionnaire (SDQ) in 2015-9 (T1) and again in 2021 (T2). The SDQ assesses children's emotional and behavioural adjustment in dimensional terms (emotional difficulties, conduct problems, hyperactivity and prosocial behaviour). Data was obtained at both T1 and T2 on 1,064 participants.

Results:
At T1, 64% of participants with ASD had scores in the ‘very high’ range, 18% in the ‘high’ range, 10% ‘above average’ range and 8% in the ‘typical’ range for children of equivalent age. Comparative proportions from participants whose ID was not associated with ASD were 43% in the ‘very high’ range, 15% in the ‘high’ range, 18% in the ‘above average’ range and 24% in the ‘average’ range. 59% of ASD participants remained in the same severity band category from T1 to T2, 17.4% deteriorated and moved into a higher severity band, whereas 20.8% improved and moved to a lower severity band. In comparison, in those without ASD 56.7% remained stable, 19.7% deteriorated and 23.6% improved.

At both T1 and T2 the mean total SDQ score for participants was in the ‘very high’ range for those with (M\(_1\)=21.9, SD\(_1\)=5.8; M\(_2\)=20.5, SD\(_2\)=5.9) and without ASD (M\(_1\)=18.3, SD\(_1\)=6.9; M\(_2\)=17.7, SD\(_2\)=6.6). Paired comparison of the SDQ subscales for those with ASD showed a significant reduction in conduct and hyperactivity symptoms and a significant improvement in prosocial ability from T1 to T2. Emotional difficulties remained in the ‘high’ range from T1 to T2. Data from children with ID that was not associated with autism also showed a significant reduction in conduct and hyperactivity difficulties from T1 to T2. Emotional difficulties also remained stable from T1 to T2, as did prosocial ability.

Conclusions:

In ASD that is associated with ID of genetic aetiology, co-occurring symptoms of conduct problems and hyperactivity tend to improve slightly over the period from middle childhood to adolescence, and there are associated improvements in prosocial behaviour too. By contrast, emotional difficulties remain stable. Significant improvements on the overall emotional and behavioural adjustment during follow-up was found more frequently in children whose ID was not associated with autism.
leading to a smaller network size, density, node degree and node strength on average over the 1st-5th postnatal week (Figure 2A). This altered network development predicts impaired cellular-scale information processing that may underlie the cognitive dysfunction in Rett syndrome. To develop a platform for testing novel strategies to restore function in human cortical networks, we created MeCP2-deficient ALI-COs from Rett syndrome patient-derived induced pluripotent stem cells (iPSCs) and isogenic controls. Both MeCP2-deficient and isogenic control iPSCs form viable ALI-COs and show network activity at days-in-vitro (DIV) 75, 100, 150 in culture (Figure 2B).

Conclusions: MeCP2-deficient murine cortical cultures reveal early impairments in the formation of functional cortical networks and key metrics of cellular-scale information processing. Restoration of cellular-scale network function provides a novel therapeutic target that can be implemented in our human cerebral organoid model of Rett syndrome and some genetic causes of ASD. Our analyses of network function in ALI-COs demonstrate that they can serve as a platform for investigating underlying mechanisms and screening new therapies. Our MEA network analysis pipeline (MEA-NAP) also enables other investigators to apply a cellular-scale network approach to other murine and human in vitro models of ASD.

417.324 (Poster) Altered Metabolite and Microbiota Profiles Associated with Social Deficits in Autistic Children and Their Unaffected Siblings
Y. C. Chen and S. S. F. Gau, (1)National Taiwan University, Taipei, Taiwan, (2)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan

Background: Autism spectrum disorder (ASD) is a highly clinically and genetically heterogeneous neurodevelopmental disorder with impaired social interactions and communication and restricted, repetitive behaviors/interests. Further, individuals with ASD display metabolic imbalances and gastrointestinal (GI) symptoms. According to the literature, metagenomic dysregulation is associated with the core symptoms of ASD. Herein, we compared the metabolite profiles and taxa diversity of ASD with their healthy biological unaffected siblings (US) in the same family, who shared similar environmental conditions. We hypothesized that bidirectional interactions between metabolite profiles in plasma and the gastrointestinal tract (brain-gut axis) and the role of the gut microbiota in ASD. However, little is known about the metagenomic-mediated ASD symptoms and there is no human data about biomarker for developing a safe and effective treatment for ASD.

Objectives: We aim to present a comprehensive comparison of extensively identified metagenome profiles of feces and plasma from cohorts of matched ASD, unaffected siblings, and typically developing control youths.

Methods: A total of 344 samples were assessed, including 242 ASD youth (M:F=214:28, age= 15.32±4.52), 102 US (M:F=61:41, age= 14.51±6.21) and 80 healthy controls (HC) (M:F= 63:17, age= 15.67±3.21). The data about ASD and other diagnoses (ADI-R, ADOS, K-SADS-E), autistic symptoms (SRS), and all the samples were analyzed with 16s metagenome sequencing as well as untargeted metabolomic profiling. We conducted metagenome analysis, and applied linear mixed effect model for statistical analysis to connect the microbiota and behavioral assessments done via QIIME2 and R, with the significance level being the FDR-corrected q value <0.05.

Results: The gut microbiome of ASD contained a higher species level of relative abundance of Lactobacillus mucosae, Lactococcus garvieae subsp garvieae, Clostridium baratii and butyricum than US and HC. The abundance of microbiota was associated with the concentration of L-asparagine, glucosamine 6-sulfate and DL-glutamate, which was found to have higher expression levels in ASD than US and HC. Further, the total SRS score significantly positively correlated to abundance of Lactobacillus mucosae and Lactococcus garvieae subsp garvieae in ASD and US. Finally, the concentration of L-asparagine as the moderator to interpret the altered microbiota and the severity of social deficits in youths with ASD and their siblings.

Conclusions: We identified the metagenome profiles among the ASD, unaffected siblings, and control groups via feces and plasma samples. The altered microbiota involved amino acid and protein metabolism demonstrated by peripheral circulation. Further, the correlation of specific microbiota in ASD and US with clinical social scores shows that gut microbiota dysbiosis may affect behavioral symptoms. These findings support the concept of healthy distal gut microflora in developing neural systems. Moreover, our results provide insights that altered metagenome profiles, as one of the possible etiologies of ASD, may be identified via the comparison between ASD probands and their healthy, unaffected siblings, who might be at risk of ASD.

417.325 (Poster) Autism-Linked Mutations Disrupt the Protein Network States That Mediate Homeostatic Plasticity
S. E. Smith, University of Washington, Seattle, WA

Background: Following the -omics revolution, we are able to list the DNA, RNA and protein molecules that comprise a cell. However, a cell is a dynamic system that uses its protein machinery to sense and respond to signals in complex ways, integrating information from multiple sources. The network-level mechanisms that allow a proteome to perform these biological ‘computations’ are difficult to study because the tools to make high-dimensional measurements of dynamic protein interaction networks are lacking. Here, we use a multiplex co-immunoprecipitation approach to monitor a protein network composed of ASD-linked gene products as it undergoes homeostatic plasticity, an important form of intrinsic synaptic plasticity.
Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition characterized by the presence of persistent deficits in social interaction and communication, as well as restricted social interests and repetitive behaviors. Currently, there are no therapeutics approved to treat the core symptoms of ASD. Drug discovery in this area has been hindered by a limited understanding of the biology of ASD. In addition, the heterogeneity of clinical presentation, including severity, and the limitations of the disease models make it even more challenging to develop therapies for ASD. Focusing on single-gene alterations causing ASD, such as ADNP, FOXP1, SHANK3, and DDX3X, which are among the top high-risk autism genes, is one approach that could mitigate these challenges. Furthermore, the use of translational tools, such as in-depth characterization of neurons derived from patients’ induced pluripotent stem cells (iPSCs), opens up new avenues for drug screening and discovery in order to identify pharmaceutical compounds for the treatment of ASD’s core symptoms.

Objectives: The main objective is to discover and validate drug candidates targeting functional deficits caused by genes associated with ASD. We plan to perform an in-depth and medium-throughput characterization of cellular phenotypes in human neurons generated from iPSC lines derived from ASD patients and their siblings as controls. Additionally, we aim to establish models based on known ASD-associated mutations that could be used for drug screening.

Methods: To develop in-depth high-content phenotypic characterization in human ASD in vitro models, we established and optimized protocols to study neuronal morphology and electrophysiology features. Our method involves large-scale generation of mature glutamatergic neurons using the Ngn2-mediated differentiation protocol. For morphology, neurons are stained with a neuronal marker (MAP-2) and neuronal shape is measured by a High-Content Screening (HCS) Platform in an automated and simultaneous way. For electrophysiology, multielectrode array (MEA) technology is used to measure neuronal activity during neuronal maturation.

Results: We have applied our high-content characterization approach to describe neuronal morphology and activity for the establishment of phenotypes associated with SHANK3 mutations. Differentiated neurons from three Phelan-McDermid (PMS) patient-derived iPSC lines with three different SHANK3 mutations were compared with their respective siblings. Preliminary results of cell body measurements, neurite number and neurite length identified trends towards reduced neurite outgrowth SHANK3 deficient neurons. Moreover, preliminary analyses of neuronal networks in neurons from PMS patients suggested a trend of decreased activity in two of the SHANK3-mutants. We observed variability among differentiations and cell lines. To tackle this, we are currently optimizing the differentiation protocol by generating stable patient-derived iPSCs with an integrated dox-inducible Ngn2.

Conclusions: Identification of morphological and electrophysiological changes caused by mutations associated with monogenic ASD represent a powerful tool to describe models of ASD that can be used as a platform for drug screening and evaluation. Our approach of modeling ASD with human neuronal cultures offers a platform that can be used to describe the effects of ASD associated mutations. This provides a great opportunity to identify molecules with therapeutic potential, contributing to the intense research efforts to develop pharmacological treatments for ASD.
**Background:**

The microbiota-gut-brain axis has been recently recognized as a key modulator of neuropsychiatric health and its dysregulation might be significantly implicated in the aetiology and/or symptomatology of Autism Spectrum Disorder (ASD). Microbiota alterations and gut inflammation are linked with behavioral symptoms. The benefit of deriving probiotic candidate strains from fermented foods seems strategic to develop functional foods for a personalized dietary intervention in ASD. 

*Lactiplantibacillus* (*Lpb.* *plantarum*) is one of the most versatile and robust dominant species in fermented foods, is considered safe for humans and is included in the Qualified Presumption of Safety (QPS) list of the European Food Safety Authority. Mechanisms underlying host-microbiota interactions are not fully clear yet and the endocannabinoid system (ECS) could play a key role.

**Objectives:**

The aim of this exploratory study was to evaluate the suitability of selected strains of food-borne *Lpb. plantarum*, administered to a genetic animal model of ASD, as a putative strategy to ameliorate ASD behavioral and gastrointestinal (GI) symptoms, through the involvement of the ECS.

**Methods:**

A total of 18 male mice 9-weeks old, either wild type (WT) or Neuroligin-3 R451C knockin, was fed with *Lpb. plantarum* strains for five weeks starting from weaning. Behavioral studies, elevated plus maze and marble burying tests, were used to assess whether the administration of *Lpb. plantarum* could ameliorate the anxious and obsessive-compulsive behavioral characteristics. Following behavioral testing, mice were euthanized and gastrointestinal regions and blood were immediately collected. The mRNA levels of all endocannabinoids (eCBs) metabolic enzymes and cannabinoid receptors (CBR), as well as Zona occludens-1 (ZO-1) and tight junctions were determined by RT-qPCR in colon samples. Levels of the two major eCBs, anandamide (AEA) and 2-arachidonoylglycerol (2-AG), and the endocannabinoid-like mediator, palmitoylethanolamide (PEA), were measured in plasma samples through UPLC/MS-MS.

**Results:**

Although treatment did not induce significant changes in behavioral profile (probably because of limited sample size so far obtained), molecular data indicate a clear modulation of ECS following *Lpb. plantarum* treatment. In particular, 2-AG content (but not AEA and PEA) and the expression of type-2 CBR gene (main target of 2-AG) as well as of claudin 1, claudin 3 and ZO-1 gene (involved in gut mucosal structure maintenance and permeability) were restored at the WT levels in ASD mice nourished with *Lpb. plantarum*. Consistently, the mRNA levels of MAGL, 2-AG hydrolyzing enzyme, resulted downregulated in the same animal group.

**Conclusions:**

Overall, our findings provide evidence of an effective cross-talk between functional microorganisms and ECS in a mouse model for the study of ASD. These encouraging results underline a potential implication of the host-microbe interaction in terms of alleviation of ASD-GI symptoms, opening the way to human clinical trials in order to develop functional foods that can vehicle specific probiotic strains directly isolated from fermented foods.
Objectives:

Our overarching objective is to develop a novel scalable high-throughput platform to quantify the morphological effects of CRISPR-based transcriptional repression (CRISPRi) in multiple ASD-risk genes simultaneously in human neurons. Thus, we aim to 1) develop neuronal cell-filling optical cellular barcodes linked to CRISPR perturbations that can be identified using immunofluorescence; 2) optimize cyclic immunofluorescence enabling the analysis of morphometric signatures caused by multiple perturbations in a pooled format; and 3) identify common cellular and molecular phenotypes of ASD-risk genes to uncover convergent mechanisms.

Methods:

We cloned different combinations of 3 linear epitopes as protein barcodes (Pro-Codes) fused to a neuron-filling scaffold protein coupled with individual targeting single guide RNAs (sgRNAs) for CRISPRi perturbations. We designed Pro-Codes using unique triplet combinations of 6 epitopes for 8 ASD risk genes along with a positive control and non-targeting negative control in duplicate. We packaged these 20 Pro-Codes in lentivirus individually and then pooled them. We delivered this pool to induced pluripotent stem cells (iPSCs) at a low multiplicity of infection, such that each cell received only 1 Pro-Code. Using Ngn2 overexpression, we differentiated these cells into induced neurons (iNeurons) and used antibiotics to select for Pro-Code expressing cells. Cells were then fixed and stained for 3 epitopes for immunofluorescence imaging. Fluorophores were then bleached, and cells were re-stained with antibodies against the remaining 3 epitopes for neurite tracing. This was followed by another round of bleaching and staining with antibodies against synaptic markers. We quantified neuronal morphology and synaptic markers in thousands of iNeurons for each ASD gene perturbation using CellProfiler.

Results:

We validated 10 epitopes, allowing us to create 120 unique Pro-Codes for barcoding and neurite tracing. We then successfully performed 3 rounds of bleaching and re-staining of epitopes in these iNeurons without damaging the epitopes or cells. Furthermore, we benchmarked our high-throughput pooled assay against conventional arrayed knock-down of the same genes. Finally, we analyzed the effects of knock-down of 8 autism-risk genes and observed striking changes in neuronal survival, axonal and dendritic arborization, and synaptogenesis.

Conclusions:

We have established POINT-MAP as a novel mid-throughput CRISPRi platform to study the effects of knock-down of ASD-risk genes on neuronal morphology. Our protein barcoding strategy enables the study of the morphological effects of multiple ASD risk genes at once. Our technology facilitates the discovery of convergent mechanisms across ASD risk genes which could inform targets for broadly applicable therapeutics.

417.329 (Poster) Ex Vivo Exposure to Polybrominated Diphenyl Ether Selectively Affects the Immune Response in Children with ASD

J. Van de Water, M. E. Akintunde, I. Hertz-Picciotto and P. Ashwood. (1)MIND Institute, University of California, Davis, Davis, CA, (2)Internal Medicine, University of California Davis, Davis, CA, (3)Tobacco related diseases research program, University of California, Office of the President (UCOP), Oakland, CA, (4)University of California at Davis, Davis, CA, (5)UC Davis, Sacramento, CA

Background: Children with autism spectrum disorder (ASD) have immune dysregulation that often correlates with behavioral deficits, and it is thought that the post-natal environment affects immune function.

Objectives: To examine the association between plasma levels of polybrominated diphenyl ether (PBDE) and immune cell function in age-matched children with and without ASD.

Methods: Plasma from children with (ASD; n=38) and controls (TD; n=60) were analyzed for 14 major PBDE congeners by mass spectrometry. Cytokine/chemokine production was measured in peripheral blood mononuclear cell (PBMC) supernatants with and without ex vivo BDE-49 exposure using multiplex analysis for IFN-γ, IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-10, IL-12 (p40), IL-12 (p70), IL-13, IL-17, MCP-1, MIP-1α, MIP-1β GM-CSF and TNF-α.

Results: Total plasma concentration (Σ PBDE14) and individual congener levels were also correlated with T cell function. Σ PBDE14 did not differ between diagnostic groups but correlated with suppressed immune function in ASD. Higher Σ PBDE14 levels also negatively correlated with adaptive T cell cytokine production following activation of PBMC. Baseline production of IL-2 and IFN-γ were reduced by several individual BDE congeners in ASD compared to TD, especially BDE-49 (p<0.001). ASD PBMC exposed ex vivo to 50 nM BDE-49 produced elevated levels of IL-6, TNF-α, IL-1β, MIP-1α and MCP-1 (p<0.05). Finally, increased IL-6 (p=0.01) and GM-CSF (p=0.03) following ex vivo exposure to 250 nM BDE-49 was positively correlated with higher plasma BDE-49, but not BDE-47 or BDE-95, in ASD vs TD.
Conclusions:

Despite similar plasma levels of PBDE, ex vivo exposure differentially impacted immune cell function in cells from subjects with ASD compared to TD control suggesting an underlying association between susceptibility to PBDE exposure and immune anomalies in children with ASD. These findings highlight the need to include cellular functional exposure studies when examining the effects of toxicant exposure in a study population.

417.330 (Poster) Folic Acid Supplementation or Depletion Alters Cortical Neurodevelopment and Neuron Maturation; Implications for Neurodevelopment.

S. Salloum-Asfar, R. Taha and S. Ali Abdulla, (1)Qatar Biomedical Research Institute (QBRI), HBKU, Qatar Foundation, Doha, Qatar, (2)Qatar Biomedical Research Institute, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar, (3)Neurological Disorders Research Center, Qatar Biomedical Research Institute, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar

Background: Optimal folate levels during early pregnancy can reduce the risk of neural tube defects. However, there is concern about inadequate folate intake as a result of consuming higher doses of folic acid (FA) with potentially minimal additional benefits, and excessive intake may be associated with neurodevelopmental risks.

Objectives: To determine the effects of FA depletion and supplementation on the functionality and neuronal development of hiPSC-derived neural precursor cells (CRTD5-NPCs) and during differentiation of cortical neurons.

Methods: The cytotoxicity of FA dose was assessed before and after exposure to eight different concentrations of FA gradients (0 - 1000 uM). Three different concentrations of FA were administered to NPCs and differentiated cortical neurons: 1) FA normal (FN) (2.27 uM; the concentration used in the manufacture of neuronal medium), 2) FA deficient (FD) (no FA), and 3) FA oversupplementation (FO) (1000 uM at the NPC stage and 100 M during eight weeks of cortical differentiation). Elecsys Folate III was used to measure intracellular folate levels. FACS was used to evaluate cell viability and apoptosis. Four points of analysis were used in this study: week 0 (W0), which represents NPCs after five days of treatment, and weeks 3, 6 and 8 (W3), which represent differentiated cortical neurons. Across each time frame, quadruplets were compared with corresponding controls. Neurobasal Medium was used to differentiate hPSC-derived NPCs into cortical neurons. To assess neuronal function, VGCCs and whole-cell patch clamp electrophysiology were used. IHC staining was performed to detect mature neuron markers and cortical neurons (MAP2, NeuN, TBR1, CTIP2, BRN2, SATB2, Synaptophysin and phosphorylated-neurofilament-H). The expression of genes and proteins was analyzed using RNA-seq and proteomics techniques.

Results: The preliminary results indicate that FD and FN cells showed similar proliferation and viability during the NPC stage, as well as during the early stages of cortical differentiation. FD cells began to apoptose at W6 and detached from the laminin-coated wells. When FO cells were supplemented with excess FA, they displayed an increase in proliferation at the NPC stage. FD and FO differentiated neurons, however, exhibited an increase in apoptosis at W6. Both FA deficiency and abundance enhanced apoptosis at W6 by adapting different mechanisms. Calcium imaging of individual cells is an indirect indicator of neural activity, which measures changes in intracellular calcium levels. According to the VGCC results, cells differentiated into neurons after W3 and responded to the KCL stimulus with no difference between groups. As a result, neural activity is similar regardless of FA status. According to the patch clamp results, by W6, FO significantly increased the percentage of neurons generating action potentials compared to their respective controls. The presence of neuronal markers was confirmed by immunohistochemistry.

Conclusions: In the context of mandatory FA fortification, preliminary evidence indicates that FA intake below and above the physiologic dose alters neuronal maturation. All supplements should be carefully monitored to prevent toxicity and hypervitaminosis. We are validating our findings and more research should be conducted to examine the nutritional disparities at each stage of pregnancy in greater detail.

417.331 (Poster) From Rare Mutations to Common Pathways in ASD

M. A. Lalli, U. Thopte, X. Wang and J. D. Buxbaum, (1)Psychiatry, Icahn School of Medicine at Mount Siani, New York, NY, (2)Psychiatry, Seaver Autism Center, New York, NY, (3)Mount Sinai School of Medicine, New York, NY

Background:

The latest exome-wide association study in neurodevelopmental disorders identified over 350 genes that harbor mutations strongly contributing to the risk for autism spectrum disorder (ASD) and developmental delay. To translate these findings into eventual therapeutics, we first need to investigate the functions of each of these genes and their mutations in the context of brain development. Studying each of these genes separately in animal or cell models is a daunting task. As an alternative to traditional approaches, we have implemented a high-throughput method to study the functions of multiple ASD risk genes in disease-relevant human neuronal cells.

We have coupled CRISPR-Cas9 transcriptional repression (CRISPRi) to single-cell RNA sequencing (scRNA-seq) to enable high-throughput perturbation of multiple ASD risk genes at once with a parallel functional readout of the transcriptional consequences. Here, we...
have used this technology to extract functional signatures for 77 of the top ASD risk genes in human neural progenitor cells and neurons derived from induced pluripotent stem cells (iPSCs).

Objectives:

We sought to identify transcriptional and functional signatures for each of 77 high-confidence, large-effect ASD risk genes in human neural cells. Next, we sought to compare signatures across genes to discover shared mechanisms of ASD risk genes. We also examined the functional impact of ASD gene repression on cell fate specification of neural progenitor cells and on the trajectory of neuronal differentiation. Finally, we sought to discover ASD risk genes with shared gene expression signatures.

Methods:

We differentiated human iPSCs into neural progenitor cells and performed CRISPRi of 77 ASD risk genes. We collected scRNA-seq data from ~60,000 cells across 2 biological replicates to identify transcriptional signatures of ASD risk genes. Using dimensionality reduction followed by clustering, we identified neural cell types. We tested for alterations in cell-type proportions caused by ASD risk gene knockdown. Next, we used pseudotime analysis to determine the effects of ASD risk genes on neural differentiation. To identify convergent signatures of ASD risk genes, we clustered ASD risk genes by the similarity of co-expressed gene modules.

Results:

We achieved effective knockdown for at least 60/77 target genes in iPSC-derived neural progenitor cells. Interestingly, we identified several ASD risk genes that altered cell fate specification when repressed. Several ASD risk genes pushed neural progenitor cells to adopt glial fates. Furthermore, we identified multiple ASD risk genes that altered neural differentiation, including some that accelerated or delayed this process. Finally, we found that ASD risk genes clustered by shared co-expression modules, indicating shared signatures.

Conclusions:

We have demonstrated a high-throughput platform to evaluate the effects of ASD risk genes on human neurodevelopment. Our approach enables the discovery of transcriptomic and functional consequences of ASD risk gene perturbation in human neural cells in a cell-type-specific manner. We have identified potential convergence across ASD risk genes on cell fate specification, neuronal differentiation, and gene expression signatures. Overall, these results improve our knowledge of ASD risk gene mechanisms, pinpoint commonly disrupted pathways, and nominate targets for future therapeutic intervention.

**417.332 (Poster) Genome-Wide Screen for Genes Essential for Neuronal Differentiation and Their Association with ASD**

**A. Amalan, E. Dvir and S. Shifman, (1)The Hebrew University of Jerusalem, Jerusalem, Israel, (2)Hebrew University of Jerusalem, Jerusalem, Israel**

**Background:**

The genetics of autism spectrum disorder (ASD) is very complex and with large genetic heterogeneity. The search for de novo and rare variants in ASD resulted in more than a hundred genes significantly associated with ASD. With large genetic heterogeneity, it is important to identify convergent pathways and molecular mechanisms that explain how mutations in so many genes contribute to the disorder. Enrichment analyses have revealed that ASD risk genes are involved in neuronal differentiation, synaptic activity, and, most notably, chromatin and transcription regulation. These chromatin regulators may contribute to multiple molecular processes, and several recent studies have suggested that they can direct neural progenitor cells (NPCs) toward proliferation and differentiation.

**Objectives:**

This study aims to identify shared mechanisms for ASD genes and their involvement in neuronal differentiation.

**Methods:**

To perform a genome-wide screen for genes that influence neuronal differentiation, we used CRISPR pooled libraries to knockout almost all genes in the genome. The screen was performed using mouse embryonic stem cells. Each cell in the culture carries a distinct genetic manipulation based on the single guide RNA (sgRNA) introduced into the cell. The cells were differentiated into NPCs and later into neurons. In some cells, the sgRNAs deaktivate a gene essential for proliferation or differentiation and confer an advantage or disadvantage. Thus, the readout in this experiment is the abundance of sgRNAs. Targeted sequencing was used to compare the levels of sgRNAs at different stages of neuronal differentiation and to reveal the genes whose loss offers a growth advantage (positive selection) or disadvantage (negative selection).
Results:

We identified 2554 significant genes whose loss is positively or negatively selected during neuronal differentiation. Those genes were more likely to be intolerant to mutations and associated with brain size and neurodevelopmental disorders. The genes whose loss offered growth advantage were associated with enlarged brain size. Based on the dynamics of the sgRNAs during the differentiation process, we separated the genes into eight different clusters. Multiple clusters were associated with neurodevelopmental disorders and changes in brain size, but only one cluster was enriched with ASD genes.

Conclusions:

We identified multiple genes that are new candidates for being risk factors for neurodevelopmental disorders and found functional convergence of ASD genes by studying the essential genes during neuronal differentiation. Our results support the hypothesis that deficits in the proliferation and differentiation of NPCs lie at the heart of ASD pathology.

417.333 (Poster) Hnmpu Expression Affects Transcriptional Programs and Chromatin Organization during Neuronal Maturation

F. Mastropasqua, M. Oksanen, C. Soldini, S. Alata, A. Arora, R. Ballarino, F. Agostini, M. E. Watts, M. Becker, A. Poulet, N. Crosetto, M. Bienko, S. Bolte and K. Tammimies, (1)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (2)Department of Medical Biochemistry and Biophysics, SciLifeLab, Stockholm, Sweden, (3)Department of molecular cellular and developmental biology, Yale University, New Haven, CT

Background: HNRNPU (Heterogeneous nuclear ribonucleoprotein U) protein is known to regulate interphase chromosome structure, transcription, and alternative splicing. Recently, it was shown that the downregulation of HNRNPU expression affects 3D genome organization. Pathogenic genetic variants affecting HNRNPU located on chr1q44 have been shown to cause HNRNPU-related developmental syndrome, including autism spectrum disorder (ASD), seizures, intellectual disability (ID), and developmental delay. The role of HNRNPU in neural development and the biology behind the associated phenotypes caused by the genetic variations have not yet been characterized.

Objectives: We aimed to discover the effects of HNRNPU deficiency during early neural development and connect these changes to biological processes behind ASD and other neurodevelopmental disorders. Specifically, we focused on the impact of HNRNPU deficit on transcriptome and chromatin organization.

Methods: Fibroblasts, used for the formation of induced pluripotent stem cells (iPSC), were donated by neurotypical controls and individual diagnosed with ASD and carrying a heterozygous deletion of ~44.3Kb that involves HNRNPU, COX20, and antisense HNRNPU1, hereby called HNRNPUdel cells. iPSC-derived neuroepithelial stem (NES, D0) cells and undirected neural differentiation for 28 days (D28) were used for this project. In parallel, siRNA experiments on control cells have been performed. The neural maturation trajectory was evaluated by assessing the percentage of neural progenitor and dividing cells at D28 by immunofluorescence and BrdU assay. Both bulk RNA and Hi-C sequencing were performed to evaluate the transcriptomic and chromatin organization differences in HNRNPU deficiency states.

Results: Transcriptome analyses illustrated that at D28, chromatin organization and cell division pathways are upregulated, while synaptogenic pathways are downregulated in HNRNPUdel/siHNRNPU. The transcriptome variability at D28 determined by differential exon usage was increased and overrepresented for genes previously associated with ASD, intellectual disability, epilepsy, and developmental delay. We demonstrate a significantly higher proportion of neuro progenitors and altered chromatin organization at D28 upon HNRNPU deficiency. Specifically, we showed a dramatic switch of the compartment structure, with enrichment of the inactive B compartments under HNRNPU deficiency conditions. Interestingly, the genes mapping in the compartments switching from active (A) to inactive (B) chromatin status and downregulated at the transcript level were enriched for genes implicated in ASD and epilepsy.

Conclusions: We provide the first evidence of the functional consequences of pathogenic genetic variants affecting HNRNPU in human neural progenitors in the form of an inadequate switch to neurogenesis. These results are accompanied by large-scale effects on chromatin organization and transcriptional landscape at later stages of neural development and presumably lead to diverging trajectories of maturation of neurons and other neural cells. Our results show similar biological insights that have been indicated in other ASD-associated genes to have in early neural development.

417.334 (Poster) Metabotropic Glutamate 5 Receptor Availability Differences in Twin Pairs Discordant for Autism and Controls: Do Shared Genetics Matter?

G. Griffioen, M. Andersson, A. Tangen, M. Bolin, C. Halldin, L. Farde, S. Bolte, J. Lundberg and J. Borg, (1)Karolinska Institute, Stockholm, Sweden, (2)Karolinska Institutet, Stockholm, Sweden, (3)Department of Clinical Neuroscience, Karolinska Institutet,
Background:

Glutamate is the principal excitatory neurotransmitter and is important for brain development and plasticity. Evidence from post-mortem and animal studies has implicated the metabotropic glutamate receptor 5 (mGluR5) in autism spectrum disorder (ASD). Two recent positron emission tomography (PET) studies showed higher mGluR5 availability in ASD individuals compared to neurotypical controls in certain brain regions (1, 2).

Objectives:

Here, we aim not only to replicate prior findings but in addition compare mGluR5 availability in twin pairs discordant for autism. This design allows us to minimise confounding random variation in genetic and environmental factors, and isolate ASD specific variation in mGluR5.

Methods:

Seven adult twin pairs discordant for ASD (three male/four female pairs; six monozygotic/one dizygotic pair; five qualitatively/two quantitatively discordant pairs) and eight typically developed control subjects were examined with PET and radioligand 
$[^11]F$FPEB binding to mGluR5. The mGluR5 binding was quantified using the simplified reference tissue model with centrum semi-ovale as reference region.

First, within-pair comparisons of mGluR5 binding were analysed using paired t-tests in only the twin pairs. Second, including all subjects, generalized estimating equation (GEE) models were run, where the standard errors are corrected for familial clustering. Finally, Pearson’s r was calculated for correlations between mGluR5 availability and ASD traits measured with social and cognitive tasks and questionnaires.

Results:

Comparing the ASD probands with their unaffected co-twins, we found no significant differences in mGluR5 availability in any brain region. Four of the probands displayed slightly higher mGluR5 binding than their co-twins whereas two of the probands displayed lower binding. The direction the difference was not associated with zygosity, sex or quantitative/qualitative discordance. The GEE regression models revealed no statistically significant differences between the probands and their co-twins for any brain region. For the neurotypical control subjects, mGluR5 receptor availability was significantly lower than the ASD probands in most brain regions (B-coefficient between -0.3 and -2.1, p-values ranging from 0.001 to 0.049). No significant correlations were found between ASD behavioural traits and mGluR5 availability (Pearson’s r ranging from -0.35 to 0.25).

Conclusions:

Our finding of lower mGluR5 availability in neurotypical control subjects compared to subjects with ASD is in line with the findings of the two previous PET studies (1, 2). However, the within-pair and GEE analysis revealed no differences in mGluR5 binding between the ASD twins and their unaffected co-twins. Using a discordant twin design, we were able to control for genetic and environmental confounders to a high degree. We also found no significant correlations between mGluR5 binding and any ASD trait or symptom measurements. Thus, our results suggest that higher mGluR5 availability is associated with genetic risk for ASD but not to the clinical phenotype display.

1. Carey C, et al. From bench to bedside: The mGluR5 system in people with and without Autism Spectrum Disorder and animal model systems. Transl Psychiatry [Internet]. 2022

Background: The Fragile X Mental Retardation Protein (FMRP) is a nucleo-cytoplasmic RNA Binding Protein that regulates translation of mRNAs, essential for synaptic development and plasticity. The loss of FMRP results in Fragile X Syndrome (FXS). FMRP interacts with a
specific set of mRNAs and regulates their translation through its association with ribosomes. But the biochemical nature of this interaction is currently undefined.

Objectives: To determine the nuclear and cytoplasmic role of FMRP-ribosome interaction in regulating neuronal protein synthesis.

Methods: Small RNA sequencing and Ribo-Meth Sequencing was performed in WT and FMR1 KO Human Embryonic Stem Cells to identify the snoRNA interactome and capture alterations in rRNA 2’O Methylation patterns. FMRP domain variants were overexpressed in rat primary cortical neurons (DIV 11) to elucidate their structural contribution in ribosome binding, protein synthesis inhibition and granule formation.

Results: FMRP-snoRNA interaction regulates 2’O Methylation on rRNA, which results in ribosomes with differential methylation patterns. In the cytoplasm, FMRP recognizes ribosomes carrying specific methylation patterns on rRNA and the recognition of methylation pattern by FMRP may potentially determine the translation status of its target mRNAs. Polysome profiling and FUNCAT structurally reveals that the C-terminus domain of FMRP alone is sufficient to bind to ribosomes and inhibit protein synthesis, akin to the full-length protein. However, FMRP-mediated puncta formation is favored by the synergistic combination of FMRP domains and not by individual domains. Phosphorylation of hFMRP at Serine-500 is important in modulating the dynamics of translation by controlling ribosome/polysome association. This is a fundamental mechanism governing the size and number of FMRP puncta, which appear to contain actively translating ribosomes. Experimental data with patient identified FMR1 mutations describe a hierarchy in the contribution of FMRP domains in translation regulation

Conclusions: FMRP both influences the generation of ribosomes bearing a distinct 2’O-Methylation pattern on its rRNA component and also recognizes that pattern. FMRP exhibits a ranking in the functionality of its domains in cellular mechanisms leading to translation regulation. The C-terminus domain of FMRP is essential and sufficient enough to bind to the ribosome to regulate translation inhibition and this function is modulated by its phosphorylation status. On the contrary, the KH domains are essential for puncta formation, a mechanism that precedes ribosome binding.

417.336 (Poster) SHANK3-Catenin Interaction and the Clinical Features of Phelan-Mcdermid Syndrome
E. V. Branco1, C. I. Samogy Costa1, A. C. Girardi1, I. C. Ramos1, G. Kobayashi1, L. Carvalho1, A. Krepischi1 and M. R. Passos-Bueno1,
(1)Genetics and evolutionary biology, Institute of Bioscience, University of São Paulo, São Paulo, Brazil, (2)Genetics and evolutionary biology, Institute of Biosciences, University of São Paulo, São Paulo, Brazil, (3)Genetics and evolutionary biology, Instituto de Biociências, Universidade de São Paulo, Sao Paulo, Brazil

Background:

SHANK3 gene encodes a large scaffold protein that are essential for synaptic development, located at the core of postsynaptic density. Haploinsufficiency of the SHANK3 gene is causally linked to Phelan-McDermid syndrome, which is characterized by moderate to profound intellectual disability (ID), severely delayed or absent speech and autism spectrum disorder (ASD). Recently results indicate and epigenetic roll of SHANK3 either directly or indirectly, mediated by nuclear location of b-catenin (codified by CTNNB1 gene), principal effector of Wnt signaling. Shank3 are responsible for sequestering b-catenin at post-synaptic site and as a consequence, heterozygous loss of Shank3, allows for increased translocation of b-catenin to the nucleus where it may induce transcription of responsive genes. There are still unanswered issues regarding how the Shank3/b-catenin relationship operates and if changes in it might affect clinical variance. An atypical case of PMS with IQ within the normal range and mild autistic characteristics were reported by us (doi: 10.1186/s11689-019-9273-1). Exome sequencing revealed a missense variant (p.V424I) at CTNND2 gene, responsible for codified delta-catenin protein, also a protein of the catenin family associated with b-catenin nuclear translocation and recently founded like a direct interaction partner of Shank3 at post synaptic density.

Objectives:

Our main goal is to evaluate if the variant found in CTNND2 could modulate the expression and localization of nuclear beta-catenin and interaction with SHANK3, leading to the less severe PMS clinical phenotype. Our hypothesis is that this variant could decrease the amount of nuclear beta-catenin, and as a consequence, maintain the expression of genes responsive to it.

Methods:

To evaluate the impact of this variant in a neural model, we used cortical neurons derived from induced pluripotent stem cells (iPSC) from PMS atypical patient, two PMS patients and three healthy controls. We analyzed expression of cortical neurons markers, and also CTNNB1, CTNND2 and SHANK3.

Results:
The samples were characterized using specific neural markers, and all of them had the expected profile according to the cell type analyzed. All PMS patients showed reduced expression of SHANK3 in relation to controls. It was not observed difference in CTNNB1 expression among samples, but clearly the atypical patient shows a reduction in CTNND2 expression in relation to other patients and controls.

Conclusions:

Our preliminary results suggest that the CTNND2 variant may interfere in protein function and might be related with a less severe phenotype, but more experiments are needed. We expect that our study will contribute to a better management and therapy in neurodevelopmental disorders. This work is being performed in collaboration with PMS Brazilian association.

417.337 (Poster) The PTCHD1 Gene, Associated with ID and ASD, Is a Regulator of Cytoskeleton Remodeling at Synapse

D. C. Ung, S. Marouillat, J. Halewa and F. Laumonnier, (1)Neurogenomics and neuronal physiopathology, INSERM U1253 Imaging and Brain, Tours, France, (2)Neurogenomics and neuronal physiopathology, INSERM U1253 Imaging and Brain, Tours*, France

Background: Neurodevelopmental disorders (NDDs) are prevalent neurodevelopmental conditions with enormous burden for patients and families and without effective treatment. Deleterious mutations in the PTCHD1 (Patched domain containing 1) gene have been described in male patients with X-linked ID (Intellectual Disability) and ASD (Autism Spectrum Disorders) and might account for up to 1% of diagnoses in males. We have used neurobiology and molecular biology techniques, applied to mouse models, to discover that genetically deleting Ptchd1 in mice affects the synaptic transcriptome and impairs synaptic structure and activity, leading to cognitive dysfunction, motor disabilities and hyperactivity (Ung et al., Mol Psy, 2018). We also described that PTCHD1 can bind to scaffolding proteins of the postsynaptic density, PSD-95 and SAP102 through a PDZ-binding motif at the C-terminal intracellular end of PTCHD1. Recently, we analyzed 13 missense variants in the PTCHD1 gene (Halewa et al, Human Mut, 2021) causing alteration of its membrane subcellular localization and leading to ASD and ID in patients.

Objectives: The objective of the study is to further understand the molecular and cellular role of PTCHD1 at synapse, as well as the pathological impact observed in male patients with ASD and ID.

Methods:

To dissect the molecular mechanisms allowing PTCHD1 receptor interactions at synapse, we performed co-immunoprecipitation and GST pull down interaction assays using purified synapses (synaptosomes) lysates from mouse cortices, and proximity ligation assay and immunocytochemistry on hippocampal primary neurons. We also evaluated the impact of Ptchd1 deletion in our Ptchd1 KO mouse model using Mass-spectrometry analysis of the synaptic proteome. To continue our characterization of PTCHD1 candidate missense variants in NDD, we studied protein expression and subcellular localization in HEK293T cell line and in mouse hippocampal primary neuronal cultures.

Results:

We determined that the C-terminal region of PTCHD1 independently of its PDZ-binding motif, interacts with Rac1, a RhoGTPase essential for cytoskeleton activity and remodeling, and synapse plasticity. The Mass-spectrometry analysis highlighted, in Ptchd1 KO mice, a decreased expression of proteins acting in pathways regulating actin cytoskeleton, RhoGTPase and translation and an increase in proteins involved in translation initiation and cellular metabolism. By overexpressing PTCHD1 novel missense variants in HEK293T cells, we demonstrate the pathogenicity of several variants either by decrease in protein expression or by difference in subcellular localization in cell line or at dendritic spines in mouse hippocampal neurons.

Conclusions: Highlighting PTCHD1 novel interacting partners and PTCHD1 missense mutations functional impact will allow a better understanding of those neurodevelopmental disorders and give potential answers to patients and families.

417.338 (Poster) The Role of Ciliogenesis, Rfx-Factors and Their Genomic Binding Sites in Autism and Neurodevelopment

M. E. Watts, D. Snævarsson, A. Arora, A. Coschiera, P. Swoboda and K. Tammimies, (1)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (2)Department of Biosciences and Nutrition, Karolinska Institutet, Huddinge, Sweden

Background:

The cilium is a unique organelle that protrudes from cellular surfaces as a hair-like structure containing a microtubule core and a specialised ciliary membrane. Within the brain, non-motile primary cilia are found on most cell types and are essential to proper brain patterning, neurogenesis, and neural migration. Neurodevelopmental differences and cognitive difficulties are also common features of genetic ciliopathy disorders where ciliogenesis and cilia function are disrupted. Members of the RFX transcription factor family, which
regulate ciliogenesis gene networks, are essential for proper cilia formation and knockout of RFX factors causes neurodevelopmental defects in mice. Recently, RFX3 was implicated as a candidate gene for autism following the identification of damaging, rare de novo and inherited variants in RFX3 in four separate studies.

**Objectives:**

Although ciliary function is critical for normal brain development, the role of cilia in Neurodevelopmental Disorders remains unexplored. Symptomology of ASD, however, overlaps with ciliary-related disorders and rare RFX3 variants found in ASD cases suggest that disruption of gene networks regulating ciliogenesis may contribute to the development and pathogenesis of ASD. We, therefore, aim to determine the effects of RFX3 loss-of-function on neurodevelopment and neural function in human models and explore the potential role of RFX target genes in the etiology of ASD through analysis of X-box promotor motifs.

**Methods:**

We have introduced both heterozygous and homozygous RFX3 loss-of-function mutations in human induced pluripotent stem cells (hiPSCs) using CRISP/Cas9 gene editing technology. Utilising various molecular and cellular analysis, we are examining effects of RFX3 variants in hiPSC-derived neuronal models alongside isogenic controls. Bioinformatics approaches are also being employed to characterise RFX target genes and examine variants in X-box motifs.

**Results:**

Our preliminary analyses found that homozygous RFX3 loss-of-function results in reduced length of the cilium in human neural progenitors. Additionally, both homozygous and heterozygous RFX3 mutation led to decreased activation of the ciliary signalling pathway, Shh, and a substantial increase in the rate of progenitor proliferation. Of interest, we found that risk genes for ASD, Schizophrenia and Neurodevelopmental Disorders more broadly, are enriched for X-box promotor motifs. Comparison with expression data also highlighted genes containing X-box motifs are expressed in relevant cell types during early neurodevelopment, including neuronal populations and intermediate progenitor cells.

**Conclusions:**

While our initial results indicate a significant effect of RFX3 mutation in human neural progenitor function, we are currently further examining effects in additional hiPSC-derived in vitro models including 2D differentiating neurons and 3D cortical organoids. We are also exploiting large-scale ASD genomic data from thousands of cases to explore non-coding variants occurring in X-box motifs. Our study will provide novel insight into the functional causes of ASD and the role of cilia in neurodevelopment and cognition, an area that is currently largely under investigated.

417.339 (Poster) Uncovering the Contribution of SPTBN1 to Neurodevelopment and Autism Using Cellular and Mouse Models

A. Slavutsky and D. N. Lorenzo, Cell and Developmental Biology, University of Pennsylvania, Philadelphia, PA

**Background:** βII-spectrin, encoded by *SPTBN1*, is an essential component of the cytoskeleton across all cell types in the nervous system. Tetramers of βII-spectrin and its partner αII-spectrin assemble to crosslink actin filaments to form a periodically organized scaffold that lines the neuronal membrane. The submembrane spectrin network provides mechanical support to membranes, organizes critical membrane proteins into specialized signaling and excitable domains, and promotes organelle transport in neurons. We recently reported de novo *SPTBN1* variants as the genetic cause of a global developmental delay (DD) syndrome that is comorbid with intellectual disability (ID), autism spectrum disorder (ASD), and epilepsy. We found that mouse models of βII-spectrin haploinsufficiency or total loss in the brain recapitulate DD, hyperactivity, social deficits, and brain anatomical changes observed in affected individuals, which supports a loss of function mechanism. However, our new preliminary findings suggest that a group of *SPTBN1* variants within the actin-binding domain operate through gain of function mechanisms likely to impact cytoskeletal organization and synaptic function.

**Objectives:** By combining studies in knock-in mouse lines and patient induced pluripotent stem cell- (iPSC) derived neurons that harbor heterozygous *SPTBN1* variants relevant to ASD and DD, we aim to identify robust phenotypes that are reproducible across these experimental systems. Our goal is to gain mechanistic insights into cell type vulnerability and specific effects of variants that increase risk for ASD.

**Methods:** We developed a screening platform to mechanistically interrogate *SPTBN1* variants via behavioral, live cell and super-resolution microscopy, ‘omics, and electrophysiological studies. This system combines complementary studies in knock-in mice bearing disease variants with potential gain of function effects, and neurons differentiated from patient iPSCs bearing the same variants and their isogenic controls.
Results: We identified that a subset of \textit{SPTBN1} variants that cause ASD, ID and DD alter the interactions of βII-spectrin with F-actin and other critical components of the neuronal cytoskeleton, often leading to their accumulation within cytosolic aggregates. Through biochemical and imaging studies conducted in brain preparations and primary neuronal cultures from knock-in mice and in iPSC-derived neurons, we determined that βII-spectrin deficits altered the organization and macromolecular composition of axonal and dendritic domains required for proper synaptic excitability. Our transcriptomics and proteomics findings point to novel and convergent mechanisms that implicate βII-spectrin in the regulation of ion channel function.

Conclusions: We report the first functional evaluation of ASD-linked \textit{SPTBN1} variants predicted to operate via dominant effects both in vivo and in human neurons. Our findings uncovered deficits in βII-spectrin stability, in its interaction with critical cytoskeletal partners, and in synaptic function as convergent pathological mechanisms shared across all variants. We will also discuss our findings from mouse models that add insights into cell type vulnerability and disease progression, which will inform the design of therapies targeting specific mutant alleles and convergent pathology.

Sensory, Motor, and Repetitive Behaviors and Interests

PANEL DISCUSSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

201 - Advancing Understanding of Repetitive Behaviours: From Nosology and Assessment to Neurobiology to Treatment

Panel Chair: Mirko Uljarevic, Melbourne School of Psychological Sciences, Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Parkville, VIC

Discussant: Thomas Frazier, Psychology, John Carroll University, Cleveland, OH

Despite the centrality to autism diagnosis and significant impact on autistic individuals and their families, critical gaps remain in our understanding of the restricted and repetitive behavior (RRB) domain. Most pressingly, our field has been faced with inconsistencies in the conceptualization and measurement of RRB, a lack of robust and replicable insights into the neurobiology of RRB, and lack of effective, targeted intervention and support approaches. The proposed panel brings together state-of-the-art measurement, genetic and treatment-related empirical work aimed at advancing the science and clinical management of RRB. Proposed investigations span a range of approaches including (i) new, open-source, comprehensive, quantitative assessment developed and validated through a combination of meta-analytic and big data approaches, (ii) largest to date investigation of the genetic architecture of specific, well-defined RRB subdomains, (iii) randomized controlled trial (RCT) of a novel parent group intervention for managing RRB, and (iv) multicentre RCT to evaluate the effectiveness of tDCS for reducing specific RRB. By integrating novel measurement and computation approaches, the latest insights into underpinning neurobiological mechanisms, and advances in terms of novel and effective, diverse treatment options, the proposed panel is particularly timely and holds promise for positively impacting both research and clinical practice.

201.001 (Panel Discussion) Combining Meta-Analytic and Big Data Approaches to Develop and Validate a New Quantitative Measure of Restricted and Repetitive Behaviors

M. Uljarevic, B. Jo, E. K. Spackman, J. M. Phillips, A. Y. Hardan, E. Youngstrom and L. Scadhill, (1)Melbourne School of Psychological Sciences, Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Parkville, VIC, (2)Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, Stanford, CA, (3)The Melbourne School of Psychological Sciences, University of Melbourne, Parkville, VIC, Australia, (4)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (5)University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)Marcus Autism Center, Atlanta, GA

Background: Inconsistencies in the organization, division, and measurement have pervaded the restricted and repetitive behaviors (RRB) research to date. Although several well-researched RRB instruments exist, they have been limited by poor (i) domain representation (e.g., capturing only certain subdomains and not others) and coverage (e.g., only a few items per subdomain), (ii) psychometric properties, and (iii) ability to capture subtle symptom expressions and track change. Noted measurement limitations have stifled progress in the RRB research and clinical field. Thus, new instruments designed to systematically and comprehensively capture all relevant RRB subdomains using contemporary measurement development techniques and validated through state-of-the-art analytical approaches are needed to enhance insights into the clinical correlates, underpinning neurobiological mechanisms and treatment options of diverse RRB subdomains.

Objectives: To describe the development and preliminary validation of the Dimensional Assessment for Restricted and Repetitive Behaviors (DARB)—a new, comprehensive, quantitative, informant-rated measure of RRB in children and adolescents with autism.

Methods: Evidence-based taxonomy of RRB is a prerequisite for the measurement development, thus, we have utilized a cross-measurement meta-analytic approach across RRB factor analytic studies published studies to date (N= 41) to derive a robust, comprehensive, and replicable conceptual model of RRB. Identified RRB model encompassed the following 8 subdomains: repetitive...
sensory-motor behaviors (RSMB), insistence on sameness (IS), restricted interests (RI), unusual interests (UI), sensory sensitivity (SS), self-injurious behaviors (SIB), obsessions and compulsive behaviors (OCB) and repetitive language (RL).

A comprehensive set of items was developed to capture each of the eight identified RRB subdomains. Parents of 1892 youth with autism (M_{age} = 10.81 years, SD_{age} = 4.14) recruited from the Simons Foundation Powering Autism Research for Knowledge (SPARK) research match completed the DARB items, several existing RRB instruments, and measures of social and communication impairments and anxiety. A subsample of 450 parents completed the DARB items after two weeks in order to evaluate test-retest stability.

**Results:** Exploratory graph analysis conducted in the exploratory subsample (n = 921) identified eight dimensions that were aligned with hypothesized RSMB, IS, RI, UI, SS, SIB, OCB, and RL RRB subdomains. The confirmatory application of the exploratory structural equation modeling conducted in the confirmatory subsample (n = 971) showed that the derived factor structure had a good fit to the data (CFI = .932; TLI = .922; RMSEA = .044; SRMR = .036). Model reliability was excellent across identified factors (ω ≥ .86) and item response theory indicated at least good conditional reliability from low scores (theta -1) to very high scores (theta +3) for all DARB subscales. Two-week test-retest stability was excellent (ICC ≥ .89) and generalized additive modeling demonstrated that DARB subscales showed a distinct pattern of associations with key demographic, cognitive, and clinical correlates.

**Conclusions:** DARB will be useful in a variety of research and clinical contexts considering the prominence and clinical impact of RRB in ASD. The strong preliminary evidence indicates that the new scale is comprehensive and captures a wide range of distinct RRB subdomains not simultaneously captured by any of the existing instruments.

**Background:** Recent large-scale consortium-led genetic studies of autism, including exome sequencing and genome-wide association studies (GWAS) have identified over a hundred genes and genetic loci, providing valuable new insights into underlying biology. Despite this progress, efforts to elucidate genetic mechanisms contributing to autism have been substantially hindered by pervasive phenotypic heterogeneity. Given that autism phenotypic complexity likely reflects distinct underlying neurobiological mechanisms, it has been reasoned that focusing on more precisely defined symptom domains could increase the power to detect specific genetic influences. The examination of the restricted and repetitive behaviors (RRB) domain has been suggested as a promising approach for reducing genetic heterogeneity, however, previously reported findings of potential RRB-associated loci have not been replicated. The major obstacle for robust and replicable identification of genetic mechanisms of RRB, aside from the limited sample sizes, has been a lack of clarity around the structure and conceptualization of RRB. We propose that integration of large samples with advanced latent variable approaches to establish consistent and generalizable RRB structures for each domain across existing instruments represents a promising avenue for research aimed at understanding the genetic basis of variation in RRB.

**Objectives:** The current investigation aimed to utilize single- and multi-measurement RRB factor scores derived across the most commonly used general autism severity and dedicated RRB measures as quantitative traits to investigate genetic architecture of specific, well-defined RRB subdomains.

**Methods:** Confirmatory application of exploratory structural equation modelling (ESEM) was utilized to derive single- and multi-measurement RRB factor scores across from the Autism Diagnostic Interview-Revised (ADI-R), the Social Responsiveness Scale (SRS-2) and the Repetitive Behavior Scale-Revised (RBS-R) measures available in the Simons Simplex Collection (SSC), Autism Genetic Resource Exchange (AGRE) and Simons Foundation Powering Autism Research (SPARK) cohorts (total N = 20,612). Derived RRB subdomain scores were utilized as inputs in genetic studies, including GWAS (i.e. analysis of common genetic variation). For each GWAS, we further calculated SNP heritability and genetic correlation using LD score regression and ran gene-based analysis using MAGMA. We constructed polygenic risk scores (PRS) from autism or autism-related GWAS using PRS-CS and explored the association between PRS and endophenotypes.

**Results:** GWAS identified a total of seven SNPs surpassing genome-wide significance (GWS, p-value < 5e-8), including 3, 2 and 2 SNPs in the SSC, AGRE and SPARK cohorts (respectively), mostly for insistence on sameness phenotypes. Importantly, there was significant (albeit modest) replication of association signals across cohorts for IS phenotypes. We identified three genes (BRDT, ZW10, SLC43A2) associated with different insistence on sameness endophenotypes, after correcting for the number of genes per endophenotype. We observed widespread positive correlations between endophenotypes and autism or autism-related PRS.

**Conclusions:** Though the combination of fine-grained, well-defined RRB subdomains and access to the largest currently existing autism genetic datasets, this study provides important knowledge of the genetic architecture of RRB. It also provides crucial insights into the...
limitations of the current measures and data infrastructure that will be necessary to further advance our understanding of the genetic basis of phenotypic heterogeneity in autism.

**201.003 (Panel Discussion) A Randomised Controlled Trial to Evaluate Clinical Effectiveness of a Parent Group Intervention to Manage Functionally Impactful Restricted and Repetitive Behaviours.**

*V. Graume* and J. Rodgers*, (1)Cambrria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (2)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom*

**Background:** Restricted and repetitive behaviours are a core feature of autism, and frequently, reported by autistic people to be enjoyable, functional and helpful. However, some can be an outward sign of anxiety, cause distress or have a functional impact, causing harm to the child or restrict their access to learning or participation in their community. We have, together with parents, developed an 8 week face to face group based intervention. Managing Repetitive Behaviours (MRB) which aims to support parents to recognise, understand and learn how to respond to their child’s repetitive behaviours that can be functionally restricting.

**Objectives:** Compare the clinical effectiveness of the MRB intervention for NHS community clinical practice with psychoeducation, for the management of functionally impactful RRB in autistic children at 10, 24 and 52 weeks follow-up.

**Methods:** The study is a clinical effectiveness, multi-site randomised controlled trial of the Managing Repetitive Behaviours (MRB) parent group intervention versus a psychoeducation parent group Learning about Autism (LAA) (n=250; 125 intervention/125 psychoeducation; ~83/site) for parents of children aged 3-9 years 11 months with a diagnosis of autism. Assessments were administered at baseline, 10 weeks, 24 weeks (primary endpoint) and 52 weeks follow-up. The Learning About Autism (LAA) parent group, is equivalent to best current practice. It allows us to control for the non-specific social group benefit of mutual sharing of experience and support between parents.

**Results:** Rates of recruitment, participation and completion of follow-up assessments indicate that families found the study to be feasible and acceptable. Fidelity analysis indicated that both MRB and LAA groups were delivered with fidelity to the manual. There was no evidence of difference between the MRB and LAA parent group arms for the primary outcome measure (Clinical Global Impression-Improvement) at 24 weeks. However, analysis of the secondary outcomes indicated that children in the MRB arm compared with those in the LAA arm were more likely to be rated as responders and the impact on the family was attenuated in relation to the functionally impactful RRB identified by parents at baseline, at 10 and 24 weeks. Improvement from baseline in parental functioning (self-efficacy, stress and wellbeing) and family functioning were apparent across both intervention programmes, with no evidence of differences between the two approaches.

**Conclusions:** Our findings indicate that the MRB parent group intervention has the potential to improve the well-being of children and their families in relation to functionally impactful RRB.

**201.004 (Panel Discussion) Change in Different Dimensions of Rrb By Tdcs of Bilateral Tpj - Results of the Pilot-Iia Randomized, Controlled European Multi-Centre Study Stimat**

*C. M. Freitag*, A. Dempfle*, M. Schütz*, A. Mühlherr*, M. Siniatchkin*, J. Siemann*, M. Castelo-Branco*, F. Bonnet-Brilhaut*, C. Ricou*, M. Latimis* and C. Luckhardt*, (1)Autism Research and Intervention Center of Excellence Frankfurt, Goethe Universitat Frankfurt am Main, Frankfurt, GERMANY, (2)Institute of Medical Informatics and Statistics, Kiel University, Kiel, Germany, (3)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany, (4)Department of Child and Adolescent Psychiatry and Psychotherapy, Protestant Hospital Bethel, Bielefeld, Germany, (5)Coimbra Institute for Biomedical Imaging and Translational Research, ICNAS, University of Coimbra, Coimbra, Portugal, (6)UMR iBrain 1253, Inserm, University of Tours, TOURS, France, (7)UMR 1253, iBrain, Université de Tours, Insérm, Tours, France, (8)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, GERMANY

**Background:** Transcranial direct current stimulation has been discussed as a new intervention method to improve core ASD symptoms and associated emotions and behavior. No randomised controlled trial has yet been done on TDCS stimulation of the temporo-parietal junction (TPJ), despite the central role of TPJ function in social cognition, and TPJ attenuated functioning in ASD.

**Objectives:** Here, we report the results of the StimAT study regarding feasibility, acceptability, safety, and effect sizes of change in core ASD and associated behavioral symptoms.

**Methods:** Randomised controlled, multi-centre, parallel-group phase IIa pilot study on 2mA bilateral anodal TPJ stimulation. Stimulation intensity was locally optimised to 2mA. Duration: 20min per day over 2 x 5 days. Control condition: sham stimulation. Both groups completed a computer based socio-cognitive training during stimulation.
**Results:** N=24 ASD individuals aged 10-17 years old with IQ >= 70 were included (see table 1). Feasibility was low regarding recruitment, but high for ASD individuals starting the stimulation, with 23/24 completing the 10 sessions. Acceptability was high, as were patients’ and parents’ expectations towards stimulation. No serious, and a limited number of adverse events occurred.

Regarding core ASD symptoms, effect size estimates showed a better effect of sham than tDCS on the SRS16 summary score (post intervention [T3] -0.28, 95%-CI -3.33 to 2.77; four weeks follow-up [T4] -3.16, 95%-CI -6.19 to -0.14) and RBS-R based repetitive behaviour (T3 -1.58, 95%-CI -4.39 to 1.24; T4 -0.98, 95%-CI -3.36 to 1.41), but a stronger effect of tDCS than sham on RBS-R based obsessive-compulsive behaviour (T3 1.14, 95%-CI 0.19 to 2.10; T4: 0.30, 95%-CI -1.25 to 1.84.

**Conclusions:** tDCS stimulation is well accepted by ASD patients and parents. Results of this study show that TPJ stimulation may have contrasting effects on core ASD symptoms and obsessive-compulsive symptoms in ASD.

**PANEL DISCUSSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS**

**218 - Individual Variability in Sensory Processing and Developmental Links to Autism: Interdisciplinary Findings from Infancy to Adulthood.**

**Panel Chair:** Giorgia Bussu, *Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden*

**Discussant:** Carissa Cascio, *Department of Psychiatry and Behavioral Science, Vanderbilt University Medical Center, Nashville, TN*

Sensory processing refers to the ability to organize incoming sensory information from the surrounding environment and generate behavioural responses accordingly. Differences in behavioural responses to sensory input (i.e., sensory features), such as hypo- and hyper-responsiveness, and sensory-seeking behaviours, have been widely reported in autistic individuals, with studies providing evidence for their heterogenous manifestations across the lifespan. Yet, our understanding of the mechanisms underlying this variability and its developmental impacts within and beyond the autism spectrum remains limited. Here, we present novel findings from well-characterised longitudinal datasets spanning from early infancy to school age, adolescence, and adulthood across different interdisciplinary projects. We combine innovative methodological approaches, ranging from multivariate twin analysis and longitudinal modelling of sensory features in pediatric population-based samples, to molecular genetics, brain imaging and psychophysical measures of sensory processing in autistic individuals and neurotypical controls. Our studies highlight the relevance of studying sensory differences at different levels of investigation, integrating genetic, neurobiological and behavioural perspectives on developmental mechanisms underlying individual variability in sensory processing and how this may impact outcomes across function and symptom domains. Understanding developmental cascades linked to variability in sensory processing may provide potential targets for individualized and timely support strategies across the neurodevelopmental spectrum.

**218.001** *(Panel Discussion)* Etiological Architecture of Sensory Processing: An Infant Twin Study.

*G. Bussu*, A. M. Portugal and T. Falck-Ytter, (1)Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden, (2)Karolinska Institutet, Uppsala, Sweden

Background: Infants vary significantly in the way they process and respond to sensory stimuli. This variability is evident across the entire neurodevelopmental spectrum, with altered sensory processing being reported frequently among autistic individuals. Previous work with
adolescents and adults suggests that variability in sensory processing may have a genetic basis (Assary et al., 2021). However, we know little about the etiological factors influencing sensory differences in a critical developmental period like infancy, and its potential link to autism.

Objectives: This study investigated sensory processing profiles early in infancy with the aim to test: (1) genetic and environmental influences on individual variability in sensory processing; (2) to what extent these influences are shared or unique to different sensory domains; (3) developmental associations with later autistic traits.

Methods: We used multivariate twin models to analyse standardized parent-report scores from the Infant/Toddler Sensory Profile (ITSP; Dunn, 2002), measuring sensory processing across four quadrants: low registration; sensation seeking; sensory sensitivity; sensation avoiding. We analysed data from a community sample of monozygotic (MZ) and dizygotic (DZ) same-sex twins at 5 months of age (n=285 pairs, n=158 MZ pairs, n=150 male pairs) from the BabyTwins Study in Sweden (BATSS; Falck-Ytter et al., 2021). We selected an ACE model, estimating additive genetic (A), shared environmental (C), and nonshared environmental (E) effects, to decompose variance and covariance across the four quadrant scores, accounting for parental age and parental education covariates, across different multivariate model solutions: the correlated factors, the independent pathway, and the common pathway model (Rijsdijk & Sham, 2002). Furthermore, we used generalized estimating equations (GEE, Carlin et al., 2005) and Cholesky decomposition (Neale & Cardon, 2013) to test phenotypic and etiological associations between ITSP quadrant scores at 5 months and total scores from the Quantitative Checklist for Autism in Toddlers (Q-CHAT; (Allison et al., 2008)) at 24 months.

Results: The independent pathway model provided the most parsimonious solution to the multivariate problem, suggesting that the ITSP quadrants share common genetic and environmental influences but still represent separable constructs (see Figure 1). Shared variance ranged between 20% (sensation seeking behaviours) and 58% (sensory sensitivity), with contributions from both additive genetics and shared environmental factors. Genetic influences were overall moderate, with largest heritability for sensory sensitivity (A=0.41, CI=[0.30; 0.55]; see Figure 2), 39% of which was explained by shared genetic influences. Shared environment explained most of the variance in sensory seeking (C=0.67, CI=[0.55; 0.75]) and low registration (C=0.64, CI=[0.54; 0.74]), largely through unique factors. Contributions from unique environment were minimal. GEE associations to later autistic traits were not significant. Accordingly, Cholesky decomposition showed negligible overlap (approximately 1%) between genetic and environmental components of sensory processing at 5 months and autistic traits at 24 months.

Conclusions: This study delineates the etiological structure underlying individual variability across different sensory processing domains early in infancy. Results support Dunn’s sensory model by showing etiological separability between sensory quadrants. Findings also indicate that infants’ sensory differences do not correlate with trait-level autism later in development in the general population, neither phenotypically nor etiologically.

218.002 (Panel Discussion) The Developmental Impacts of Sensory Features on School-Age Functional Outcomes in Autistic and Non-Autistic Children

Y. J. Chen1, J. Sideris2, L. R. Watson3, E. Crais1, and G. T. Baranek1, (1)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3)Department of Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Sensory features, including hyperresponsiveness, hyporesponsiveness, and sensory seeking/repetitions, are widely observed in but not exclusive to autistic children. While previous evidence revealed concurrent associations between sensory challenges and other behavioral domains (e.g., adaptive/maladaptive behavior) across autistic and non-autistic populations, their longitudinal associations remain unclear. A better understanding of how sensory features that emerge early in life may pose cascading impacts on children’s later functional outcomes could inform targeted and timely sensory-based intervention for those who are susceptible to later functional challenges within and beyond the autism spectrum.

Objectives: This study aimed to examine 1) the impact of sensory development from age 1 to 6 on children’s adaptive/maladaptive and participation outcomes at school age; and 2) the variances of children’s participation outcomes as explained by demographics, sensory growth parameters, maladaptive behavior, and adaptive/motor functioning in autistic and non-autistic outcome groups.

Methods: The current sample (N=1517) is a birth cohort recruited through North Carolina vital records, and was followed when children were 1, 3, and 6 years old with parent-report questionnaires (First Years Inventory-v3.1 and Sensory Experiences Questionnaire-v2.1) about children’s sensory features. School-age functional outcomes were further assessed with the Vineland Adaptive Behavior Scales (VABS-3) and Participation and Environment Measure for Children and Youth (PEM-CY) in a subset sample (N=389). The hypothesized structural equation model (Figure 1) was fitted to examine the adjusted predictive effects of latent growth parameters of sensory features on functional outcomes. The variances (R²) of distal outcome (i.e., participation level indexed by frequency and involvement for each PEM-CY activity category) explained by adding each predictor variable group (PVG1-4) were evaluated in a series of multigroup path models.
Results: The hypothesized full model fitted the data well (CFI=.987/TLI=.957, RMSEA=.027), indicating that the effects of the change rate of hyperresponsiveness on participation in home-based social/routine activities and classroom activities were mediated by adaptive functioning ($\beta=-.09$ to -.13, all $p<.05$), and by motor functioning and internalizing behavior for community-based physical activities ($\beta=-.07$ & -.06, both $p=.03$). Children’s more participation in classroom activities was directly predicted by more decrease in hyperresponsiveness ($\beta=-.34$, $p=.001$). The change rate of hyperresponsiveness was the strongest predictor of adaptive/maladaptive outcomes ($\beta=.15$ to .43, all $p<.05$). All the predictors together explained 21-49% of participation outcomes across activity categories in autistic children, as compared to 7-29% in their non-autistic peers (Figure 2). Particularly, sensory growth parameters added 3-30% variances in predicting participation outcomes across activity categories in autistic children (vs. 0-17% in non-autistic children).

Conclusions: This study examined the developmental impact of sensory features on the higher-level functional outcomes concerning what children can do and take part in within their daily lives. Early sensory features, particularly hyper- and hyporesponsiveness, may be important intervention targets for improving children’s school-age adaptive and participation outcomes regardless of autistic outcome status. However, our multigroup analysis revealed the relative importance of sensory development for predicting autistic children’s participation in certain activity categories (e.g., classroom activities). These findings highlight the potential of addressing children’s sensory needs early on for optimizing their long-term functional outcomes.

**218.003 (Panel Discussion) Tactile Sensitivity in Autism across the Lifespan: A Multi-Site Study**

**Background:** Sensory differences are common in autism, with differences in touch processing being amongst the most common. Indeed, many individuals on the autism spectrum report discomfort with regard to clothing (e.g., shirt tags and shoes), as well as interpersonal social touch. Much of the previous literature on tactile differences in autism have used informative yet inherently subjective self-report questionnaires which do not differentiate between low-level perceptual sensitivity and higher-level affective reactivity to sensory input. Psychophysical approaches can address this issue by providing robust and objective measures of the former (i.e., of perceptual sensitivity).

**Objectives:** We aimed to 1) compare tactile perceptual sensitivity thresholds between a large and wide age-range sample of individuals meeting criteria for an autism spectrum disorder (ASD), attention-deficit/hyperactivity disorder (ADHD) and typically developing controls (TDC), and 2) assess and characterize the developmental trajectory of tactile sensitivity in these groups.

**Methods:** The sample consisted of 768 participants. There were 298 autistic participants (age range = 5-27), 120 participants with ADHD (age range = 8 to 34) and 350 TDCs (age range 3-41). All participants completed a vibrotactile battery assessing reaction time (RT) and RT variability, static and dynamic detection thresholds, simultaneous amplitude discrimination with and without adaptation and temporal order judgement. The software and hardware used across sites was identical, ensuring consistency. Tactile performance was compared between the three groups using analysis of variance followed by Tukey’s post hoc tests. Exploratory non-linear normative modelling using locally estimated scatterplot smoothing was used to create a model of developmental trajectory of tactile perceptual sensitivity for all three groups.

**Results:** There were significant group differences between the autism group and TDC on most tactile tasks, as well as age-group effects, but no significant interactions, with p-values ranging between 0.045 to < 0.0001. There were also differences between the ADHD group and TDC group on the tactile tasks associated with temporal processing. Across all tasks, the ADHD and TDC groups showed similar developmental trajectories, with tactile thresholds slowly decreasing (i.e., improving) and then levelling out in early adolescence. In contrast, the autism group showed an offset in childhood, followed by a developmental delay for most tasks where tactile thresholds were substantially higher before the age of fifteen and only reached a neurotypical level after this age (Figure 1).

**Conclusions:** Here, we presented the largest psychophysical dataset in autism to date. Using data collated across five sites, we show differences in tactile perception in autism and ADHD across the lifespan. The developmental delay in autism is consistent with models suggesting alterations in brain excitation and inhibition which we previously associated with differences in touch perception. In future work we aim to compare age-related trajectories between cohorts and quantify whether deviation from the neurotypical mean correlates with clinical severity. These findings are compelling, as an apparent developmental delay in autism could have severe repercussions for social relationships and core autism symptoms, which could be crucial in informing future approaches to diagnosing and developing support for autism.
Background:
The pathophysiology of autism is still relatively unknown. The excitatory/inhibitory (E/I) imbalance hypothesis posits that imbalance between excitatory (glutamatergic) and inhibitory (GABAergic) mechanisms underlies the behavioral autism characteristics. However, whether and how E/I mechanisms differ across autism symptom profiles and brain regions is not well understood.

Objectives:
To broaden the understanding of how E/I mechanisms may differ across symptom profiles and brain regions, we investigated links between behavioural autism characteristics, genetic variance and brain structure.

Methods:
Autistic participants (n=359) and neurotypical controls (n=279) were recruited from the Aims-2-Trials LEAP (Longitudinal European Autism Project) consortium where we used behavioural autism phenotypes, genotype data and structural T1-weighted 3T-MRI scans to measure cortical thickness. We performed competitive gene-set analysis using MAGMA to investigate associations between glutamatergic ($n_{genes}=72$) and GABAergic ($n_{genes}=124$) signaling pathway gene-sets and clinical measures. We also looked at expression profiles of the genes within those sets throughout the brain and how those profiles correlate to cortical thickness differences between autistic and neurotypical participants, as well as in separate sensory subgroups.

Results:
The glutamate gene-set was associated with all autism symptom severity scores on the Autism Diagnostic Observation Schedule-2 (ADOS-2) and the Autism Diagnostic Interview-Revised (ADI-R) within the autistic group. In adolescents and adults, brain regions with greater gene-expression of glutamate and GABA genes showed greater differences in CT between autistic and neurotypical control participants although in opposing directions. This can be seen in the figure. Additionally, the gene expression profiles were associated with CT profiles in separate sensory subgroups.

Conclusions:
These analyses suggest differential roles for glutamate and GABA in the relationships between glutamate and GABA genes, and autism characteristics and brain structures. These effects may also be mediated through altered cortical thickness. Further replication and extension of this work is needed to derive more targeted treatment options for autism.
Background: According to the monotropism hypothesis (Murray et al., 2005), autism is characterized by hyper-focus on interests. Hyper-focus is also common in ADHD (Hupfeld et al., 2019). However, attention in autism and ADHD also seems more likely to be captured by distractors (Adams et al., 2019; Kuehn et al., 2019). Atypical sensory experiences are prevalent and impactful in both autism and ADHD (Ben-Sasson et al., 2019; Lane & Reynolds, 2019).

Objectives: This study tests whether hyper-focus and inattention are associated rather than opposed, and whether these attention styles are related to auditory sensory discomfort (e.g., by aversive stimuli capturing highly focused attention).

Methods: 404 adults (129 autism+ADHD, 99 ADHD-only, 87 autism-only, 89 comparison; 39% male, 49% female, 12% nonbinary/other; Mage=36.06) from online survey platforms (SPARK, Prolific, CloudResearch) screened as eligible to participate and provided usable data. Participants listened to and rated the Core Discriminant Sounds for Misophonia (MISTS-M), a psychoacoustic measure of misophonia (Enzler et al., 2021), and completed questionnaires including ASRS-18 (Kessler et al., 2005), Multidimensional Inventory of Sound Tolerance in Adults (MISTA; http://dx.doi.org/10.13140/RG.2.2.10492.28802/1), Vanderbilt Auditory Distractibility Questionnaire (VADQ; http://dx.doi.org/10.13140/RG.2.2.14831.36000), and an adapted Adult Hyperfocus Questionnaire (AHQ; Hupfeld et al., 2019). Ordinal tests were used (Kruskal-Wallis, Mann-Whitney, and Spearman correlation tests); Holm-Bonferroni corrections were applied to group comparisons.

Results: Relative to controls, all neurodivergent groups reported more AHQ dispositional hyper-focus, p’s≤.0001. Autism+ADHD and ADHD-only had more hyper-focus than autism-only, p’s≤.0003. Per Fisher’s exact test, neurodivergent groups were more likely than controls to have an intense interest, p’s≤.0003; autism+ADHD were more likely than ADHD-only, p=.01.

Neurodivergent groups had more MISTA sensory symptoms in all domains, and higher VADQ scores, than controls, p’s<.0001. Autism+ADHD reported more MISTA fear/panic than autism-only, p=.03, and more MISTA loudness/overwhelm, anxiety/avoidance, pain, and fear/panic and higher VADQ scores, p’s≤.03, than ADHD-only. After correction, neurodivergent groups did not differ in MISTA anger/misophonia. On the CDS, ADHD-only and autism+ADHD rated misophonic trigger sounds more negatively than controls, p’s≤.02, while autism-only and autism+ADHD rated pleasant sounds more negatively than controls, p’s≤.01. CDS ratings of misophonic sounds were correlated with MISTA anger/misophonia in autism+ADHD and autism-only, p’s≤.02, with weak effect sizes.

Controlling for inattention, VADQ scores were associated with dispositional hyper-focus in autism+ADHD, p=.03. Controlling for inattention, MISTA loudness/overwhelm scores were associated with dispositional hyper-focus in autism+ADHD and controls, p’s≤.002; controlling for dispositional hyper-focus, loudness/overwhelm was associated with inattention in ADHD-only and controls, p’s≤.04. Controlling for inattention, MISTA anger/misophonia scores were correlated with dispositional hyper-focus in autism+ADHD and controls, p’s≤.02; controlling for hyper-focus, anger/misophonia was associated with inattention in autism-only, ADHD-only, and controls, p’s≤.04.

Conclusions: Hyper-focus and sensory discomfort were common in neurodivergent people. As expected, phenotypes of auditory sensory discomfort were associated with hyper-focus as well as inattention, suggesting these sensory experiences at least partly reflect real-world attention allocation. Unexpectedly, hyper-focus, but not intense interests, seemed elevated in ADHD relative to autism. This could suggest hyper-focus and monotropic attention have multiple dissociable aspects. Thus, further research on characterization and measurement of hyper-focus in neurodivergent and neurotypical populations appears necessary.

Objectives: This study tests whether hyper-focus and inattention are associated rather than opposed, and whether these attention styles are related to auditory sensory discomfort (e.g., by aversive stimuli capturing highly focused attention).

Methods: 404 adults (129 autism+ADHD, 99 ADHD-only, 87 autism-only, 89 comparison; 39% male, 49% female, 12% nonbinary/other; Mage=36.06) from online survey platforms (SPARK, Prolific, CloudResearch) screened as eligible to participate and provided usable data. Participants listened to and rated the Core Discriminant Sounds for Misophonia (MISTS-M), a psychoacoustic measure of misophonia (Enzler et al., 2021), and completed questionnaires including ASRS-18 (Kessler et al., 2005), Multidimensional Inventory of Sound Tolerance in Adults (MISTA; http://dx.doi.org/10.13140/RG.2.2.10492.28802/1), Vanderbilt Auditory Distractibility Questionnaire (VADQ; http://dx.doi.org/10.13140/RG.2.2.14831.36000), and an adapted Adult Hyperfocus Questionnaire (AHQ; Hupfeld et al., 2019). Ordinal tests were used (Kruskal-Wallis, Mann-Whitney, and Spearman correlation tests); Holm-Bonferroni corrections were applied to group comparisons.

Results: Relative to controls, all neurodivergent groups reported more AHQ dispositional hyper-focus, p’s≤.0001. Autism+ADHD and ADHD-only had more hyper-focus than autism-only, p’s≤.0003. Per Fisher’s exact test, neurodivergent groups were more likely than controls to have an intense interest, p’s≤.0003; autism+ADHD were more likely than ADHD-only, p=.01.

Neurodivergent groups had more MISTA sensory symptoms in all domains, and higher VADQ scores, than controls, p’s<.0001. Autism+ADHD reported more MISTA fear/panic than autism-only, p=.03, and more MISTA loudness/overwhelm, anxiety/avoidance, pain, and fear/panic and higher VADQ scores, p’s≤.03, than ADHD-only. After correction, neurodivergent groups did not differ in MISTA anger/misophonia. On the CDS, ADHD-only and autism+ADHD rated misophonic trigger sounds more negatively than controls, p’s≤.02, while autism-only and autism+ADHD rated pleasant sounds more negatively than controls, p’s≤.01. CDS ratings of misophonic sounds were correlated with MISTA anger/misophonia in autism+ADHD and autism-only, p’s≤.02, with weak effect sizes.

Controlling for inattention, VADQ scores were associated with dispositional hyper-focus in autism+ADHD, p=.03. Controlling for inattention, MISTA loudness/overwhelm scores were associated with dispositional hyper-focus in autism+ADHD and controls, p’s≤.002; controlling for dispositional hyper-focus, loudness/overwhelm was associated with inattention in ADHD-only and controls, p’s≤.04. Controlling for inattention, MISTA anger/misophonia scores were correlated with dispositional hyper-focus in autism+ADHD and controls, p’s≤.02; controlling for hyper-focus, anger/misophonia was associated with inattention in autism-only, ADHD-only, and controls, p’s≤.04.

Conclusions: Hyper-focus and sensory discomfort were common in neurodivergent people. As expected, phenotypes of auditory sensory discomfort were associated with hyper-focus as well as inattention, suggesting these sensory experiences at least partly reflect real-world attention allocation. Unexpectedly, hyper-focus, but not intense interests, seemed elevated in ADHD relative to autism. This could suggest hyper-focus and monotropic attention have multiple dissociable aspects. Thus, further research on characterization and measurement of hyper-focus in neurodivergent and neurotypical populations appears necessary.
Methods: Latent Profile Analysis was conducted on a sample of 1892 autistic youth (M<sub>age</sub> = 10.82, SD<sub>age</sub> = 4.14; 420 females) using items from the RI and UI subdomains of the Dimensional Assessment of Restricted and Repetitive Behaviours. Identified profiles were then compared on key demographic, cognitive, and clinical variables including age, sex, IQ, language level, anxiety, and core autism characteristics.

Results: Three profiles of autistic individuals were identified, characterized as Low CI, Predominantly RI, and Predominantly UI. This model exhibited high entropy (.92) and high latent profile probabilities (.97, .93, 1.00, respectively) indicating good classification accuracy. Profiles differed on several key demographic and clinical variables, such that participants in the predominantly RI profile were significantly older (F = 9.21, p < .001, $\omega^2 = .009$), scored higher on cognitive functioning (F = 10.41, p < .001, $\omega^2 = .019$), and showed higher language levels (F = 27.84, p < .001, $\omega^2 = .028$) than the participants in low CI or predominantly UI profiles. They also presented with more anxiety (F = 5.64, p = .004, $\omega^2 = .007$) and obsessive-compulsive behaviors (F = 4.87, p = .008, $\omega^2 = .004$) than the low CI profile. Meanwhile, participants in the Predominantly UI profile presented with significantly greater social and communication impairments than participants in the other two profiles (F = 4.77, p = .009, $\omega^2 = .004$). Finally, profiles differed on sex composition with males significantly more likely to be in the low CI profile and females significantly more likely to be in the predominantly RI profile ($\chi^2 = 9.09$, p = .011, V = .070).

Conclusions: Although replication across other samples is needed, profiles identified in this study are potentially promising for future research given their distinct profiles of RI and UI endorsements and unique patterns of associations with key cognitive and clinical variables. Indeed, that profiles differed on key clinical variables provides preliminary evidence that distinct profiles may be underpinned by unique cognitive, and possibly neurobiological mechanisms, and may thus show different patterns of support needs.

Background: Circumscribed interests (CI) are a core diagnostic feature of autism spectrum disorder estimated to be present in upwards of 75% of autistic individuals. Interests and related behaviors encompassed within this domain can be characterized by either a high intensity but otherwise usual topic (e.g., an interest in videogames and music), referred to as restricted interests (RI), or by a focus on topics that are not salient outside of autism (e.g., a fascination with traffic lights or categorization), referred to as unusual interests (UI). Importantly, previous research has demonstrated pronounced variability across individuals in terms of the endorsement of specific RI and UI, however, this variability has not yet been quantified and fully characterized in large samples using formal subtyping approaches.

Objectives: The current study aimed to characterize profiles of CI among autistic youth. It further aimed to explore the association between the identified profiles and key clinical and developmental variables.

Methods: Automated Detection of Video Segments Containing Stereotypical Movements of Young Children with ASD

Background:

Stereotypical movements (e.g., hand flapping) and a common symptom in many children with ASD. Previous studies of stereotypical movements have mostly been limited to using questionnaires and clinical observations that assess the presence or absence of these movements in a subjective manner. However, quantifying stereotypical movements directly and objectively in individual children is important for setting personal intervention goals and assessing treatment efficacy.

Objectives:

We describe a set of deep learning algorithms that can automatically identify and quantify the presence of stereotypical movements in video recordings of children with ASD. We demonstrate the accuracy of this system in quantifying stereotypical movements during ADOS-2 assessments.

Methods:

We manually annotated video segments with stereotypical movements in 316 videotaped ADOS assessments of 265 children with ASD between the ages of 1.4 and 6.7. The start and end times of each movement were noted, yielding a library with >10000 exemplars of stereotypical movements. We utilized the OpenPose algorithm to extract the skeleton of all individuals in each video frame and applied the
YOLOv5 model trained to detect the child in each frame, from the multiple individuals presented (i.e., clinician and parents). The child’s skeleton was used as input to train a deep neural network, PoseC3D, to identify segments where the child performed stereotypical movements.

We used exemplars from 218 children to train the algorithm and tested its accuracy on exemplars belonging to 47 independent children (i.e., different children).

After training the algorithm, we ran a sliding window of fixed size over the videos of the testing set and computed a likelihood score for the presence of a stereotypical movement on each segment/window. The accuracy of the algorithm was then compared to manual annotations by examining the intersection-over-union that gives each pair of segments an overlapping score between 0 to 1.

Results:

The algorithm detected 24.16 stereotypical movements per assessment, on average, in each of the children from the test dataset. These movements had a mean duration of 10 seconds. Overall, we achieve an accuracy score of 94.5%. The detected movements overlapped with 79% of the manually annotated movements demonstrating high accuracy in identifying existing stereotypical movements (i.e., 79% recall). However, the precision of the algorithm was only 55% indicating that the algorithm also classified many segments as containing stereotypical movements that did not contain such movements according to manual annotation (i.e., false positives).

Conclusions:

The results demonstrate promising results regarding the ability to accurately identify and quantify stereotypical movements from video recordings of children with autism. Further refinement of this technique will enable both basic and clinical research to quantify stereotypical movements in a direct and objective manner to understand underlying mechanisms and the clinical efficacy of interventions.

304.004 (Oral) A Different Spectrum of Power Laws for Autistic Movements

J. L. Cook1, D. S. Fraser2, L. J. Hickman3, R. Brewer4 and D. Huh5, (1)School of Psychology, University of Birmingham, Birmingham, (2)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (3)University of Birmingham, Birmingham, United Kingdom, (4)Department of Psychology, Royal Holloway, University of London, Egham, United Kingdom, (5)MIT-IBM Watson AI Lab, Cambridge, MA

Background:

Many autistic people move their body in a different way from non-autistic people. Indeed, a number of motion tracking studies have shown that autistic people tend to move with increased jerk (where jerk is defined as a change in acceleration). Mathematical laws of biological motion predict that people should move in a smooth, ‘minimally jerky’ fashion. Thus, the finding that autistic individuals move with increased jerk is striking because it potentially indicates a departure from highly replicable laws of motion. Studies to date have not, however, directly tested this hypothesis. Since deviations from classic laws of motion may indicate differences in motor cortical control policies and/or biomechanical constraints understanding whether autistic movements deviate from these laws can help us progress towards an understanding of the mechanisms underpinning motor control differences in autism.

Objectives:

Here we investigated whether movements executed by autistic adults diverged from the typical power law relationship that links movement speed and curvature.

Methods:

x and y position of the stylus tip was recorded at 133 Hz while 21 autistic (M:F = 19:2; mean age = 36 years, mean IQ = 110) and 19 non-autistic (M:F = 18:1; mean age = 30 years, mean IQ = 108) age-, IQ- and sex-matched adults traced, on a tablet device, a range of shapes that varied in angular frequency (the number of curvature oscillations per cycle) from 2/33 (spiral-like shapes) to 4 (square-like shapes). The gradient of the relationship between speed and curvature for each angular frequency-defined shape is reliably predicted by a set of mathematical equations often referred to as ‘fundamental power laws’, thus to assess deviations from power laws we compared autistic and non-autistic participants in terms of these speed-curvature gradients. To gain insight into potential mechanisms underpinning any differences we also used fast Fourier transform to explore amplitude spectral density across all angular frequencies.

Results:
Compared to non-autistic adults, autistic adults exhibited significantly steeper speed-curvature gradients (main effect of group: \( F(1,1300) = 4.35, p = .037 \)). Fast Fourier transform further revealed differences between the groups (main effect of group: \( F(1,1298) = 4.69, p = .031 \)). Non-autistic participants exhibited highly precise modulation of speed oscillations around the target frequency. For example, when drawing an ellipse their speed profile was dominated by speed changes in a band centred around the angular frequency two with minimal changes in other bands. Autistic adults, in contrast, exhibited less precise modulation of speed oscillations around the target frequency, a result that is reminiscent of a literature reporting broader auditory filters in autistic individuals.

Conclusions:

1. These results evidence, in autistic adults, a deviation from the power laws that typically govern movement and suggest differences in motor cortical control policies and/or biomechanical constraints.

### POSTER SESSION — sensory, motor, and repetitive behaviors and interests

#### 425 - Sensory, Motor, and Repetitive Behaviors and Interests I

**425.289 (Poster) A Longitudinal Comparison of Self-Injurious Behavior Among a Clinical Cohort of Young Children with Autism and Developmental Delay**  
**A. F. Dimian and F. J. Symons, University of Minnesota, Minneapolis, MN**

**Background:** The developmental trends associated with the emergence and persistence of self-injurious behavior (SIB) are not well understood. There is considerable heterogeneity early on and the research to date is not clear on how SIB developmentally changes and further how to identify those with an elevated likelihood of severe or chronic SIB. Early identification is critical to leverage intervention programming to decrease SIB and increase quality of life.

**Objectives:** The purpose of this preliminary study was to assess the longitudinal trends of SIB within a clinical cohort of children with neurodevelopmental disabilities. We compared SIB prevalence and incidence rates over approximately a year at three time points. We also assessed differences in SIB trends, repetitive restrictive behavior, and sensory features among children with autism spectrum disorder (ASD) and children with global developmental delay or other neurodevelopmental disabilities (e.g., ADHD).

**Methods:** We recruited a clinical cohort of children (n=32; 75% male, age 1-10 yrs (M=5.25 yrs)) receiving care at a medical center for developmental delay and related disabilities. Tele-based remote assessments were administered every 4-6 months, on average, at three time points over a 1-year time period. The assessments included parent reported electronic surveys to assess SIB, repetitive behavior, and sensory related behaviors. We evaluated SIB/repetitive behavior using the repetitive behavior scale for early childhood (RBS-EC; Wolff et al., 2016) and the sensory experiences questionnaire (SEQ 2.1; Baranek, 1999) at each time point as well as demographics and service utilization. We evaluated SIB trends using descriptive analyses as well as mean differences between diagnostic groups using Independent samples T-tests.

**Results:** The cohort included 59% with ASD, 34% with Global Developmental Delay and 31% with co-occurring neurodevelopmental disorders or delays (e.g., ADHD). SIB point prevalence was 75%, 66%, and 63%, respectively at timepoint 1, 2, and 3. SIB incidence was 37.5% over 12-months. Persistent SIB estimates (i.e., SIB endorsed at each timepoint) was 56%. Hits self with body part or against surface was the most endorsed topography of SIB across each timepoint (40%-47%). The odds of engaging in persistent SIB was 3.5 times higher among autistic children compared to children with developmental delay within the cohort. At timepoint 3, parents endorsed significantly more severe and interfering SIB (M= 5.21, SD= 5.23) among children with ASD in comparison to those without ASD (M= 1.85, SD= 3.83), \( \tau(29) = -2.09, p = .04 \). There were no other significant effects across the timepoints evaluated or among sensory features.

**Conclusions:** The results of our preliminary study indicated that SIB was highly prevalent, more severe, and persistent among children with ASD in comparison to those with other neurodevelopmental disabilities. These results have implications for clinical care in that SIB should be monitored and assessed early especially for children with ASD. A limitation of this study is the small sample size, which limits the external validity of the results reported. Future research and clinical care should focus on the behavioral mechanisms related to the incidence and persistence of SIB among autistic children to inform more precise care and intervention.

**425.290 (Poster) A Multimodal Approach Can Identify Specific Motor Profiles in Autism and Attention Deficit/Hyperactivity Disorder**  
**S. De Francesco 1,2, M. Fioravanti 1, L. Morello 1, C. Cassaro 1, S. Busà Cecarelli 1, M. Nobile 1, M. Molteni 1 and A. Crippa 1, (1)Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosissio Parini, Italy, (2)Department of Psychology, Sigmund Freud University, Milano, Italy, (3)Department of Psychology, University of Milano-Bicocca, Milano, Italy, (4)Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosissio Parini, ITALY**

**Background:** The developmental trends associated with the emergence and persistence of self-injurious behavior (SIB) are not well understood. **Conclusions:** The results of our preliminary study indicated that SIB was highly prevalent, more severe, and persistent among children with ASD in comparison to those with other neurodevelopmental disabilities. These results have implications for clinical care in that SIB should be monitored and assessed early especially for children with ASD. A limitation of this study is the small sample size, which limits the external validity of the results reported. Future research and clinical care should focus on the behavioral mechanisms related to the incidence and persistence of SIB among autistic children to inform more precise care and intervention.
Background: A rapidly growing literature supports the presence of extensive motor alterations in autism, with effect sizes ranging from 0.87-1.85. This observation has recently prompted a debate about the opportunity of adding motor to the autism definition in future revisions of diagnostic manuals. Whether and to what extent these impairments are specific to autism represents a hot topic within this debate. Previous research suggests that motor difficulties could be common to other neurodevelopmental conditions, but those observed in autism are more severe and persistent. To date, no studies have compared motor skills in autism and attention deficit/hyperactivity disorder (ADHD) through the concurrent use of standardized motor tests, caregiver reports, and kinematic analysis of an upper limb action task. The hypothesis examined in the current study is whether this multimodal approach has the potential to identify more fine-grained motor profiles, specific to each condition.

Objectives: To determine whether a multimodal assessment of motor skills could accurately discriminate autistic children from both ADHD and typically developing (TD) peers.

Methods: 75 children aged 7-13 years and with a full-scale intelligence quotient (IQ) > 80, equally divided into three groups (autism, ADHD, TD), were assessed with the Developmental Coordination Disorder Questionnaire (DCDQ), the Movement Assessment Battery for Children – 2nd edition (MABC-2), the sensorimotor subtests of NEPSY-II, and the kinematic analysis of a reach-to-drop task. Two different principal component analyses (PCA) were applied to MABC-2/NEPSY-II scores and to the 17 kinematic features, respectively, to reduce the quantity of dependent variables while retaining the variation present in the data set. Group differences on DCDQ, PCA1, and PCA2 scores were then analyzed by multivariate analysis of covariance (with age and IQ as covariates). Last, three separate logistic regression models (autism vs TD, ADHD vs TD, and autism vs ADHD) were used to predict group membership based on variables showing between-group differences at analysis of covariance.

Results: Results from PCA on MABC-2/NEPSY-II identified three factors — namely, Object Interception & Balance, Motor Imitation, and Fine-Motor Skills — whereas PCA on kinematic variables identified four factors, as previously done (Crippa et al., 2021). In the model comparing motor functioning of autistic and TD children, DCDQ total score and Motor Imitation factor predicted membership with an accuracy of 87.2%. In the model comparing ADHD and TD group, Fine-Motor Skills predicted membership with an accuracy of 79.6%. In the last model, Object Interception & Balance factor differentiated autistic from ADHD children with an accuracy of 73.5%.

Conclusions: The present study shows that specific motor profiles in autism and ADHD can be isolated with a multimodal investigation of motor skills. On one hand, this study adds to prior studies documenting distinct motor difficulties in autism on standardized measures of motor function. On the other hand, in line with our recent findings (Crippa et al., 2021), kinematics did not differentiate school-aged autistic children from ADH and TD peers, substantiating the evidence that kinematic measures could be more appropriate for identifying autistic toddlers (Crippa et al., 2015).

425.291 (Poster) A Preliminary Investigation of Tactile Reactivity in Autistic Children

Background: The diagnostic criteria for autism spectrum disorder include differences in sensory reactivity (DSM-5; APA, 2013). Sensory reactivity is commonly measured using indirect proxy reports (e.g., Sensory Experiences Questionnaire; (Baranek et al., 2006). Quantitative sensory testing (QST; Walk et al., 2009) is a method that may provide insight into underlying pathophysiological mechanisms in relation to somatosensory function. Although limited, there have been applications of QST to samples of autistic individuals (Fründt et al., 2017; Vaughan et al., 2020). However, QST requires the ability to self-report and relies on reaction times, thus posing issues for individuals with complex communication needs or motor delays. In samples with intellectual disabilities, cerebral palsy, and Rett syndrome, we established initial validity evidence for a modified QST (mQST) approach that is not dependent on language or reaction time (Barney et al., 2020; Merbler et al., 2020; Symons et al., 2010). However, feasibility and validity of the mQST in autistic samples are yet to be established.

Objectives: The objective of the current study was to conduct a preliminary investigation of the feasibility of the mQST in detecting sensory reactivity differences to tactile stimuli among autistic and nonautistic children.

Methods: The mQST protocol was implemented with 10-year-old children (n = 8 autistic; n = 37 nonautistic). The mQST protocol consisted of 6 sensory stimuli (light touch, pinprick, cool, pressure, repeated Von Frey, and heat) and a sham. Behavioral reactivity scores for each participant for each stimulus were quantified using a behavioral coding scheme to capture gross motor, facial, and vocal responses to each stimulus. Descriptive statistics (mean and standard deviation), two-sample t-tests, and effect size (Cohen’s d) were computed.

Results: Two-sample t-tests compared behavioral reactivity to mQST stimuli in autistic and nonautistic children. Autistic children demonstrated significantly increased sensory response, with medium to large effect sizes, compared to nonautistic children, for light touch (t(43) = -2.38, p = .045, d = -1.35), heat (t(43) = -2.80, p = .023, d = -1.29), pinprick (t(43) = -2.56, p = .025, d = -0.91), and the last five
Background: Autism spectrum disorder (ASD) defines a group of heterogeneous neurodevelopmental conditions that are commonly associated with Sensory processing (SP) impairment. Otoacoustic emissions (OAEs) are weak acoustic signals emitted from the outer hair cells in the cochlea, spontaneously or in response to sensory stimulation. In all mammals, OAE production is regulated by the brainstem to facilitate auditory processing. Multiple non-ASD related studies linked aberrant OAE patterns with a decreased speech recognition, impaired brain connectivity and aberrant sensory processing in general (visual, auditory, olfactory, gustatory, and tactile).

Objectives: To assess the feasibility of a novel OAE assessment paradigm, to detect aberrant OAEs in young children with ASD compared with matched typically developing children.

Methods: An OAE measurement device recorded both the ipsilateral and the contralateral auditory efferent pathways. The vowel "Eh" was used as stimuli. This stimulus is longer, more complex and includes vowel formants as compared with standard OAE tests stimuli. Time/frequency/volume distribution patterns relative to the basic stimulus profile were assessed in 12 children with ASD (ages 2-9 years) and 12 age and gender matched typically developing (TD) children.

Results: Sub-sections analysis of the OAE measured response matrix revealed a significant group difference between the ASD and TD groups. Standard OAE response to the first 3 vowel formants was observed in all the TD participants. However, the OAE response to the vowel formants in all the ASD participants was either delayed, blurred or absent completely.

Conclusions: Using a novel OAE assessment paradigm, we were able to demonstrate aberrant OAE response profiles in all of the children with ASD compared with none of the TD children. OAE response profiles are associated with speech processing, connectivity, and SP in general. Hence, these results support the feasibility of OAE measurement as a non-invasive, diagnostic, and possibly stratifying pathophysiologic biomarker for ASD. Further studies are required to assess the sensitivity, specificity, and stratification validity of OAE measurement in young children with ASD.
Background: Children with ASD have a high rate of co-occurring irritability symptoms, which are associated with poor outcomes. Irritability, defined by frequent and impairing anger outbursts, affects approximately fifty percent of children with ASD. Irritability is associated with poor emotion regulation (Stringaris, 2018), communication deficits, and sensory sensitivities (Kanne, 2011). However, as irritability has not been investigated.

Objectives: We aimed to examine the association of sensory processing differences and irritability in children with a diagnosis of ASD.

Methods: We used data from a sample of autistic children (N=55; 11.3±2.45, 18.2% female) with IQ>=85. All children had a diagnosis of ASD, supported by the Autism Diagnostic Interview-Revised (ADI-R) and the Autism Diagnostic Observation Schedule (ADOS). Irritability was quantified using the Aberrant Behavior Checklist (ABC; irritability subscale T-score), and sensory differences were measured using the Short Sensory Profile (SSP). The SSP has seven subscales: tactile sensitivity, taste/smell sensitivity, movement sensitivity, underresponsive/seeks sensation, auditory filtering, low energy/weak, and visual/auditory sensitivity. The sample was further characterized on IQ using the full scale-4 IQ and autism traits using the Social Communication Questionnaire (SCQ). Linear regression analysis was used to examine the association of sensory processing differences and irritability in the sample at a significant level of 0.05, using individual models for each SSP subscale, and correcting for multiple comparisons using the FDR method (7 subscales of the SSP). To control for the effects of symptom intensity and cognitive ability, we first regressed irritability against SCQ and IQ (sequentially) and used the residuals to examine the impact of SSP.

Results: After accounting for the effects of autism traits (Social Communication Score) and full scale IQ, increased sensory differences were found to be significantly associated with increased irritability in the auditory filtering (F(1,118)=7.25, p-corr=0.04) and under responsive/seeks sensation subscales of the SSP. Using age and sex as covariates did not change the conclusions.

Conclusions: From our results, significant and negative correlation was found between the factor of fine motor/perceptual in SP and language conceptual inference ability in children with ASD, but not in the TD children (i.e., more problems in the fine motor/perceptual characteristics are associated with lower language conceptual abilities in children with ASD). In children with ASD, difficulties of integrating sensory information perceived from inside and outside the body and adjusting fine movements are related to deficiencies of language semantic conceptual formulation.

425.294 (Poster) Association between Sensory Processing Differences and Irritability in ASD

S. Alatash, A. Kushki, T. Paul, R. Cardy, B. Andrade, S. Monga, J. A. Bruny and E. Anagnostou, (1)University of Toronto, Toronto, ON, Canada, (2)Holland Bloorview Hospital, Toronto, ON, Canada, (3)Autism Research Centre, Bloorview Research Institute, Bloorview Research Institute, Toronto, ON, Canada, (4)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (6)Centre for Addiction and Mental Health, Toronto, ON, Canada, (7)The Hospital for Sick Children, Toronto, ON, Canada, (8)Autism Research Centre, Bloorview Research Institute, University of Toronto, Toronto, ON, Canada
Objectives: The study investigated the association of irritability with the dimensions of RRB measured by the Repetitive Behavior Scale-Revised (RBS-R) (Bodfish, 2000).

Methods: The sample included 82 children with ASD, ages 8-15 years (M = 11.73, SD=1.74); 19 identified as female and 63 as male. Diagnosis was based on the ADI-R conducted by a research-reliable clinician and corroborated with the patient's medical history. Full-scale IQ was evaluated using the Differential Abilities Scales (DAS). Parents completed the Affective Reactivity Index (ARI), the Repetitive Behavior Scale-Revised (RBS-R), and the Social Responsiveness Scale-2 (SRS-2). Pearson correlations with Holm-Bonferroni correction were used to test bivariate associations of irritability with the six subscales of the RBS-R. To examine the contribution of restricted repetitive behavior to irritability in ASD, a hierarchical linear regression predicting ARI irritability was conducted. Age, IQ, and social communication difficulties, as indexed by the Social Communication and Interaction (SCI) subscale of the SRS, were controlled for in the analyses.

Results: The sum score of three of the six subscales in the RBS-R were included in the analyses. Irritability as measured by the Affective Reactivity Index was correlated with (1) Sameness Behavior (r80 =0.46, p<0.001), (2) Ritualistic Behavior (r80 =0.30, p=0.007), and (3) Compulsive Behavior (r80 =0.28, p=0.013). As these RRB subscales were significantly intercorrelated, their sum score was used in the regression analyses to avoid multicollinearity. After accounting for age, IQ and social communication difficulties as covariates in our regression model, there was a significant positive effect of restricted repetitive behavior on irritability (Model \( R^2 =0.516, R^2 \text{ change}=0.071, F_{1,68}\text{change}=6.388, p<0.014 \)).

Conclusions: RRBs are classified into subtypes consisting of stereotyped behavior, self-injurious behavior, compulsive behavior, insistence on sameness, ritualistic behaviors, and restricted interests. Results indicated that only insistence on sameness, ritualistic behaviors, and compulsive behaviors were associated with greater irritability in autistic children. Within the sample, rates of stereotyped behavior and self-injurious behaviors were relatively low in comparison to previous findings. Additionally, the mean IQ of our sample was 99.9 (SD = 19.7). Therefore, these findings may not generalize to severely affected individuals with ASD. However, the study provides evidence for the association between irritability and insistence of sameness, and ritualistic behaviors in ASD populations. These domains of restricted repetitive behavior may provide a target for future psychosocial interventions aimed at improving emotional well-being of children with ASD.

425.296 (Poster) Associations between Brainstem Maturation and Sensory Issues in Autistic Individuals
A. Seif, C. Marceau-Linhares, S. Schmid and R. A. Stevenson, (1)University of Western Ontario, London, ON, Canada, (2)Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada

Background:
Autistic individuals often suffer from auditory sensory processing disruptions. We have hypothesized that auditory sensory issues may be related to delays in auditory brainstem maturation in autism, which has been structurally observed by neuroimaging and post-mortem analysis. Functionally, this delay is measured through the auditory brainstem responses (ABR), an auditory evoked potential recorded through electrodes on the scalp. Alterations in ABR latencies indicate a reduced sound sensitivity which seems counterintuitive given the increased sensory sensitivities reported by autistic individuals. This discrepancy could be due to the heterogeneity of autism.

Objectives:
To investigate the link between brainstem development indexed via ABR and sensory issues using a parent-reported sensory measure.

Methods:
Autistic (n=12; data collection ongoing) and non-autistic (n=12) children aged 8–13years completed a hearing evaluation and an ABR recording session. The hearing evaluation consisted of a visual inspection using an otoscope, tympanometry (226Hz probe), audiogram (250-8kHz), and distortion product otoacoustic emission evaluation (2kHz–8KHz). The ABR paradigm consisted of a slow click-rate (19.1clicks/second) and a fast click-rate (59.1clicks/second), and acoustic stimuli at 80dBnHL intensity across both ears. Participants listened passively while watching a silent video. Parents completed the Sensory Profile questionnaire.

We conducted three-way, mixed-model, repeated-measure ANOVAs with within-subject factors of ear and stimulus click-rate, and a between-subject factor of diagnostic group. Absolute latencies of peaks I, II, III and V, and the inter-peak latencies (IPL) of peaks I-III and I-V were evaluated. Peak latencies with a significant group difference were correlated with the sensory seeking, sensory avoiding, and sensory sensitivities quadrants of the sensory profile.

Results:
Background: Over 90% of children with ASD have atypical sensory experiences that can exacerbate learning, developmental, and behavioral difficulties (Leekham et al., 2007, Henry et al., 2007). Additionally, early sensory-regulatory and social-communicative deficits contribute to later language outcomes (Baranek et al., 2018). Sensory features in infancy may be a factor that discriminates ASD in early development, yet few studies have investigated sensory profiles in infants younger than 18 months (Garon et al., 2009).

Objectives: 1) Describe sensory profiles in 9-month-old infants with elevated genetic likelihood for ASD, infants born preterm, and with low likelihood for ASD. 2) Investigate associations between sensory profiles and social communication risk.
Methods: Participants include 9-month-old infants (N=68) at elevated genetic likelihood for ASD (EL; n=19), infants born preterm (PT; <37 weeks; n=23), and low likelihood for ASD (LL; n=26). Parents completed the Infant Toddler Sensory Profile-II (ITSP-2, Dunn 2014) to evaluate sensory profiles in 9-month-old-infants and the First Year Inventory (FYI, Baranek et al 2003) to assess behaviors in 12-month-old-infants that suggest risk for ASD. Group differences in sensory profile raw scores (seeking, avoiding, sensitivity, and registration) and sensory processing (general, auditory, visual, touch, movement, body position, and oral sensory) raw scores were investigated using a one-way ANOVA. These raw scores were then dichotomized into “High” and “Low” categories based on the ITSP-2 manual to examine associations between sensory profiles and FYI social communication scores.

Results: A one-way ANOVA showed significant group differences for sensory seeking F(2,65)=12.61, p<0.05, movement processing F(2,65)=5.46, p<0.05, and visual processing F(2,65)=4.25, p<0.05. Post hoc analyses (Tukey’s HSD) indicated: 1) lower seeking in EL infants compared to LL and PT infants 2) lower movement processing in EL infants and PT infants compared to LL infants 3) and lower visual processing in EL infants than LL infants and PT infants (Fig 1). Results revealed non-significant group differences for other sensory processing patterns & subtests (all p’s>0.05). Paired sample t-tests were used to assess associations between sensory profiles with significant group differences (seeking, movement, and visual) and social communication risk. Results revealed that low sensory-seeking infants showed a higher social communication risk score compared to high sensory-seeking infants (t(39.81)=2.36, p<0.05; see Fig 2). Infants with low movement processing scores also showed higher social communication risk compared to infants with high movement processing (t(39.81)=-2.10, p < 0.05). There was no significance between social communication risk and visual processing (p>0.05).

Conclusions: Our findings suggest that EL infants exhibit a sensory profile characterized by reduced sensory seeking, particularly for movement and visual behaviors, compared to LL and PT infants. In movement behaviors, PTs were similar to ELs. Infants with low sensory seeking and low movement processing were associated with higher social communication risk. This suggests that sensory seeking and movement processing may be features associated with atypical social and language development. Further understanding of the use of differential sensory processing patterns in early infancy may provide more salient markers for early-emerging ASD symptomology.

425.299 (Poster) Associations between Specific Motor Skills and Daily Living Skills in Consideration of Age and IQ

E. Skaletski, S. Cortes-Cardona and B. G. Travers, (1)University of Wisconsin-Madison, Madison, WI, (2)Universidad de Puerto Rico-Mayaguez, Mayaguez, PR, (3)University of Wisconsin Madison, Madison, WI

Background: Motor skills and daily living skills (DLS) relate in both autistic and non-autistic individuals (Bremer & Cairney, 2018; Fears et al., 2022; Fisher et al., 2018; Travers et al., 2017, 2022). However, “motor skills” covers a broad spectrum of motor tasks, and more information on how specific motor tasks map onto daily living skills is needed. Two previous studies (Bremer & Cairney, 2018; Fears et al., 2022) found that fine motor skills but not balance related to daily living skills. However, IQ was not considered as a moderator, though previous research found that balance-DLS relations were only observed in those with lower-than-average IQ (Fisher et al., 2018). Research is needed to further examine DLS in relation to fine motor tasks, while also examining potential balance-IQ interactions and other aspects of motor performance, such as bilateral coordination, speed/agility, and strength.

Objectives: We sought to determine how items on the Bruininks-Oseretsky Test of Motor Proficiency, 2+ edition (BOT-2) Short Form related to DLS standard scores on the Vineland Adaptive Behavior Scales-2+ or 3+ edition (VABS-II, Vineland 3). We hypothesized that fine motor precision (drawing a line through a crooked path, folding paper), fine motor integration (copying a square, copying a star), and manual dexterity (transferring pennies) tasks would be related to DLS, but upper limb coordination (dropping and catching a ball, dribbling a ball) would not. Additionally, we hypothesized an interaction of IQ on balance and DLS. Lastly, we explored how bilateral coordination (jumping in place, tapping feet and fingers-same sides), running speed and agility (one-legged stationary hop), and strength (push-ups, sit-ups) individually relate to DLS, novel areas of study.

Methods: Participants were 103 autistic children (between ages 6-17) with an IQ of 60 or higher. Participants completed the BOT-2 Short Form and parents/caregivers completed the VABS-II/Vineland-3 depending on study timing. Most (n= 84) had VABS-II data. We used partial correlations adjusting for age and IQ to analyze which motor skills related to DLS, with false discovery rate corrections. We used multiple linear regression to determine whether IQ interacted with balance in relating to DLS, controlling for age.

Results: Only drawing (r = .32, p = .01) and folding (r = 0.30, p = 0.02) related to DLS, both with small effect sizes. IQ interacted with balance, b = -0.04, SE = 13.84, t(99) = -2.06, p = 0.04.

Conclusions: The results suggest that only fine motor precision tasks were related to DLS, which supports the need for fine motor precision in real-world tasks, such as shoe-tying. This finding also emphasizes the need for fine motor precision skill development in interventions. These results did not find that bilateral coordination, speed/agility, nor strength were related to DLS. Similar to Fisher et al. (2008), balance-DLS relations were only observed in the lower-than-average IQ group. This finding suggests that balance likely interacts with cognitive factors to impact DLS, perhaps suggestive of compensatory strategies implemented to offset balance differences during DLS performance.

425.300 (Poster) Characterizing the Complexity of Insistence on Sameness: From Nosology to Mechanisms
Background: Insistence on Sameness (IS) is a complex and heterogeneous domain that encompasses a range of behavioral patterns, including, but not limited to, inflexible adherence to routines, ritualized patterns of behaviors, and resistance to change. IS has consistently emerged as a single factor across previous factor analytic studies of general autism assessment measures and dedicated RRB instruments. However, the majority of current measures underscore the breadth and diversity of behaviors, which might have precluded identification of more distinct subdomains. Thus, with more comprehensive domain coverage, it is possible that distinct subdomains may emerge. Further, while previous research has identified several potential mechanisms that may underpin IS, including anxiety, sensory atypicalities, and self-regulation difficulties, it is unclear whether these constructs play similar roles in the expression and severity of different facets of the IS domain.

Objectives: The current study aimed to characterize the structure of IS. Further, if different IS subdomains were identified, it aimed to explore potentially distinct patterns of associations between identified IS factors and key demographic, cognitive and clinical correlates, such as age, gender, cognitive functioning, anxiety, social abilities, and different aspects of self-regulation, and sensory atypicalities.

Methods: The parents of 1892 autistic youth (M<sub>age</sub> = 10.82, SD<sub>age</sub> = 4.14; range: 3-18 years; 420 females), collected through SPARK, completed a battery of online surveys including the Dimensional Assessment of Restricted and Repetitive Behaviors, Social Communication Questions, Parent-Rated Anxiety Scale – ASD, and the Sensory Experiences Questionnaires-3. Exploratory graph analysis (EGA) was conducted on the exploratory subsample (n=971) to examine the network structure of the IS subdomain. The confirmatory application of exploratory structural equation modelling (ESEM) was used in the confirmatory subsample (n=921) to confirm the fit of the model. Generalized Additive Models were used on the combined sample to assess non-linear relationships between each of the identified IS subdomains and key variables.

Results: Three IS subdomains were identified, labelled ritualistic behaviors (IS-Ri), routines (IS-Ro), and sameness behaviors involving another individual (IS-I). This model showed strong structural consistency (replicated in 82% of bootstraps), excellent mean item stability across replications (.94), and was a good fit to the data (CFI=.96; TLI=.95; RMSEA=.06; SRMR=.03). Each subdomain showed a unique pattern of association with key variables. More specifically, while hypersensitivity and social interaction were significantly associated with the IS-Ri and IS-Ro subdomains (F=15.39, p < .001; F=17.83, p < .001), they were not associated with IS-I. Further, while emotional dysregulation was a unique predictor of IS-Ri (F=11.76, p < .001, but not IS-Ro or IS-I, behavioral dysregulation was a unique predictor of IS-Ro (F=4.30, p < .010), but IS-Ri or IS-I.

Conclusions: Current findings provide preliminary evidence that the broad domain on IS may consist of distinct subdomains, each possibly underpinned by different cognitive, and potentially neurobiological mechanisms. Further, the study provides important targets for future research including the possibility of different aspects of self-regulation playing different roles in specific IS manifestations. Therefore, the subdomains identified in this study represent and important, albeit preliminary, step towards informing more targeted IS research and interventions.

425.301 (Poster) Characterizing the Experience of Itch in Autistic Adults Using an Online Survey
G. Tackley, J. Underwood, K. L. Unwin and C. R. Jones, (1)Cardiff University Brain Research Imaging Centre (CUBRIC), Cardiff University, Cardiff, United Kingdom, (2)Neuroscience and Mental Health Innovation Institute, Cardiff University, Cardiff, United Kingdom, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (4)Wales Autism Research Centre, School of Psychology, Cardiff University, Cardiff, United Kingdom

Background:

Despite increased recognition of the sensory differences experienced by autistic people (APA, 2013), itch remains understudied. Anecdotal reports of distress and injury caused by itch for autistic people suggest characterization of the experience of itch for autistic people is needed.

Objectives:

To characterize the experience of itch in autistic adults using an online survey.

Methods:
Participants (N = 282; 197 female; mean age 42.6 years (SD= 12.9)) completed an online survey about their itch experience. Participants self-categorized into one of three groups: diagnosed autistic (N = 154), self-identified autistic (N = 37), and non-autistic (N = 85). There were no group differences in age or sex.

Participants reported on the frequency, severity and impact of three categories of itch: spontaneous itch (no identified sensory trigger), provoked itch (sub-categories for clothing/material, human touch, contact with objects, or secondary to painful stimuli), and medically caused itch (multiple sub-categories). Autistic traits (Autism Spectrum Quotient-10, AQ10; Allison et al., 2012) and general sensory experiences (Glasgow Sensory Questionnaire, GSQ; Robertson and Simmons, 2013) were also measured.

Results:

AQ10 scores were significantly different across groups (p<0.01), with higher mean scores for the diagnosed autistic group, followed by the self-identified autistic and non-autistic groups. GSQ scores followed the same pattern (p<0.01).

Across all itch categories, itch was most frequently reported in the diagnosed autistic group compared to the non-autistic group (all p≤0.02). For provoked and medically caused itch, the frequency of itch was higher in the self-identified group compared to the non-autistic group. For spontaneous itch, the pattern was slightly different (self-identified autistic > diagnosed autistic > non-autistic).

Across all itch categories, itch was reported as more severe in the diagnosed autistic than the non-autistic group (p<0.01). The self-identified autistic group also reported greater severity than the non-autistic group (significant for spontaneous itch; p<0.01). The same significant patterns of group differences were found for all subcategories of provoked itch except for itch provoked by warm or cool objects. For medically caused itch, there were significant group differences for dermatological causes, but not for itch caused by systemic problems or infections and infestations.

All three types of itch impacted sleep, work and leisure activities significantly more in the diagnosed autistic group compared to the other groups (spontaneous itch: p <0.01; others: all p<0.05).

Higher AQ10 and GSQ scores were associated with significantly higher spontaneous and provoked itch severity (r = 0.42-0.52; all p <0.01), with weaker correlations for medical itch (r = 0.16-0.19; all p <0.01).

Conclusions:

Diagnosed autistic adults reported a greater frequency and severity of itch compared to non-autistic adults. This was true for all itch types but most prominently for spontaneous and provoked itch. Itch was also reported as having a more significant impact on sleep, work, and leisure activities for autistic adults compared to non-autistic adults. The experiences of self-identified autistic people tended to fall between diagnosed autistic adults and non-autistic adults. The findings highlight the importance of considering the experience of itch for autistic people.

425.302  (Poster) Clinically-Significant Falls and Fall-Related Injuries Occur at a Much Higher Rate in Autistic Compared to Non-Autistic Young Adults Aged 18-35 Years

I. Munoz Orozco and H. L. Miller, (1)School of Kinesiology, University of Michigan, Ann Arbor, MI, (2)School of Kinesiology, University of Michigan, Ann Arbor, MI

Background: Falls and fall-related injuries are a common cause of injury, mobility limitation, morbidity, and death. Studies have shown that autistic individuals experience motor difficulties and have trouble with balance and coordination, perhaps placing them at higher risk of falls than their non-autistic peers. The autistic community has expressed anecdotally that these motor problems lead to fear of falling, reduced participation, and injury. However, little is known about the specific prevalence and nature of falls and fall-related injuries in autism, and their clinical significance.

Objectives: To determine the incidence of falls experienced by autistic young adults (18-35 years) compared to non-autistic young adults in the University of Michigan healthcare system during a 5-year period from 2017-2022.

Methods: We accessed retrospective data from the electronic medical records of autistic young adults who were seen by Michigan Medicine providers (University of Michigan healthcare system) between October 2017 and October 2022. Data were obtained using the university’s data warehousing service, DataDirect. To separate the autistic and non-autistic cohorts, we filtered patients by problem list and list of diagnoses using a total of 81 codes related to autism. These included ICD-9 and ICD-10 codes, DSM-5 codes, and internal Michigan Medicine billing and diagnostic codes.
Results: 361,982 young adult patients (18-35 years) in the U-M health record were seen clinically in the 5-year period from October 1, 2017 to September 30, 2022. Of these, 24,988 were diagnosed with autism, and 336,994 were not. 5.91% (n=1,478) of autistic young adults were seen clinically for falls or fall-related injuries compared to 0.96% (n=3,225) of non-autistic young adults. In other words, clinically-significant falls or fall-related injuries were more than six times more common among autistic young adults than non-autistic young adults over this 5-year period (Fig.1). We then examined annual data from October 1 to September 30 of each year (2017-2022). While the group difference in incidence of clinically-significant falls or fall-related injuries was slightly smaller in the annual data than in the 5-year aggregate data, autistic young adults were still consistently seen for falls at much higher rates (Fig.2).

Conclusions: The results of this study highlight the disparity in falls and fall-related injuries experienced by autistic young adults. It is concerning that autistic young adults are seen clinically for these issues at more than six times the rate of their non-autistic peers over a 5-year period, at a time in the lifespan where frequent falls do not serve a developmental purpose. The difference between the 5-year and annual incidence rates observed in this dataset is likely a reflection of the number of patients who are seen chronically for falls over multiple years. Future studies should carefully investigate the reasons for falls and fall-related injuries, the incidence of repeated falls, and the incidence of benign falls for which young adults may not seek clinical care. This knowledge can inform efforts to reduce fall risk and increase access to fall-prevention strategies and motor interventions in autism, for example, those that focus on improving dynamic postural control and mobility.

425.303 (Poster) Decreased Sensory Threshold in 22q11.2 Deletion Carriers Is Associated with Thalamocortical Hyperconnectivity, but Not Sleep Disturbance
K. P. O’Hora1, C. Schleifer2,3, L. Kushan4 and C. E. Bearden1,4, (1)Department of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)Neuroscience Interdepartmental Program, University of California, Los Angeles, Los Angeles, CA, (3)David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, (4)Department of Psychology, University of California, Los Angeles, Los Angeles, CA

Background: Study of highly penetrant genetic mutations that confer increased likelihood of being autistic can reveal novel genetic and neurobiological mechanisms associated with common challenges of autistic individuals. One such mutation is a deletion in the 22q11.2 locus (22qDel), which confers an approximately 8-fold increase in likelihood of autism. Studies of both 22qDel carriers and individuals with idiopathic autism report hyperconnectivity between the thalamus and cortical sensory regions during resting-state functional magnetic resonance imaging (rs-fMRI). In idiopathic autism, this thalamocortical hyperconnectivity is associated with sensory sensitivity and sleep problems, suggesting thalamic over-relay of sensory information could underlie both of these distressing challenges. Our previous work in 22qDel carriers found thalamocortical hyperconnectivity was associated with more severe sleep disturbance, but the role of sensory sensitivity in this relationship is unclear.

Objectives: To characterize sensory profiles of 22qDel carriers and test the hypothesis that a lower sensory threshold (sensory sensitivity) is associated with increased thalamocortical connectivity and worse sleep in 22qDel carriers.

Methods: As part of an ongoing longitudinal study, 22qDel carriers (n=50; M_age=230.0 months, 46% male) and typically developing (TD) controls (n=44; M_age=204.2 months; 45.5% male) completed rs-fMRI scans and assessments of sleep and sensory profiles. We used the Adolescent/Adult Sensory Profile to measure four dimensions of sensory processing. Higher scores on the Low Registration and Sensation Seeking domains indicate increased sensory thresholds, while higher scores on Sensory Sensitivity and Sensation Avoiding domains indicate decreased sensory thresholds. General sleep disturbance was measured by a clinician-rated scale on the Structured Interview of Psychosis-risk Syndromes (SIPS). First, we tested group differences in sensory domains between 22qDel carriers and TD subjects. Second, we examined the relationship between resting-state thalamocortical coupling with the Somatomotor network (thal-SOM), and sensory profiles in 22qDel carriers. Lastly, we assessed the relationship between sleep disturbance and sensory profiles. For each analysis, we used linear mixed-effects models including Subject ID as the random effects term as well as age and sex covariates. To account for multiple comparisons, a False Discover Rate correction was applied.

Results: Compared to controls, 22qDel carriers scored higher on all sensory domains (q<0.006), except Sensation Seeking, which showed lower scores in 22qDel carriers (q=0.001). Within 22qDel carriers, thal-SOM hyperconnectivity was associated with increased Sensory Sensitivity (b=0.23, q=0.046) and Sensory Avoiding (b=0.250, q=0.039) domain scores. In contrast, worse sleep in 22qDel carriers was associated with higher scores on Low Registration (b=0.31, q=0.032). There were no other significant relationships between sleep disturbance and sensory domains.

Conclusions: As in studies of idiopathic autism, we found 22qDel carriers exhibit increased levels of sensory difficulties. Our results support the hypothesis that thalamocortical hyperconnectivity is associated with a lower sensory threshold in 22qDel carriers. However, contrary to our hypothesis, sleep disturbance was not associated with a lower sensory threshold. These results, along with our previous findings, suggest that thalamocortical hyperconnectivity is related to both sensory sensitivity and sleep disturbances in 22qDel carriers. However, more research is needed to determine if sleep disturbances associated with autism are attributable to sensory sensitivity.

425.304 (Poster) Development and Validation of the Glasgow Sensory Questionnaire Short (GSQ-14)

1016
Background:

Many autistic people find that differences in their sensory processing present challenges when interacting with the world, especially when not supported. Repeated negative sensory experiences limit the number of environments accessible to the autistic person, reducing both mental health and quality of life. Equally, some sensory experiences can be extremely positive and have the opposite effects.

Objectives:

The Glasgow Sensory Questionnaire (GSQ) is a questionnaire which asks questions about the hyper- and hypo-reactivity of the five main senses, as well as proprioception and the vestibular sense. The standard questionnaire contains 42 questions, which can be burdensome on those completing it. As such, this study aimed to construct and then validate a shortened version of the Glasgow Sensory Questionnaire which can be more easily deployed.

Methods:

The Glasgow Sensory Questionnaire Short (GSQ-14) was constructed using secondary data initially collected by Horder et al. (2014), Ward & Filiz (2020), and unpublished data from our lab. In total, the sample consisted of 787 participants, all of whom completed both the GSQ and Autism Spectrum Quotient (AQ). Several Confirmatory Factor Analysis (CFA) models were compared for best fit. The item with the highest loading for each subscale from the best fitting model were selected for inclusion in the GSQ-14.

The validation data were separately and specially collected using an online sample recruited through Proﬁlic. Our pre-registered power analysis indicated that 75 participants would be sufficient. Exactly 75 participants completed both the AQ-10 and GSQ-14.

Results:

The best fitting CFA model was found to be where the 14 subscales were defined as latent variables and allowed to correlate with each other. Continuing to use the initial construction data, the internal reliability of the new GSQ-14 was found to be good with a Cronbach’s alpha of .84. The GSQ-14 and AQ were found to have a significant correlation ($\rho (785) = 0.49, p < .001$).

These results were then replicated in the validation sample, with the GSQ-14 again being found to have good internal reliability with a Cronbach’s alpha of .83, and having a significant correlation with the AQ-10 ($\rho (73) = 0.59, p < .001$).

Conclusions:

This study has successfully constructed and validated a short version of the GSQ, demonstrating that it is appropriate for wider use. The factor analyses used during the construction also point towards the importance of considering both the hyper- and hypo-reactivity of each sense when researching the sensory processing of autistic people.

---

**425.305 (Poster)** Development of the Consortium for Motor Behavior in Neurodivergence (COMBINE)

**H. L. Miller**, N. E. Fears and P. M. Tamplain, (1)School of Kinesiology, University of Michigan, Ann Arbor, Ann Arbor, MI, (2)School of Kinesiology, Louisiana State University, Ann Arbor, MI, (3)University of Texas at Arlington, Arlington, TX

Background: There is increased awareness of co-occurrence among neurodevelopmental conditions. Many neurodivergent self-advocates have posed questions about overlapping characteristics among conditions, which have important implications for assessment and intervention/accommodation. However, much research is conducted in silos with tightly-controlled groups, limiting the ability to detect transdiagnostic patterns. Specifically regarding motor behavior, a transdiagnostic approach is needed to determine whether features cluster by diagnosis, or in another manner. Data sharing can help to answer these questions by maximizing sample size and diversity. Models for data sharing exist for other domains including neuroimaging (ABIDE) and general child development (Databrary), specific populations like autism (NDAR, SPARK), or general health outcomes in a specific region (CAPriCORN). Yet, none specifically aggregates data describing motor behavior in neurodivergence across multiple diagnostic groups, ages, and countries. Without such a resource, it is difficult to identify meaningful phenotypic patterns that transcend diagnostic labels.

Objectives: To understand neurodivergent motor behavior across the lifespan by building an international data-sharing consortium.
Methods: We contacted stakeholders in the self-advocate, research, and clinical communities to determine whether COMBINE would be appropriate and useful. We then conducted a literature search to identify researchers using standardized motor assessments in neurodivergent populations, and to create a list of variables. We developed a workflow (Fig.1) by which researchers could join the consortium, initiate regulatory agreements, and deposit/access data. COMBINE was launched at the 15th Developmental Coordination Disorder meeting (July 2022). We disseminated information through communication channels of societies, professional meetings, and targeted emails to specific researchers.

Results: Key infrastructure resulting from the development process included a website (combinedata.org), REDCap forms and R/Excel templates for joining and depositing data, data use agreement and IRB templates, and templates for data access proposals and reporting of results. Required variables include: Movement Assessment Battery for Children (MABC) or Bruininks-Oseretsky Test of Motor Proficiency or Peabody Developmental Motor Scales, age at date of testing, diagnosis, sex assigned at birth or gender, country, site/institution. Recommended variables include additional demographic features and motor and cognitive assessment scores. We identified >50 investigators from 15 countries who have eligible data. The COMBINE database currently includes >500 participants from studies conducted in Texas, Louisiana, and Michigan, with data deposits pending from new members in Australia, Belgium, the United Kingdom, Canada, and other sites in the United States. The dataset includes participants aged 3-52 years diagnosed with one or more conditions including autism, attention deficit hyperactivity disorder, developmental coordination disorder/dyspraxia, dyslexia, dysgraphia, dyscalculia, anxiety, depression, intellectual disability, Down syndrome, sensory processing disorder, speech-language disorders, and mood disorders.

Conclusions: There is a critical need to share data in order to improve the replicability and impact of clinical research. COMBINE has several key advantages over single-site datasets: it is lifespan, transdiagnostic, interdisciplinary, multidimensional, and geographically- and culturally-diverse. This enables data-driven approaches to identifying new patterns of association between and within neurodevelopmental conditions, in order to determine where they converge or diverge in their motor and behavioral characteristics. Ultimately, this knowledge will benefit both clinical practice and our societal understanding of neurodiversity.

425.306 (Poster) Developmental, Motor, and Gender Correlates of Gait Abnormalities in Autism

C. Shulman and Z. Nir, (1)The School of Social Work, Hebrew University of Jerusalem, Jerusalem, Israel, (2)Child and Adolescent Psychiatry, Hadassah Medical Center, Jerusalem, Israel

Background:

Autism, a neuro-developmental disorder, is characterized by impairments in social interactions, alongside repetitive and stereotyped patterns of behavior (APA, 2013). Persons with autism also demonstrate a variety of motor symptoms which include alterations in motor milestone development (Provost et al., 2007), hypotonia (Calhoun et al., 2011), and postural control impairments (Esposito, 2011; Pradhan et al., 2022). These motor symptoms can compromise the ability to walk, which in turn may affect the individual’s functionality, independence and quality of life. Although it has been shown that autism is associated with abnormal gait patterns (for a review see Lum et al., 2022), few studies have examined gait patterns and their correlates. Furthermore, inconsistencies in the findings from existing research make the examination of the correlates of gait abnormalities an important contribution to understanding the heterogeneity in autism.

Objectives:

The main objective of this study is to identify developmental, motor and gender correlates to the presence of gait abnormalities as reported by parents of children with autism. The developmental correlates examined included the ages when the child began to speak and to walk as well as the developmental trajectory of gait abnormalities; the motor correlates examined were mannerisms and motor stereotypes. These correlates were also analyzed separately for boys and girls. The aims of this research are to identify which developmental and motor correlates are similar and which are different in female and male autism symptomatology.

Methods:

The parents of 112 children were interviewed using the Autism Diagnostic Interview-Revised (ADI-R). Fifty-three girls and 59 boys were matched on cognitive functioning and chronological age. The ADI-R items of interest included the age when the child began to walk unaided, age of first words, age of first phrases, hand and finger mannerisms, as well as complex mannerisms.

Results:

Significant developmental and motor correlates of gait abnormalities emerged for specific ADI-R items, revealing different developmental and motor relations in boys and girls at different ages. Gait abnormalities in preschool-aged girls were correlated with age of walking, age of first phrases, and complex mannerisms, whereas gait abnormalities in preschool boys were correlated with complex mannerisms only. A significant correlation between gait abnormalities and age of first words emerged among school-aged girls, whereas a significant correlation between gait abnormalities and age of first phrases emerged for school-age boys. A significant correlation between age and gait
abnormalities emerged for girls and not for boys. In addition, a significant negative correlation emerged between age and gait abnormalities for the girls but not the boys.

Conclusions:

The results of this study suggest that age and sex have a differential impact on gait abnormalities in autism. As the girls got older fewer gait abnormalities were reported, which did not occur for the boys. Since gait abnormalities can affect independent functioning and quality of life, it is important to understand their developmental trajectory and expression at different ages among boys and girls with autism.

H. Sykes Haas and Y. S. Bonneh; (1)School of Optometry and Vision Science, Bar-Ilan University, Ramat Gan, Israel, (2)School of Optometry and Vision Science, Bar-Ilan University, Ramat Gan, Israel

Background: An extensive body of research exists in visual perceptual processing in verbal individuals with autism. Among others, findings support a local over global visual processing style or bias. In contrast, the minimally verbal (< 30 spoken words, mvASD), comprise almost a third of individuals with autism, yet little is known about their visual perceptual processing. This subgroup is underrepresented in the research literature. Likely due to difficulty conforming to behavioral requirements in existing testing methods

Objectives: To overcome experimental challenges and investigate basic visual processing among children with mvASD.

Methods: Fifteen children with mvASD, ages 6-12 were tested in three separate visual processing tasks on a touch screen. (1) In the oddball paradigm they had to point to an odd target among an array of distractor elements. The low-level stimuli comprised odd colour, size, and shape. Whereas the mid-level stimuli consisted of 3D shapes from shading and perspective. We further examined the impact of distractor saliency and 1st and 2nd order orientation gratings. (2) in the contour detection task by pointing, a circular contour was embedded among increasing number of Gabor elements at 3 levels of difficulty. (3) in the final task a single Kanizsa triangle, was presented as well as 3 modulated versions accentuating (illusory) triangle. Spontaneous pointing and eye gaze were recorded as distance (pix) from centre of the Kanizsa. Verbal instructions and prompted practice trials were provided prior to testing. General cooperation and successful responding was rewarded with praise and access to preferred items.

Results: Already at the low-level vision tests two groups emerged. Ten participants detected the oddball at or near ceiling, whereas the other 5 performed at or slightly above chance. Successful responding among lowest performers increased with reduced distractor saliency. With increasing complexity from 1st to 2nd order gratings and at midlevel vision tests, performance deteriorated among some previously 'high' performers. For the single Kanizsa, pointing and eye gaze were at the local elements, unlike controls, but shifted towards the centre of the Kanizsa with modulations that emphasized the triangle.

Conclusions: All children could do the tasks, with performance sensitive to the distractor saliency and stimulus complexity, but the group was not homogenous and could be divided into low and high performers. The results could not be explained by limited task comprehension or lack of cooperation. They therefore suggest differences in early visual processing among children with mvASD, some presenting diminished performance of the lowest levels of visual processing. Furthermore, for the single Kanizsa, pointing and gaze responses were locally oriented (to the Pac-Men), as though the illusory surface was not perceptually inferred, but shifted to the centre with minor modulation, indicating that perceptual representation of the global does exist. Overall, visual complexity appears to jeopardize performance, suggesting that in mvASD visual perception is based on low-level representations with attenuated inference-based processing. It appears that when incompatible perceptual representations compete for selection, the stronger representation (here local) may guide behavior among minimally verbal children with autism.

425.308 (Poster) Does Disgust Contribute to Picky Eating in Autistic Adults?

Background: Autistic adults self-report symptoms related to picky eating more frequently than non-autistic adults4. Additionally, autistic individuals are five times more likely to develop eating problems including food selectivity, food refusal, and poor oral intake4. Studies have shown that individuals with food-selectivity issues replace fruits and vegetables with unhealthy processed foods, contributing to obesity4. Although higher food disgust has been associated with picky eating in non-autistic adults, most research has focused on and implicated sensory sensitivities as a driving force for picky eating among autistic individuals4,5.

Objectives: Examine the relationship between disgust and picky eating in autistic adults and whether this relationship is mediated by sensory (i.e., oral texture and/or olfactory) processing.
Background: Autistic individuals often report negative experiences with particular sensory stimuli, commonly described as atypical sensory processing. There is a high level of heterogeneity in responses to sensory stimuli, both between individuals, but also within individuals across different contexts. While some previous research has sought to determine the contextual factors that influence sensory processing in autistic individuals, a number of methodological issues have led to inconsistent results, specifically the lack of ecological validity in many lab-based studies and recall bias in qualitative and questionnaire studies.

Objectives: The purpose of this study was to determine the contextual factors that impact sensory processing in autistic individuals using ecological momentary assessment (EMA), an in-the-moment measure of participants’ experiences, and to collect both quantitative and qualitative data on autistic individuals’ sensory experiences.

Methods: We prompted participants to complete a survey of their current sensory environment and experiences on their cellphones three times per day over the course of two weeks. The survey focused on participants’ current activities, surroundings, mood, and sensory experiences. We predicted that contextual factors such as the participants’ level of control over their environment, mood, and the sensory stimuli involved would affect their sensory processing. Additionally, participants completed a battery of standardized measures, including the Sensory Profile (SP) and the Social Responsiveness Scale (SRS).

Results: The sample (n=15) included seven adults and eight children. Participants reported more negative experiences than either positive or neutral experiences. In both children and adults, unpleasant sounds were the most reported negative stimuli and pleasant sounds were the most reported positive stimuli (Figure 1a). Participants reported more positive experiences when they felt they had a high level of control over their environment, while the reported more negative experiences when they were feeling tired or anxious and overwhelmed (Figure 1d). Interestingly, the proportion of sensory events reported as negative did not correlate with scores on the SRS (Figure 2a, p=.745), or the SP (Figure 2b, p=.436).

Conclusions: In conclusion, factors such as mood, surroundings, and the modality of the sensory stimuli all contributed to differences in autistic individuals’ sensory experiences. Differences were found both between and within individual reports of sensory experiences, which is consistent with previous findings. The lack of correlations between the standardized questionnaires and the proportion of sensory experiences reported as negative was unexpected and suggests that the questionnaires may not be a good measure of the heterogeneous sensory experiences that occur across autistic individuals’ daily activities. This could explain the inconsistent results that have been found between lab-based, qualitative, and questionnaire studies in the past. These findings help acknowledge the role that context plays in autistic individuals’ sensory experiences and can have implications for creating supportive environments by controlling for different contextual factors. These findings also have implications for helping autistic individuals develop coping strategies for dealing with these experiences, such as deep breathing or wearing headphones to help reduce feelings of anxiety in situations where they have little control over their environment.
425.310 (Poster) Effect of Restricted and Repetitive Behaviors on Imitation Skills and Parental Stress in Young Children on the Autism Spectrum
O. Adedipe and K. M. Walton, Nisonger Center, The Ohio State University, Columbus, OH

Background: Restricted and repetitive behaviors (RRBs) are core characteristics of autism spectrum disorder and can interfere with the individual’s and their family’s functioning (Harrop et al., 2016; Ulijarević et al., 2022). Research within the past few decades has demonstrated the association between overall social communication deficits and RRBs (Chaxiong et al., 2022; Jones et al., 2018; Lampi et al., 2020; Martínez-González et al., 2022), however little is known about the influence of RRBs on different aspects of early social communication such as imitation (Bruckner & Yoder, 2007). Additionally, a few studies have shown that clinician-observed RRBs measured by the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2; Lord et al., 2012) relate to maternal stress (Schutte et al., 2018), but more information is still needed to understand this relationship. Examining the distinctive contribution of RRBs can help us discern the underlying mechanisms of these behaviors.

Objectives: The present study aimed to examine the relationship between RRBs and spontaneous imitation skills during play among 17 autistic children aged 28 to 57 months old ($M = 40.41$, $SD = 8.65$; 76% males). The secondary aim of the study was to evaluate relationship of RRBs on parental stress.

Methods: Data was drawn from baseline assessment of an on-going RCT of parent-mediated vs. therapist-mediated Reciprocal Imitation Training (RIT). The measures used in this analysis include developmental level (Mullen Scales of Early Learning; Mullen, 1995), autistic symptomatology (ADOS-2; Lord et al., 2012), parent stress (PSI-4; Abidin, 1995), and object and gesture imitation abilities on a play-based assessment (UIA-O & UIA-G; Ingersoll & Meyer, 2011). Hierarchical multiple regression analyses were used to investigate the relationship between total RRBs score on the ADOS-2 and object and gesture imitation skills on the UIA, and parent stress on the PSI. Age equivalents on the visual reception and expressive language domains of the Mullen were entered simultaneously in the first step as covariates, followed by total RRBs in Step 2.

Results: Higher RRBs significantly predicted lower object imitation skills after controlling for nonverbal cognitive skills and expressive language ($β = −1.19$, $t(13) = −2.25$, $p = .042$). RRBs uniquely accounted for 20% of the variance in object imitation abilities, $F(3, 13) = 4.13$, $p = .030$, $ΔR^2 = .20$. RRBs were not associated with gesture imitation skills or total parent stress.

Conclusions: The results of this study demonstrate the relationships between RRBs and object imitation skills in young children with autism. This knowledge is important for understanding how RRBs may relate to other key behaviors in early play and social development. These findings suggest that children with more repetitive behaviors may also struggle to expand their play through imitation, further impeding learning during natural play interactions. Future research should investigate how different subtypes of RRBs (stereotypic movement, insistence on sameness, restricted interests and preoccupations, and sensory difficulties) may impact foundational social communication skills, such as imitation, joint attention, and play.

425.311 (Poster) Effects of Intrapersonal Synchrony on Responses, Gaze Behavior and Judgements of Autistic and Non-Autistic Observers
C. Bloch1, R. Tepest1, S. Koerogi1, M. Jording1, K. Vogeley1 and C. M. Falter-Wagner1, (1)Department of Psychiatry and Psychotherapy, LMU Hospital Munich, Munich, Germany, (2)Department of Psychiatry and Psychotherapy, University Hospital Cologne, Cologne, Germany, (3)Institute of Neuroscience and Medicine (INM3), Research Center Jülich, Jülich, Germany, (4)Department of Psychiatry and Psychotherapy, Medical Faculty, LMU Munich, Munich, Germany

Background: Temporal structures of movements that occur between (INTERpersonal) and within (INTRApersonal) individuals shape social encounters. Intrapersonal synchronization (IaPS) of multimodal signals determines the perception of meaningful signal-units from the stream of movements by observers and thus affects reciprocal response behavior (Bloch et al., 2019; Cañigueral & Hamilton, 2019). Studies showed that autistic individuals elicited larger and more variable temporal delays between communicative signals (de Marchena & Eigsti, 2010; Bloch et al., under review). It can be assumed that differences in IaPS systematically influence observers’ perception of a course of motions, which may additionally be influenced by the observer’s diagnostic status. In this study, these assumptions were investigated experimentally.

Objectives: Virtual characters were animated in a way, that they exhibited controlled temporal coupling of deictic gaze and gesture signals. Based on a recent empirical study, the behavior resembled measurements in autistic adults (IaPSASC) and in typically-developed (TD) adults (IaPSTD). This allowed for a controlled experimental manipulation and investigation of the effects of group-specific IaPS on response behavior and post-hoc judgments of autistic and non-autistic observers.

Methods: 68 adults ($n = 34$ with F84.5 diagnosis) were tested. Groups were matched on gender identity (female $n = 12$; male $n = 22$); age ($M_{ASD} = 39.52$ ($SD = 12.80$); $M_{TD} = 37.77$ ($SD = 12.73$)), and IQ ($M_{ASD} = 109.88$ ($SD = 11.39$); $M_{TD} = 107.03$ ($SD = 8.88$)). In a crossed design, autistic and non-autistic participants interacted with the two virtual characters, resembling the IaPS behavior of autistic or TD persons, in 3 blocks of 18 trials per character. In the IaPSASC condition, gaze-gesture delays were enlarged ($M = 450$ ms) and more variable.
(SD = 128 ms) compared to the IaPS\textsubscript{STD} condition (M = 200 ms; SD = 68 ms). The task per trial was to select an object by keypress that indicated by the virtual partner (Figure 1). Gaze was recorded (Eyelink 1000 Plus). After the initial interaction phase, participants rated both interaction partners on items that referred to communication quality and person likeability.

Results: Likelihood ratio tests of linear mixed effects models predicting response times showed significant main effects for group (p = .005), IaPS (p < .001), and a significant interaction of group * IaPS (p = .047), see Figure 2. Exploratory gaze analysis (gaze type classification by dwelltimes on predefined gaze regions & fixations during responses) indicated different strategies in groups: While TD adults showed a primary focus on the partner's gaze region, autistic adults showed a diversified gaze behavior. There were no effects of IaPS on post-hoc judgements beyond chance-level.

Conclusions: The results are consistent with an automatic gaze focus during the perception of gaze and pointing signals in TD observers (Caruana et al., 2021), whereas response strategies in autistic adults were characterized by an increased prioritization of gesture signals. Intrapersonal synchronization of signals affected observers' responses differently depending on the strategy used. The study supports the assumption that social interaction in autism can be characterized by timing features in production and perception.

425.312 (Poster) Efficacy of the First Years Inventory (FYIv3.1) Infant Screener in Predicting Autism Risk Status at 3 Years of Age

J. Sideris, L. R. Watson, E. Crais, Y. J. Chen, E. Campi, E. Choi and G. T. Baranek, (1) Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2) Department of Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3) Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (4) Chan Division of Occupational Science and Occupational Therapy, University of Southern California - T.H. Chan Division of Occupational Science and Occupational Ther, Los Angeles, CA

Background: The First Year(s) Inventory, version 2.0 (Turner-Brown et al., 2013) has demonstrated utility as a screening tool in a community sample of 12-month-olds, at least in part because of the inclusion of items designed to tap both prodromal sensory-regulatory (SR) and traditional social-communication (SC) features. The newest version, FYIv3.1 (2013) was expanded to screen a broader age range (6-16 months) and to provide a more comprehensive assessment of SR and SC features. Research on this version confirmed seven risk dimensions: two SC (Communication, Imitation & Play [CIP]; Social Attention & Affective Engagement [SAE]), four SR [Sensory Hyperresponsiveness [HYPER]; Sensory Hyporesponsiveness [HYPO]; Self-regulation in Daily Routines [SREG]; Sensory Interests, Repetitions, Seeking Behaviors [SIRS]), and one in motor development (Motor Coordination and Milestones [MCM]) (Baranek et al., 2022).

Objectives: We aimed to test the efficacy of the FYIv3.1 dimensions in predicting later outcomes groups: No Diagnosis/Concerns (ND), Autism Diagnosis/Concerns (AUT), or Other Diagnosis/Concerns (OD). We estimated sensitivity (true positive rate), specificity (true negative), positive predictive value (true positives/all positive) and negative predictive value (true negatives/all negative).

Methods: Parents of infants ages 6-16 months were recruited through state birth records and asked to complete the FYIv3.1. Scoring of the FYIv3.1 based on frequency probabilities across respondents in this large sample (N=6427). At age 3, a subset (N=2211) completed the Developmental Concerns Questionnaire (DCQ), reporting medical/developmental history/diagnoses, and the Social Responsiveness Scale (SRS-2) to quantify autistic traits. Based on these measures, children were coded into outcome groups, ND, AUT, and OD. We applied machine learning random forest (RF) models using the seven FYIv3.1 risk dimensions, gender and age to develop a decision tree to optimally sort children into ND and AUT groups. We used a 70%-to-30% training to validation ratio. Next, we tested models with progressively greater sensitivity targets. Finally, we applied the initial decision tree to all respondents with 3-year-old outcomes (AUT, OD, ND) to determine the proportion classified correctly into each group.

Results: Results for the training model indicated that 8 variables (6/7 risk dimensions, plus age and sex) were useful in building the decision tree in the training sample; only five of variables (HYPER, SIRS CIP, sex, and age) were needed in the validation sample. Model results can be used to select cut-points over ranges of sensitivity and specificity. We evaluated the model requiring specificity to be at least 95%, yielding a sensitivity of 38% (Table 1). Requiring greater specificity results in loss of sensitivity, but improved PPV. Between 3% and 11% of the OD sample were classified as AUT depending on the specificity of the model.

Conclusions: Results indicate that the FYIv3.1 can be effectively used to accurately classify 38% of children during infancy that later have AUT outcomes with very high specificity (>95%). Sensitivity may be optimized to a much higher level, but with costs to specificity and PPV. These tradeoffs require consideration for different contexts and purposes of screening (e.g., level 1 population screening versus high-risk clinic versus research).

425.313 (Poster) Emotional Regulation Challenges in Children in a Broad Neurodevelopmental Concern Cohort

Background: Children with neurodevelopmental concerns (NDC) commonly present to community practices with prominent emotional dysregulation. To the best of our knowledge, there has not been an assessment or characterization of emotional regulation in this setting. Furthermore, emotional regulation may overlap with sensory processing disorders, specifically tactile sensitivity. This study aims to determine the rate of emotional dysregulation in all comers to a community neurodevelopment practice, determine if this prevalence differs between children with and without autism, and whether there is a correlation with tactile processing differences.

Objectives: N/A

Methods: Participants in this study are children seen at Cortica between 8 and 12 years of age. They are sequentially offered participation in a broader neuroimaging study of which emotional regulation and sensory processing assessment are constituent parts. For this study, parents completed the Short Sensory Profile (SSP; Dunn 1999) and the Behavioral Assessment System for Children, Third Edition (BASC-3; Pearson 2015) parent questionnaires. Additionally, children who scored above 15 on the Social Communication Questionnaire (SCQ; Rutter 2003), were subsequently evaluated with the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2; Lord 2012). Those exceeding ASD threshold on both SCQ and ADOS-2 were assigned to the ASD cohort. Three subscales of the BASC-3 were relevant to this analysis of emotional dysregulation: “Anger”: irritated quickly, coupled with an inability to regulate affect and self-control; “Emotional Self-Control”: ability to regulate one’s affect and emotions; and “Negative Emotionality”: tendency to react in an overly negative way to changes in activities/routines. The Tactile Sensitivity (TS) cohort scored 1 standard deviation or greater above the mean for tactile sensitivity section, based on 7 questions.

Results: Of the total NDC population (n=111; 70% male), approximately 60% were found to be either at-risk or showing clinically significant concern for emotional dysregulation across all three relevant subscales of the BASC-3. Although the ASD group (n=17; 82% male) trended towards higher rates of emotional dysregulation, no statistical significance was observed (anger p=0.06, emotional self-control p=0.11, negative emotionality p=0.24). Of the total population, 74 children (66%) were found to be Tactile Sensitive (TS) and in this cohort 75% scored 1 SD or above on all three relevant subscales anger p=3.9 x 10^-7, emotional self-control p=5.4x10^-9, and negative emotionality p=9.0x10^-8; Figure 1). Thus, the TS endophenotype is strongly associated with emotional dysregulation.

Conclusions: Emotional dysregulation occurs in roughly two-thirds of all children presenting for evaluation and support for neurodevelopment. Children with tactile sensitivity are far more likely to struggle with emotional regulation than their peers with NDC who do not experience tactile sensitivity. Conversely, in this initial investigation, autism does not appear to differentiate those with and without emotional dysregulation. The rate of emotional dysregulation suggests a need for a more robust delineation of the neural mechanisms of both tactile information processing and emotional regulation for better clinical understanding and support for these processes.

425.314 (Poster) Examination of the Prevalence and Severity of Self-Injurious Behavior in a Large Sample of Children with ASD from the SPARK Cohort.

M. Hale1, A. Gutierrez2, M. Alessandri1, E. Espanola1, A. Maharaj3, D. Hennelly1, D. Correa4 and G. David4, (1)University of Miami, Coral Gables, FL, (2)University of Miami, Miami, FL, (3)University of Massachusetts Boston, Boston, MA, (4)Center for Autism and Related Disabilities, University of Miami, Coral Gables, FL

Background:

Self-Injurious behavior (SIB) are commonly reported in individuals with developmental disabilities and Autism Spectrum Disorder (ASD). Estimates of the prevalence and severity of various topographies of SIB vary substantially across studies. Further research is needed to gain clarity about the occurrences of variables associated with the occurrences of SIB in children with ASD.

Objectives:

The purpose of this study is to examine patterns of caregiver-reports of SIB and among a large sample of children with ASD.

Methods:

Data from 3,9685 children (mean age= 8.99 years) registered in the Simons Foundation Powering Autism Research for Knowledge (SPARK) was analyzed. All children had a parent-reported diagnosis of ASD. Data on self-injurious behavior was obtained from caregiver responses on the Repetitive Behavior Scale–Revised questionnaire and included information about the occurrence and severity of eight topographies of self-injurious behavior within the past month. Additional information includes reports of children’s cognitive functioning, language ability, and social and communication impairments.
Results:

Results showed that most of the children in the sample (75.2%) were reported to engage in at least one topography of SIB and more than half (39.1%) in more than one topography, while no SIB was reported for 24.8% of the children. The most commonly endorsed topography of SIB was hitting self with body, followed by hitting self against object, skin picking, rubbing or scratching self, pulling (hair or skin), self-biting, hitting self with object, and inserting finger (eye-poking). Females were reported to have higher levels of SIB than males. In addition, lower levels of language ability were associated with higher levels of SIB.

Conclusions:

These findings expand the current literature on SIB in children with ASD. SIB was reported for a substantive majority of children in the sample and at higher levels than what has been reported in previous studies. These findings suggest that occurrence of SIB may be underestimated in samples that do not include direct assessment (e.g., caregiver report). This information is important for improving the identification of SIB and guide evidence-based intervention of self-injury in individuals with ASD.

425.315  (Poster) Examining Autism Assistance Dog Interventions in Repetitive Behaviors: A Thematic Analysis of the Literature

B. TAS and S. West, (1)University of Kassel, Kassel, Germany, (2)Department of Social Work and Social Welfare, Universität Kassel, Kassel, Germany

Background:

Autism assistance dogs are trained to perform a variety of tasks, including interrupting certain restricted repetitive behaviors for the purpose of remediating them. Restricted repetitive behaviors, renamed by autistic self-advocates as “stims or stimming,” have been explored and discussed in the literature as problematic in certain contexts, and necessary for the individual to cope with sensory issues in other contexts. Clinicians often tend toward the former, though a growing representation of behavior analysts voice concern about intervening in stim behaviors unless they are harmful. Autistic self-advocates tend toward the latter, arguing that stim behaviors are an autonomous right of autistic individuals, provided that the behaviors are not destructive. At present, no literature directly examines the purpose or specific training of assistance dog interventions in stim behaviors and the outcomes for individuals whose repetitive stim behaviors are remediated by an assistance dog.

Objectives:

This study aims to identify what constitutes undesirable stim behaviors in the literature that would justify targeted assistance dog intervention. This study further aims to investigate whether any positive or negative outcomes have been identified specifically in association with assistance dog interventions of repetitive stim behaviors.

Methods:

17 published studies addressing repetitive stim behaviors, 8 studies on disability assistance dogs, and 5 studies on autism assistance dogs have so far been examined together for evidence relevant to quality-of-life outcomes for autistic individuals, their caregivers, or families. The aims and methods have been reviewed, with open and axial coding applied to the findings, limitations, and conclusions to generate concepts and categories for a thematic analysis of the literature.

Results:

An analysis of the synthesized literature suggests that no evidence exists to demonstrate that assistance dog interventions in repetitive stim behaviors positively or negatively impact the autistic individual’s quality of life. Quality of life for families of autistic children has demonstrably improved due to autism assistance dog interventions, however, no evidence exists that the dogs’ intervention in repetitive stim behaviors contributes to this improvement. Furthermore, long-term outcomes of interventions in stim behaviors for the individual have not been considered. Evidence was found that varying standards of knowledge and expertise exist within general disability assistance dog training programs and facilities, further complicating the discussion on what procedures are appropriate specifically within the domain of autism assistance dog training.

Conclusions:

This study examines a variety of factors behind determining what kind of repetitive stim behaviors are unacceptable and justify assistance dog interventions. A link between undesirable behaviors as outlined in the DSM-5 diagnostic criteria for autism and the training of autism assistance dogs to mitigate these behaviors is strongly implied in the current literature, with no attention to physical, emotional, or
psychological outcomes for the individual whose stim behaviors are interrupted. More attention is needed both to the purpose of training assistance dogs to interrupt stim behaviors and to the specific short and long-term outcomes of this type of intervention.

425.316 (Poster) Examining Data Loss and the Pupillary Light Reflex As a Function of Sensory Sensitivities in Children with and without ASD: Results from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)  
S. Cramer-Benjamin, M. A. Aziz, A. Napole, K. Chawarska, G. Dawson, S. Faja, R. A. Bernier, S.Jeste, J. Dziura, S. J. Webb, C. Sugar, F. Shic, and J. McPartland, (1)McPartland Lab, New Haven, CT, (2)Child Study Center, McPartland Lab - Yale Child Study Center, Yale School of Medicine, New Haven, CT, (3)Child Study Center, Yale University, Child Study Center, New Haven, CT, (4)Child Study Center, Yale School of Medicine, New Haven, CT, (5)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (6)Boston Children’s Hospital, Boston, MA, (7)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (8)Children’s Hospital Los Angeles, Los Angeles, CA, (9)Yale University, New Haven, CT, (10)University of California, Los Angeles, Los Angeles, CA, (11)Center for Child Health, Behavior and Development, Seattle Children’s Research Institute, Seattle, WA, (12)Child Study Center, Yale Child Study Center, New Haven, CT

Background: The pupillary light reflex (PLR) is a promising biomarker for autism spectrum disorders (ASD) given its direct linkage to neural mechanisms of arousal, sensation, and behavioral activation. However, the standard PLR experimental presentation, a bright flash of light, may be aversive and lead to selective data loss in autistic participants with more sensory sensitivities. This phenomenon causes current research to reflect only a subset of autistic individuals, potentially underrepresenting the utility of the PLR as a biomarker for ASD. The present study examined whether sensory sensitivities predict subsequent lost data in PLR experiments.

Objectives: We predicted that heightened sensory sensitivities would be predictive of missing data (ETLoss), and that participants with increased sensitivities would learn to anticipate and subsequently avoid (close their eyes, look away) PLR-trials over time (PLRLoss). Additionally, the relationship between sensory sensitivities, PLRLoss, and PLR-latency was examined. We predicted that participants with heightened sensory sensitivities and more PLRLoss would have longer PLR-latency (time from flash to pupillary constriction). Overall, these patterns were expected to persist over time.

Methods: Data from 277 autistic and 119 typically developing (TD) children (ages 6-11) was collected through the Autism Biomarkers Consortium for Clinical Trials (ABC-CT). All participants completed eye-tracking paradigms and clinical assessments across three timepoints (6-week and 6-month delay). Sensory sensitivities were determined using t-scores from the PDDBI: Sensory Subscale. Each visit included two sessions of eye-tracking, each containing nine PLR-trials. Each PLR-trial consisted of a (133ms) flash, followed by a dark screen. Data quality and dependent measures (PLR-latency) were determined by manual coding. Regression models examined relationships between PLRLoss, sensory sensitivities, and PLR-latency.

Results: Overall, autistic children had greater PLRLoss (M=56% valid, p<.001), ETLoss (M=88% valid, p<.001), sensory sensitivities (M=46.73, p<.001), and latency (M=284.38, p<.001) than TD children (Mblaze=69% valid; Mlatency=94% valid; Mlatency=36.02; Mlatency=280.73). Both autistic and TD children demonstrated increased PLRLoss over time, both within (r=−9.92, p<.001) and across (r=−12.74, p<.001) timepoints. Increased sensory sensitivities in ASD predicted greater PLRLoss (F(1, 1585)=21.17, p<.001), and this pattern persisted within (r=−4.60, p<.001) and across (r=−11.88, p<.001) timepoints. Finally, greater sensory sensitivities predicted longer PLR-latency (F(1, 7988)=36.41, p<.001). Ongoing analyses will explore these data using a mixed effects framework.

Conclusions: Consistent with previous research, autistic children demonstrated longer PLR-latencies, more lost data, and greater sensory sensitivities than TD children. All participants lost more data over time. These findings suggest that children experience the flash as aversive, are predicting when it will come, and are looking less at the screen during the PLR-paradigm, resulting in fewer valid trials over time. Additionally, autistic children with more sensory sensitivities had fewer valid PLR-trials and longer PLR-latencies on remaining trials than those with fewer reported sensitivities, a relationship that also persisted over time. These data suggest current research about group differences between ASD and TD children may therefore be underrepresenting the strength of biomarkers, like PLR because data loss is greatest in the populations for which these biomarkers are most representative.

425.317 (Poster) Examining the Relationship between Sensory Hyperreactivity, Hyporeactivity, and Seeking on Adaptive Behavior in Children on the Autism Spectrum  
L. Massa, C. Layton, T. Levy, J. Zweifach, D. Halpern, J. H. Foss-Feig, J. D. Buxbaum, A. Kolevzon and P. M. Siper, (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)The Seaver Autism Center for Research & Treatment, New York, NY, (3)Seaver Autism Center at Mount Sinai, New York, NY, (4)Mount Sinai School of Medicine, New York, NY

Background:

Sensory reactivity differences are one core feature of autism spectrum disorder (ASD) in the Diagnostic and Statistical Manual of Mental Disorders (DSM-5). The DSM-5 describes three types of sensory symptoms: hyperreactivity, hyporeactivity and seeking. Previous studies identified a relationship between overall sensory symptoms and adaptive functioning; however, few examined differences within specific domains. In addition, existing literature relies on caregiver- and self-reported symptoms. This study used the Sensory Assessment for
Neurodevelopmental Disorders (SAND) (Siper & Tavassoli, 2021), a standardized clinician-administered observational assessment and corresponding caregiver interview, to quantify sensory hyperreactivity, hyporeactivity, and seeking across visual, tactile, and auditory modalities compared to a standardized adaptive behavior assessment.

Objectives:

To examine the relationship between sensory hyperreactivity, hyporeactivity, and seeking on adaptive behavior.

Methods:

Participants included 104 children between the ages of 2 and 12 years old (6.52± 2.71) who met DSM-5 criteria for ASD (87 male) based on a consensus diagnosis which included a clinical interview and the Autism Diagnostic Observation Scale, Second Edition (Lord et al., 2012). Participants were administered the SAND and the Vineland Adaptive Behavior Scales Survey Interview Form, Second Edition (Sparrow et al., 2005). Higher scores on the SAND are indicative of a greater number of sensory reactivity symptoms; lower standard scores on the Vineland-II are indicative of poorer functioning. Pearson correlation coefficients were calculated to examine the relationship between the two measures.

Results:

Significant correlations were identified between SAND Total Score and the Vineland-II Adaptive Behavior Composite (ABC) as well as all four Vineland-II domains (Communication, Daily Living, Socialization, Motor – for age 6 and under, n=79) (r’s =-.404 to -.525; p’s<.05). Within SAND domains, Total Hyperreactivity was not significantly correlated with any Vineland-II domains nor the ABC. SAND Total Hyporeactivity scores were significantly correlated with Vineland-II Communication (r=.419, p<.001), Daily Living Skills (r=.338, p<.001), Socialization (r=.423, p<.001), and Motor (r=.222, p=.049) scores as well as the ABC (r=.402, p<.001). Similarly, SAND Total Seeking scores were significantly correlated with Vineland-II Communication (r=.402, p<.001), Daily Living Skills (r=.339, p<.001), Socialization (r=.453, p<.001), and Motor (r=.476, p<.001) scores and the ABC (r=.420, p<.001). An analysis of SAND subdomains indicated that the Vineland-II ABC was significantly correlated with Visual Hyperreactivity, Hyporeactivity, and Seeking (r’s=.213 to -.283; p’s<.05), Tactile Hyperreactivity and Seeking (r’s=.214, -.315; p’s<.05), and Auditory Hyporeactivity and Seeking (r’s=.374, -.407; p’s<.05). Tactile and Auditory Hyperreactivity were not correlated with overall adaptive behavior.

Conclusions:

Results indicate a moderate to strong relationship between adaptive behavior and overall sensory hyporeactivity and seeking, but not hyperreactivity. Specifically, poorer adaptive functioning was associated with a greater number of hyporeactivity and seeking symptoms across visual, tactile, and auditory modalities. Interestingly, visual hyperreactivity was the only hyperreactivity subdomain associated with adaptive behavior. Understanding the relationship between specific sensory reactivity differences and adaptive behavior may offer clues into underlying mechanisms and ultimately inform the development of novel targets for the treatment of sensory reactivity and adaptive behavior challenges. Treatments targeting specific sensory reactivity differences may lead to improved adaptive functioning.

**425.318 (Poster) Fast but Not Slow Force Development Is Impaired in Autism**

N. C. Foster, M. Memeo, C. Ansuini, F. Battaglia, L. Nobili, D. Farina, C. Becchio and A. Del Vecchio, (1) Cognition, Motion and Neuroscience, Istituto Italiano di Tecnologia, Genova, Italy, (2) IRCCS Istituto Giannina Gaslini, Ospedale Pediatrico, Genova, Italy, (3) Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics and Maternal and Child’s Science, University of Genoa, Genova, Italy, (4) Department of Bioengineering, Imperial College London, London, United Kingdom, (5) Department of Neurology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, (6) Department Artificial Intelligence in Biomedical Engineering, Friedrich-Alexander University, Erlangen, Germany

**Background:** Individuals with autism spectrum disorders (ASD) show specific difficulties in producing and modulating the initial muscular forces required for a given action (Elliott et al., 2020; Foster et al. 2020; Glazebrook et al. 2006). This initial planning behaviour influences downstream visuomotor processing associated with limb control, and while feedback corrective processes have been shown to be operational during force production tasks, the forces produced are less accurate and more variable throughout sustained contractions (Mosconi et al., 2015). Here, we examined how changes in the rate of force development affect force production during ankle flexion contractions in ASD.

**Objectives:** (1) To examine force production in ASD

**Methods:** Thirteen autistic (mean age: 10.7 (1.4) years; 2 female) and thirteen matched neurotypical (mean age: 11.8 (1.9) years; 2 female) children volunteered for the study, which was approved by the local ethics committee. After measuring children's maximal voluntary contraction (MVC) force during ankle flexion they completed two blocks of ramp contractions: Fast Ramp (20% MVC/s) and Slow Ramp (5% MVC/s). Each contraction can be separated into 3 distinct phases: (i) Recruitment (2s duration in Fast Ramp, 8s in Slow Ramp); (ii)
Results: Overall, ASD force production was less accurate (AE) and more variable (TP; p< 0.01). Specific differences between the two groups were shown for the Recruitment phase of the Fast Ramp contractions. During this phase, ASD children showed significantly greater AE and TP (p < 0.05) in comparison to neurotypical children. In contrast, there was no specific differences during the Recruitment phase of the Slow Ramp contractions, or between the groups during the Sustain and Derecruitment phases for either contraction (p > 0.05).

Conclusions: The current findings support previous research that force production is less accurate and more variable in ASD. Furthermore, the presence of group differences during the recruitment phase of Fast Ramp but not Slow Ramp contractions (nor during the Sustain and Derecruitment phases of Fast and Slow Ramp contractions) suggests a specific problem with the rate of force development. The current findings may help explain why individuals with ASD typically take longer to prepare and execute movements (Glazebrook et al. 2006) and have relevance when discussing how feedforward and feedback motor control combine to impact social behaviours in ASD.

Background: Toe walking is a clinical motor sign present in 20% of individuals with autism spectrum disorder (ASD). Because this behavior is also found during standing or running, the term tip-toe behavior (TTB) seems to be more appropriate. A systematic review found a lacking of studies that quantify TTB in individuals with ASD. The most used and reliable instrumental tool to quantify motor deficit during standing and walking is the gait analysis, but this approach requests the positioning of a large number of markers on the skin of the patient, a long time to prepare the patient for the execution of the test and is conducted in a non-ecological setting. For all these reasons gait analysis could be difficult to use with individuals with severe ASD because of their clinical condition. Thus, a simpler instrumental approach that uses wearable sensors usable in an ecological setting could be a useful resource to quantify TTB in individuals with severe ASD.

Objectives: The aims of this pilot study are: 1) to verify the feasibility and acceptability of wearable sensors in individuals with severe ASD; 2) to quantify TTB using wearable sensors during structured standing and walking tasks.

Methods: Subjects with ASD diagnosed according to DSM-5 criteria and confirmed using the Autism Diagnostic Observation Schedule were admitted to the study. TTB was quantified using “Sensoria® Smart Socks” (SSS), a commercially available wireless gait monitoring technology (Figure 1). SSS was found a valid measure instrument in a previous study. To assess the TTB quantity during standing and walking we used a static and dynamic test following the methodology proposed in a previous study. The static test consisted in playing while standing in front of a table for 3 minutes. The dynamic test consisted in transporting 1 object (puzzle, Lego®, ...) from the therapist while standing in front of a table for 3 minutes. The dynamic test consisted in transporting 1 object (puzzle, Lego®, ...) from the therapist to the playing table situated 2 meters away and back again 15 times. The test is conducted without shoes albeit with SSS. The same person was tested three times on three different days (9 acquisitions). The data acquired from the SSS were elaborated from a dedicated algorithm. The result of the dynamic test is presented as the mean percentage number of toe steps and the result of the static test is reported as the mean percentage of seconds in TTB.

Results: Three individuals with severe ASD and TTB were assessed. Their age was 10.9yrs, 12.8yrs and 13yrs (3/3 males) and their ADOS CSS was 9, 10 and 8, respectively. We found the SSS was feasible and acceptable in the three individuals with severe ASD and TTB in all three trials. We were also able to quantify TTB during both the static and the dynamic tests using the SSS tool in 9/9 of the acquisition (100%) (example in Figure 2).

Conclusions: “Sensoria® Smart Socks” seems to be a feasible and acceptable wearable sensors approach for quantifying TTB in individuals with severe ASD and TTB. Further research is required to confirm these preliminary results.

425.319 (Poster) Feasibility and Acceptability of Using Wearable Sensors to Quantify Tip Toe Behavior in Individuals with Severe Autism Spectrum Disorder: Preliminary Results

G. Valagussa1, L. E. Molteli1, M. Boccotti1, G. Andreoni1 and E. Grossi1, (1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)Program in Physical Therapy, School of Medicine and Surgery, University of Milano Bicocca, Monza, Italy, (3)Department of Design, Politecnico di Milano, Milan, Italy, (4)Bioengineering Laboratory, Scientific Institute IRCCS “E.Medea”, Bosisto Parini, Italy, (5)Autism Research Unit, Villa Santa Maria SCS, Tavernerio, Italy
Background: Sensory processing involves recognising and regulating sensory information as well as responding appropriately (Gourley et al., 2012). Sensory processing difficulties can occur in autistic children and they tend to be more sensory seeking than neurotypical (NT) children (Tomcheck & Dunn, 2007). Fidgeting occurs in children who are sensory-seeking (Ben-Sasson et al., 2009) and it has been suggested that suppressing fidgeting hinders children’s ability to thrive in a classroom environment (Lengel & Kuczala, 2010). Occupational therapists and educational psychologists have introduced fidget toys to serve as coping mechanisms for addressing sensory needs (Benson et al., 2018). Nevertheless, there are a very limited number of studies investigating fidget toy use in autistic children. Ledford et al. (2020) found children’s engagement in the classroom did not improve and their focus was on manipulating the fidget toy rather than attending to the teacher. However, Fletcher-Watson and May (2018) found fidget toys can reduce anxiety in other settings.

Objectives: There is an ongoing debate about the benefits and risks of using fidget toys as there is insufficient evidence to suggest whether fidget toys help or hinder children’s emotional wellbeing and academic progress and how this may relate to children’s sensory profiles. The current study addresses this gap by examining the perspectives on fidget toys and fidget spinners in parents of autistic children and NT children. This study investigated whether fidget toys and fidget spinners contribute positively or negatively to the behaviour and emotional outcomes of children. The relationship between children’s sensory-seeking scores and parental views about fidget toys was also investigated.

Methods: 129 parents/carers of children (aged 3-16, M= 9 years, 3 months) with an autism diagnosis (n = 53) or NT children (n= 76) completed an online survey. The survey consisted of questions relating to their own child’s use of fidget toys and specifically fidget spinners as well as the perceived benefits (e.g., improves concentration, reduces anxiety) and risks (e.g., distraction, harmful). Parents also completed the Sensory Profile questionnaire 2 to obtain perspectives about their child’s sensory behaviours.

Results: Findings demonstrated that parents of autistic children perceived both fidget toys and fidget spinners to be more beneficial than NT parents, especially in relation to reducing anxiety. They perceived fidget toys as improving their child’s concentration more than parents of NT children. Higher sensory-seeking scores in autistic children were associated with greater parental agreement for fidget toys and fidget spinners being beneficial, for fidget toys reducing anxiety and being less harmful, and for fidget spinners being less distracting.

Conclusions: In summary, parents of autistic children perceived fidget toys to be overall more beneficial for their child, improving concentration and reducing anxiety compared to NT parents. Implications include that educators should consider parental views when forming policies about the use of fidget toys in schools. Findings also imply that the sensory profiles of autistic and NT children should be considered in relation to the use of fidget toys.

425.321 (Poster) From “One Big Clumsy Mess” to “a Fundamental Part of My Character.” Autistic Adults’ Experiences of Motor Coordination
E. Gowen, L. Early, A. Waheed and E. Poliakoff, (1)School of Health Sciences, University of Manchester, Manchester, UNITED KINGDOM, (2)School of Health Sciences, The University of Manchester, Manchester, United Kingdom, (3)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom

Background:

Altered motor coordination is common in autistic individuals affecting a range of movements such as manual dexterity, eye-hand coordination, balance and gait. However, motor coordination is not routinely assessed leading to motor coordination difficulties remaining undiagnosed and untreated, particularly in autistic adults. This situation has arisen partly because autism research has focussed on social functioning, but another reason may be because a rich description of coordination difficulties and their impact from the viewpoint autistic people is lacking. Therefore, the current study used qualitative methods to document the experience of motor coordination difficulties from the viewpoint of autistic adults.

Objectives:

Focus groups were conducted with autistic adults in order to understand how they experience and describe motor coordination across their life span, the impact of motor coordination issues on daily living skills, social and emotional wellbeing and their experiences of learning new motor tasks and using strategies.

Methods:

17 autistic adults (19 to 67 years; mean 53.7 years; 5 female) took part in five focus groups conducted either via Zoom video or text chat. The facilitator followed a semi-structured schedule that was developed through discussion with members of the Autism@Manchester expert by experience group. Reflexive thematic analysis was used, following the 6 step technique advocated by Braun and Clarke. The COREQ (COnsolidated criteria for REporting Qualitative research) Checklist was completed.
Results:

Four main themes were identified. First, motor coordination difficulties were pervasive and variable, being present life-long and affecting multiple types of movement and many aspects of life. However, the nature of the difficulties was variable within and between participants along with differing awareness of their own ability. Second, participants described motor coordination as an active process, requiring concentration for most actions and at a level seemingly greater than other people. Sensory issues were closely entwined with movement difficulties, making movement more challenging. Third, motor coordination difficulties impacted upon social and emotional wellbeing by placing strain on relationships, prompting bullying and exclusion, putting safety at risk and causing a range of negative emotions. Fourth, participants described multiple learning and coping strategies in the absence of any support.

Conclusions:

Findings highlight that it is essential to address the current lack of support for motor coordination difficulties in autism considering the significant social and emotional consequences described by our participants. Further investigation of motor learning and interactions between sensory and motor performance in autistic adults is also warranted.

425.322 (Poster) Gathering Autistic Adult’s Visual Sensory Experiences: A Qualitative Interview Study

F. Rattray¹, M. Ruane¹, N. Saliko², M. Absoud³ and F. Happe⁴, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK, London, United Kingdom, (2)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Department of Women and Children's Health, King's College London, London, United Kingdom, (4)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM

Background:

Altered sensory processing is widely recognised in autism and reported to interfere with daily function and quality of life. However, there is limited understanding of the personal sensory experiences of autistic individuals across the lifespan, particularly relating to visual stimuli. Increased awareness of visual sensitivities and preferences is important if environmental adaptations are to be meaningful for autistic individuals.

Objectives:

To qualitatively explore autistic adults' visual sensory experiences with a view to informing environmental adaptations.

Methods:

Twenty autistic adults aged between 18-89 years were recruited primarily via social media (70% identified as female). Semi-structured interviews, lasting on average around 60 minutes, were conducted online. Participants also completed a short, online survey with demographic and autism diagnosis questions and the AQ10. Reflexive, thematic analysis was used to analyse the interview data, with adherence to Braun and Clarke’s six-step framework for thematic analysis.

Results:

Emerging themes included hypersensitivity, altered face processing, coping strategies and desired adaptations. Although the emergence of clear themes reflected shared experiences in response to visual stimuli (for example hypersensitivity), within themes individual experiences were nuanced (such as sensitivity to specific types of lighting, colour, visual clutter, and motion). Natural and artificial light sensitivity were widely endorsed: “... sunshine is my biggest issue. I am extremely light sensitive”; “I have a real issue with fluorescent lights. Even when I close my eyes it’s like they’re burning my eyes.” Regarding face processing, the majority of participants reported difficulties with facial recognition: “I have no facial recognition at all”. Conversely, a few participants described significant strengths in this area: “I usually recognise people who I haven’t see for 15 years...”, highlighting significant inter-individual differences. Most participants expressed an aversion to eye contact: “... eye contact is quite excruciating... that's something I definitely avoid”. Findings revealed the considerable impact for some individuals of visual sensory experiences on physical and mental well-being: “Certain kinds of lights like fluorescent lamps, light, make me feel like hot and sweaty, and nauseous and that kind of thing...”. However, some visual stimuli were reported to have a positive effect on mood, including natural moving patterns such as waterfalls and candle flames. Several coping strategies employed to reduce negative impact were described: “So, I use sunglasses or a hat, so I don’t have the light coming straight into my eyes”. Desired adaptations emphasised the importance of designing work and community spaces in consultation with autistic individuals alongside a need for improved understanding across contexts of visual sensory sensitivities.

Conclusions:
This study provided detailed information on the visual sensory experiences of autistic adults. By providing valuable insight into the impact of visual stimuli on overall well-being, this research highlights a need for greater community awareness of visual sensory differences and for environmental adaptations. Findings also stress the importance of understanding individual needs and preferences within broader visual sensory themes.

425.323 (Poster) Grapheme-Color Synesthesia in Autistic Adults

G. Michel, J. Cratcher and I. M. Eigsti, Psychological Sciences, University of Connecticut, Storrs, CT

Background: People experiencing synesthesia report that sensory input in one modality, such as the name of a letter or number, triggers another sensory experience (such as a specific color; Eagleman et al., 2007). Synesthesia is reported as more prevalent in autism spectrum disorder (ASD) than in the general population (Baron-Cohen, 2013), and may be associated with autistic traits and sensory sensitivities in particular (Leeuwen et al., 2021).

Objectives: The current study probes the prevalence of grapheme-color synesthesia in ASD, and the consistency of grapheme-color associations. We also examine synesthesia’s association with autistic symptomology and circumscribed interests.

Methods: 198 autistic and non-autistic (NA) adults (167 after rule-outs) completed an online Prolific survey; Table 1. Autistic/NA groups did not differ in age, gender, or race/ethnicity. Participants completed the Autism Spectrum Quotient Questionnaire (AQ) and answered questions about demographics, color/grapheme associations, and circumscribed interests (using a modified version of the Yale Special Interests Survey, YSIS). Each participant completed a synesthesia assessment, in which they were presented with graphemes A-Z and 0-9 in a randomized order, twice each. Participants clicked on a color-wheel representing Red, Green, Blue (RGB) values in two dimensions, identifying the best match for each grapheme. The RGB Euclidean distance formula, adapted for a two-trial condition, was used to calculate color distance (CD) scores. Lower CD scores indicate greater response consistency, and the threshold of 0.32 and lower represents the cut-off for grapheme-color synesthesia.

Results: Some 20% of the ASD group (24/120) self-reported the experience of grapheme-color associations, compared to 11% (5/47) of the NA group; the difference was not significant, \( p = .15 \). There were also no differences in CD-based synesthesia performance: 13% (16/120) of the ASD group versus 15% (7/47) of the NA group scored below the CD threshold, \( p = .92 \). In the ASD group, 6% (7/120) scored below the synesthesia CD threshold and reported synesthesia. Across these seven “true” synesthetes, the majority had highly consistent scores for 0, 2, 4, 5, 6, 9 and B, H, M, R, T, Z. One participant described letter associations as follows: “vowels have very warm tones, consonants have bright sharp colors.” In the NA group, 4% (2/47) scored below the synesthesia CD threshold and reported synesthesia. Across autistic and NA groups, CD and AQ scores were negatively correlated, \( r(165) = -.21, p = .007 \); Figure 1.

Conclusions: Results suggest an increased prevalence of self-reported synesthesia in autism, though there was no difference in objectively-measured synesthesia between groups. However, there was a significant relationship between autism traits and grapheme-color synesthesia. We will discuss implications for sensory processing in ASD.

425.324 (Poster) Informant Discrepancy of Intolerance of Uncertainty Predicts Restricted and Repetitive Behaviors

M. I. Cargill, B. Jeyanayagam, W. DeFilippo and E. Kang, (1)Department of Psychology, Montclair State University, Montclair, NJ, (2)Montclair State University, Montclair, NJ

Background: Restricted or repetitive behaviors or interests (RRBIs) are a hallmark of autism (APA, 2013) and are often characterized as challenging or disruptive by parents (South et al., 2005). Scholarship suggests that RRBIs may be related to intolerance of uncertainty (IU)—a facet of anxiety—which is the inability to tolerate unwanted effects triggered by perceived lack of information (Carleton, 2016). IU is more frequently observed in autistic than non-autistic youth (Vasa et al., 2018), and RRBIs may be overt manifestations of IU resulting from attempts to impose sameness (Rodgers et al., 2012). Integrating multiple informants in assessment of IU is important because parents may be limited by reliance on observable behavior, while children may struggle with introspection (Storch et al., 2012). Compared to single-informant report alone, informant discrepancy, which is the degree of divergence between reporters, can provide additional information regarding child psychopathology, including autism (Lerner et al., 2012). While difference scores have historically been used to calculate informant discrepancy, polynomial regression seems more appropriate when examining child psychopathology (Laird & De Los Reyes, 2013). The link between RRBIs and IU in autism has garnered attention recently, and this novel analytic approach in assessing informant discrepancy may offer insight into this nuanced relationship.

Objectives: We examined the predictive power of informant discrepancy between child- and parent-reported IU on RRBIs. We hypothesized that (1) higher child- and parent-reported IU would each predict more RRBIs, and that (2) the degree of child-parent informant discrepancy in IU would also significantly predict RRBIs.
Methods: Thirty-four autistic and non-autistic youth (61.8% male; \( M_{\text{age}} = 10.24, SD_{\text{age}} = 3.16; 58.8\% \) White; \( M_{IQ} = 112.41, SD_{IQ} = 20.22 \)) and their parents completed a measure of IU (IU subscale of the Anxiety Scale for Children-Autism Spectrum Disorder [ASC-ASD; Rodgers et al., 2016]). Parents also completed the Repetitive Behavior Scale – Revised (RBS-R; Bodfish et al., 1999) on their children’s RRBIs.

Results: Parent-reported IU, but not child-reported IU, was associated with RBS-R (see Table 1). Polynomial regression indicated that the linear interaction between child- and parent-reported IU was a predictor of total RBS-R score in addition to parent-reported IU. The interaction was interpreted with child-reported IU as the moderator, reflecting parent-reported IU more strongly relates to RBS-R score at high (\( b = 3.38, SE = .72, p = .001 \)) and mean (\( b = 1.87, SE = .50, p = .009 \)) levels of child-reported IU, but not at low levels (\( b = .35, SE = .62, p = .58 \); see Figure 1). This pattern indicates that the congruence of high parent-reported IU and high child-reported IU is associated with the highest levels of RRBIs.

Conclusions: Above and beyond what parent-reported IU accounts for, findings suggest the degree of agreement/discrepancy between child and parent explains unique variance in RRBIs, such that RRBIs may be most pronounced when informants agree on the severity of IU. These findings reaffirm the need to consider multiple informants’ perspectives, especially when considering child psychopathology (De Los Reyes et al., 2015). Overall, considering informant discrepancy, specifically with this polynomial regression approach, presents a more nuanced understanding of the relationship between covert experiences, such as IU, and overt behaviors, such as RRBIs.

425.325 (Poster) Internalizing and Externalizing Symptomatology in Autistic Youth: The Role of Sensory Processing
D. C. Martino; J. R. Bertollo; E. A. DeLucia; M. Fok and A. Scarpa; (1)Department of Psychology, Virginia Tech, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA

Background: Sensory processing difficulties are a common feature of autism, with up to 95% of caregivers of autistic youth reporting that their child shows some degree of atypical sensory behavior. Research has shown that autistic youth who exhibit difficulties in sensory processing may be more likely to demonstrate internalizing and externalizing problems. However, less is known about the specific domains of sensory sensitivity that may be associated with such symptomatology. This highlights the need for research that investigates which sensory sensitivities in particular are most strongly related to internalizing and externalizing behaviors in autistic youth.

Objectives: To assess how various sensory processing domains are related to internalizing and externalizing symptomatology in autistic youth.

Methods: Participants included 57 autistic youth aged 2-11 years (\( M_{\text{age}} = 5.53, SD_{\text{age}} = 2.46; 84\% \) male) whose caregivers completed the Short Sensory Profile (SSP) and Child Behavior Checklist (CBCL). A series of hierarchical linear regressions were conducted. Five separate models were run with each CBCL domain (anxious depressed problems; aggressive behavior; anxiety symptoms; ADHD symptoms; oppositional defiant symptoms) as the outcome. All results of model comparisons are reported after entering covariates of age and IQ, followed by SSP domains (tactile sensitivity; taste/smell sensitivity; movement sensitivity; under-responsive/seeks sensation; auditory filtering; low energy/weak; visual/auditory sensitivity) as predictors. Lower SSP scores indicated greater sensory processing difficulties.

Results: Results for anxious/depressed problems indicated that 38% of the variance was explained by sensory processing (\( \Delta R^2 = .38, \Delta F(1,42) = 5.50, p = .001 \)), specifically, movement sensitivity (\( \beta = -1.54, p = .006 \)). For aggressive behavior, 37% of the variance was explained by sensory processing (\( \Delta R^2 = .37, \Delta F(1,42) = 5.70, p < .001 \)), specifically, movement sensitivity (\( \beta = -1.38, p = .019 \)) and under-responsivity/sensation-seeking (\( \beta = -1.60, p = .018 \)). Regarding the DSM-5 Oriented CBCL scales, for anxiety symptoms, sensory processing explained 35% of the variance (\( \Delta R^2 = .35, \Delta F(1,41) = 3.83, p = .004 \)), specifically sensitivity to taste/smell (\( \beta = -.61, p = .036 \)). For ADHD symptoms, sensory processing explained 50% of the variance (\( \Delta R^2 = .50, \Delta F(1,41) = 12.40, p < .001 \)), specifically under-responsivity/sensation-seeking (\( \beta = -.74, p < .001 \)) and auditory filtering (\( \beta = -.47, p = .036 \)). Finally, sensory processing explained 22% of the variance in oppositional defiant symptoms (\( \Delta R^2 = .22, \Delta F(1,43) = 3.50, p = .015 \)), specifically, movement sensitivity (\( \beta = -1.10, p = .045 \)).

Conclusions: This study shows that a number of sensory processing domains have strong associations with both internalizing and externalizing symptomatology in autistic youth, accounting for 22-50% of the variance, even after controlling for age and IQ. Moreover, these symptoms may be associated with specific patterns of sensory issues. Future research is needed that explores how specific sensory processing patterns may increase internalizing and externalizing concerns among autistic youth. This study underscores the importance of identifying strategies that can be used to support youth with a range of sensory processing difficulties in home, school, and community settings, with the goal of ameliorating emotional and behavioral challenges faced by these individuals.

425.326 (Poster) Investigating Action Perception, Imagery and Execution in Autistic and Non-Autistic Individuals
Y. Bar, E. Poliakov, T. N. Welsh, M. Brillinger, A. Karlinsky and E. Gower; (1)The University of Manchester, Manchester, United Kingdom, (2)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom, (3)Faculty of Kinesiology & Physical Education, University of Toronto, Toronto, ON, Canada, (4)University of Toronto, Toronto, ON, Canada, (5)Kinesiology department, California State University, San Bernardino, San Bernardino, CA, (6)School of Health Sciences, University of Manchester, Manchester, UNITED KINGDOM
Background: Performing and observing others’ actions is crucial for successful communication, social interaction, and navigating our environment. The ideomotor or common coding theory is based on the premise that there is a close relationship between the sensory and motor systems. Accordingly, the neural codes that are engaged during action execution are also engaged in action perception. Motor imagery (imaging movement) may also activate neural areas involved in execution. As motor coordination difficulties occur in ~80% of autism, it is possible that dysfunctional perception-action codes may contribute to reduced ability to perform actions as well as perform imagery and perceive (recognise and interpret) the actions of others. One method of comparing execution, imagery, and perception is using the Fitts Law task where participants are asked to perform, imagine, or watch hand movements between targets that vary in width and distance. According to the Fitts Law relationship, movement duration is longer when the movements are more difficult - targets are smaller and further apart. Findings in non-autistic individuals show that movement duration increases with difficulty level for movement perception, imagery, and execution, demonstrating similar processing. To date, no previous studies have compared action perception, imagery, and execution in autism.

Objectives: This project was designed to examine whether autistic individuals are able to use motor imagery and further investigate whether executing, perceiving, and imagining hand movements differs between autistic and non-autistic adults.

Methods: Methods and analysis were pre-registered. Autistic (n=20) and non-autistic (n=20) participants were asked to complete execution, imagery, and perception tasks with their dominant hand during an online experimental session. The execution task required participants to move their index finger between two targets on the screen. The imagery task used the same procedure, but asked participants to imagine making the movements and indicate when they had finished. For the perception task, participants were asked to watch an animation of a finger moving between the targets (which varied in speed across trials) and indicate whether they could perform the presented movement. Target size and distance were systematically varied across trials in all tasks to manipulate difficulty. Altered imagery, perception, or execution processes in the autistic group would be apparent as a lack of, or reduced positive correlation, between movement duration and difficulty level. Furthermore, if motor imagery is altered in the autistic group, a larger difference in movement duration between execution and imagery conditions will be apparent compared with the non-autistic group.

Results: A similar Fitts Law relationship was present in both groups demonstrated by a significant positive correlation between movement time and difficulty in all three tasks. This result indicates that autistic individuals are using simulation for imagery and perception. As with previous work in non-autistic individuals, movement times were significantly longer in the imagery condition than in the execution and perception conditions which did not differ between the groups.

Conclusions: The results are consistent with ideomotor accounts of action perception and imagination, and indicate that the processes of motor imagery and simulation may be relatively intact in autistic individuals.

425.327 (Poster) Is Visual Sensitivity Coupled to Superior Visual Search in Children and Adolescents with Autism Spectrum Disorders?

S. T. Peitersen1, B. Aggernaes1, S. Angstman2, J. Lassen2, M. Foldager3, S. M. Arnfred4,5 and M. Gøtzsche4, (1)The research department of Child and Adolescent Psychiatry, Copenhagen University Hospital – Psychiatry Region Zealand, Roskilde, Denmark, Region Zealand, Denmark, (2)PP Clinic Copenhagen, Denmark, Gentofte, Denmark, (3)Department of Child and Adolescent Psychiatry, Copenhagen University Hospital – Psychiatry Region Zealand, Research Unit, Roskilde, Denmark, Roskilde, Denmark, (4)Department of Child and Adolescent Psychiatry, Copenhagen University Hospital – Psychiatry Region Zealand, Research Unit, Roskilde, Denmark, Roskilde, Denmark, (5)Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark, (6)Psychiatric Research Unit, Region Zealand, Denmark, Roskilde, Denmark, (7)Research Unit for Psychotherapy & Psychopathology, Mental Health Service West, Copenhagen University Hospital – Psychiatry, Slagelse, Denmark

Background:

Children with Autism Spectrum Disorders (ASD) have a high prevalence of sensory sensitivity. Children with ASD often display superior detection of subtle perceptual target features hidden among distractors in visual search paradigms when compared to their typically developing peers. Other lines of evidence however, show that children with ASD are sensitive to environments with high perceptual complexity and sensory noise.

Objectives:

The present study addresses how the superior ability to identify subtle visual features is associated with visual sensitivity to perceptual complexity in ASD, and whether superior visual search and sensitivity to perceptual complexity is associated with autistic traits and daily functioning in children and adolescents with ASD.

Methods:

The present study used a novel visual search task to investigate search times for identifying a target hidden among distractors. Each target and distractor were made up of five visual features, which could be similar or differ from each other in shape and colour. The target was
more perceptual subtle by lowering the number of visual features that made up the target. If the visual features of the target were dissimilar so were the distractors and the perceptual complexity of the visual environment was therefore high and noisy. We hypothesized that children and adolescents with ASD aged 7–14 years (n=59) would display shorter search times in homogenous environments with few signal features compared to typically developing controls (n=59). Inversely, we hypothesised that children with ASD would have longer search times than controls when perceptual complexity was high. Parents answered the Autism Spectrum Rating Scales (ASRS) and Behaviour Rating Inventory of Executive Functions (BRIEF-2) to examine if group differences in search times were associated with autism traits and daily level in executive functioning, respectively. Our hypotheses were tested with repeated measures ANCOVA and multiple linear regression models corrected for age, sex, parental education and intellectual ability.

Results:

Across all children, search times got longer with fewer signal features present and with increasing perceptual complexity (p<0.001). A significant interaction between groups and conditions (p=0.004) confirmed our hypothesis, as children with ASD displayed superior search times in conditions with few signal features and low perceptual complexity (p=0.0012). In contrast, the control group had shorter search times than the ASD group in conditions with high perceptual complexity (p=0.001). Those children who displayed superior search times for subtle target features in contrast had slower search times in conditions with high perceptual complexity (p<0.001), both of which was related to reduced executive functioning and more autism symptoms (p<0.05).

Conclusions:

Superior visual search in children and adolescents with ASD was coupled to their visual sensitivity to more perceptual complexity, which negatively seem to affect their otherwise superior detail-oriented style. This processing style may interfere with the daily lives and functioning of children with ASD.

425.328 (Poster) Kinematic and Force Control Features in Autistic Adults during Curvilinear Movements
S. C. Lu, P. Rowe, F. E. Pollick and J. Delafield-Butt, (1)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (2)Department of Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom, (3)School of Psychology, University of Glasgow, Glasgow, United Kingdom

Background: Motor challenges have been reported in 87% of autistic children (Bhat, 2020) and may persist into adulthood (Cho et al., 2022), which could underpin autistic social difficulties. Kinematic differences between individuals with autism spectrum disorders (ASD) and typical development (TD) have been reported across activities. The two-thirds power law (2/3 PL) defines the relationship between moving speed and the curvature of moving path. Different adherence to 2/3 PL was observed in autistic children (Fourie et al., 2022), but not yet tested in autistic adults. Additionally, force modulation is affected in autistic individuals (Shafer et al., 2021). Force quantification during the 2/3 PL task can help further understand autistic motor regulation during the task. This contributes to the computational characterisation of ‘autism motor signature’ (Anzulewicz et al., 2016), leading to a better understanding of motor challenges and required support in autism.

Objectives: Quantify the kinematic and force control features in autistic adults during curvilinear movements, and to test if these differ from their TD counterparts.

Methods: Nine autistic and twelve typically developing adults (age ranged 19–57 years) participated in this study. Participants used a stylus (Apple Pencil) to trace and draw ellipses on a smart tablet (iPad Pro 11-inch) while timestamped on-screen trajectory and force data were recorded. An elliptical path was shown on screen for tracing while an empty canvas was provided for drawing ellipses (Figure 1). Each participant performed 5 trials of tracing and then 5 trials of drawing activities. Each trial lasted around 15 seconds. The longest continuous movement was extracted from each trial for further analyses. The radius of curvature and tangential velocity were computed to give the $\beta$ value (Tangential Velocity = $K \times$ Radius of Curvature ) representing adherence to 2/3 PL. Force data were first normalised by the maximum value of the trial and then averaged, indicating the average ratio of force applied with respect to the maximum force. Kolmogorov-Smirnov test was used to compare the distributions of kinematic and force variables between ASD and TD movements.

Results: In comparison to typically developing adults, autistic adults demonstrated greater deviation from the 2/3 PL ($\beta=0.333$) in both tracing (ASD Mdn=.302, TD Mdn=.323, p=.010) and drawing (ASD Mdn=.306, TD Mdn=.323, p=.002) activities (Figure 2a). In addition, autistic adults applied greater normalised force in both tracing (ASD Mdn=.501, TD Mdn=.452, p=.038) and drawing (ASD Mdn=.498, TD Mdn=.453, p=.032) activities than their typically developing counterparts (Figure 2b).

Conclusions: This study revealed the kinematic and force control differences in autistic adults during ellipse tracing and drawing activities. These differences could lead to an impact on their quality of life as curvilinear movements are essential in daily life activities such as writing, ball throwing, and turning a car wheel. Understanding motor control differences may help develop intervention plans to overcome motor challenges and hence improve life quality. Furthermore, these motor control differences may be related to their brainstem function (Delafield-Butt & Trevarthen, 2018). This research paradigm could support future investigations on the relation between motor features.
**425.329 (Poster) Longitudinal Analysis of Sensory Responsivity from Infancy to School Age in Children at High and Low Familial Likelihood for Autism**

Background: Empirical evidence regarding the development of sensory responsivity in young children at high likelihood to develop autism spectrum disorder (ASD) remains relatively limited. Due to this gap in research, it is unclear how sensory responsivity behaviors such as hypo-responsivity, hyper-responsivity, and sensory seeking may change over time and impact later developmental outcomes. Of the limited studies examining the development of sensory features, many are restricted in detail given that only two assessment points were analyzed. Longitudinal analysis of sensory responsivity data from children seen multiple times builds knowledge about the developmental course of sensory responsivity, including the shape of that trajectory.

Objectives: Goals of this study were to 1) characterize developmental trajectories of sensory responsivity from infancy into school age (~12 months, 24 Months, and 6-9 years) in children at high and low familial likelihood for ASD; and 2) determine if sensory responsivity in infancy predicts adaptive and cognitive functioning at school age among children with ASD.

Methods: Generalized mixed effects models were used to examine total sensory responsivity, hypo-responsivity, hyper-responsivity and sensory seeking scores from the Sensory Experiences Questionnaire (SEQ: Baranek et al., 2006) in three groups of children, including high likelihood children later diagnosed with ASD (HL-ASD; n = 31, 81% male), high likelihood children without ASD (HL-Neg; n = 149, 58% male), and low-likelihood control children not meeting diagnostic criteria (LL-Neg; n = 94, 59% male). Hierarchical linear regression was then used to examine the association between sensory responsivity scores in infancy (~12 months) and functional adaptive on the Vineland Adaptive Behavior Scales -3 (Veland; Sparrow, Cichetti, & Saulnier, 2016) and cognitive outcomes on the Differential Ability Scales (DAS; Elliot, 1990) at school age (~6-9 years).

Results: Results of fit statistics showed that the trajectory of sensory responsivity scores was best estimated by Group (HL-ASD, HL-Neg, LL-Neg), Age, and the interaction of Age and Group. High likelihood children with ASD showed increasing total, hypo- and hyper-responsivity scores and decreasing sensory seeking scores from infancy to school age that widened over time from the groups of children without ASD. Both the high and low likelihood groups without ASD showed lower sensory responsivity scores as compared to children with a diagnosis. Additionally, early elevated hypo-responsivity scores negatively associated with later adaptive behavior (F(3, 337) = 68.18, p < .001), indicating hypo-responsivity was a significant predictor of adaptive behavior scores (β = -4.17, p < 0.001) at school age. Sensory responsivity in infancy did not predict cognitive scores at school age.

Conclusions: Overall, differences in the degrees of sensory responsivity are detectable in children’s behavioral repertoires by 12 months of age and continue to differentiate children who develop ASD by middle childhood, pointing to the importance of early detection and treatment of sensory behaviors to improve children’s functional outcomes later in life.

**425.330 (Poster) Longitudinal Associations of Restricted and Repetitive Behaviors and Hyperactivity in Children with and without ASD**

A. Boxberger, E. V. Edgar, K. All, V. Donthireddy, E. Hong, C. Bianco, B. Gordon, A. Vernetti, K. K. Powell, S. Macari, and K. Chawarska, (1)Child Study Center, Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Child Study Center, Yale School of Medicine, New Haven, CT

Background: Restricted and repetitive behaviors (RRBs) are a core feature of autism spectrum disorder (ASD; APA, 2013), and additionally manifest in other neurodevelopmental disorders (Briery et al., 2021). RRBs are positively associated with hyperactivity (Avni et al., 2018), and both behaviors are related to response inhibition deficits (Barkley, 1999; Turner, 1999) and altered connectivity in similar brain areas (Estes et al., 2011; van Rooij et al., 2015), suggesting a shared neural substrate. Prior studies examined associations between these symptoms cross-sectionally but few longitudinally (Zachor & Ben-Itzchak, 2019). As RRBs and co-occurring hyperactivity result in changes for children and families, understanding their early development is crucial for tailored intervention.

Objectives: Examine in children with and without ASD: 1) concurrent associations of RRBs and hyperactivity at 3 and 5 years, 2) stability of RRBs and hyperactivity from 3 to 5 years, and 3) an exploratory aim, the longitudinal contributions of hyperactivity to RRBs and vice-versa from 3 to 5 years.

Methods: Participants included 150 toddlers with ASD (n=57) or without ASD (TD:n=54, ATP:n=39) at Time 1 (T1, Mage=39.2mo); of these children, 89 (ASD:n=34; TD:n=31, ATP:n=24) were followed prospectively to Time 2 (T2, Mage=69.9mo). RRBs were quantified...
using Social Responsiveness Scale (SRS) RRB t-scores. Hyperactivity was measured using Early Childhood Inventory (ECI-5) ADHD-Hyperactive severity scores. Data were analyzed using Pearson’s r correlations and regression analyses with T1 RRBs, hyperactivity, and group predicting T2 RRBs or T2 hyperactivity.

Results: T1 RRBs were positively associated with T1 hyperactivity in the ASD ($r=.47, p<.001$) and non-ASD groups ($r=.57, p<.001$; Fig.1A). T2 RRBs were positively associated with T2 hyperactivity in the ASD ($r=.66, p<.001$) and non-ASD groups ($r=.72, p<.001$; Fig.1B). T1 and T2 RRBs were correlated in the ASD ($r=.64, p<.001$) and non-ASD groups ($r=.80, p<.001$; Fig.1C). T1 and T2 hyperactivity was correlated in the ASD ($r=.67, p<.001$) and non-ASD groups ($r=.62, p<.001$) (Fig.1D, Table 1A). Linear regression predicting T2 RRBs revealed main effects of T1 RRBs ($\beta=.57, p<.001$), T1 hyperactivity ($\beta=.27, p=.003$), and group ($\beta = .18, p = .011$), with no significant interactions (Fig.1E). An analogous regression predicting T2 hyperactivity revealed main effects of T1 hyperactivity ($\beta=.59, p<.001$), T1 RRBs ($\beta=.44, p=.004$), and an interaction between group and RRBs ($\beta=-.29, p=.028$), though group was not significant (Fig.1F, Table 1B).

Conclusions: RRBs and hyperactivity were positively associated in children with and without ASD at ages 3 and 5, and demonstrated stability between timepoints. After controlling for severity of RRBs at 3 years, hyperactivity at 3 years predicted increased RRBs at 5 years for all children. Similarly, after controlling for severity of hyperactivity at 3 years, RRBs at 3 years predicted increased hyperactivity at 5 years for all children, though this increase was greater for children without ASD. These findings, consistent with previous research in older children, suggest the possibility of a shared underlying mechanism and motivate future studies investigating a common neural substrate. The prospective associations between hyperactivity and RRBs underscore the importance of early assessment of ADHD and ASD-related behaviors for tailored interventions.

**425.331 (Poster) Machine Learning Classification of ASC through Dyadic Social Interaction**

(1) Department of Psychiatry and Psychotherapy, Medical Faculty, Hospital LMU Munich, Munich, Germany, (2) Department of Psychiatry and Psychotherapy, Medical Faculty, LMU Munich, Munich, Germany, (3) Department of Psychiatry and Psychotherapy, Medical Faculty, Ludwig-Maximilians-University, Munich, Germany, (4) Max Planck Institute of Psychiatry, Munich, Germany, (5) Institute of Psychiatry, Psychology and Neuroscience, King’s College, London, United Kingdom

**Background:**

People on the autism spectrum demonstrate a diverse range of social interaction and reciprocal communication difficulties, as reflected in a variety of diagnostic instruments. However, diagnostic clarification remains a lengthy process, with few available experts and an increasingly large number of individuals seeking consultation in adulthood. This results in a bottleneck which is further exacerbated by the lack of objective diagnostic markers. Therefore, improved and efficient diagnostic measures are critical in need. Notably, with social interaction difficulties presenting as one of the hallmark symptoms in autism, social reciprocity offers a fruitful setting for developing such markers.

**Objectives:**

The following study aimed at quantitatively capturing aspects of nonverbal social interaction in autistic adults across multiple modalities and training a machine learning algorithm for classification. Importantly, considering the interactional nature of many of the social difficulties in autism, we incorporated dyadic as well as individual attributes.

**Methods:**

28 autistic participants (mean age = 37.18, 18 females) were paired with a non-autistic participant to complete two conversational tasks (28 ASC-CONTROL dyads). Additionally, 16 CONTROL-CONTROL dyads completed the same tasks (mean age of all non-autistic participants = 31.48, 26 females). Dyads were filmed with three cameras capturing their respective facial and body movement. Videos were post-processed with OpenFace and Motion Energy Analysis (Ramseyer & Tschacher, 2011) to extract behavioral time series of activated action units (AUs) in faces, as well as changes in head and body movement. The resulting time series were cross-correlated to compute the degree of inter- as well as intrapersonal synchrony. Separate Support Vector Machine (SVM) classification models were preprocessed and trained in NeuroMiner on all participants, using features grouped according to the interaction modality (facial expression, head and body movement, intrapersonal coordination, and total movement). A stratified, nested k-fold cross-validation scheme was implemented to ensure maximum generalizability. The models as well as a stacking framework-based combination were optimized based on prediction accuracy. Additionally, model outcomes were investigated for associations with a range of clinical questionnaire measures as well as facial emotion recognition capabilities.

**Results:**
With a balanced accuracy of 79.5%, the preliminary SVM classification based on facial expression synchrony between two participants yielded the highest accuracy in predicting participants of ASC-CONTROL vs. CONTROL-CONTROL dyads, followed by the models based on total facial and body movement, and head synchrony. Overall prediction performance was not increased in the stacking model. Though autistic participants showed reduced accuracy and increased response time in a facial emotion recognition task, we found no significant associations with the facial expression model outcome. Further associations with clinical questionnaire measures, as well as important features for classification will be discussed.

Conclusions:

Our classification models were able to detect autistic social interaction characteristics with a high accuracy. Importantly, they did so based on data from a low-cost, low-barrier, scalable setup and a largely automatized analysis framework. This suggests a high usability of SVM classification models for diagnostic purposes in the clinical setting.

425.332 (Poster) Motor and Communication Delays in Infants Who Later Developed ASD and Their Relationship to Future Outcomes and Services Received: A SPARK Study Analysis.
A. N. Bhat, Department of Physical Therapy, University of Delaware, Newark, DE

Background:

87% of school-age children with autism spectrum disorder (ASD) were at-risk for motor difficulties (Bhat, 2020). These difficulties were uniquely associated with certain core / diagnostic and co-occurring / general delays of children with ASD (Bhat, 2021). However, we do not know the trajectory of motor development in the first 1-3 years of life in this large SPARK study sample.

Objectives:

This analysis of SPARK study data will compare trajectories of early motor and communication delays between children with ASD and their unaffected siblings and link their early delays to future social communication, language, and motor difficulties as well as therapeutic services (OT, PT, speech) received at school-age.

Methods:

18,022 children with ASD from the SPARK study and their unaffected siblings (N=8,548) between 2-15 years of age were included (Mean (SD): 9(4.1) years., Feliciano et al., 2018). Demographic, milestone, and medical data were examined in both groups. Parents also completed measures of a) social communication delay based on Social Communication Questionnaire (SCQ), b) parent-reported measure of language delay (0=no delay, 1=some delay, 2= significant delay compared to peers), and c) risk for motor difficulties based on the Developmental Coordination Disorder Questionnaire (DCD-Q). Based on recall and memorabilia, parents provided the age in months and years for when their child first sat without support, crawled, walked, fed self with spoon, used first words, and combined words to phrases/sentences. They also reported the therapeutic services their children currently received (speech, OT, PT, etc.).

Results:

The developmental trajectories for all motor and communication milestones significantly differed between groups with greater delays in children with ASD compared to the UA group. 34.5%-55.5% of children with ASD had gross motor delays and 74.5% children with ASD had a fine motor/self-feeding delay compared to UA. 68.7%-84.7% children with ASD were delayed in using words and combining words/phrases compared to unaffected siblings. Early motor and communication delays of children with ASD were somewhat associated with their current levels of social, language, and motor difficulties (Correlation=0.1-0.2). While 82-86% children received OT and speech services only 33% received physical therapies. While speech and OT services increased with increasing early or current language/motor difficulties; this was not the case for PT services that remained low regardless of the level of motor difficulties. Additional analyses to predict a future diagnosis of ASD/non-ASD based on early delays will also be discussed.

Conclusions:

Children with ASD had more fine/gross motor and communication delays in the first 1-3 years of life compared to the UA group. Early motor and communication delays are greater in children with more severe future social, language, and motor delay/difficulties. Assessing early motor and communication delays could enhance the sensitivity of predicting ASD. While substantial Speech and OT services were provided to children with ASD, there are fewer PT/gross motor services provided. Future studies must further examine motor development in ASD beyond motor milestones to make a case for better early intervention services that include multisystem/gross motor interventions.

425.333 (Poster) Neural Correlates of the Visual Expectation of Active and Passive Touch in Autistic Adults
**Background:** Atypical sensory reactivity is an important facet of autism that can manifest as hyper and hypo-sensitivity to sensory experiences such as touch. This broad spectrum of tactile perception can lead to discomfort and harm that affects development and well-being. Tactile experiences can be further broken down into self-generated active touch and externally-generated passive touch. Behavioral evidence shows that autistic people often avoid passive touch that is out of their control but seek out self-initiated touch that is within their control. These sources of somatosensation have been shown to affect how neurotypical individuals perceive physical touch, but the differentiation between these types of physical contact remains poorly studied in ASD.

**Objectives:** This project compares the electrophysiological responses of predictable and unpredictable vibrotactile stimulation that is either actively or passively triggered. The overarching goal of this study is to provide information about how autistic individuals interact with their physical environment and quantify how the volition and predictability of the tactile sensation affects how it is experienced.

**Methods:** This project combines electroencephalography (EEG) and vibrotactile stimulation to map the cortical responses to active and passive tactile sensations in adults with autism and neurotypical controls. This project also takes advantage of recent advancements in virtual reality technology to pair virtual targets with somatosensory stimulation in a more naturalistic environment than traditional lab experiments. Here, we use electroencephalography (EEG) to measure cortical activity while virtual reality creates the visual expectation of touching an object that is paired with vibrotactile feedback. In the active condition, the participant reaches toward the virtual object and triggers tactile input. In the passive condition, the virtual object moves toward the participant and triggers tactile input. This experiment measures an electrophysiological phenomenon called the mismatch negativity (MMN), a distinct deflection in the EEG waveform shown to index a deviation from an established pattern in sensory stimuli. To elicit an MMN, we manipulate the duration of the vibrotactile stimuli, with 80% being 100 ms long and 20% being 160 ms long. The identified components of interest include the MMN, N1, and P2.

**Results:** Current data includes five (1M/4F) individuals in the neurotypical group and two (1M/1F) in the autism group and data collection is ongoing at a rate of 3-4 per week. Our early data demonstrate robust and reliable electrophysiological activity in response to all stimulus types. While these data are preliminary, they suggest larger a P2 in the autism group in the active condition as well as larger MMNs in the autism group in the active and passive conditions.

**Conclusions:** Our experiment exhibits strong potential to discriminate whether there are electrophysiological differences in how adults with and without autism process anticipated and unanticipated active and passive tactile experiences.

Foxe, (1)Medical Scientist Training Program, University of Rochester Medical Center, Rochester, NY, (2)Department of Brain and Cognitive Sciences, University of Rochester, Rochester, NY, (3)The Ernest J. Del Monte Institute for Neuroscience, University of Rochester Medical Center, Rochester, NY

---

**Background:** Chromatin Modifying Disorders (CMD) are caused by mutations affecting proteins responsible for chromatin remodeling and have emerged as one of the most rapidly expanding genetic disorders associated with Autism Spectrum Disorders, ASD (Lasalle, 2013; de Rubeis et al., 2014). Motor impairments are also prevalent in CMD and may play a role in the neurodevelopmental phenotype. Additionally, evidence indicates that neurological dysfunction may be treatable postnatally in CMD, thus deep phenotyping to identify clinical trial treatment targets is crucial (Fahrner & Bjornsson, 2019). We conducted motor and neurological phenotyping of two CMDs, ASXL1 and ASXL3, given their unique motor profiles and penetrance with ASD.

**Objectives:** To phenotype the motor and neurodevelopmental profile of ASXL1 and ASXL3. To examine the association of motor impairments and autism diagnosis.

**Methods:** Extensive phenotyping was conducted on 9 individuals with ASXL1 and 9 with ASXL3. Caregivers completed a comprehensive medical background form, the Movement Assessment Battery for Children (MABC) checklist - a standardized measure of motor function examining manual dexterity, aiming, catching, and balance, and the Developmental Coordination Disorder Questionnaire (DCDQ) - a measure of functional activities. Participants underwent neurological examination and quantitative gait analysis.

**Results:** Demographic information in Table 1. 38% of both groups had an autism diagnosis. Average age of first developmental concerns was 3 months in ASXL1 and 8 months in ASXL3. 5/9 ASXL1 participants achieved locomotion, with average age of first steps at 39 months; in ASXL3, average age of first steps was 28 months.

MABC: All ASXL1 (n = 7) subjects with MABC had severe motor impairments in all motor domains as did 4 ASXL3 subjects (n = 5). One ASXL3 subject had little to no motor difficulty. 75% of ASXL1 and 17% of ASXL3 noted movement difficulty affected classroom learning.
DCDQ: 100% of ASXL1 and ASXL3 met a diagnosis of developmental coordination disorder.

Neurological examination: Most ASXL1 participants had both axial and appendicular hypo and hypertonia across the lifespan. Hypotonia was most notable in ASXL3. On gait, ASXL1 showed difficulty with ambulation without supports, eversion of feet, and lower extremity spasticity. ASXL3 subjects had a wide based, clumsy gait.

ASXL1 showed distinctive differences in all quantitative gait variables compared to individuals with ASXL3. ASXL1 had (a) slower pace characterized by smaller normalized velocity, cadence, and step length, and (b) less postural control characterized by a wider stride width (Figure 2).

Participants with ASXL3 and ASD showed more severe motor impairments compared to ASXL3 and No-ASD. This was not the case in ASXL1.

Conclusions: We found that motor impairments are prevalent and pervasive across ASXL1&3 with and without ASD, and these impairments negatively impacted engagement in school-based activities. Unique neurodevelopmental and motor findings in our data include a mixed presentation of hypo and hypertonia in ASXL1 across a lifespan, slower gait, and poorer postural control compared to ASXL3. ASXL3 exhibited hypotonia and greater variability in motor skills. This deep phenotyping can aid in appropriate clinical diagnosis, referral to interventions, and serve as meaningful surrogate endpoints in clinical trials.

425.335 (Poster) Oculomotor Randomness As a Marker for Autism and Its Severity in Children: A Large Sample Study

I. Ziv, I. Avni, G. Meiri, I. Dinstein and Y. S. Bonneh, (1)School of Optometry and Vision Science, Bar-Ilan University, Ramat Gan, Israel, (2)Cognitive and Brain Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, (3)26 YA’ARA ST., Beer-Sheva, Israel, (4)Cognitive and Brain Sciences Department, Ben Gurion University, Beer Sheva, Israel

Background: Movement disturbances are often associated with Autism Spectrum Disorder (ASD), including the movement of the eyes. However, oculomotor abnormalities in ASD have been typically studied in terms of the social aspects of visual exploration, analyzing gaze direction to points of social interest, or comparing gaze behavior to that of typically developing individuals. Here we analyzed the temporal randomness of saccades in free viewing, inspired by a recent measure of “randomness” applied to pointing in ASD (Torres et al. 2013).

Objectives: Investigate the temporal aspects of eye movements in a large dataset of children viewing short video clips. Develop measures that could validate the diagnosis of ASD and its severity.

Methods: We analyzed a large eye-tracking data set, n=240 children, 190 with ASD, 50 with typical development (TD), age range of 1-10, average 4.5 ± 2.0 years, obtained at the national autism research center of Israel. The children watched three short (~1.5 min) video clips with social content, repeated twice. Here, we investigated the involuntary aspects of eye movements, specifically, the “randomness” of saccade timing assessed via gamma fitting of the inter-saccadic interval distribution, excluding recordings with less than 50% of the data or poor gamma fitting.

Results: Overall, the ASD children had significantly more gaps in their data, presumably due to excessive movement. The measure of saccade time “randomness”: (1) was significantly higher in ASD compared to the TD children; (2) was positively correlated with severity (ADOS comparison score); (3) was higher in ASD for all three video clips in different degrees. The effects were highly significant and robust, discriminating between groups with an AUC of ~0.82, which could be further improved by combining several oculomotor markers.

Conclusions: Increased “randomness” of eye movements in ASD children watching video clips could be related to “neural variability” or noise, reduced executive control, reduced engagement with the movies, or difficulty dealing with visual clutter. These findings could contribute to the future development of oculomotor biomarkers as part of an integrative diagnostic tool for ASD.

425.336 (Poster) Open Video Data Sharing from and Beyond Motor Development in Neurodevelopmental Conditions

P. B. Marschik, T. Kulvicius, K. Nielsen-Saine, S. Bolte, L. Poustka, I. Sigafos, F. Wörgötter, C. Einspieler and D. Zhang, (1)Department of Child and Adolescent Psychiatry and Psychotherapy, University Medical Center Göttingen, Göttingen, Germany, (2)University of California Los Angeles, Los Angeles, CA, (3)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (4)Education, Victoria University of Wellington, Wellington, New Zealand, (5)University of Goettingen, Goettingen, Germany, (6)Division of Phoniatrics, Medical University of Graz, Graz, Austria, (7)Child and Adolescent Psychiatry and Psychotherapy, University Medical Center Goettingen, Goettingen, Germany

Background: Video recording is a widely used method for documenting infant and child behaviours in research and clinical practice. Video data has rarely been shared due to ethical concerns of confidentiality, although the need of shared large-scaled datasets remains increasing.
This demand is even more imperative when data-driven computer-based approaches are involved, such as screening tools to complement clinical assessments.

Objectives: To share data while abiding by privacy protection rules, a critical question arises whether efforts at data de-identification reduce data utility? We addressed this question by showcasing the Prechtl's general movements assessment (GMA), an established and globally practised video-based diagnostic tool in early infancy for detecting neurological deficits, such as cerebral palsy – and also discussed in terms of its predictive value in neurodevelopmental disorders including autism spectrum disorder (ASD).

Methods: To date, no shared expert-annotated large data repositories for infant movement analyses exist. Such datasets would massively benefit training and recalibration of human assessors and the development of computer-based approaches. In the current study, sequences from a prospective longitudinal infant cohort with a total of 19451 available general movements video snippets were randomly selected for human clinical reasoning and computer-based analysis.

Results: We demonstrated for the first time that pseudonymisation by face-blurring video recordings is a viable approach. The video redaction did not affect classification accuracy for either human assessors or computer vision methods, suggesting an adequate and easy-to-apply solution for sharing movement video data.

Conclusions:

These findings and the predictive value of GMA for ASD will be critically discussed. We call for further explorations into efficient and privacy rule-conforming approaches for deidentifying video data in scientific and clinical fields beyond movement assessments. These approaches shall enable sharing and merging stand-alone video datasets (e.g. of prodromal data in neurodevelopmental disorders) into large data pools to advance science and public health. Abstract and article @ https://arxiv.org/abs/2207.11020

425.337 (Poster) Parasympathetic Influences on the Relation between Sensory Reactivity and Restricted and Repetitive Behaviors in Non-Autistic Children

S. Soker-Elimaliah and J. B. Wagner, (1)Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Department of Psychology, College of Staten Island, CUNY, Staten Island, NY, (3)Department of Psychology, The Graduate Center, City University of New York, New York, NY

Background:

Sensory reactivity is prevalent in autism (Ben-Sasson et al., 2009) and in the general population (Jussila et al., 2020), and it is usually discussed in three patterns: hypo-reactivity, hyper-reactivity, and sensory seeking (Baranek et al., 2006). These patterns have been found to be associated with restricted and repetitive behaviors (RRB) in autistic and non-autistic children (e.g., Feldman et al., 2020). Because RRB are thought to play a self-regulatory role during sensory experiences (e.g., Kapp et al., 2019), studies have begun to examine the autonomic nervous system (ANS) as a potential underlying mechanism. A key branch of the ANS is the parasympathetic nervous system, which is most active during rest. Recent studies have shown that reduced parasympathetic activity was associated with increased sensory reactivity (Daluwatte et al., 2015) and more RRB in autistic children (Condy et al., 2017). However, it remains unclear how parasympathetic activity might influence the relationship between sensory reactivity and RRB, and how this mechanism might look in the broader population.

Objectives:

The current study will examine whether parasympathetic activity interacts with sensory reactivity patterns in predicting RRB.

Methods:

The sample included 62 2- to 12-year-old non-autistic children (M_age=6.56 years, SD=2.73). During a 5-minute baseline period, children’s heart rate signals and respiration were recorded using a Biopac BioNomadix wireless system. Respiratory sinus arrhythmia (RSA), which refers to the variation in timing between heartbeats in the frequency of respiration, was then calculated as a marker of parasympathetic activity. Caregivers also filled out the Repetitive Behavior Scale-Revised (RBS-R; Bodfish et al., 1999) to assess RRB and the Sensory Experiences Questionnaire (SEQ; Baranek et al., 2006) to measure sensory reactivity patterns. Five RBS-R subscale scores (sensory-motor, restricted interests, self-injurious, compulsive, ritualistic/sameness; Bishop et al., 2013) and three SEQ sensory reactivity pattern scores (hypo-reactivity, hyper-reactivity, sensory seeking; Boyd et al., 2010) were calculated.

Results:

A set of hierarchical multiple regression models examined the contribution of each sensory reactivity pattern and RSA, as well as the interaction between them, in predicting each of the five RRB subtypes (see Table 1). Significant interactions were found between hypo-
reactivity and RSA in predicting sensory-motor behaviors ($B=.23$, $p=.044$), between sensory seeking and RSA in predicting self-injurious behaviors ($B=-.55$, $p<.001$), and between hyper-reactivity and RSA in predicting ritualistic/sameness behaviors ($B=-.30$, $p=.040$). Additionally, when predicting compulsive behaviors, the interactions between hypo-reactivity and RSA ($B=-.24$, $p=.047$) and hyper-reactivity and RSA ($B=.28$, $p=.046$) were significant.

Conclusions:

The current study found that the relationships between sensory reactivity patterns and sensory-motor, self-injurious, compulsive, and ritualistic/sameness behaviors change as a function of RSA levels. These preliminary results show that dysregulated parasympathetic activity at baseline might influence the relationship between sensory reactivity and restricted and repetitive behaviors in non-autistic children. The current study begins to uncover the complexity of physiological processes underlying sensory experiences and behaviors. Future work will examine the effect of sympathetic activity, as well as the interaction of both branches of ANS activity on the relationship between sensory reactivity and RRB, and will examine these questions in autistic children.

425.338 (Poster) Parents’, Professionals’, and Autistic Adults’ Perspectives on the Context and Emotions Surrounding Repetitive Behaviors in School-Aged Autistic Children

K. Sotelo1, I. Soulieres1, V. Courchesne1, M. Couture1, G. Thermidor2, L. Mottron, M.D.1 and C. Jacques1, (1)University of Quebec in Outaouais, Gatineau, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l’Île-de-Montréal, Montréal, QC, Canada, (3)Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (4)Centre for Addiction & Mental Health (CAMH), Montréal, QC, Canada, (5)CAMH: Centre for Addiction and Mental Health, Toronto, ON, Canada, (6)Université de Sherbrooke, Sherbrooke, QC, Canada, (7)Université du Québec en Outaouais, Gatineau, QC, Canada

Background:

Some studies suggested that repetitive behaviors (RBs) would be problematic, disruptive, dangerous and serve minimal functional purpose (Lin & Koegel, 2018; Ventola et al., 2016; Jaffey & Aschwin, 2022). Other studies argued that RBs, in addition to participate in autistic learning strategies, may have a self-regulating and adaptive outcome, such as a way to cope with anxiety (Collis et al., 2022; Kapp et al., 2019), to express emotions or as a form of play and a stimulating approach (Conn et al., 2015; Jaffey & Aschwin, 2022). These studies propose a new way of documenting the onset of RBs based on the perspective of autistic adults, parents, or teachers. It would be interesting to compare the content reported by different observers using a global method over the developmental period.

Objectives:

To document contexts and emotional circumstances surrounding occurrence of repetitive behaviors in school-aged autistic children based on parents’, autistic adults’, and professionals’ perspectives, as well as to compare the content reported by the different observers.

Methods:

The online French version of the Questionnaire on Repetitive Behaviors and Interests in School-Aged Autistic Children was completed via LimeSurvey by 107 autistic adults in a retrospective manner (27 men, 67 women, and 13 non-binary), by 76 parents of autistic children aged between 6.1 and 12.9 years old (63 boys and 13 girls), and 24 professionals (i.e. teachers, specialized educators, psychoeducators, speech therapists, psychologists, and social workers). Participants were asked to describe the contexts and emotions eliciting RBs. Thematic content analysis was conducted to identify contexts and emotional circumstances surrounding occurrence of RBs. Inter-coder reliability of 87% was obtained on 20% of the randomly selected verbatim. Triangulation of the data was performed to contrast the perspectives of each group.

Results:

Two types of contexts were identified by the three groups as likely to elicit RBs: social interactions and/or events (autistic adults: 38% of respondents; professionals: 31%; parents: 10%) and emotional contexts (autistic adults: 39%; professionals: 54%; parents: 31%). Also, professionals and autistic adults identified sensory overstimulation as being an important trigger of RBs (46% and 19% respectively) and parents reported changes in routine as another prevalent context triggering RBs (33%).

Anxiety/stress was the most identified emotion eliciting RBs in the three groups (autistic adults: 50%; professionals: 43%; parents: 44%). Two groups identified joy and happiness as being another important trigger of RBs, namely professionals (52%) and autistic adults (37%). Parents rather identified anger, frustration, or impatience as a frequent trigger of RBs (37%).

Conclusions:
According to all groups, RBs are triggered by specific contexts and are largely associated with emotions in autistic children. Studying the context in which RBs occur is instrumental to understand the function of these behaviors. These results also highlight the importance and richness of considering multiple respondents as different context and emotions were identified by the different groups, including autistic persons themselves, to obtain a broader understanding of RBs occurrence in autistic children.

**425.339** *(Poster)* Passion and Needs Satisfaction in Young Autistic Adults: Links with Optimal Functioning

* A. J. Meilleur 1, N. Cusson 1, R. J. Vallerand 2, M. Couture 1, E. Gilbert 1, I. Soulières 1  and E. L. Bussières 1, 2, (1) Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (2) Autism Research Group, CIUSSS du Nord-de-l’Île-de-Montréal, Montréal, QC, Canada, (3) Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (4) Psychology, Université du Québec à Montréal (UQAM), Montréal, QC, Canada, (5) Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (6) Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (7) Department of Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (8) Psychology, Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada

Background: Autistic individuals are known to have intense passions. The Dualistic model of passion (Vallerand, 2015) posits the existence of two types of passion: harmonious and obsessive. Harmonious passion (HP) has a positive impact on optimal functioning (i.e., well-being, physical health, relationship quality, performance, and contribution to society). Conversely, obsessive passion (OP) typically leads to negative effects on optimal functioning. As such, understanding how to nurture a positive and HP is key to optimal functioning. In non-autistic samples, the development and maintenance of HP is thought to depend on different factors, such as psychological needs satisfaction.

Objectives: The first aim was to investigate associations between HP, OP, needs satisfaction and optimal functioning and autistic quality of life (ASQoL). It was expected that needs satisfaction would be positively associated with HP, and negatively with OP, and that passion would be associated with optimal functioning and ASQoL.

Methods: Participants were recruited on social media through different autism associations. A total of 31 autistic individuals (24 women; M=25.68 years; SD=5.23) took part in an online study. Thinking of their favorite interest, participants completed questionnaires on passion, needs satisfaction in life, optimal functioning, and ASQoL. A path analysis with three needs satisfaction (autonomy, competence, relatedness) as an exogenous independent variables, HP and OP as endogenous independent variables and optimal functioning and ASQoL as dependent variables was performed.

Results: Participants showed high levels of HP (M=5.62/7; SD=0.91) and moderate levels of OP (M=3.28/7; SD=1.39). They spent on average 21.40 hours/week (SD=12.69) on their interest and had been practicing it for approximately 13.5 years (SD=8.89). The path analysis revealed that autonomy satisfaction positively predicted HP (β = .483; p = .007), whereas competence and relatedness were not significantly associated with HP (β = -.261; p = .148; β = .212; p = .104). Additionally, competence satisfaction negatively predicted OP (β = -.664; p = .001). Autonomy and relatedness were not significantly associated with OP (β = .082; p = .665; β = -.030; p = .857). In turn, HP predicted ASQoL (β = .503; p = .008) but was only tangentially related to optimal functioning (β = .178; p = .104). Conversely, OP negatively predicted optimal functioning (β = -.689; p < .001) but was unrelated to ASQoL (β = -.233; p = .201).

Conclusions: HP was associated with having greater psychological needs satisfaction in life, whereas OP was associated with having these psychological needs less fulfilled. Results are consistent with the hypothesis that OP might be a compensatory mechanism when psychological needs such as competence are unmet. Thus, OP might be fulfilling these unmet needs, in some cases leading to behavioral addiction (Holding et al., 2021; Lalande et al., 2017). As expected, the presence of passion was associated with optimal functioning and ASQoL in a sample of autistic young adults. HP was found to positively predict ASQoL whereas OP negatively predicted optimal functioning. Optimal functioning and ASQoL might be measuring complementary aspects of well-being and quality of life for autistic people.

**425.340** *(Poster)* Prevalence of Early Interest in and Precocious Ability with Written Material in Autism in a Representative Population

* A. Ostrolenk 1, M. Boisvert 2, O. Lemire 1, S. C. Dick 1, A. Clermont 1, M. P. Côté 1 and L. Mottron 1, (1) Department of Psychiatry and Addictology, Université de Montréal, Montréal, QC, Canada, (2) Autism Research Group, CIUSSS du Nord-de-l’Île-de-Montréal, Montréal, QC, Canada, (3) Department of Psychology, Université de Montréal, Montréal, QC, Canada

Background: Although the scientific community has not come to an agreement on the definition of hyperlexia, it is commonly described as an intense and precocious interest in written material and a discrepancy between advanced decoding and weaker comprehension when reading. Hyperlexia is the most frequent special ability in autism (up to 20% in the literature). However, there are no recent studies assessing the prevalence of hyperlexic features in a large population of autistic children. Our study focuses on the most precocious and specific sign of hyperlexia, early interest in written material.

Objectives:
We documented the prevalence of this interest and the history of its emergence in a large representative population referred for an autism diagnostic assessment and compared the results between autistic and non-autistic individuals. A secondary objective was to collect information on other manifestations of hyperlexia and the development of oral language.

Methods:

The participants were all the children up to 6 years old who were assessed at our autism assessment clinic between 2018 and 2021, whatever their outcome diagnosis, and a neurotypical control group. They constituted a representative population from a defined geographic area in northern Montreal. The families were enrolled in two complimentary projects: (1) The medical files of all the participants (N=698, 393 autistic, 305 negative diagnosis; M\text{age}=52.12 months, SD=13.54, range=18-83) were examined using a rating grid investigating the child’s interest in letters and numbers, and (2) the families who consented to be contacted (N=255, 116 autistic, 81 negative diagnosis, 58 neurotypical; M\text{age}=53.34 months, SD=14.17, range=24-83) answered a 45-minute phone questionnaire shortly after the assessment. The questionnaire was developed based on a literature review, a previous pilot questionnaire, and experts’ opinions. It included questions about the child’s interest in letters and numbers, related behaviours and skills, oral language level, parental attitude regarding written material, and relevant qualitative information. This double approach allowed us to gather information on the entire population to ensure the representativity of our sample while obtaining more detailed information on a sub-sample.

Results:

Both studies yielded similar results: the autistic group showed a superior level of interest than both the negative diagnosis and the neurotypical groups. Significantly more autistic children had an intense or exclusive interest in written material (39.7% vs. 23.5% of the negative diagnosis and 29.8% of the neurotypical group, $\chi^2=6.02, p<0.05$). Only in the autistic group, the higher the interest, the earlier was its onset. Although most autistics did not communicate verbally, a large portion could name letters and numbers in two languages or more. Of the 30 autistic children described as completely nonverbal, 6 sang the alphabet, 7 named letters, and 2 read words. The children’s interest in numbers was investigated in the same way with similar results.

Conclusions:

These results highlight the large proportion of autistic children with a strong interest in written material at the age of diagnosis, which could be the first sign of hyperlexia. This confirms the need for more research on hyperlexia and the factors involved in its emergence.

*E. Randell and R. McNamara, Cardiff University, Cardiff, United Kingdom*

Background:

The majority of autistic children have sensory processing difficulties, which can impact on participation in daily life, education and leisure activities. One therapy that may be helpful is Sensory Integration Therapy (SIT), however there is currently insufficient evidence on its effectiveness. SenITA was a UK randomised controlled trial of sensory integration therapy (SIT) plus usual care versus usual care alone for children with autism and sensory processing difficulties.

Objectives:

Embedded within the trial was a process evaluation in accordance with MRC guidance to examine: i) recruitment of participants and therapists; ii) Retention; iii) Fidelity; iv) Acceptability; v) adherence; vi) adverse effects; vii) contamination.

Methods:

The process evaluation employed a mixed methods approach. Quantitative methods were used to assess recruitment rates/patterns, attendance and intervention fidelity. Qualitative interviews were used to examine experiences of the trial recruitment process, acceptability of trial processes and measures, intervention implementation and acceptability, and the role of contextual factors.

Results:

258 carers contacted the study team to express an interest in taking part. Screening appointments were held with 150 carers and children from which 138 children were randomised into the trial (92% of those screened, 53.5% of those who expressed an interest in taking part). Participants were likely representative of the wider population of children in primary education with a diagnosis of autism presenting to services. The majority were male (79%) and white British (88%)
107 participants (77.5%) provided follow-up data at the primary outcome timepoint (6 months) and 69.6% at the 12-month follow-up. SIT delivered met fidelity with 10 out of 12 therapists scoring an average of at least 80/100 on the process fidelity measure for at least 80% of each of their sessions.

Semi-structured interviews were conducted with 30 carers of children and 13 therapists involved in intervention delivery. Transcripts were analysed thematically using a framework approach. Changes in children following the SIT were perceived to have a positive impact on family life. Parents also reported that the therapy helped them develop a better understanding of their child. Observed changes were not always sustained, and some therapists did not believe that SIT was the most appropriate approach for all children, and outcomes were dependent on parental engagement. Overall, 54 participants allocated to the SIT arm received at least 13 SIT sessions during the intensive stage (78.3%). The median number of SIT sessions received was 20 (IQR: 16 to 21).

There were no serious adverse events (SAE). Most carers reported that there had been no changes to the support their child received during the trial period.

Conclusions:

The process evaluation demonstrated that recruitment of participants and therapists and delivery of intervention all met required thresholds. Retention was good and carers generally found trial processes acceptable. Adherence to the intervention was high with no serious adverse events reported. There was minimal contamination in the usual care arm, and families allocated to SIT did not report receipt of any other significant intervention or contact with services.

425.342 (Poster) Relationships between Sensory Reactivity and Aberrant Behavior in Autism and Two Neurogenetic Syndromes: Phelan-McDermid Syndrome and Adnp Syndrome

(1)University of Rochester, Rochester, NY, (2)The Seaver Autism Center for Research & Treatment, New York, NY, (3)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (4)Seaver Autism Center at Mount Sinai, New York, NY, (5)Mount Sinai School of Medicine, New York, NY

Background: Phelan-McDermid syndrome (PMS) and activity-dependent neuroprotective protein (ADNP) syndrome are neurogenetic syndromes associated with autism spectrum disorder (ASD) and intellectual disability (ID). Recent literature describes high levels of sensory hyporeactivity in PMS (Tavassoli et al., 2021) and seeking in ADNP syndrome (Siper et al., 2021). Studies in autism more broadly describe the impact of sensory reactivity on internalizing and externalizing symptoms (Rossow et al., 2020). Understanding these relationships is important in the context of clinical trials in both syndromes.

Objectives: To examine the relationship between sensory reactivity and aberrant behavior in PMS, ADNP, and idiopathic ASD (iASD).

Methods: Participants included 36 individuals with PMS (Mage = 7.34), 19 with ADNP syndrome (Mage = 6.87), 28 with iASD and ID (Mage = 6.32), and 18 without ID (Mage = 6.56). The Sensory Assessment for Neurodevelopmental Disorders (SAND), a clinician-administered observation and caregiver interview, measured sensory hyporeactivity, hyporeactivity, and seeking. The Aberrant Behavior Checklist (ABC) measured irritability, social withdrawal, stereotypy, hyperactivity, and inappropriate speech. Bivariate correlational analyses were explored.

Results: Overall sensory reactivity significantly correlated with social withdrawal in PMS, ADNP, and iASD with ID (r's = .39-.60, p's < .037), and with stereotypy in PMS (r = .46, p = .004) and ADNP (r = .64, p = .003). Overall sensory symptoms were also moderately correlated with irritability in ADNP (r = .59, p = .008) and iASD with (r = .51, p = .005) and without (r = .482, p = .043) ID. Hyporeactivity correlated with social withdrawal in PMS (r = .54, p = .001) and ADNP (r = .54, p = .016), but not iASD. Hyporeactivity also correlated with stereotypy in PMS (r = .55, p = .001), and hyperactivity in ADNP (r = .71, p = .001). Individuals with PMS and ASD (n = 29) drove relationships between hyporeactivity and social withdrawal (r = .50, p = .006) and stereotypy (r = .47, p = .010). However, the relationship between hyporeactivity and hyperactivity in ADNP remained strong for those with (n = 9, r = .84, p = .005) and without ASD (n = 10, r = .69, p = .029). Hyperreactivity strongly correlated with social withdrawal (r = .69, p = .026) in ADNP and irritability in iASD without ID (r = .63, p = .005). Finally, sensory seeking strongly correlated with irritability (r = .69, p = .001) in ADNP (r = .69, p = .001) and iASD without ID (r = .63, p = .005).

Conclusions: Relationships between sensory reactivity and aberrant behavior were identified, with notable differences based on diagnostic group and the presence of ASD or ID within them. Overall sensory symptoms were most consistently related to social withdrawal in groups with ID. The presence of ASD impacted findings in PMS, but not ADNP syndrome. While further investigation of these relationships is needed, significant correlations across domains of sensory reactivity and aberrant behavior suggest interventions targeting sensory symptoms may be a critical avenue to explore with probable downstream effects on aberrant behavior.
Background: Autism Spectrum Disorder (ASD) encompasses a broad range of behavioral and functional deficiencies, often displaying wide divergence in presentation. Repeated attempts have been made to understand if there is any common underlying causality that can explain this wide presentation. It has been hypothesized that ASD could be a result of disorder in prediction capabilities in human brain. However, it’s unclear as to what extent both spatial and temporal predictive abilities are impaired.

Objectives: To determine if prediction abilities in temporal and spatial domains, and their combination which is of relevance in a dynamic real-world environment, are impaired in ASD children. This study specifically focusses in age ranges of 8 – 12 years, using Machine-Learning based interactive video games that provide a customized challenge as per the response of the child depending on the severity of the symptoms in the spectrum.

Methods: Participants were 16 ASD and 16 age-matched Neurotypical (NT) controls in the age range of 8-12 years. All were healthy individuals with CARS score in mild-moderate ASD range. Reinforcement-Learning based interactive video games were developed that measure and analyze the responses of the player to determine their prediction abilities. These games analyzed both the temporal and spatial predictions.

For example, how long(temporal estimations involved) they need to estimate a certain distance (spatial estimation involved) presented to them in a dynamic environment with an avatar, as well the accuracy of the estimation computed via various metrics. The distance of the computed barrier is dynamically updated using ML-techniques based on prior responses. They were presented to the participants on Android-based Lenovo Tab with 8” screens for clear visibility and had sound effects to increase immersion.

There was a 20-minute priming exercise to get comfortable and understand the game. During this priming exercise, their parents and a team of psychologists additionally supported them. Following the familiarization process, they were comfortably seated in a distraction-free room and played the games. Their performance was recorded on remote high compute Amazon Web Servers. The Individual Prediction maps (based on Gaussian and Bayesian analysis) were precomputed for better performance. Based on the subject’s response, the next task was dynamically presented through the Reinforcement Learning frame work to improve their prediction abilities.

Results: We observed that prediction accuracy in the static ambience seemed to be comparable with neuro typical subjects under certain condition, while differing in other conditions. We also noted correlations between various other parameters such as motor skills, eye contact and prediction abilities. However, we noted significant deficiencies in the dynamic ambience, i.e. when the game environment was altered in a sensory-affective manner. Also, failure patterns were significantly detected in ASD subjects, which was not observed in the case of NT subjects.

Conclusions: In this study, we intend to present these novel findings that prediction accuracy in the static ambience seemed to be comparable with neuro typical subjects under certain conditions and also there is correlation between various parameters. Also, studying these patterns in more detail and characterizing them is a topic of further studies.
Methods: We analyzed relationships between three tasks with different stimulus modalities and time scales: 1) a Method of Constant Stimuli (MCS) task to test perceived synchrony of individual heartbeats and visual stimuli as a function of temporal offset, yielding a temporal binding window (Brener and Ring, 2016); 2) Legrand et al.’s (2022) heart rate discrimination (HRD) task to test discrimination of heart versus auditory rate changes (not requiring perception of individual beats), yielding estimated heart rate precision; and 3) Walsh et al.’s (2019) respiration integration task (RIT) to test whether breathing synchronized with a moving visual stimulus improves subsequent visual speed discrimination relative to an exteroceptive-only baseline, yielding a threshold difference score. Participants included n = 23 non-autistic (NT, 22% male) and n = 14 autistic (AUT, 64% male) individuals ages 8-52 years, though most were adults (75%). Relationships between task variables were assessed with Pearson correlation.

Results: In both groups, wider temporal binding windows between heartbeats and visual stimuli (as assessed by MCS) were highly correlated with less precise heart rate discrimination assessed by HRD, though this was especially prominent in the autistic group (AUT: R-squared = 0.62, NT: R-squared = 0.06). Improvements in detecting visual speed changes with synchronized breathing (as assessed by RIT) were not significantly correlated with either cardiac task. Preliminary relationships with age suggest that integration precision increased with age for both the HRD and RIT tasks (but not the MCS), though these relationships were stronger in the non-autistic group (HRD: R-squared = 0.25 and RIT: R-squared = 0.21) than the autistic group (HRD: R-squared = 0.16 and RIT: R-squared = 0.03).

Conclusions: Our results suggest that these tasks may indeed index some shared and some distinct aspects of IE integration; for example, single heartbeat integration may impact the ability to contextualize heart rate changes related to threat. However, individual differences in IE integration may vary substantially by interoceptive stimulus (cardiac versus respiration). Further, these findings point to potential group differences in how integration develops with age, though confirmation of these preliminary patterns is needed. Future work in larger samples will study relationships between these measures, diagnostic group status, and physical/emotional health outcomes.

436.289 (Poster) Quantitative Assessment of Tip Toe Behavior in Individuals with Autism Spectrum Disorders Using a Structured Methodology: Comparison between Video-Recording and Wearable Sensors Approaches. G. Valagussa1, L. E. Moltchen2, M. Boccotti3, G. Andreoni1 and E. Grossi1, (1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)Program in Physical Therapy, School of Medicine and Surgery, University of Milano Bicocca, Monza, Italy, (3)Department of Design, Politecnico di Milano, Milan, Italy, (4)Bioengineering Laboratory, Scientific Institute IRCCS “E.Medea”, Bosisio Parini, Italy, (5)Autism Research Unit, Villa Santa Maria SCS, Tavernerio, Italy

Background: Tip-toe behavior (TTB) is showed by about 20% of individuals with ASD and is poorly quantified with structured methods. In a previous study, we proposed a standardized method to quantify TTB during static and dynamic tasks using a video-recording approach in an ecological setting. This testing approach is very time-consuming and operator dependent requiring an operator to review the videos and computing the parameters. To overcome these limitations, an instrumental approach using wearable sensors (WS) and an automated calculation system was developed and applied. Moreover, WS approach would also permit monitoring gait for a longer time during the day.

Objectives: This study aims at implementing a WS-based protocol for the quantitative assessment of TTB and its validation by the comparison with the reference video-recording approach.

Methods: Individuals with ASD diagnosed according to DSM-5 criteria and a diagnosis confirmation using the Autism Diagnostic Observation Schedule (ADOS) were involved in the study. TTB was quantified during structured static and dynamic tasks using a video-recording approach, previously described. All the tests were performed without shoes albeit with “Sensoria® Smart Socks”. The dynamic test consists in transporting 1 object (e.g. puzzle piece, Lego®) from the therapist to the playing table situated 2 meters away and back again 15 times. The static test consists in playing while standing in front of a table for 3 minutes. Both assessments were repeated on three different days for each individual (9 assessments). “Sensoria® Smart Socks” (SSS) are the validated WS used during the video-recorded tests. In this way, we were able to collect data obtained from video-recording and WS approaches at the same time. The result of the video-recording and WS approaches were analyzed. The intraclass correlation coefficient (ICC) was used to assess the reliability between the video-recording and WS approaches in quantifying the mean percentage of toe steps and the mean percentage of the time spent in TTB.

Results: We assessed 3 individuals with ASD and TTB. The age was 10.9yrs, 12.8yrs and 13yrs (3/3 males) and their ADOS calibrated severity score was 9, 10 and 8, respectively. The normal distribution of data was confirmed (Shapiro-Wilk test p > 0.05). The ICC values of the mean percentage of toe steps and the mean percentage of the time spent in TTB were 0.778 (excellent) and 0.731 (good), respectively.

Conclusions: The “Sensoria® Smart Socks” used for the quantitative assessment of TTB in individuals with ASD showed good-to-excellent reliability in comparison with the reference video-recording approach both during a static and dynamic tests. Further research is required to confirm the results of this preliminary study.
Background: Although speech impairment is highly prevalent in autism spectrum disorder (ASD), the neurophysiological barriers to speech remain poorly understood.

Objectives: This study measured the response to simulated speech errors via real-time alterations in auditory feedback of one’s speech in order to examine the use of feedforward control of speech production in participants with and without ASD.

Methods: Participants were 73 children and adolescents ages 8-17 years who were diagnosed with ASD (N=46) or were typically developing control (TDC) participants (N=28). Participants underwent diagnostic and neuropsychological testing and were administered an altered speech feedback task. For this task participants spoke the word “bed” upon cue into a headset microphone and heard their speech through headphones via a digital signal processing system. The inter-trial-interval between cues was 2.5 seconds. For the first and last 20 trials the auditory feedback of speech produced into the microphone was unaltered. For trials 21-70 the formants F1 and F2 were shifted in real time by the digital signal processing system. F1 was raised 200Hz and F2 was reduced by 250Hz to make the vowel sound /æ/ sound closer to /eh/, simulating a speech error. The compensatory vocal adjustment in response to this shift (sensorimotor adaptation) was quantified to compute adaptation according to the following procedures. The applied formant shift and produced formants were represented as vectors from baseline formant values in an F1-F2 (first and second formants) Euclidean space. Produced formant frequencies were extracted from spectrograms of entire vowel utterances. Trials with formant drops and incorrect tracking were excluded from. The scalar projection of the produced formants vector on the formant shift vector was determined. Percentage adaptation was calculated as $-100 \times (1 - \text{scalar projection})$/binomial magnitude of applied shift for each trial. The mean percent adaptation of all altered feedback trials was calculated for each participant, compared between groups, and examined in relation to oral motor speed (diadochokinetic rate for “puh-tuh-kuh”).

Conclusions: Speaking rapidly allows less time for online processing and utilization of auditory feedback of one’s own speech. Thus, ability to produce rapid speech can indicate successful use of feedforward control mechanisms. The reduced speech adaptation identified in the ASD group suggests that individuals with ASD may struggle with learning in the feedforward system. The association between reduced adaptation (indicative of poor feedforward learning) and slower diadochokinetic rate may suggest that some individuals with ASD need to rely more on feedback control mechanisms (which only work at slow speech rates) for speech production to compensate for an inability to rely on feedforward control.

436.291 (Poster) Reduced Thalamic Inhibition Relates to Neural Mechanisms of Sensory over-Responsivity in ASD Youth

Background: Sensory processing atypicalities are present in over 90% of autistic youth (Leekam et al., 2007), and excitation/inhibition imbalance has been theorized to contribute to sensory issues in autism spectrum disorder (ASD). Reduced GABA levels in the thalamus (i.e., sensory relay station) have recently been linked to sensory over-responsivity (SOR) in autism (Wood et al., 2021), suggesting dysfunctional thalamic gating of sensory signals to downstream sensory regions in ASD. Previous research has shown that SOR is associated with heightened activation in sensory cortical regions (Green et al., 2013, 2015); however, whether there is a link between thalamic GABA levels and cortical sensory over-responsivity remains unclear.

Objectives: To assess whether thalamic GABA modulates sensory-evoked neural activation differently in ASD and typically developing (TD) youth.

Methods: In a sample of 13 ASD and 16 TD participants (aged 8.6-17.7 years), we collected functional magnetic resonance imaging (fMRI) data during mildly aversive tactile and auditory stimulation. In addition, single-voxel edited 1H-MR spectra from the thalamus were collected with a MEGA-PRESS pulse sequence on a 3T Siemens scanner and analyzed using the Gannet pipeline. GABA+/creatinine ratios ([GABA]) were entered as a bottom-up regressor in within- and between-group analyses predicting neural responses to sensory stimulation. Results were cluster corrected for multiple comparisons at $p<0.05$ and thresholded at $z>2.3.$
Results: In TD, lower levels of thalamic [GABA] were associated with stronger activation in ventromedial and dorsomedial prefrontal cortex (Figure 1). In ASD, lower thalamic [GABA] was related to stronger activation in visual, auditory, and somatosensory cortical regions as well as frontal cortex and cerebellum. Thalamic [GABA] was more strongly negatively related to neural sensory responses in the same sensory and frontal regions in ASD compared to TD.

Conclusions: Reduced thalamic inhibition is associated with sensory cortical overactivation in ASD. These findings indicate that reduced filtering of sensory information at the level of the thalamus may underlie the previously reported relationship between SOR and heightened neural activation, providing a link between neurochemistry of the thalamus, atypical sensory-evoked neural responses, and sensory processing issues in autism. Future research in animal models will be instrumental in investigating a causal link between thalamic inhibition and SOR.

**436.292 (Poster) Relating Altered Auditory Habituation to Sensory Reactivity in Autism Spectrum Disorder**

**Y. Braverman, G. Parra, C. MacKay, K. E. Takachi, L. Cornelissen and A. R. Levin; (1)Neurology, Boston Children's Hospital, Brookline, MA, (2)Boston Children's Hospital, Brookline, MA, (3)Anesthesiology, Boston Children's Hospital, Boston, MA**

Background: Sensory hyper- and hyposensitivity are characteristic of autism spectrum disorder (ASD) and can paradoxically co-occur in the same individuals. Changes in stimulus response over time (i.e., in response to repeated stimuli) could contribute to this sensory processing paradox. Indeed, prior studies in school age children and adolescents have found reduced auditory habituation in individuals with ASD compared to typically developing (TD) individuals. However, few studies have examined auditory habituation in preschool children or the relationship between auditory habituation and paradoxical hyper- and hyposensitivity. Measuring cortical responses to repeated sensory stimulation in preschoolers with ASD provides an opportunity to objectively and quantitatively evaluate sensory processing and establish the interaction between paradoxical sensory reactivity at a global level.

Objectives: To evaluate whether auditory habituation measured via EEG 1) differs in preschoolers diagnosed with ASD compared to age matched TD children and 2) correlates with sensory features of ASD, namely hyperreactivity and hyporeactivity composite scores derived from the Sensory Profile 2 (SP2).

Methods: Multichannel EEG data were collected from 3-4 year old children with ASD (n = 14, 85% male) and TD (n = 13, 69% male) during an auditory temporal habituation paradigm consisting of 5 repeating tones per trial. Global Field Power (GFP) was computed for 156-204 ms post tone onset, consistent with prior studies. For each participant, auditory habituation was operationalized as the slope of GFP values across tones 1-5. For a subset of this sample (nASD = 14, nTD = 11), caretakers completed the SP2. To measure sensory reactivity using the SP2, hyporeactivity was defined as the sum of the Registration and Seeking quadrants while hyperreactivity was defined as the sum of the Sensitivity and Avoiding quadrants. An independent t-test examined whether auditory habituation differed between diagnostic groups. Finally, for those with SP2 data, we conducted Pearson correlations to examine whether habituation significantly related to domains of sensory processing, namely hyporeactivity and hyperreactivity.

Results: Auditory habituation was significantly reduced in ASD compared to TD participants (p = .03). On average, participants with ASD had increasing GFP (i.e., facilitation) over the 5 tones, while TD participants had decreasing GFP (i.e., habituation). Within ASD participants, habituation significantly positively correlated with hyporeactivity (r = 0.56, p = .03) and had a trending positive correlation with hyperreactivity (r = 0.50, p = .06).

Conclusions: Our study is among the first to examine auditory habituation in young children. We found reduced auditory habituation in preschoolers with ASD compared to TD peers, replicating previous findings in older cohorts. Specifically, while TD participants habituated across repeated tones, ASD participants exhibited a facilitation response. ASD participants who habituated less to auditory tones tended to have higher SP2-derived hyporeactivity composites. This hyporeactivity-habituation correlation, coupled with trending significance in the hyperreactivity-habituation correlation, lend preliminary support for habituation as an account for the co-occurrence of hypo and hypersensitivity in ASD (i.e., hyposensitivity to initial stimuli followed by hypersensitivity to repeated stimuli). This study is actively recruiting and will be conducted with larger samples to continue exploring auditory habituation in ASD and young children.

**436.293 (Poster) Restrictive and Repetitive Behaviors in Children with and without Autism Spectrum Disorder: Associations with Amygdala Subnuclei and Anxiety**

**D. Seguin, A. Hennessy, S. Correa and E. Duerden; (1)Western University, London, ON, Canada, (2)Western University, London, ON, Canada, (3)1137 Western Rd, Faculty of Education Building, Rm 1031, Western University, London, ON, Canada**

Background: The presence of restrictive or repetitive behaviors (RRBs) are required for a diagnosis of Autism Spectrum Disorder. These behaviors can include resistance to changes in routine or play, and repetitive motor patterns. Although prevalent in ASD, RRBs occur in other disorders, as well as in the typically-developing population. It has been proposed that RRBs may serve to alleviate anxiety, which is heightened in ASD compared to non-ASD individuals. The amygdala is associated with both anxiety and ASD symptomatology.
Objectives: Our main aim was to determine whether there was an association between parent-reported anxiety and amygdala subnuclei volumes in predicting RRB scores, and whether these associations differed between children with and without ASD.

Methods: All data was collected by the Healthy Brain Project. Data from 66 children were included in all analyses, 30 with an ASD diagnosis (24M, mean age 8 yrs) and 36 without an ASD diagnosis (12M, mean age 7.86 yrs). All children were 5-10 years of age. Parents completed the Repetitive Behavior Scale, as well as the Screen for Child Anxiety Related Disorders (SCARED-P). Children underwent an MRI and amygdala subnuclei volumes were extracted with Free Surfer. T-tests were run to compare RBS and anxiety scores between groups. A generalized linear model (GLM) was then run with RBS scores as the dependent variable, and amygdala subnuclei volumes, anxiety, and diagnosis as the independent variables, adjusting for sex, age, and total cerebral volume (TCV) to examine the association between amygdala volumes and anxiety with RBS scores. GLM post hoc tests were run to examine significant interaction effects.

Results: Children with ASD had significantly higher RBS (p<.001) and anxiety (p=.009) scores than children without ASD. The left medial (p=.004) and right corticoamygdaloid transition area (CAT) (p=.009) volumes were significantly associated with RBS scores, as was anxiety (p<.001). Post hocs reveal that in non-ASD children, smaller left medial volumes were associated with higher RBS scores (p<.001), as association not seen in ASD children. It was also found that greater anxiety was associated with greater RBS scores in ASD children (p<.001), while the opposite relationship was seen in non-ASD children (p=.011).

Conclusions: Smaller left medial and larger right CAT nuclei and were associated with higher RBS scores. The medial nucleus is associated with social and emotional responding while the CAT region has been implicated in affective disorders. Of note, children with ASD displayed different associations between anxiety and RRBs than non-ASD children, suggesting the mechanisms underlying these behaviors may differ in ASD. Further investigations into ASD-specific phenotypes of anxiety are necessary.

436.294 (Poster) Rewarded Inhibitory Control As a Marker of Repetitive Behaviors and Their Underlying Pathophysiology in Adolescents with Autism Spectrum Disorder

K. E. Unruh, S. E. Kelly, R. Hamidpour, and M. W. Mosconi; (1)Kansas Center for Autism Research and Training (K-CART), University of Kansas Life Span Institute, Lawrence, KS, (2)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (3)Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS, (4)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (5)University of Missouri-Kansas City, Kansas City, MO, (6)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS.

Background: Restricted and repetitive behaviors (RRBs) significantly interfere with multiple aspects of daily life and persist throughout the lifetime, but are not consistently or effectively treated due to a limited understanding of their underlying psychological and neural mechanisms. Data from our lab and others indicate that individuals with ASD show a reduced ability to inhibit contextually inappropriate behaviors (inhibitory control) that is associated with more severe clinical RRBs. Studies of typical development have shown that inhibitory control is strongly influenced by the extent to which inhibition of a response is associated with a reward, particularly during adolescence, suggesting that a reduced ability to modulate task-relevant brain networks based on reward contingencies may contribute to RRBs in ASD.

Objectives: In this study, we used a novel quantitative assessment of rewarded inhibitory control to test whether the interaction of inhibitory control and reward processes better predicts clinical RRB severity than existing unidimensional models. We also examined relationships between task performance and resting state connectivity of inhibitory control brain networks.

Methods: Eleven adolescents with ASD and 8 age-matched controls (mean age = 13.9 years) were tested using a novel rewarded antisaccade paradigm. Participants were instructed to inhibit eye movements (prosaccades) toward peripheral targets and instead look immediately to the mirror location of the target in the opposite hemifield (antisaccades). Prior to target appearance, a cue indicated whether reward could be earned for correct performance on the trial (blocks were randomized for reward or no-reward contingencies); a green checkmark was presented following correct antisaccade performance on rewarded trials. RRB severity was measured using the Flexibility Scale. Resting-state functional connectivity (rsfMRI) also was examined. Data collection is ongoing.

Results: Antisaccade accuracy was reduced in ASD relative to controls (d=.98) during no-reward trials, but similar across groups during reward trials. Improvements in accuracy during rewarded relative to non-rewarded trials (“reward gain”) were greater in ASD than controls (d= .89). RRB severity was modestly negatively correlated with non-reward antisaccade accuracy (R² = .34), but strongly negatively correlated with rewarded antisaccade accuracy (R² = .51). In participants with ASD, increased reward gain was associated with reduced striatal-ventral lateral prefrontal (vIPFC) rsfMRI connectivity.

Conclusions: We present novel data suggesting that inhibitory control and reward cumulatively contribute to RRB severity and that a multi-factor model accounting for their interaction may provide a more robust predictor of clinical RRBs. Inhibitory control and reward processes each are supported by parallel, but interactive brain circuitries involving connections between cortex and striatum that have been heavily implicated in RRB development and severity and are known targets of medications commonly prescribed to individuals with ASD (e.g., selective serotonin reuptake inhibitors; SSRIs). Our data demonstrating associations between reward gain and cortical-striatal
connectivity suggests this may constitute a key mechanism that can be used in future studies to identify predictive outcomes for therapeutics targeting RRBs in ASD.

**436.295 (Poster) Self- Versus Parent-Reported Measures of Sensory over-Responsivity: Associations with Neural Activation in Autism**

*M. Banchik, S. Y. Bookheimer, M. Dapretto and S. A. Green*, (1)University of California, Los Angeles, Los Angeles, CA, (2)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (3)Dept of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA

Background: Sensory over-responsivity (SOR), a heightened negative reaction to aversive sensory stimuli, affects over half of autistic individuals. Despite its prevalence, methods for measuring SOR are still widely understudied and under debate (Cascio et al., 2016). Parent-reported data capture observed sensory related behavior and are often used in younger children who may less accurately report on their sensory experiences. Self-reported data are a more reliable measure of internalizing symptoms such as anxiety in older children, and thus may capture internal SOR experiences beyond what is observable (Baxter et al., 2016). Parent-reported SOR in autistic children is related to heightened sensory-limbic activation during aversive sensory stimulation (Green et al., 2015). However, it is unknown how such neural sensory responses might relate differently to self- versus parent-report of SOR, especially across ages. Understanding how age affects self- versus parent-report can inform decisions about optimizing SOR assessment.

Objectives: To examine the relationship between sensory brain responses and parent- versus self-reported SOR in children through young adults with autism.

Methods: Autistic individuals ages 10 to 22 (n=31, mean=15.7, SD=3.66) and their parents completed the Sensory Processing 3-Dimensions Inventory (SP3D) about their own and their child’s sensory processing, respectively. Each participant underwent a functional MRI (fMRI) scan during which they were presented with mildly aversive tactile and auditory stimuli. FMRI analyses were performed at a threshold of Z=2.3, p>.05. Parent and self-reported SOR scores were entered in two separate bottom-up regressions to examine how each independently predicted brain responses.

Results: Self- and parent-reported SOR were correlated (r=.44, p=.014, and each showed different relationships with brain activation. Lower parent-reported SOR correlated with regions involved in higher-level cognition and regulation (paracingulate, frontal pole, superior frontal gyrus, supplementary motor area; Figure 1). By contrast, lower self-reported SOR correlated with more activation of regions involved in emotion and sensory integration (supramarginal gyrus, angular gyrus, precentral gyrus, and temporal pole; Figure 2). Higher SOR did not predict higher activation in either analysis. Additional analyses with younger participants will investigate the role of age in these two SOR measures.

Conclusions: Correlations between parent- and self-reported scores indicate consistency between both measures, however, each is related to distinct brain responses suggesting they capture different aspects of SOR. The relationship between lower parent-report SOR and activation in regions involved in emotional and behavioral regulation suggests that parent-report may better capture behavioral responses to sensory input, while self-report may capture how a person feels about sensory experiences regardless of behavior. Contrary to prior research (Green et al., 2015), we did not find positive correlations between parent-reported SOR and brain responses, which could be due to the older age of this sample. It is possible that, like with other internalizing symptoms, children become better regulators with age and show fewer outward behaviors, thus accuracy of parent-reported SOR will decrease and individuals may become better reporters of their own internal sensations. The difference between younger and older participants in the relative associations of parent- and self-reported SOR with brain responses will be discussed.

**436.296 (Poster) Sensory Processing Abilities on Adaptive Behavior in Autistic Adults**

*V. V. Izaac, M. Fok, J. R. Bertollo, E. A. DeLucia and A. Scarpa*, (1)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Department of Psychology, Virginia Tech, Blacksburg, VA, (3)Virginia Tech, Blacksburg, VA

Background:

Sensory processing is the ability to process multisensory input for appropriate action (Mueller and Tronick 2020). Previous research indicates that sensory processing difficulties can predict behavioral, communication, and social performance difficulties in autistic children (Lane et al., 2010; Hilton et al., 2007). In autistic adults, sensory processing difficulties, particularly low registration or the tendency to demonstrate a high threshold and not attend to typical sensory elements, mediates the relationship between attention and social responsiveness (Crasta et al., 2020). However, the relationship of sensory processing difficulties and adaptive behavior has not been explored in an autistic adult sample.

Objectives:

To examine the relationship between sensory processing difficulties and adaptive behaviors in autistic adults.
Methods:

Participants were recruited as part of an ongoing assessment database of autistic and non-autistic children and adults maintained by a specialty autism center in southeastern US. The current study included 28 autistic adults (17 females/11 males; M_{age}=30.96 years SD_{age}=11.09; 82% White) who completed an autism assessment consisting of a battery of clinical interviews, behavioral assessments, and questionnaires to inform an ASD diagnosis. Participants completed the Adolescent/Adult Sensory Profile (AASP; Brown and Dunn 2002) and the Adaptive Behavioral Assessment System-3 (ABAS-3; Harrison and Oakland 2015) as part of their assessment. The AASP yields total raw scores across four domains of sensory processing (low registration, sensation seeking, sensory sensitivity, and sensation avoiding), with higher scores indicating more difficulty. The ABAS-3 yields age-normed scaled scores across 10 domains of adaptive behaviors (Communication, Community Use, Functional Academics, Home Living, Health and Safety, Leisure, Self-Care, Self-Direction, Social, Work), with lower scores indicating worse functioning.

Results:

Partial correlations, controlling for gender and race, revealed significant negative relationships between the AASP Low Registration domain and the ABAS-3 subdomains: Communication, Self-Care, Self-Direction, Health and Safety, and Social skills (Table 1); between the AASP Sensory Sensitivity domain and the ABAS-3 subdomains: Communication, Self-care, and Self-Direction; and between the AASP Sensation Avoiding domain and the ABAS-3 subdomains: Communication and Social skills on the ABAS-3 (Table 1). There were no significant correlations between the AASP Sensation Seeking domain and any of the ABAS-3 subdomains.

Conclusions:

Sensory processing abilities can affect social skills, communication, attention, work and academic achievement in autistic adults. Low registration, which impacts self-regulation to sensory input (Machingura et al. 2019), appears to have particularly widespread effects on multiple domains. These findings suggest areas of consideration when developing or delivering treatment with autistic adults, such as including an evaluation of sensory processing abilities and utilizing sensory based interventions.

436.297 (Poster) Sensory Responsiveness and Activity Participation in Autistic Adolescents

C. L. Hilton and K. Ratcliff, Occupational Therapy, University of Texas Medical Branch, Galveston, TX

Background: Participation in daily self-care, academic, and leisure activities is essential to the growth and development of children and adolescents and continues to directly relate to a person’s health and well-being. These meaningful activities, or occupations, support development of interests and identities, well-being and quality of life (Gutman & Schindler, 2007; Hilton & Ratcliff, 2021; Potvin et al., 2012). Studies have shown that autistic children experience lower participation diversity than those without an autism diagnosis, and that these levels of participation decrease over time (Hilton et al., 2008; Potvin et al., 2012; Simpson et al., 2019). Better understanding of relationships between sensory processing and aspects of participation can increase our ability to support improved growth and development, health, and well-being in autistic individuals. Most previous studies examining the relationship between atypical sensory processing and activity participation among children with no autism diagnosis have included children younger than 13 years of age.

Objectives: To examine the relationship between sensory processing and out-of-school activity participation diversity, intensity, and enjoyment in autistic adolescents.

Methods: Forty-two autistic adolescents (male = 36) from age 12 to 18 years (mean = 16.10 years age =30.96 years) who completed an autism assessment consisting of a battery of clinical interviews, behavioral assessments, and questionnaires to inform an ASD diagnosis. Participants completed the Adolescent/Adult Sensory Profile (AASP; Brown & Dunn, 2002) and participation (Children’s Assessment of Participation and Enjoyment; CAPE; King et al., 2004) questionnaires. Relationships between sensory quadrant scores and participation diversity, intensity and enjoyment were examined.

Results: All sensory quadrants scores showed some atypical scores (30 to 35% of scores), except sensation seeking (4.8%). Sensation seeking was significantly positively related with out-of-school activity for most categories of enjoyment and for most categories of diversity and intensity. Among the sensory quadrants, sensation seeking consistently had the strongest relationships with out-of-school activity participation. It had significant relationships with overall activity diversity and intensity. For diversity activity categories, all were significantly correlated with sensation seeking except recreational and self-improvement activities. For intensity activity categories, all were significantly correlated with sensation seeking except recreational activities. For activity enjoyment categories, all were significantly correlated with sensation seeking except for recreational activities. Relationships between individual activity enjoyment and sensory quadrant scores revealed 12 items being correlated with sensation seeking.

Conclusions: Findings indicate that sensory processing patterns are related to participation in the out-of-school activities in which autistic adolescents engage for the sensation seeking sensory quadrant. Sensation seeking was generally similar to or less than most people and was related to several categories of activity participation diversity, intensity, and enjoyment and to enjoyment of various physical activities,
lessons, shopping and arts and crafts. Adolescents with limited participation should be encouraged to explore areas of interest to them involving rich sensory experiences and develop strategies that will allow them to increase their sensation seeking to support skill development, health, and well-being.

436.298 (Poster) Sex Differences in Motor Functioning of Typically Developing and Autistic Youth

S. Bar Yehuda, Y. Estrugo, E. Karin and N. B. Bauminger-Zviely, (1)Faculty of Education, Bar-Ilan University, Ramat - Gan, Israel, (2)Faculty of Education, Bar-Ilan University, Ramat-Gan, Israel, (3)Faculty of Education, Bar-Ilan University, Ramat-Gan, Israel, (4)Faculty of Education, Bar-Ilan University, Ramat Gan, Israel

Background:

Sex differences in prevalence, diagnosis, and core symptoms of autistic individuals have recently gained increasing research attention. Another recently targeted research area is these individuals’ substantial impairment and delay in motor-related development (e.g., Zampella et al., 2021) including gross-motor skills (e.g., poor lower- and upper-limb, locomotor, and gait coordination); fine-motor skills (e.g., ineffective scissor-cutting); and joint action (JA) abilities (e.g., reduced dyadic motor coordination). Though both research areas are of rising interest, the intersectional investigation of sex differences and motor functioning is scarce in children and adolescents with autism spectrum disorder (ASD).

Objectives:

This study compared cognitive able youngsters with ASD to typically developing (TD) age-matched controls to examine individuals’ sex (boys/girls), group (ASD/TD), and motor functioning (gross/fine coordination) as contributing to dyads’ joint motor coordination (JA). First, we investigated group and sex differences in individual and dyadic motor coordination. Next, we analyzed the associations between individual and dyadic motor coordination for each sex. Then, we examined whether the relationship between sex and dyadic motor coordination via individual motor functioning is moderated by group. Understanding the role group and sex differences play in individual and dyadic motor functioning may encourage the development of gender-personalized interventions for autistic youngsters.

Methods:

Study participants included 90 children and adolescents: 46 with ASD (M=11.35yrs, IQ=94.78, 14 girls) and 44 with TD (M=10.82yrs, IQ=108.64, 16 girls). Group and sex differences on age and IQ were nonsignificant. Individual motor functioning was evaluated by the Individual Motoric Observation Scale (IMOS) based on participants’ fine-motor abilities (cutting, nailing) and gross-motor abilities: object use (dribbling, ball throw-and-catch) and locomotion (jumping, heel-to-toe walking, skipping). To evaluate dyadic motor abilities, dyads in each group were paired by sex, IQ, and chronological age. They performed a JA-walking task with their peer (side-by-side walking with legs coordinated with their partner), which was coded for frequency of co-occurring steps.

Results:

A series of GroupXSex ANOVAs yielded significant main effects on Group (ASD < TD) for object use [F(1, 86)=22.75, p=.000], locomotion [F(1, 86)=35.97, p=.000], fine-motor [F(1, 86)=13.94, p=.000], and JA-walking task [F(1, 86)=13.00, p=.001]. Main effect on Sex (boys < girls) emerged only for gross-motor locomotion [F(1, 86)=14.87, p=.000]. Also, significant GroupXSex interactions emerged for locomotion (TD-boys > ASD-boys; ASD-girls > ASD-boys) and for JA (see Figure 1). Significant positive correlations emerged between fine-motor and JA in girls (r=.31, p=.047) and between gross-motor and JA in boys (r=objects=.37, p=.002; rlocomotion=.33, p=.005), beyond group. The moderated mediation analysis indicated a significant sex effect on locomotion with group moderation in boys only; thus, ASD-boys' poor and TD-boys' elevated locomotion ability predicted a better JA-Walking coordination (see Figure 2).

Conclusions:

Boys with ASD are the most vulnerable subgroup in terms of their individual and dyadic motor skills, specifically in gross-motor locomotion, which hinders their ability to jointly act with their peers during a routine walking task. This calls for intervention to promote ASD-boys' social-motor development.

436.299 (Poster) Structure, Stability, and Clinical Correlates of Obsessive-Compulsive Behaviors in Youth with Autism

O. Linkovski, E. K. Spackman, A. Y. Hardan, T. W. Frazier and M. Uljarevic, (1)Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)The Melbourne School of Psychological Sciences, University of Melbourne, Parkville, VIC, Australia, (3)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (4)Psychology, John Carrol University, Cleveland, OH, (5)Melbourne School of Psychological Sciences, Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Parkville, VIC
Background: Distinct obsessive-compulsive behaviors (OCB) are common in youth with autism. However, there is limited understanding about the structure of OCB in autism and how it compares to the structure of this important clinical domain in other populations. Further, majority of previous investigations have focused on broad OCB domains rather than on specific behaviors, thus frequency and correlates of distinct facets of OCB in autism remain poorly characterized. The current study aimed to characterize the frequency and clinical correlates of OCB in youth with autism.

Objectives: To utilize Dimensional Assessment of Repetitive Behaviors (DARB)—a novel, comprehensive assessment of different aspects of restricted and repetitive behaviors, including OCB and large, representative of youth with autism to characterize OCB factor structure, frequency of specific facets of OCB and investigate their associations with key demographic, cognitive and clinical correlates.

Methods: Parents of youth with autism (N=1830) were recruited through the Simons Foundation Powering Autism Research for Knowledge (SPARK) cohort and completed the Dimensional Assessment of Repetitive Behaviors (DARB) and a series of dedicated measures of anxiety, externalizing and internalizing problems and sensory features. The DARB includes a subscale of OCB with 14 items. Item prevalence and severity was reported. We employed exploratory graph analyses (EGA) and confirmatory application of the exploratory structure equation modelling (C-ESEM) to characterize OCB structure. Generalize additive modeling was utilized to characterize the association between identified OCB factors with key correlates including anxiety, dysregulation, hypersensitivity.

Results: Majority of youth with autism endorsed at least one of the OCB. EGA indicated that the following four factors corresponding to hypothesized dimensions showed a good fit to the data in exploratory subsample: contamination, mental neutralizing, checking, and rumination. All items had excellent stability indices (.93-.1.0) and this structure was replicated 94% of the time. C-ESEM was run in confirmatory subsample demonstrating that noted four-factor solution had excellent fit (CFI=.988, TLI=.973, RMSEA=.048; SRMR=.022). Expected factor loadings (.515-.026) were higher than non-expected factors (.024-.370). Generalized Additive Models suggest that the four OCB factors were strongly associated central clinical challenges in OCD – anxiety, dysregulation, and hypersexuality. “Mental neutralizing” factors was also associated with IQ, social skills, and communication. There were no gender differences in OCB dimensions.

Conclusions: OCB are prevalent in autism and their structure is largely similar to OCB in obsessive-compulsive disorder. Although preliminary, findings reported here provide additional insights into clinical correlates of distinct OCB subdomains in autism.

436.300 (Poster) Synchrony and Flexibility in Parent-Child Interactions and Relations with Restricted and Repetitive Behavior
B. J. Byiers, J. Gunderson; C. Roberts, A. F. Dimian and F. J. Symons; (1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)Psychiatry and Psychology, Mayo Clinic, Rochester, MN, (3)University of Minnesota, Minneapolis, MN

Background: Parent-child interactions are critical for social, emotional, and linguistic development. Dynamic systems theory (DST) posits that the resilience of many systems, including parent-child interactions, can be characterized by the system's flexibility. Although flexibility is necessary, predictability is also critical for optimal development (Glynn & Baram, 2019), particularly within negative or hostile interactions. These dynamic features are influenced by the characteristics of both members of the dyad, as well as environmental/contextual factors. Although it has been suggested that restricted and repetitive behaviors (RRBs) may influence how parents interact with their children with autism spectrum disorder (ASD) and other forms of developmental disabilities (DD; e.g., Freeman & Kasari, 2013), no studies have yet investigated associations between RRBs and dyadic flexibility and positive synchrony among young children with DD and their parents.

Objectives: To test the relationships between RRBs and features of parent-child interactions among dyads with young children with DD/ASD.

Methods: Data from 35 parent-child dyads were analyzed. The children were aged between 2 and 6 years, and predominantly male (N = 24; 70.6%). All children met criteria for Global Developmental Delay, and most were diagnosed with autism spectrum disorder (ASD; N = 22; 64.7%). Brief (5-min) unstructured parent-child play sessions were recorded remotely. The quality and structure of the interactions were quantified using a measure of positive dyadic synchrony (i.e., the proportion of the interaction during which both members of the dyad were engaged in positive behavioral states) and a measure of dyadic flexibility (i.e., the rate per minute of dyadic behavioral transitions). RRBs were assessed the Repetitive Behavior Scale – Revised (RBS-R; Bodfish et al., 1999) with subscale scores based on the structure reported by Russell et al., 2019. Generalized linear models were used to regress dyadic synchrony, dyadic flexibility, and the interaction between these factors on each subscale score, controlling for child age, sex, and ASD diagnostic status.

Results: Dyads with ASD diagnoses had higher scores on all four RBS-R subscales and showed lower dyadic synchrony and higher dyadic flexibility, on average. The interaction between dyadic flexibility and dyadic synchrony was significant for the Stereotyped (p = .009), Self-Injurious (SIB; p < .001), and Compulsive Behavior (p = .007) subscales, but not the Ritualistic/Sameness Behavior subscale (p = .591).

For the three subscales with significant interaction effects, overall patterns of results looked similar, with the highest predicted values associated with low synchrony and high flexibility and/or high synchrony and low flexibility.
Background: Sensory processing difficulties are one of the hallmark features of Autism Spectrum Disorder (ASD). Individuals with ASD also exhibit heightened sleep problems as compared to their typically developing (TD) peers. Previous research has found a significant association between sleep and sensory processing difficulties in ASD (Mazurek & Petroski, 2015; Souders et al., 2017), however, it is not clear which aspects of sensory processing drive this relationship. This study investigated the relationship between sleep difficulties and sensory processing in youth with ASD using objective and subjective measures.

Objectives: To assess which domains of sensory processing difficulties are most strongly linked to sleep difficulties in youth with ASD using both objective (actigraphy) and subjective (parent-report) measures.

Methods: Participants were youth diagnosed with ASD (n=17, M_age=8.82, SD=3.41) and TD controls (n=11, M_age=11.09, SD=3.78) ranging from 6 to 17 years. ASD diagnoses were confirmed using the Autism Diagnostic Observation Schedule-2 and the Social Communication Questionnaire. Sensory processing difficulties were measured using the Social Profile-2 (SP-2; Dunn, 2014) or the Adult/Adolescent Sensory Profile (AASP; Brown & Dunn, 2002). Total raw scores for the SP-2 and AASP were converted into percentages to compare across both versions of the measure (Armstrong-Heimsoth et al., 2021). Caregivers reported on their child’s sleep via the Children’s Sleep Habits Questionnaire (CSHQ; Owens et al., 2000). Sleep was objectively measured via actigraphy and averaged over a consecutive 14-day period following assessment.

Results: Preliminary analyses showed that TD controls demonstrated a significant correlation between better actigraph averages of sleep duration (but not efficiency) and lower SP-2/AASP sensitivity (r=-.776, p<.05) and registration scores (r=-.779, p<.05; see Table 1). No significant correlations were detected between the SP-2/AASP and actigraph averages of sleep efficiency and duration in the ASD group. A significant relationship was found between CSHQ-Total and SP-2/AASP Quadrant scores across all groups. Elevated sensory seeking behaviors (r=.503, p=.009), elevated sensory avoiding behaviors (r=.496, p=.010), high sensitivity to sensory stimuli (r=.663, p=.001), and elevated sensory registration (i.e., missed detections of sensory stimuli; r=.548, p=.004) were related to greater sleep disturbance. Post-hoc analyses revealed that these relationships appear to be driven by the ASD group specifically, as higher CSHQ-Total scores were correlated with higher sensory sensitivity (r=.604, p=.017) in this group, especially driven by the tactile (r=.641, p=.025), and oral (r=.657, p=.020) domains on the SP-2/AASP. Further data collection is underway to increase sample size.

Conclusions: Our findings indicate that sensory processing difficulties are associated with sleep problems across all participants regardless of diagnosis. The association between sleep problems and elevated sensory seeking and avoiding behaviors highlight that sleep can be impacted by either form of sensory processing difficulties (i.e., seeking and avoiding), both of which are common in individuals with ASD. The insignificance between sensory processing and actigraphy in the ASD group likely reflects recent literature indicating subjective sleep measures are more consistently related to behavior in ASD than objective measures (Baddam et al., 2018). Future research should investigate how addressing tactile and oral sensitivities through intervention may help improve sleep in youth with ASD.

Background: Restricted interests (RIs), characterized by their intense focus on a restricted range of topics that interfere with other activities, are an under-researched component of autism. Research with autistic adults suggests that RIs are intrinsically motivated and maintained by feelings of competence in the skills related to their interests (Grove et al., 2018). Similarly, typical interests are maintained by fulfilling the psychological needs for competence, relatedness, and autonomy (Deci & Ryan, 1980), and through the integration of an intense passion into one’s sense of identity (Vallerand et al., 2003). Given research suggesting that interests may be used by autistic youth to facilitate social interactions (Sedgewick et al., 2018), it is worthwhile to investigate the purpose and motivations for these interests from autistic youth themselves.

Objectives: To understand and compare the motivating factors for intense interests in autistic and non-autistic children ages 6 to 12 years old.
Methods: Thirty autistic \((m_{age}=9.73, SD=1.91; 20 \text{ boys})\) and 22 non-autistic children \((m_{age}=8.84, SD=1.67; 12 \text{ boys})\) and their caregivers participated in the study. Caregivers completed the Social Responsiveness Survey, 2nd Edition (SRS-2) and a demographic questionnaire. Participants completed the Wechsler Abbreviated Scale of Intelligence, 2nd Edition (WASI-II) and completed a semi-structured interview investigating the characteristics of, and motivations for, interests adapted from Winter-Messiers (2007). The interview explored interest topics, how the interest started, behaviours associated with the interest, where and with whom their interest is pursued, how important these interests are to the youth, and the reasons for engaging in the interest. Interviews lasted between 6 and 21 minutes and were transcribed verbatim. An Interpretative Phenomenological Approach (IPA) was followed in the coding and thematic analysis of transcripts.

Results: Four themes were identified: social engagement and interaction, skill development, internal pressure and obsession, and escape. Many autistic and non-autistic participants indicated that their interests are socially motivated, although certain autistic participants demonstrated an absence of social motivation. The desire to overcome challenges and improve skills motivated interests in both groups and certain autistic and non-autistic participants were motivated to teach other people the skills they developed. Many autistic participants, and certain non-autistic participants reported obsessive thoughts about their interests, which greatly interfered with school, peer relationships, and home responsibilities. Other autistic and non-autistic participants demonstrated an intense engagement in their interests, but these did not interfere with other activities and were harmoniously integrated into their identity and positively contributed to their sense of self. Interests were also used by some to escape and cope with negative experiences such as bullying or family problems (e.g., divorce).

Conclusions: RIs are not disruptive or interfering in all autistic youth and may fulfill psychological needs for relatedness, competency, and autonomy. Interests may also positively contribute to a youth’s self-identity but may become problematic when thoughts become obsessive and the child feels pressure to pursue their interest. A better understanding of the motivation for RIs may help to facilitate peer interactions, social development, and identify sources of poor socioemotional functioning in autistic children.

436.303 (Poster) The Relationship between Picky Eating and Health Outcomes in Autistic and Non-Autistic Young Adults  
R. A. Rivera and L. Bennett, Psychology, University of Rochester, Rochester, NY

**Background:** Concerns surrounding feeding behavior are a common occurrence for autistic people. Among these concerns is picky eating, which can lead to health negative outcomes including disordered eating, obesity, and mental health concerns. Picky eating is well known in autistic children, and our recent work suggested that this continues in young adulthood.

Research on long-term outcomes resulting from picky eating is sparse since most people outgrow the behavior after childhood; however, if pickiness persists into young adulthood for autistic people, it is imperative to better understand how and when it impacts their health. Moreover, research in broader samples of young adults suggests picky eaters may experience additional challenges surrounding eating behaviors, such as social anxiety, which could further exacerbate social difficulties for autistic people.

**Objectives:** This study aimed to broaden our understanding of picky eating for autistic and non-autistic young adults, and identify characteristics that may increase risk for potential mental and physical health outcomes.

**Methods:** The sample comprised 237 young adults aged 18 to 25, including 120 autistic and 117 non-autistic individuals. Food pickiness was assessed using a comprehensive assessment of preference and frequency of eating individual food items, assessment of preference based on food qualities, food neophobia (e.g., refusal to try new foods), and self-reported food pickiness (e.g., preferring variety or sameness in daily diet). Health outcomes assessed included: fear and avoidance of social situations using the Liebowitz Social Anxiety Scale, BMI, and current eating disorder diagnoses.

**Results:** Autistic young adults reported greater picky eating compared to non-autistic controls across multiple measures: self-reported picky eating \((p = .006)\), individual food item selectivity \((p = .002)\), food quality selectivity \((p < .001)\), and food neophobia \((p < .001)\). Autistic participants also reported significantly greater social anxiety \((p < .001)\), including both fear of \((p < .001)\) and avoidance of social situations \((p < .001)\), and were also more likely to report an eating disorder diagnosis than non-autistic young adults \((p = .001)\). Additionally, those with an eating disorder reported more food pickiness \((p = .003)\). Consistent with our hypothesis, self-reported picky eating and overall social anxiety were significantly correlated \((p = .009)\). Additional planned analyses further examine the structural model of diagnostic status, food pickiness, and health outcomes to determine how autistic picky eaters may differ from non-autistic picky eaters in young adulthood.

**Conclusions:** This study improves the understanding of food pickiness in autistic and non-autistic young adults by assessing multiple picky eating constructs and their relationship to mental and physical health outcomes. The results of this study underscore the need to assess picky eating in autism across the lifespan and to identify individuals who may have a higher likelihood of negative health outcomes related to food pickiness. Moreover, this can help inform development of evidence-based interventions related to picky eating in young adults.

436.304 (Poster) The Relationship between a Novel Clinician-Administered Sensory Measure and Analogous Parent-Report Measure in Children with Autism Spectrum Disorder
**Background:**

The nervous system takes in a range of stimuli from the environment, constantly adjusting the strength of response based on perceived importance of incoming stimuli. The DSM-5 includes altered sensory reactivity in its criteria for autism spectrum disorder (ASD). Most existing assessments measuring sensory behaviors (e.g., Sensory Profile 2 (SP2)) rely on caregiver report, although the recently developed Sensory Assessment for Neurodevelopmental Disorders (SAND) includes a clinician-administered observational assessment.

**Objectives:**

We examined the relationship between clinician-administered and parent-report assessments of how children on the autism spectrum, children with sensory processing concerns without ASD (SPD), and typically developing (TD) children respond to sensory inputs. We hypothesized scores of seeking on the SP2 would positively correlate with seeking scores on the SAND. We predicted that seeking and hyporeactivity behaviors would be positively correlated, especially in ASD, as this cohort may seek more intense stimuli to receive similar input.

**Methods:**

SP2 and SAND data were collected on 58 children between the ages of 3-4 years old (29 ASD, 11 SPD, 18 TD). The SP2 includes questions for parents about a child’s responses to stimuli across sensory modalities (Auditory, Visual, Touch, Movement, Body Position, and Oral). The SAND involves a clinician-administered observation and corresponding caregiver interview that quantifies a child’s hyporeactivity, hyperreactivity, and seeking across visual, tactile, and auditory modalities. To enable comparison between the measures, hyporeactivity on the SP2 was defined as the sum of Seeking and Registration quadrants, and hyperreactivity as the sum of Avoiding and Sensitivity quadrants. Pearson correlations were used to evaluate the association between corresponding SP2 and SAND domains, and between different domains on the same assessment. Given our sample sizes, we focus on analyses involving children from all cohorts, although future analyses will examine these correlations within each individual cohort.

**Results:**

There was a positive correlation between the SP2 and SAND in the seeking domain (r = 0.577, p < .01) and hyperreactivity domain (r = 0.446, p < .05), but not in the hyporeactivity domain. Paradoxically, the hyporeactivity and hyperreactivity domains on the SAND measure are positively correlated (r = 0.384, p < .05).

**Conclusions:**

The correlation between seeking domains & hyperreactivity domains on both measures suggests parents’ perception of these behaviors in their children corresponds with the clinician-administered observation and corresponding caregiver interview in the SAND. The positive correlation between hyporeactivity and hyperreactivity domains on the SAND mirrors the positive correlation previously seen on preliminary data from our group using the SP2. This paradoxical finding may suggest that children who over-respond to certain stimuli may under-respond to others, or that neural circuit mechanisms leading to sensory over-responsivity at some times may lead to under-responsivity at others. More effective classification of sensory preferences will enable better analysis of brain-based signatures; these profiles will guide us towards a more robust understanding of underlying biological mechanisms in sensory behaviors.

436.305 **(Poster)** The Relationships between Emotions about Stimming and about Special Interests in Autistic High School and College Students

**Background:**

Stimming and special interests (SIs) are common characteristics of autistic individuals. Stimming and SIs share some common functions, including their use as emotion regulators (Kapp et al., 2019; Winter-Messiers, 2007). SIs and stimming have been found to trigger feelings of enthusiasm and joy (Winter-Messiers, 2007). However, stimming is often stigmatized (Kapp et al., 2019).

**Objectives:**

1. Analyze if stimming and SIs both produce more positive than negative emotions (Kapp et al., 2019; Winter-Messiers, 2007).
2. Assess whether stimming produces fewer positive vs. negative emotions than SIs, potentially due to the stigma surrounding stimming (Kapp et al., 2019).
3. Discover whether students characterize stimming and special interests as coping mechanisms (e.g., dispel negative emotions).
4. Assess whether older students are more likely to have identified their SI special interest than younger students because they will have had more time to develop their interests.

Methods:

23 autistic students (M_age= 16.78; Table 1) who participated in a game design and employment workshop answered questions about stimming and SIs via a survey before and after the workshop. Responses were qualitatively coded by independent coders. Inter-rater reliability >88.8%.

Results:

Most students (n=19) already knew their SI(s) before the workshop. There was no relationship between age and knowing one’s SI (p=.65). 56% of participants reported STEM SIs; 13% reported creative and natural world SIs.

Participants reported more positive feelings about SIs than stimming (p=.0003; Table 2). Participants more frequently reported positive feelings about SIs (p=.0026), but less frequently reported positive feelings about stimming (p=.0347) than would be expected by chance. Participants reported negative feelings about stimming (p=.0026) and SIs (p=.01) less frequently than would be expected by chance, with no difference between the two (p>.05).

Participants reported using SIs for emotion regulation less frequently than would be expected by chance (p=.0005), and reported using stimming for emotion regulation as frequently as would be expected by chance (p=.20), with no differences between the two (p=.16). There was a negative correlation between age and use of stimming for emotion regulation (r(21)=-.69, p<.001) but no relationship between age and use of SIs for emotion regulation (p=.86).

There was a negative correlation between age and positive feelings associated with stimming (r(21)=-.54, p=.008) but no correlation between age and positive feelings associated with SIs (p=.49).

Conclusions:

Findings provide limited evidence for the use of either stimming or SIs for emotion regulation. SIs triggered more positive feelings than stimming. Older students were less likely to use stimming as an emotion regulation tool, and to have positive feelings while stimming. This could be due to a heightened awareness of the stigma surrounding stimming. The small sample size and high representation of STEM SIs limit the generalizability of findings. Another limitation is that this research is correlational, and thus, cannot determine if stimming or SIs directly cause the emotions participants reported. Future research should gather larger samples and evaluate if stimming and SIs cause specific emotions.

436.306 (Poster) Trajectories of Sensory Symptom Severity and Core Symptom Severity in Autism Spectrum Disorders

L. Colomar, M. Parellada, B. Oakley, E. Jones, (1)Instituto de Investigación Gregorio Marañón, Madrid, Spain, (2)Child and Adolescent Psychiatry, Instituto de Investigación Gregorio Marañón, Madrid, Spain, (3)Institute of Psychiatry, Psychology and Neuroscience, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom

Background: The study of changes in symptom severity across time is a key factor in Autism Spectrum Disorder (ASD) research, as it is considered a neurodevelopmental condition. So far, the literature on severity symptoms trajectories in ASD shows mixed results. A commonly reported pattern in previous studies shows that most of the participants (>80%) follow a stable symptom trajectory, while a minority of the sample shows significant change (improvement or worsening) in their symptoms. However, some recent studies have reported higher rates of change, with around 50% of participants following a changing severity symptom trajectory.

Objectives: Our goal is to study the trajectories of symptom severity in a sample of participants with ASD and to explore the relationship between them. We focus on three main areas: sensory alterations, social-communicative skills, and restrictive interests and repetitive behaviours.

Methods: 457 participants with ASD were evaluated longitudinally as a part of the multi-centre EU-AIMS Longitudinal European Autism Project (Charman et al., 2017, Loth et al., 2017). The Short Sensory Profile (SSP), the Autism Diagnostic Observation Schedule (ADOS), and the Social Responsiveness Scale, Second Edition (SRS-2) parents form were applied at two time points, 12 to 24 months apart. We studied trajectories of symptom severity by estimating the individual change per year for each symptom and establishing a threshold of significant change.
Results: We used a hold-out validation approach (70%-30% for training and hold-out sets). The training sample consisted of 317 participants with ASD (age range: 6-30.6 years, 28.7% females). Different sub-samples were used for the analyses based on the availability of scores at the two time points for each participant and test (SSP, ADOS, SRS-2). Regarding sensory symptoms (n=88), the 76.14% of the sample followed a stable severity trajectory, while a 14.77% and 9.09% showed improving and worsening trajectories, respectively. Symptom stability measured using the ADOS (n=160) ranged from the 57.7% to the 64.37% of the sample, with the ADOS Restrictive Repetitive Behaviours subscale (ADOS RRB) showing the greater proportion of change. Finally, almost 70% of the participants showed stable trajectories for the symptom severity using the SRS (n=92). Furthermore, we found a significant correlation (r=-0.65, p<0.05) between the change in SRS-2 total scores and the change in SSP total scores.

Conclusions: In this study we explored the severity trajectories for sensory, social, and restrictive repetitive behaviours symptoms in a sample of participants with ASD. In general, participants showed stability in their symptoms, with the proportion of participants following stable trajectories for the different tests ranging from 57.7% to 76.14%. Besides, we found that the change in severity of sensory symptoms across time was directly correlated with the change in core ASD symptoms.

436.307 (Poster) Understanding Family Mealtime Challenges in Autistic Children: The Role of Feeding Self-Help Skills
H. J. Laufenberg, G. Sylvester, B. M. St John and K. K. Ausderau, University of Wisconsin-Madison, Madison, WI

Background: Self-feeding is an important milestone in a child’s development with independent self-help skills emerging by 18 months of life. Up to 84% of autistic children have feeding difficulties with the most common challenge discussed in the literature involving sensory-based food selectivity. However, essential aspects of feeding and the mealtime process, such as independence in self-help skills, have not been well characterized in autistic children or considered in the context of independence during family mealtime.

Objectives: The purpose of this study was to characterize feeding self-help skills using a large national sample of young autistic children with feeding challenges and explore the relationship between child independence and family mealtime.

Methods: The cross-sectional study uses data from the Survey for Characterizing Feeding Challenges in Autistic Children. Data from 427 caregivers of autistic children (ages 2 to 12 years) with feeding challenges was included. Children were an average age of 8.42 years old (SD = 2.95 years). The Feeding and Eating in Autisim Together (FEAST) assessment was used to assess feeding challenges. Descriptive statistics were used to describe child’s feeding challenges including level of independence in feeding and self-help skills. A composite score of child’s feeding independence was created using independence in four feeding self-help skills (use of fork, spoon, open cup, and straw). Pearson’s r correlations were used to explore relationships between feeding independence composite and other family mealtime variables.

Results: Data collected identified 21.78% of autistic children needed assistance in at least three of the four measured self-help skills (fork, spoon, open cup, and straw), while 53.86% needed assistance in at least one area. See Table 1 for additional self-help descriptives. However, child age was only moderately correlated with the self-help composite score (r= 0.32, p<0.001) and mildly correlated with child eating independently (r=0.17, p<.001). Small significant correlations were identified between the self-help composite score and mealtime variables including caregiver preparing a separate meal for the child (r=−0.18, p<.001), child willingness to accept new foods when offered (r=0.14, p<.001), and child’s feeding challenges disrupting family mealtime (r=−0.10, p=0.04). Additional significant relationships between child independence and mealtime variables will be presented.

Conclusions: Challenges with independent feeding in autistic children can significantly impact family mealtime and adult support required for successful eating. While the majority of autistic children in the study were mostly independent in self-help skills, many required assistance in skills that would be expected for the included age range of 2 to 12 years. In our sample, there was only a moderate correlation between self-help skills and age, which could indicate delays in self-help skills are a significant feeding concern. Future research focused on interventions targeting self-help skills to support increased independent feeding during mealtime could greatly benefit both the development of the child and the success of family mealtime.

436.308 (Poster) Understanding Sensory Fluctuations in Autistic Adults; Profiles, Causes and Coping Strategies.
D. Ropar, E. Howard and R. Newport, (1)University of Nottingham, Nottingham, UNITED KINGDOM, (2)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (3)University of Loughborough, Loughborough, United Kingdom

Background: Research suggests autistic individuals can experience both hyper- and hyporeactivity within a single sensory domain (Elwin et al., 2012). However, these fluctuations in sensory experience are not currently captured in commonly used sensory questionnaires (e.g. Sensory Profile 2 and Sensory Perception Quotient). Additionally, most sensory assessments focus on vision, audition, olfaction, gustation, tactile, but neglect interoception, vestibular, and proprioception. To date, there has been no research exploring experiences of sensory fluctuations across the full range of sensory modalities. It is key to understand these nuances of sensory experience, not only because it significantly impacts on autistic people, but also because it allows for the development of theoretically sound and valid assessment tools.
Objectives: A mixed methods (quantitative/qualitative) approach was used to answer five questions: 1) what is the frequency of hyper- and hyporeactivity across all senses; 2) what is the frequency of sensory fluctuations across all senses; 3) how do autistic adults experience sensory fluctuations 4) what are perceived causes of sensory fluctuations 5) what strategies are used to manage sensory fluctuations.

Methods: Thirty-eight autistic adults (24 women, 5 men, 9 non-binary, M\_age=29.29) completed a sensory questionnaire online. Diagnosis was confirmed using Ritvo Autism and Asperger Diagnostic Scale-14 (RAADS-14) and the Autism Quotient-10 (AQ-10). Content analysis was used on closed questions and inductive thematic analysis was used to generate themes from the open questionnaire data to provide a rich picture of sensory experience in autistic individuals.

Results:

</tr>
</tbody>
</table>

Conclusions:

The figure shows sensory differences and sensory fluctuations are prominent in autistic adults. Hyporeactivity was most reported for internal senses (proprioception/interoception/vestibular) whilst hyperactivity was most reported for external senses (vision/olfaction/audition/gustation/touch). The impact of these sensory differences is wide and complex, affecting physical, mental, and social well-being. The perceived causes of sensory fluctuations are complex and can interact with coping mechanisms. These findings emphasise the need to include sensory fluctuations in theoretical frameworks and in measures of sensory experience.

436.309 (Poster) Using Immersive Virtual Reality (VR) to Understand the Inner Perceptual World of Diagnosed Autistic Participants: Multiple Case Studies

S. Savickaite, R. Airlie, N. McDonnell, and D. R. Simmons, (1)School of Psychology, University of Glasgow, Glasgow, United Kingdom, (2)University of Glasgow, Glasgow, United Kingdom, (3)School of Philosophy, University of Glasgow, Glasgow, United Kingdom, (4)School of Psychology and Neuroscience, University of Glasgow, Glasgow, UNITED KINGDOM

Background:

Sensory reactivity in autistic individuals, and how this differs from that of non-autistic individuals, has been extensively documented in the literature (for a recent example, see MacLennan, O’Brien & Tavassoli, 2022). It could therefore be argued that the perceptual experience of autistic individuals, and how it is interpreted, is qualitatively different. Links between sensory information processing and cognitive processing have led to theories, such as Weak Central Coherence and Enhanced Perceptual Functioning, which attempt to explain distinctive autistic performance in cognitive tasks. Historically, this ‘above average’ and/or distinct behaviour was described in terms of “islets of ability.” Recent discoveries have given rise to the concept of “autistic intelligence”, which is defined as a qualitatively different type of intelligence that relies less on verbal comprehension than standardized tests (Russell et al, 2019; Roth, 2020).

Virtual Reality (VR) techniques have the potential to create highly immersive environments that are realistic, safe and highly configurable. In the last decade, many branches of psychology have embraced this new technology to conduct easily regulated and ecologically valid experiments. Building on our previous work (Savickaite, et al, INSAR, 2020) using VR to explore autistic perceptual differences, we broadened our scope in an attempt to understand how tools available in VR can help autistic individuals communicate their perceptual experiences.
Objectives:

Our aim was to use the open-source VR drawing package – OpenBrush, to help diagnosed autistic participants describe their perceptual experiences.

Methods:

A total of 6 autistic participants were recruited for this study (4 male and 2 female). Mean age of participants was 22.66 years (SD = 3.44). Participants self-reported their autism diagnoses and also spoke about their diagnosis journey.

OpenBrush allows the user to draw freely in three dimensions in VR and has, in addition to standard pen-like tools, effects like snow and flames. Participants were asked to draw using this tool with minimum instructions. Experimenters provided some standard prompts, similar to those utilised in art therapy, to help participants get started. Videos of the drawings and audio of participants’ comments were recorded and later analysed using reflexive thematic analysis (Clarke et al, 2015).

Results:

Differences in creative styles and perceptual experiences were revealed. Three themes emerged from the VR experience of the participants: immersion, creativity, and escapism. In terms of daily experiences, three other themes emerged: autistic perception, masking/camouflage, and communication (see Figure 1).

Examples of drawings produced by participants are presented Figure 2.

Conclusions:

This exploratory study demonstrates how VR can be successfully applied to qualitative studies on autistic perception. Autism narratives clearly differ between individuals and settings. Bringing positive aspects of autism (i.e. less focus on ‘impairments’ or ‘deficits’) to the forefront could thus aid in the construction of a more nuanced narrative. In our study we demonstrate how free drawing can bridge the communication gap, allow for free self-expression, useful self-exploration and support creativity.

Cognitive Neurophysiology Lab, Department of Neuroscience, University of Rochester School of Medicine and Dentistry, Rochester, NY, 4. Department of Applied Physiology and Kinesiology, University of Florida, Gainesville, FL, 5. Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS

Background:

Sensorimotor integration deficits are highly prevalent in persons with autism spectrum disorders (ASD). Specifically, sustained, online motor control is impaired, and it is associated with the severity of core ASD symptoms. Online motor control relies both on integrating sensory feedback with motor output and forming memories of recent sensorimotor experiences. Our prior studies of visually guided precision gripping, found increased variability and regularity of force output in persons with ASD relative to controls, especially when visual feedback was disrupted, indicating that patients are over-reliant on visual feedback for online, precision motor control. When visual feedback was removed and participants attempted to maintain the same force level, patients showed a greater rate and magnitude of force decay than controls, suggesting that impaired visuomotor memory also may contribute to online motor deficits in ASD.

Objectives:

The present study aims to clarify the contributions of visual feedback (force variability, regularity, 0-4Hz power) and visuomotor memory (force decay) processes to online motor deficits in persons with ASD.

Methods:

Sixty-eight participants with ASD (21F, IQ: 103.8±15.9) and 44 controls (28F, IQ: 112.0±11.8), aged 9-35 years, completed tests of precision gripping with (Vision) and without (No Vision) visual feedback. For Vision trials, participants pressed on force sensors with their dominant hand index finger and thumb while viewing a stationary target bar and a force output bar that moved up with increased force. They were instructed to press so the force output bar reached and matched the target bar throughout the 15s trial. No Vision trials started...
the same way, but after 3s, the force output bar disappeared. Participants were instructed to continue pressing at the same level until the end of the trial (12s later). To assess visual feedback processing, force variability (coefficient of variation), regularity (sample entropy), and 0-4Hz power were examined. Force decay latency, slope, and magnitude were examined to assess visuomotor memory.

Results:

Relative to controls, persons with ASD showed elevated force variability across conditions ($t_{(44.91)} = 6.92$, $p < 0.0001$) and increased force regularity in the Vision condition only ($t_{(50.00)} = 2.03$, $p = 0.043$). Overall, the ASD group showed greater decay magnitude ($t_{(50)} = 2.15$, $p = 0.034$) and a greater age-associated reduction in decay magnitude than controls ($t_{(50)} = 2.05$, $p = 0.045$). Decay slope and latency showed no group effects. Moderate correlations were observed between autism severity (ADOS-CSS) and force variability ($r_{\text{Vis}} = -0.34$, $p = .02$; $r_{\text{NoVis}} = 0.29$, $p = .05$) and regularity ($r_{\text{Vis}} = -0.29$, $p = .05$).

Conclusions:

Our finding that the ASD group showed deficits in force regularity only when visual feedback was available supports that visual feedback processing, independent of visuomotor memory, contributes to online motor control deficits in patients. Greater decay magnitude and corresponding age-related reductions in patients relative to controls suggests that atypical neurodevelopment of visuomotor memory may also contribute. However, decay slope—a more direct measure of visuomotor memory—showed no group differences, limiting the interpretation of visuomotor memory impairment. Additionally, only force variability and regularity, particularly in the Vision condition, were associated with ASD symptomatology, emphasizing the importance of visual feedback processing issues to online motor deficits and to understanding neurodevelopmental mechanisms of ASD.

436.311 (Poster) Visual Motion Perception during Visually Guided Motor Behaviors in Autism Spectrum Disorder

E. K. Bojanek, W. S. McKinney, J. Bartolotti, K. E. Unruh, and M. W. Mosconi, (1)Cognitive Neurophysiology Lab, Department of Neuroscience, University of Rochester School of Medicine and Dentistry, Rochester, NY, (2)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, Kansas Center for Autism Research and Training (KCART), University of Kansas, Lawrence, KS, (3)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS, (4)University of Kansas Medical Center, Kansas City, KS, (5)Kansas Center for Autism Research and Training (K-CART), University of Kansas Life Span Institute, Lawrence, KS

Background: Sensory and sensorimotor issues are common in autism spectrum disorder (ASD). Specifically, motion perception is altered in ASD which can lead to disruptions in multiple aspects of development including impairments in visually guided motor behaviors. However, neurophysiological processes associated with visual motion abilities and their impact on visuomotor behavior in ASD remain unclear as examination of motion perception during motor behavior is limited.

Objectives: Develop a more mechanistic understanding of visuomotor impairments in ASD by studying visual motion processing during behavior and functional brain connectivity.

Methods: Fifty-nine autistic individuals (ages 10-33 years) and 44 age-matched neurotypical controls completed a lab-based visuomotor task. A subset of these individuals also completed an fMRI visual motion perception task. During the lab visuomotor task, participants pressed opposing load cells with their thumb and index finger. Participants viewed a static red target bar and a white force bar and were instructed to press the load cells when the target bar turned green, so that the force bar reached the level of the target bar. Participants completed the task across three visual gain conditions, in which the vertical distance the force bar moved in response to force output was manipulated. We examined the variability and complexity of the force output across visual gain conditions. During the fMRI visual motion task, participants passively viewed visual stimuli moving similar to the lab task, but they did not press. We examined brain activation and functional connectivity in key visual motion regions (V1, V3, and V5) during visual motion processing in contrast to rest. We also examined how visuomotor behavior, brain activation, and brain connectivity each were associated with sensory and clinical issues in ASD.

Results: During the visuomotor task, autistic individuals showed decreased force complexity relative to neurotypical controls during lower visual gain conditions only (group x visual angle: $p = 0.007$). There were no differences in force variability. During the fMRI visual motion task (visual motion vs. rest), there were no differences between autistic individuals and neurotypical controls in brain activation or connectivity in V1, V3, or V5; however, autistic individuals showed increased caudate activation compared to neurotypical controls. Decreased force complexity was associated with more severe social communication difficulties in ASD ($r = -0.53$, $p = .002$). Greater change in force complexity across gain conditions was marginally associated with more severe self-reported sensory sensitivity in ASD ($r = 0.40$, $p = .066$).

Conclusions: Our finding of reduced force complexity during lower gain conditions suggests that autistic individuals show an overreliance on visual feedback to carry out precision motor behaviors. Counter to our hypothesis, visual motion processing networks functioned similarly in ASD and neurotypical controls, though increased caudate activation in ASD suggests a greater reliance on subcortical networks to inhibit planned motor behaviors during passive viewing of motion. These findings indicate that differences in visually guided motor behaviors may reflect alterations of visuomotor brain networks rather than alterations in basic visual processing. We also found

1060
associations between visuomotor behaviors and core sensory and clinical symptoms implicating shared neural mechanisms underlying motor impairments and core ASD symptoms.

436.312 (Poster) What Are the Repetitive Behaviors That Discriminate Young Autistic Children from Typical Children across Early Development? a Direct and Quantified Behavioral Observation

A. Ethier1, V. Courchesne1, M. Mottron, M.D.1 and C. Jacques2, (1)Université du Québec en Outaouais, Gatineau, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l’Île-de-Montréal, Montréal, QC, Canada, (3)Centre for Addiction & Mental Health (CAMH), Montréal, QC, Canada, (4)CAMH : Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)Centre de recherche du CIUSSS-NIM, Montréal, QC, Canada

Background: Repetitive behaviors (RBs) are a central part of autism spectrum diagnostic (APA, 2013) although they are also documented in typical development (Leekam et al., 2007; Uljarević et al., 2017). Based on a repertoire of RBs, Jacques et al. (2018) demonstrated that compared to age-matched typical children, young autistic children exhibited a greater frequency and duration of three repetitive behaviors: hand flapping, close gaze at objects and arm movements. However, this study did not investigate the trajectory of the RBs in young children, and how their putative specificity interacts with age.

Objectives: Determine if specific RBs discriminate young autistic children from typical children and if these group differences change with age.

Methods: One hundred and twenty-one autistic children aged from 26 to 74 months (M=50.86) and 110 typically developing children aged from 19 to 73 months (M=44.39) were exposed to the Montreal Stimulating Play Situation (MSPS; Jacques et al., 2018). The 48 RBs listed in a previously built repertoire (see Jacques et al., 2018) were coded by two naïve raters using the Observer XT 11. Comparative multifactor analyses were conducted including individual discriminatory effects and interaction effects of group and age. Bonferroni corrections led to an adjusted alpha level of 0.001.

Results: A significant group by age interaction was observed for frequency of throwing objects, which increased in typical children, but remained low and stable in autistic children. There were no other significant group by age interactions. A main effect of group was found for the duration of close gaze at objects and spinning around and for the frequency of arm movements, putting objects in mouth, putting objects on cheeks, lateral glances at objects and close gaze at objects. All the above behaviors were displayed more in the autistic group. Finally, there was a main effect of age for the duration of holding objects in hands as well as for grouping objects according to their perceptual properties and for the frequency of flapping and spinning objects. In both groups, holding objects in hand and hand-flapping diminished with age, while grouping objects according to their perceptual properties and spinning objects increased with age.

Conclusions: Group effects are observed for several RBs. Some of these RBs, like arms movements and visual explorations, but also other perception-based exploration behaviors, seem to be very rare in typical development. Variation in the trajectory of behaviors by age in both groups underscores the importance of accounting for age when studying RBs. These results highlight the importance of characterizing and quantifying individually frequency and duration of RBs.

436.313 (Poster) What Motor Features Can Tell Us about Daily Living Skills and Brain Structures in Autistic and Non-Autistic Individuals

B. G. Travers1 and O. J. Surgent2, (1)University of Wisconsin Madison, Madison, WI, (2)The University of Wisconsin-Madison, Madison, WI

Background: Motor features are commonly reported in autistic individuals (Bhat et al., 2020) and have been linked to differences in adaptive behaviors (Fears et al., 2022), and daily living skills (Travers et al., 2017). Moreover, motor features may serve as a window into how the brain develops in autistic and non-autistic individuals. However, we are only beginning to understand which specific daily living skills may be most impacted by motor features and which specific brain structures may be underscoring motor differences in autistic individuals.

Objectives: 1) Identify how daily living skills and motor performance are related in autistic and non-autistic children, examining which specific daily living tasks are most highly linked to motor skills. 2) Use diffusion weighted and structural magnetic resonance imaging (MRI) to identify which brain structures are related to motor performance in autistic individuals, using a randomized controlled trial (RCT) of balance training.

Methods: Study 1 (Travers et al., 2022) used a descriptive study design to examine the associations between caregiver-reported daily living skills (Vineland) and standardized motor assessment using the Bruininks-Oseretsky Test of Motor Proficiency (BOT-2 short form) in 101 children (37 autistic children), ages 6.0-10.9. Study 2 (Surgent et al, 2021) used an RCT design to examine pre- and post-training changes to daily living skills and the white matter of the brain in 34 autistic and 28 non-autistic adolescents.
Results: Study 1: Multiple regression examined daily living standard scores as a function of BOT-2 standard scores (controlling for IQ) and found a significant quadratic relationship between motor and daily living skills. Ordinal logistic regression with the Vineland items showed that motor skills were associated with tasks of dressing, bathing, education, health management, cleaning/organization, meal preparation/cleanup, and safety. Study 2: Whole-brain voxel-based analysis found unique brain structures associated with balance training in the autistic group compared to the non-autistic group (fdr-corrected p<.05), even though behavioral balance gains were nearly identical (p=.88).

Conclusions: These two studies across two unique samples suggest that motor features are related to daily living skills (specifically to dressing, bathing, education, health management, cleaning/organization, meal preparation, and safety), but that 6 weeks of intensive balance training was not sufficient to increase daily living skills in adolescents. The brain imaging results further suggest unique alignment of brain-behavior relations in autistic individuals compared to non-autistic individuals, suggesting distinctive brain organization for balance performance in autism. Future research is needed to understand how distinctive brain-motor relations in autistic individuals develop from infancy to childhood and through adulthood. Taken together, these studies highlight the complex ways that motor behavior may influence daily activity and how motor behaviors may reflect unique brain organization in neurodiverse populations.

436.314 (Poster) Zooming on the Spectrum: Exploring the Relationship between Zoom Fatigue, Autistic Traits and Sensory Sensitivity

T. van Laarhoven, S. Bögels, M. Swerts and J. Vroomen. (1)Cognitive Neuropsychology, Tilburg University, Tilburg, Netherlands, (2)Department of Communication and Cognition, Tilburg School of Humanities and Digital Sciences, Tilburg, Netherlands

Background: Since the onset of the COVID-19 pandemic, the use of video conferencing (VC) has become an integral part of everyday life. Its implementations range from staying in touch with loved-ones, to work-related meetings, remote learning, and e-health services. While VC appears a convenient alternative to meeting face-to-face for many, it may be challenging for others. VC is known to induce symptoms of mental and physical exhaustion. One potential factor that may contribute to these symptoms, collectively known as Zoom fatigue, is that compared to face-to-face meetings, VC requires increased cognitive and sensory demands, which in turn may lead to sensory overload. The extent to which Zoom fatigue is experienced varies from person to person, but individuals with autism spectrum disorder (ASD) in particular may be more susceptible to Zoom fatigue. The socio-communicative symptoms associated with ASD include atypical eye gaze patterns, ineffective use of nonverbal cues, and alterations in sensory processing, including hyper- and hyposensitivity to sensory stimulation. All of these symptoms may pose as potential risk factors for zoom fatigue.

Objectives: This study aimed to examine the relationship between symptoms of Zoom fatigue, autistic traits and sensory sensitivity.

Methods: A large online survey was conducted among older adolescents and young adults with typical development and individuals in the same age range with a clinical diagnosis of ASD. Zoom fatigue was measured using the recently developed Zoom Exhaustion & Fatigue (ZEF) scale. Autistic traits were measured using the Autism Spectrum Quotient (AQ), and sensory sensitivity was measured using the Glasgow Sensory Questionnaire (GSQ). Bivariate and partial correlation coefficients were calculated to determine the relationships between these outcome measures.

Results: Data collection is ongoing and will be completed by February 2023. Preliminary data from 225 participants (184 females, 35 males, 6 non-binary, mean age: 19.45, range: 17-30 years) showed that increased autistic symptomatology was associated with increased symptoms of Zoom fatigue (r = .41, p < .001). This relationship remained significant after controlling for sensory sensitivity (r = .15, p = .03). These preliminary results suggest that, in addition to increased sensory demands, individuals with ASD may face unique challenges in the use of VC. Future analyses on the final sample will be presented at the conference, and will examine whether sensory sensitivity may act as a mediator between autistic traits and zoom fatigue.

Conclusions: Given that VC is now an intricate part of our society and is becoming increasingly more common in education and mental health services, it is important to examine how this increased digitalization of society affects the psychological well-being of neurodiverse populations such as individuals with ASD. Our preliminary results suggest that individuals with ASD may be more susceptible to symptoms of mental and physical exhaustion induced by VC. While more research is needed to examine the underlying mechanisms of this relationship, these findings may help increase awareness of neurodiversity in the field of computer-mediated communication, and may provide an impetus for the development of neurodiversity-sensitive solutions aimed at making computer-mediated communication more accessible and inclusive.

436.315 (Poster) Psychometric Evaluation of the Multidimensional Inventory of Sound Tolerance in Adults (MIST-A): A Novel Self-Report Measure Assessing Decreased Sound Tolerance Symptomatology in Autistic and Non-Autistic Adults

Z. J. Williams, D. J. Barrett, P. Dwyer, B. Keceli-Kaysili, C. J. Cascio and T. G. Woynaroski. (1)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (2)Neuroscience Undergraduate Program, Vanderbilt University, Nashville, TN, (3)Department of Psychology, Center for Mind and Brain, UC-Davis, Davis, CA, (4)Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN, (5)Department of Psychiatry and Behavioral Science, Vanderbilt University Medical Center, Nashville, TN, (6)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN
Background: Difficulty tolerating environmental sounds, referred to hereafter as Decreased Sound Tolerance (DST), is among the most prevalent and impairing sensory features of autism, occurring to a clinically significant degree in an estimated 50–70% of the autistic population (Williams et al., 2021). Despite a sizable body of literature describing this symptom cluster and its prevalence in autism, there has been relatively little work evaluating the psychometrics of measures of DST for use in autistic individuals. Moreover, measures developed to date have typically focused on only one domain of DST symptomatology rather than tapping symptoms of all major disorders of sound tolerance [i.e., hyperacusis (the perception of sounds as excessively or painfully loud), misophonia (intense and excessive emotional responses to specific “trigger” sounds such as chewing, tapping and, sniffing), and phonophobia (a specific phobia of sound)].

Objectives: To assess the psychometric properties of the Multidimensional Inventory of Sound Tolerance in Adults (MIST-A; http://dx.doi.org/10.13140/RG.2.2.10492.28802/1), a novel self-report measure of DST designed to assess hyperacusis, misophonia, and phonophobia symptoms simultaneously in both autistic and non-autistic adults (including adults with other neurodevelopmental conditions [e.g., ADHD] and adults with clinically significant DST unrelated to a neurodevelopmental condition).

Methods: Data were drawn from several large-scale survey studies of general-population adults and various clinical populations (total N=2225), including 1470 general-population US adults recruited from the Prolific crowdsourcing platform (Mage=32.46±12.51 years, 51.3% female sex, 2.2% autistic), 447 adults with a neurodevelopmental condition (i.e., autism and/or ADHD; Mage=34.59±11.36 years, 74.9% female sex, 64.0% autistic, 61.7% ADHD), and 308 adults without diagnosed neurodevelopmental conditions who reported clinically significant DST (Mage=35.85±12.72, 74.8% female sex). The MIST-A latent structure was evaluated using exploratory graph analysis (EGA) and exploratory structural equation modeling, and multiple-group item response theory models (graded response models) were fit to each subscale individually to allow for further psychometric evaluation of subscale scores.

Results: EGA (Louvain algorithm) indicated that the MIST-A comprised four subdimensions, interpreted as: Anger/aggression/misophonia, Loudness/overwhelm/fear, Anxiety/avoidance, and Pain. An exploratory structural equation model based on these four dimensions demonstrated borderline adequate global fit (CFI=0.955, TLI=0.933, RMSEA=0.084, SRMR=0.018). Examination of local misfit indicated that the “Loudness/overwhelm/fear” factor contained both “Loudness/overwhelm” and “Fear/panic” sub-dimensions. Unidimensional graded response models fit to the five MIST-A dimensions each demonstrated adequate fit (all TLI>0.964, all RMSEA<0.054, all SRMR<0.059) in the combined multiple-group sample, and strong reliabilities (empirical rs=0.799–0.911). Both clinical groups (autistic/ADHD adults and non-autistic/ADHD adults with mixed DST conditions) scored on average 1–1.5 standard deviations above the general population mean on all MIST-A subscales. Convergence was strong between MIST-A subscales and other dimensional measures of hyperacusis and misophonia (e.g., Inventory of Hyperacusis Symptoms, Duke-Vanderbilt Misophonia Screening Questionnaire), although correlations between theoretically distinct MIST-A subscales were higher than expected.

Conclusions: The newly-developed MIST-A appears both reliable and valid as a multidimensional tool to assess several facets of DST symptomatology in both autistic and non-autistic adults. This measure is among the first to screen for hyperacusis, misophonia, and phonophobia simultaneously, potentially conferring clinical utility for differential diagnoses of DST conditions.

Service Delivery/Systems of Care

Panel Discussion — Service Delivery/Systems of Care

216 - Improving Services for Externalizing Behaviors: Correlates, Unmet Needs, and Potential Service Solutions

Panel Chair: Mindy Scheithauer, Pediatrics, Emory University School of Medicine, Atlanta, GA

Discussant: Lee Wachtel, Neurobehavioral Unit, Kennedy Krieger Institute, Baltimore, MD

Behaviors such as aggression, irritability, and elopement are a prevalent concern among individuals with autism spectrum disorder (ASD). These behaviors can interfere with access to services, community integration, and are a major stressor for families. While there are some evidence-based treatments available, families often encounter barriers when accessing these treatments. This panel will delve into important considerations for service delivery for severe, challenging behaviors. The first mixed-methods study highlights the role of externalizing behaviors in accessing appropriate care for individuals with profound autism. Next, we present correlates of challenging behavior that should be considered when determining the population most at-risk, and thus most at-need for services. The final two studies discuss potential service solutions. First, we present outcomes from a clinical trial of a manualized, time-limited intervention model for elopement and implications for improving accessibility. Last, we discuss standardizing clinical pathways for irritability and related diagnoses to improve service delivery. This panel confronts issues in service delivery through a holistic approach, focusing on identifying areas of need through listening to the voices of parents, determining which individuals are most at-risk for needing treatment, and exploring potential service-delivery models to increase accessibility of services.

216.001 (Panel Discussion) Improving Services for Individuals with Profound Autism: A Mixed Methods Study of Caregiver Perspectives
Background: The notable underrepresentation of individuals with profound autism in the research literature has resulted in limited knowledge about their service needs and a lack of evidence-based practices tailored to these needs (Stedman et al., 2019). Profound autism is linked to increased symptom severity and a greater likelihood of challenging behaviors, which can overwhelm and debilitate families without access to appropriate care. Thus, emotion regulation concerns regarding both internalizing problems and externalizing behaviors are critically important to consider in the context of service needs for individuals with profound autism. The current study sought caregiver perspectives on profound autism service needs and treatment priorities in order to guide future treatment development.

Objectives: To identify patterns of service needs and treatment priorities for adolescents and adults with profound autism through quantitative and qualitative caregiver reports.

Methods: A mixed-method (QUAN -> QUAL) study design examined frequency and predictors of unmet service needs and caregiver perspectives on service utilization, barriers to service access, and service priorities. Quantitative survey data was gathered from 423 caregivers of adolescents and adults with profound autism. As part of the survey, caregivers completed the Emotion Dysregulation Inventory (EDI; Mazefsky, Day, et al., 2018), a measure of emotional distress and regulation skills. Binomial logistic regressions were conducted to ascertain the effects of demographic and clinical characterization variables on the likelihood of unmet service needs (“my child is receiving” = 0, “my child is not receiving, but needs” = 1) for the top 6 services with the greatest frequency of unmet needs. Qualitative interviews (n = 20) were coded and thematically analyzed to expand upon service needs and priorities for profound autism.

Results: The skills of recognizing emotions and calming down when upset (56.5%) and decreasing aggressive or self-harm behaviors (55.8%) were rated as priority treatment targets. Additionally, child’s behavior problems were endorsed as a barrier to service access by 54.1% of caregivers in the survey. Increasing EDI reactivity scores corresponded with an increased likelihood of needing social club/activity groups (B = .05, p = .015). Higher EDI dysphoria scores were associated with an increased likelihood of needing social skills training (B = .033, p = .044), life skills training (B = .074, p < .001), and behavioral support services (B = .043, p = .006). Qualitative interviews revealed that caregivers face many barriers to service access, including a lack of qualified service providers, long waitlists for behavioral services, one-size-fits-all service models, and exclusion from services due to the severity of behaviors and low adaptive functioning skills. Caregivers detailed the challenges associated with managing severe behaviors with limited assistance from service providers.

Conclusions: Findings highlight the lack of services for individuals with profound autism and the debilitating impacts of severe, challenging behaviors. Results underscore the importance of developing and increasing access to therapies to reduce challenging behaviors in individuals with profound autism. Such therapies have the potential to enable individuals to enjoy subsequent skill building efforts and ultimately improve the quality of life for families.

216.002 (Panel Discussion) Biopsychosocial Correlates of Challenging Behavior in Children and Adolescents with Developmental Disabilities

V. Vasudevan, M. Uljarević, A. Shih and T. W. Frazier, (1)Autism Speaks, Gainesville, FL, (2)Melbourne School of Psychological Sciences, Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Parkville, VIC, (3)Autism Speaks, New York, NY, (4)Psychology, John Carrol University, Cleveland, OH

Background: Challenging behaviors, often referred to as disruptive behavior or externalizing problems, are associated with a range of conditions and frequently occur in people with neurodevelopmental disorders, including children with autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD). There is very little prior research examining the occurrence of challenging behaviors in children with neurodevelopmental disorders while controlling for biopsychosocial correlates like parental variables and environment.

Objectives: The first aim of this study was to evaluate group level differences for challenging behavior by neurodevelopmental condition status. The second aim was to evaluate the relative contributions of clinical features, child demographic characteristics, and parent and environmental factors towards their child’s challenging behavior.

Methods: Study participants (n=2004) were recruited from the Prolific Academic online data collection service. Participants completed the following: demographic information, child’s cognitive level, Open Source–Challenging Behaviors Scale including its five subscales: (property destruction, aggression, elopement, conduct problems, and self-injury), Stanford Social Dimensions Scale, and the Executive Functioning Scale. Four mutually exclusive strata were created for study participants: neurotypical (NT), ASD, children without ASD but have ADHD, and children without ASD or ADHD but with other developmental disabilities (DD). Descriptive statistics, univariate analyses of covariance, and a series of hierarchical linear regressions were computed.

Results: Parent-reported ASD diagnoses were supported by strong differences in autism traits between ASD and non-ASD groups (d=1.79). Male children were over-represented in the ASD group (76%) and at least 80% of all groups were reported as White race. Children in the
DD group had higher rates of co-occurring diagnoses. The mean social function score was lower for the ASD group, while the executive functioning score was lower for the DD group. After controlling for age and sex, challenging behavior total scores were highest in ASD, next highest in ADHD without ASD (ASD vs. ADHD without ASD, p=.039), and slightly lower but still elevated in the Other DD group (ADHD without ASD vs. Other DD, p<.001), with a distinct pattern for ASD and ADHD groups across challenging behavior types (Figure 1). For prediction of total challenging behavior scores, clinical features and child characteristics made statistically significant contributions; while, caregiver and environmental factors did not significantly increase prediction (ΔR²<.01). Overall prediction was strongest for property destruction (R²=.41) and conduct problems (R²=.50) and weakest for self-injury (R²=.22).

Conclusions: This study was the first of its kind to explore biopsychosocial correlates of challenging behavior in children with neurodevelopmental disorders. ASD, and secondarily ADHD, had elevated levels of challenging behavior relative to other DD groups and neurotypical controls. Findings from predictive models strongly suggest that clinical features are the most important factors to consider in addressing challenging behavior in youth, with executive functioning being a major neurobehavioral construct that should be examined more closely in future studies. Future research would benefit from examining how specific forms of challenging behavior influence child and family outcomes. Existing work suggests that a child’s challenging behavior, as a diverse set of behaviors, has a strong correlation with parent and family stress and coping.

216.003 (Panel Discussion) Implementation of a Manualized Function-Based Elopement Treatment

M. Scheithauer, N. Call, L. Scahill, S. Slocum Freeman, J. Lomas Mevers and C. Muething, (1)Pediatrics, Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Emory University School of Med, Atlanta, GA, (4)Emory University, Atlanta, GA

Background: Elopement is an incredibly dangerous behavior that is prevalent among individuals with autism spectrum disorder (ASD). Fortunately, there is evidence for successful behavioral interventions reducing elopement. However, support for these interventions has primarily come from small-N studies with variable procedures across studies. Additionally, most research on elopement treatment employs specialized facilities and providers that are not readily available in most geographic areas. Thus, families of children who engage in dangerous elopement often face barriers in accessing appropriate treatment services for elopement.

Objectives: The current study evaluated a manualized function-based treatment for elopement that is intended for implementation in the home and community setting by BCBAs without specialized training in elopement or challenging behavior. In this presentation, we highlight outcomes impacting accessibility of this novel manualized intervention, including the feasibility of implementation and acceptability. We also present preliminary efficacy data.

Methods: We conducted a clinical trial of 76 participants (age 4-12) diagnosed with ASD whose parents endorsed elopement as a primary presenting concern. Participants were randomized to either a manualized elopement treatment or a parent education control group. The manual includes a parent-mediated intervention, with 12 appointments held across 16 weeks, where a therapist coaches the parent through implementing safety measures in the home, a functional analysis, and subsequent behavioral treatment strategies. We measured the percentage of appointments completed, therapist integrity, and caregiver acceptability (based on the Treatment Acceptability Rating Form at endpoint). For a subset of participants, we evaluated initial feasibility using secondary outcomes. The week before baseline and endpoint, parents recorded each day for one week whether elopement occurred. They also completed an elopement questionnaire consisting of 30 items representing situations elopement is common and rated how concerning elopement is in that setting on a nine-point Likert scale.

Results: Therapist fidelity was high (> 90%; random sample of 20% of appointments) and parents found the treatment acceptable: > 80% agreed they were satisfied with the program; found the treatment acceptable; and would recommend the program to others. In evaluating the first 32 participants randomized to treatment, several participants were not able to complete all appointments (69% completed ≥ 10 appointments). For initial feasibility, we evaluated secondary outcomes with 54 participants using a repeated measures ANOVA with time (baseline vs. endpoint) as the within subject and group (treatment vs. control) as a between subject variables. We identified significant improvement in the elopement questionnaire (F(1,53) = 14.26, p <.01) and in the percentage of days caregivers reported elopement (F(1,52) = 11.08, p <.05).

Conclusions: We found that the treatment was acceptable to parents and therapists were able to follow the manual with high integrity. However, parents were inconsistently able to attend the full 12 appointments in the 16-week time frame. Thus, it is possible that additional measures need to be taken to promote attendance or allow flexibility in scheduling. It is also possible that the COVID-19 pandemic impacted attendance. Initial feasibility results suggest promise for efficacy of the manual, which will be further evaluated in future analyses.

216.004 (Panel Discussion) Using Improvement Science to Standardize Care for Challenging Behaviors

Background: Data from parent report of challenging behavior in the Autism Care Network indicated behavior symptoms tended to cluster around three primary mental health conditions: anxiety, Irritability, ADHD. We describe our use of quality improvement methodology in a multi-center learning health network to improve the reliable implementation of practice pathways for the identification and treatment of anxiety, irritability, and ADHD.

Objectives: To standardize the reliable implementation of clinical care pathways that a) screen for challenging behaviors, and b) increase identification and management of anxiety, ADHD and irritability and associated challenging behaviors through implementation of best practices.

Methods: Network participants had previously developed evidence-informed best practice clinical pathways for treatment of ADHD, anxiety and irritability based on literature review and network research. Quality improvement science guided the formation of “learning labs” focused on reliable pathway implementation for each of these conditions. Markers of reliable pathway implementation were identified and bundled, permitting assessment at each site on consistent implementation of each marker as well as the overall bundle. Based on the Science for Improvement, sites use PDSA cycles to redesign strategies for optimal local implementation and to track data over time using Run Charts with on-going QI support. Chart reviews of children seen by clinicians at each site are conducted bi-monthly to assess the reliability of clinical uptake using four levels <80% reliability (Chaos), 80-89% reliability (Level 1), 90 – 98% reliability (Level 2), and ≥ 99% (Level 3). Participating sites receive centralized QI support, shared data and strategies for successful system changes to increase reliability.

Results: Through the first 11 rounds of data sampling, aggregate results from participating centers demonstrate improvements in at least one pathway marker, with most reaching at least level 1 reliability (80% or above). Aggregated learning lab data indicates overall improvements in the reliable implementation of the practice pathway “bundle” for all three associated conditions. For the ADHD pathway, reliability averaged 16% over the first three rounds and improved to an average of 45% over the final three rounds. Similar improvements were seen for anxiety (22% to 46%) and irritability (2% to 46%). Additionally, there is Network-wide improvement on the critical marker of asking about patient safety concerns (average of 72% on the first three rounds and an average of 90% on the final three rounds). Learning lab reliability work continues and updated data and future directions will be presented.

Conclusions: The Science for improvement can be used to increase reliable implementation of best practice pathways. Standardizing care in clinical settings is imperative to better understand what works or doesn’t work with specific autism subtypes and to track outcomes over time. Further work is planned to link improvements in the reliability of pathway implementation to outcomes.

ORAL SESSION — SERVICE DELIVERY/SYSTEMS OF CARE

323 - Increasing Knowledge & Strengthening Partnerships to Advance Supports

Moderator: Sarah Spence, Autism Spectrum Center, Boston Children’s Hospital, Boston, MA

S. M. Bury, A. Haschek, M. Wenzel, J. R. Spoor and D. Hedley, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, VIC, Australia, (3)Flinders University, Adelaide, VIC, Australia, (4)Department of Management & Marketing, La Trobe University, Melbourne, VIC, Australia, (5)Olga Tennison Autism Research Centre, La Trobe University OTARC, Melbourne, VIC, Australia

Background: People on the autism spectrum are learning about autism from more diverse sources of information that likely differ in the quality, portrayal, and nature of the information they offer. Sources of information that are more medicalised (e.g., Professionals, Parents; Crane et al., 2019; McCormack et al., 2020), stereotyped or incomplete (e.g., Movies/Television, News Media; Jones & Harwood, 2009) could negatively influence the accuracy of individuals’ autism knowledge, their experience of stigma, and may present an identity threat that influences the development and expression of an autistic identity (Dirth & Branscombe, 2018). However, given the rise of the neurodiversity movement and greater diagnosis in adulthood (Harmens et al., 2022), self-directed learning from less traditional sources (e.g., advocates, social media, online blogs) that may be more neurodiversity affirming, may positively influence the development of an autism identity, and the expression of this through more strengths-based means.

Objectives: This present study investigates where autistic people learn about autism, and whether their information source is associated with their level of autism knowledge, perceptions of stigma, and development and expression of an autism identity.
Methods: Participants were 198 autistic adults (M_age = 34.89, SD_age = 12.34; 29.3% male; 56.1% female; 14.6% non-binary) more frequently diagnosed in adulthood (M_age = 27.36, SD_age = 16.32). Participants were recruited via social media, mailing lists and from autism community groups. Participants rated on a 7-point Likert scale how much nine potential sources of autism knowledge (Professionals, Parents, Autism advocates, Television/Movies, The Media, Books/Journals, Social Media, Online Blogs, Online research) influenced their understanding of autism. Participants also completed measures of autism knowledge, internalatisation of stigma, endorsement of an autistic identity, as well as masking and promoting autism special abilities.

Results: Overall participants tended to learn more about autism from professionals, autism advocates, books/journals and online research than they did from parents, television/movies and the media (see Table 1). Participants also indicated additional avenues for autism information, namely friends, others with autism, family members, their own experience/observations, and other experts. Correlational results (Table 1) showed that conventional sources such as professionals and parents tended to be associated with more internalised stigma, lower belief in special abilities, and lower autism identity. Contrastingly, online blogs and social media as sources of knowledge were associated with lower stigma, greater endorsement of an autism identity and the expression of this through autism strengths, as well as more accurate autism knowledge.

Conclusions: The findings raise questions about how authoritative sources of information (e.g., professionals, parents) discuss autism, and the potential impact this may have on how autistic people understand and express their own autism identity. While these results may be tempered by the late diagnosis of the participants, it highlights the potential value of alternate autism affirming sources of information in promoting positive outcomes for autistic adults.

Background:

Caregivers of children with autism and other developmental disabilities (DDs) often experience challenges such as feeling stressed, facing stigma and social exclusion. Social determinants further impact how caregivers can raise their children. Families in low-resource settings may be constrained by poverty and lack access to information, resources, and services. Existing work globally suggests that caregiver empowerment has a range of beneficial outcomes. Studying similarities and differences in how caregiver empowerment is achieved across settings can help inform how to tailor empowerment approaches to specific contexts.

Objectives:

We aimed to analyse similarities and differences in perceptions of the role that caregiver empowerment may play in service development for caregivers of children with DDs, and how empowerment may be achieved in two settings: Ethiopia and Argentina.

Methods:

We used a phenomenological, qualitative multiple case study design. We conducted two case studies: in Ethiopia (including 63 individual interviews) and Argentina (32 interviews). Participants in both settings comprised caregivers of children with DDs, clinicians, representatives of non-governmental organisations and of local health, education, and social care authorities; and additionally teachers in Argentina, and community health extension workers in Ethiopia. We used thematic template analysis to compare data across the case studies, using Murdoch et al.’s 2016 framework on the role of context in complex interventions.

Results:

We developed three themes: “Societal factors influencing the caregiver experience: the macro level of context”; “Caregiver empowerment through institutions and communities: the meso level of context”; “The challenges of the caregiver journey: the micro level of context”. A key similarity across the two case studies was that caregivers’ socio-economic status, stigma and awareness about DDs and existing disability laws shaped how caregivers could exercise their agency. Caregiver initiatives remained local and informal in Ethiopia, while in Argentina formalised caregiver organisations worked towards claiming their rights. In Ethiopia, where only mothers were interviewed, the caregiving role was mostly restricted to women. Participants from Argentina, including mothers and fathers, indicated that gender-specific support would be helpful to support fathers in their caregiving roles. In both countries, caregivers and professionals highlighted that
Caregivers’ psychological resilience was difficult to achieve due to distress, social exclusion and stigma. Many Ethiopian caregivers highlighted how their faith and spiritual beliefs helped them give meaning to their experiences. Unlike Ethiopian parents, Argentinian caregivers added that internet access helped them form support groups online. Beyond caregiver empowerment, both Ethiopian and Argentinian caregivers suggested that they expected the government to facilitate service development for their families.

Conclusions:
Both Argentinian and Ethiopian stakeholders consider the goal of caregiver empowerment to be the removal of barriers that hinders caregivers from doing what they think is best for their child and family, in their own terms. This requires structural change to overcome social exclusion. Based on participant views in the two case studies, caregiver-focused interventions should build on existing expertise by experience to empower caregivers and work across sectors to overcome access barriers. A key intervention component should be supporting caregivers in accessing information about DDs and local services available.

323.003 (Oral) Prevalence, Characteristics and Healthcare Utilization Among US Children with Parent-Reported Severe Autism

P. Carbone; M. E. Villalobos; K. Campbell; A. Elzey; G. Stoddard and C. Stipelman; (1)University of Utah, Salt Lake City, UT, (2)Pediatrics, University of Utah, Park City, UT, (3)University of Utah, Durham, NC, (4)University of Utah, salt lake city, UT, (5)Department of Internal Medicine, University of Utah, Salt Lake City, UT, (6)Department of Pediatrics, University of Utah, Salt Lake City, UT

Background: In 2022 a Lancet Commission proposed the administrative term “profound autism” apply to those who require the constant presence of a caregiver to meet their safety and care needs and who are likely to have significant intellectual disability and very limited language. While this term has been broadly defined, little is documented in terms of prevalence or differences in characteristics compared with those without profound or severe autism.

Objectives: Using a nationally representative survey of US parents we: (1) estimated the prevalence of parent-reported “severe” autism, and (2) compared parent-reported child characteristics (developmental, cognitive, adaptive profiles, co-occurring conditions) between children with severe autism and mild/moderate autism.

Methods: The 2018-2019 National Survey of Children’s Health (NSCH) was used to identify children ages 6-17 years with autism and their parent-reported autism severity (“mild”, “moderate” or “severe”). We compared child and family sociodemographic characteristics and child characteristics (developmental, cognitive, adaptive profiles, co-occurring conditions) among children with severe autism with those having mild/moderate autism, adjusting for significant sociodemographic factors in multivariable analyses.

Results: The overall prevalence of autism among US children aged 6-17 years was 3.2%. Among these children (n=1,368), the proportion with parent-reported “severe” autism was 10.1%. The prevalence of severe autism, compared with mild/moderate autism, was similar across gender, age and race/ethnicity but higher among children with public insurance. Parents of children with severe autism were more likely to report language delay, developmental delay, intellectual disability and “severe” ratings of all three. Children with severe autism had more parent-reported difficulty walking, climbing stairs, dressing and bathing. With regards to physical health, parents of children with severe autism were more likely to report gastrointestinal problems and overweight/obesity but not insomnia or epilepsy. Compared with children with mild/moderate autism, those with severe autism had a higher parent-reported prevalence of depression and were less likely to stay calm when faced with a challenge. They were not more likely to have parent reported behavioral problems, ADHD or anxiety but were more likely to have “severe” parent ratings of all three. Lastly, parents of children with severe autism were significantly less likely to rate their child’s overall health as “excellent/very good”.

Conclusions: Utilizing a nationally representative parent survey of school-aged children, we found the prevalence of severe autism to be 0.3% or 1 in 333, comprising 10% of children on the autism spectrum. Compared with parents of children with mild/moderate autism, parents of children with severe autism were more likely to report many of the same defining characteristics of severe or profound autism proposed by experts, supporting the proposal for a separate administrative term. Given their distinct characteristics in the areas of development, cognition, adaptive skills and co-occurring conditions, children with severe autism and their families may benefit from this designation in order to obtain personalized services and supports. Our findings have implications on tracking the ongoing prevalence of severe autism and characterizing the experiences and needs of these children and their families using subsequent iterations of the NSCH or other parent surveys.

323.004 (Oral) Building Primary Care Partnerships to Improve Access to Diagnosis and Management of Autism Spectrum Disorder

R. Wilson; A. M. Reynolds; M. Cobian; E. M. Coan; L. Hayutin; S. Mattie; R. E. Boles and S. Friedman; (1)Developmental Pediatrics, University of Colorado Childrens Hospital Colorado, Aurora, CO, (2)University of Colorado School of Medicine, Aurora, CO, (3)Children's Hospital Colorado, Aurora, CO, (4)Pediatrics, Children's Hospital Colorado, Aurora, CO, (5)University of Colorado Anschutz Medical Campus, Aurora, CO, (6)Pediatrics, University of Colorado School of Medicine, Aurora, CO
Background: There is widespread acknowledgement that the need for autism evaluation and support services far outweigh the capacity to address in specialty clinics. Equipping primary care providers (PCPs) to be skilled and confident in identifying autism and supporting the care needs of their patients can expand critical access to appropriate care (Hyman, et al, 2020). This is particularly true in underserved, rural/remote communities where specialist care is unavailable.

Objectives: Develop a multi-faceted model for building community partnerships between PCPs and specialists by providing training to equip primary care providers with skills, knowledge, and access to consultation so that concerns for autism and healthcare management for patients with autism may be more effectively addressed in primary care.

Methods: Primary Care Provider (PCP) education included 4 training opportunities: 1) a 10 week didactic virtual series via Extension for Community Healthcare Outcomes (ECHO) on Autism Core Concepts (ACC), 2) virtual training on the Screening Tool for Autism in Toddlers (STAT), 3) PCP engagement in interdisciplinary Outreach Diagnostic Clinics at rural/remote clinics with a Developmental Behavioral Pediatrician, and psychologists (including a Spanish bilingual/bicultural psychologist), and 4) a monthly Community of Practice (CoP) with case review and an interdisciplinary team. These 4 educational approaches were designed to improve PCP skills and confidence to identify concerns for autism, diagnose clearer presentations of autism, and address ongoing healthcare needs of youth with developmental concerns. ACC, STAT, and CoP ECHO participant demographics and number of participants per session were collected in Qualtrics. Post STAT surveys were obtained using Microsoft Forms. STAT pre and post comfort-level data were measured with 5-point Likert scale and analyzed with dependent t-tests.

Results: Eleven cohorts including a total of 156 participants completed the ACC training (93% PCPs and 79% Medicaid providers). Three annual STAT trainings included 49 participants. STAT participants demonstrated significant improvement in provider comfort to identify symptoms of ASD, pretest (SD = 3.63(0.83), post-test = 4.42(0.69), p=0.001. STAT participants were “extremely likely” to recommend the course, 9.05/10. A total of 8 diagnostic outreach clinics, including 39 developmental evaluations were completed by interdisciplinary teams at 5 clinics in rural/remote settings. Evaluations included the ADOS-2 in partnership with PCPs in the program. The CoP included 29 participants (50% rural/remote communities), across 33 monthly sessions with an average of 4.6 attendees per session. Three champions were identified as frequent participants of the CoP and participated in outreach clinics in their communities.

Conclusions: Combining the training approaches of the ACC, STAT, PCP participation in outreach clinics and CoP constitutes an innovative, multifaceted approach for improving the confidence and comfort of PCPs in underserved areas for the provision of timely diagnostic identification and care for youth with autism and developmental concerns. The encouraging results suggest high acceptability and improved confidence following training. Further, providers who were frequent attendees of the CoP continue to utilize the program to sustain and improve care. Future directions include evaluating changes in PCP practices to identify concerns, diagnose autism, and enhance healthcare management for this population.
Background: Telehealth can address barriers that influence access and adherence to services, particularly for families in underserved groups (Dahiy et al., 2020). Telehealth has been shown to reduce staff shortages, cut costs, increase enrollment capacity, and service frequency (Camden & Silva, 2021; Rooks-Ellis et al., 2020). Using multiple methodologies to gain a comprehensive understanding of challenges experienced when providing telehealth can support successful implementation.

Objectives: This study examines quantitative and qualitative data to identify clinicians’ perceived barriers to delivering telehealth ABA services.

Methods: A convergent mixed methods design (QUAN + qual) was used to identify perceived barriers to telehealth and gain a comprehensive understanding of clinicians’ experiences with this modality. A total of 389 clinicians providing ABA telehealth services to autistic children completed an online survey distributed through the Behavior Analyst Certification Board. The survey included closed- and open-ended survey items related to challenges experienced when delivering telehealth. A list of common barriers to telehealth use was created using previous literature examining telehealth for broader mental health services. Items were then tailored to autistic children and families. Clinicians rated these barriers using a 5-point Likert-scale, as well as the Satisfaction Subscale of the Technology Usability Questionnaire. Clinicians were also provided an open-ended question to report on their experienced barriers. A repeated measures ANOVA was used to compare clinicians’ difficulty implementing specific services (assessment, direct treatment, parent training). Individual barriers were analyzed using descriptive statistics. A principal components analysis (with varimax rotation) was conducted with the barrier items to identify meaningful subscales. Pearson’s correlations and linear regression was used to examine whether the barrier subscales predicted clinicians’ satisfaction with telehealth. Open-ended responses were examined using thematic analysis.

Results: Clinicians rated providing direct services (M=3.52, SD=1.14) as more difficult than conducting assessments (M=3.29, SD=1.06), and both as more difficult than providing parent training (M=2.47, SD=1.11), F(2, 748)=162.26, p<.001. The PCA indicated a 3-factor solution of barriers related to: Technology (α=.82), administrative tasks (α=.88), and client characteristics (α=.88). The most frequently endorsed barriers were related to client characteristics: Working with children who elope (M=4.37, SD=.81), exhibit challenging behavior (M=4.31; SD=.83), need behavior management (M=4.11; SD=.91), or are preverbal M=4.08; SD=1.00). Technology barriers (r=-.34, p<.001), administrative task barriers (r=-.48, p<.001), and client characteristic barriers (r=-.62, p<.001) were each negatively related to telehealth satisfaction. Fewer reported barriers related to client characteristics and administrative tasks were independent predictors of telehealth satisfaction, with the total model explaining 39% of variance.

Four themes emerged from the qualitative thematic analysis: technological barriers (33% of comments), client engagement (22%), implementation of treatment strategies such as physical guidance and behavioral management (20%), and challenges related to caregiver involvement (21%).

Conclusions: Clinicians frequently reported challenges related to addressing specific client-level characteristics (such as engaging children who may struggle with attending or engage in challenging behaviors). Challenges related to client-characteristics and administrative tasks uniquely predicted clinician’s satisfaction with telehealth. These findings highlight the need for targeted strategies that facilitate telehealth use to address specific client needs.

**406.330 (Poster) A Mixed-Methods Examination of Perceived Barriers to Telehealth Delivered Applied Behavior Analysis**

A. Pomales-Ramos, M. Howard; D. Straith; B. R. Ingersoll; (1)Psychology, Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University Psychology Department, East Lansing, MI

**406.331 (Poster) A Qualitative Exploration of Community-Based Providers’ Experiences Supporting African American Autistic Children and Their Families**
J. Pearson, D. Mason Martin, and K. M. Malone, (1)Teacher Education and Learning Sciences, North Carolina State University, Raleigh, NC, (2)2310 Stinson Drive, North Carolina State University, Raleigh, NC, (3)Applied Developmental Science and Special Education, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Historically marginalized families face service utilization barriers and cultural perspectives of disability that impact their decisions to seek and utilize autism support services. Black parents raising young children with autism encounter challenges with educators, related service providers, and healthcare providers who are not responsive to the needs of their families (Pearson & Meadan, 2018; Pearson et al., 2020; Pearson & Meadan, 2021). These challenges and other barriers to service utilization have harmful impacts on outcomes for Black children with autism, including delayed communication and challenging behavior (Wright, 2016).

Objectives: The research questions were: (1) What are the experiences of parent educators who provide support for Black families of children with autism in NC? (2) To what extent do parent educators feel confident in their knowledge of autism-related strategies and resources? (3) To what extent do parent educators feel prepared to address the needs of Black families of children with autism through parent-training?

Methods: This study was a qualitative focus group design. During each focus group, participants discussed their experiences supporting families of children with autism in NC, and identified their perceived needs for both parents and parent educators. Each focus group interview lasted 1-2 hours. Following a constant comparative method, we (1) read and recorded memos for each transcript independently, (2) met to reach a consensus on initial categories, (3) revised the categories as needed, (4) developed emerging themes across the data, and (5) conducted level-two member checks.

Results: Thirty-two participants were included in this study. Findings indicated that parent educators most often provided individualized support, identified racialized experiences, and assisted with school challenges for Black families raising autistic youth. Participants also identified a number of barriers to supporting Black families raising autistic youth, such as lack of service providers, geographic limitations, and waitlists, to name a few.

Conclusions: This study provides insight about the experiences of parent educators who work with African American families raising autistic children. Our findings indicate that there is a need for a concerted effort to (a) improve parent - teacher relationships among Black families, (b) engage in targeted outreach for Black families, (c) provide culturally responsive training for parent educators, and (d) provide more resources, services and service providers to better meet the needs of historically marginalized autistic youth and their families.

406.332 (Poster) A Randomized Controlled Trial of a Client Data Collection App Incorporating User-Centered Design and Behavioral Economics Insights
A. Brown, S. Deswert, E. Becker-Haimes, E. Reisinger Blanch, D. S. Mandell, and H. J. Nuske, (1) Penn Center for Mental Health, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, (2) Penn Center for Mental Health, University of Pennsylvania School of Medicine, Philadelphia, PA, (3) University of Pennsylvania Health System, Hall Mercer Community Mental Health, Philadelphia, PA

Background: A critical component of evidence-based interventions for children on the autism spectrum is quantitative data collection to track progress. Often, one-to-one aides (“aides”) are the frontline staff responsible for data collection; yet many do not collect high-quality, quantitative data that is consistent, timely and complete. Two common practices inhibit data collection: 1) many agencies use labor-intensive pen-and-paper methods, and 2) aides’ work is by nature solitary, leaving few opportunities for timely supervisor feedback. To address these issues, we created a phone-based, behavioral health data collection application, Footsteps, using behavioral economics principles via user-centered design. Footsteps was designed to make data collection easier and more appealing via a simple digital interface, more timely via reminders to take data, and more rewarding by providing encouraging feedback after data collection.

Objectives: To test the feasibility of our recruitment strategies and test the response rate and sensitivity to change of our measures in a pilot trial of Footsteps, in preparation for a large-scale randomized trial. We also examined whether the mean differences between the treatment and control groups were in the anticipated directions.

Methods: Twenty-seven aides of students on the autism spectrum participated in a 3-week, school-based randomized controlled trial (RCT) of two versions of Footsteps: one with basic data collection features (control) and one with those features plus behavioral economics enhancements e.g., reminders and feedback; treatment). Our primary outcome measures were data collection consistency, timeliness, and completeness, collected through app analytics. Secondary outcomes included: 1) measures of intentions and determinants of intentions (attitudes, self-efficacy and norms) to estimate if these psychological constructs may mediate aides’ intentions to take data, 2) the System Usability Scale, and 3) a questionnaire regarding the app features’ usefulness. We analyzed quantitative trial results using generalized linear models (GLMs). We also conducted post-trial semi-structured interviews to better understand participants’ experience of the app as helpful, motivating, or challenging. We analyzed these data using thematic analysis guided by an integrated bottom-up/top-down approach.
Results: Despite conducting the study during a global pandemic, we recruited 90% of our anticipated sample, had an 88% response rate for all measurement periods, and saw meaningful variability in outcome measures. Groups differed at baseline on intentions (with the treatment group having stronger intentions than the control group); we controlled for this in the GLM analyses. Means were in the anticipated directions for 2 of the 3 primary outcomes, with the treatment group collecting more consistent and timely data; however, the control group had more complete data. Likewise, for the determinants of intentions, the treatment group had higher self-efficacy and better attitudes regarding data collection; however, injunctive and descriptive norms were higher in the control group. No treatment group contrasts reached statistical significance; however, all effect sizes except for attitudes were medium-large. Results of the survey and qualitative data indicated that Footsteps was usable, acceptable, helpful, and motivating to participants.

Conclusions: Results were encouraging and suggest the study methods are suitable to conduct a fully powered RCT.

406.333 (Poster) A Retrospective Chart Review of Delivering the Social ABCs As a Hybrid Model for Autistic Toddlers - Perspective from Goa, India

A. Velho1, M. Kantawalla1, E. M. Dowds1, K. Bernardi1 and J. A. Brian1, (1)Autism Services, Sethu Child Development and Family Guidance Centre, North Goa, India, (2)Autism Services, Sethu Centre, North Goa, India, (3)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital-Autism Research Centre, Burlington, ON, Canada, (4)Holland Bloorview Kids Rehab Hospital - ARC, Toronto, ON, Canada, (5)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

Background: Evidence for early social-communication intervention catering to toddlers with autism in India is currently limited. The Social ABCs (Brian et al., 2016) is an evidence-based NDBI developed in Canada, for children diagnosed with autism aged 12-36 months. It aims to improve communication and social engagement, targeting functional vocal communication and sharing of positive emotions. The intervention was implemented from January 2021 at Sethu, a community-based child development center in Goa, western India. Autism intervention models in India have long been center-based, but the COVID 19 pandemic and subsequent lockdowns prompted Sethu to shift to remote delivery, with the option for caregivers to choose their preferred model as lockdowns eased.

Objectives: To report on the delivery, feasibility and acceptability of the Social ABCs for toddlers with autism in Goa from January 2021 - October 2022.

Methods: The Social ABCs Group Model is a caregiver-mediated intervention with 15 sessions held over 6 weeks. Local clinicians trained by program developers conduct a combination of group didactics and individual parent coaching sessions. Families whose toddlers were diagnosed with autism at Sethu were offered the Social ABCs as an early social-communication intervention with information on wait time, fees and format provided in advance. Decisions around participation, scheduling, fees, sponsorship and coaching were collaboratively made. Using a retrospective chart review we have examined family demographics, attendance, implementation fidelity and child responsivity.

Results: 55 toddlers aged 20-35 months along with a primary caregiver attended the intervention over 10 groups of 2 to 8 families per group. The average wait time to start was approximately 3 months post diagnosis. Caregivers that attended included 46 mothers, 8 fathers, and one aunt. Registration data indicated family barriers around ability to pay fees, scheduling conflicts, poor internet connectivity and home language being other than English. Steps undertaken to mitigate these challenges included flexibility on criteria of the participating caregiver, heavy concessions on fees and a hybrid model with the option to choose between center-based and remote delivery. 42% and 40% of caregivers chose the online and hybrid models respectively. 20% of families received concessions ranging from 60-100% of the session fee. 20% of families chose to be coached in local languages including Konkani, Hindi or Marathi. 87% of families completed the program. Based on video-coding, 75% of the caregivers achieved fidelity of implementation. Responsivity scores increased by an average of 40 percentage points in 100% of the toddlers.

Conclusions: These findings demonstrate the portability and feasibility of the Social ABCs, developed in Canada, for use in the Indian context. Even through the pandemic, the program was well received by families. The understanding of contextual limitations by local trainers led to adaptations that mitigated challenges and enhanced feasibility. Providing caregiver-mediated support at the very earliest signs of ASD is an innovative and resource-efficient approach to meeting families’ needs and has implications for other low-resource settings.

406.334 (Poster) Access and Cost of Services for Autistic Children and Adults in Italy

M. Micai1, F. Falceri2, T. Salvitti2, G. Romano2 and M. L. Scattoni2, (1)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (2)Directorate General of Health Prevention, Ministry of Health, Rome, Italy

Background: There is very little knowledge regarding autistic services access and costs in Italy.
Objectives: This study wants to improve understanding of current access to educational, health care, social and other related services for autistic persons of all ages in Italy and opportunities for improvement as part of the Autism Spectrum Disorder in the European Union (ASDEU) project.

Methods: An online survey of services attended in the 6 months prior to completion and their costs was filled out by Italian caregivers of autistic people with autism.

Results: 303 carers of autistic people responded to the survey. Most of the autistic cared were children<18 years old (82%) (mean age: 11.61±8.24, range: 1-54), males (82%), and lived at home with their parents (97%). Most of the autistic adults were students (21%) and unemployed-but willing to work (21%). Most of the carers were employed (49%), working 32.23±9.27 [3-50] hours per week. The 82% of the carers made some absences from work/place of study during the last 6 months because they had to take care of an autistic person, for a mean of 15.56±14.70 [1-120] days in the last 6 months. On average, carers reported that they spend caring for the autistic person 58.84±48.36 [2-168] hours per week.

More than a half (55%) of the autistic people received any form of support, 5% with any residential care services (e.g., temporary institutionalization for family problems or to provide support to family members/caregivers), and 6% suffered a hospitalization. The 34% of the carers reported that the autistic person has received outpatient hospital care (i.e., the person has not been admitted to hospital overnight but has visited in hospitals, clinics or other centres for diagnosis or treatment) and the 22% took any autism-related medication (i.e., for symptoms of autism spectrum disorder or autism-related conditions). In school or college, the professional with whom autistic people interacted the most was the support teacher (18.16±7.02, 2-45 h/week). The educational psychologist (80%), psychomotorist/physiotherapist (56%), and speech therapist (51%) were the professionals most often paid by carers of autistic children and the ones paid more per hour (mean: 31, 33, 35 euros, respectively). Carers also reported that the autistic children received one of the following forms of support in the last 6 months more often from: educator (74 h/w), group therapy (32), and speech therapist (31). Psychologist (75%) and counselling/individual therapist (78%) were the figures most frequently paid by the carers of autistic children. Carers of children reported that psychiatrist and psychologist the most expensive ones (153±105 [36-400], 105±97 [14-400] euros, respectively) and that the health or social care services they used more often were the psychiatric services (8±8 [1-24] times in the last 6 months).

Conclusions: The results showed areas for potential improvement in autistic services delivery in Italy to achieve support for families.

406.335 (Poster) Accessible Social Prescribing As an Approach to Meeting Autistic Adults’ Health and Wellbeing Needs

C. Featherstone1, K. Husk2, R. Sharpe3, S. Asthana4 and N. Axford5, (1)Primary Care Team, University of Plymouth/NIHR PenARC, Plymouth, United Kingdom, (2)Primary Care Team, NIHR PenARC, Plymouth, United Kingdom, (3)Public Health, Cornwall Council, Truro, United Kingdom, (4)University of Exeter, Exeter, United Kingdom, (5)Plymouth Institute of Health and Care Research, University of Plymouth, Plymouth, United Kingdom

Background:

Autistic adults are affected by health and social disparities that impact life expectancy and quality of life (Hirvikoski et al., 2016). A lack of post-diagnostic support may contribute to these inequalities. Responding to these inequalities through acute care is costly. Social prescribing, a low-level personalised care model receiving increasing attention from UK policymakers and commissioners, may offer opportunities to address isolation, life skills and health self-management. However, research has scarcely focused on provision of social prescribing for autistic adults, who may have different needs to non-autistic adults.

Objectives:

This presentation summarises findings of a PhD project which will aim to contribute to knowledge on the factors affecting accessibility and acceptability of social prescribing for autistic adults as a potential approach to responding to unmet health and social care needs. As a complex intervention with a range of models and mechanisms which vary at different stages of the pathway (Husk et al., 2019), the present research aimed to evaluate the mechanisms of the entire pathway from initial referral through to success of individual prescribed activities.

Methods:

The research involved a literature review and mixed-methods study. We extracted data from academic and grey literature on types of community-based services for autistic adults and their outcomes, settings and service pathways. An online survey with 128 autistic adults in the UK applied Raymaker et al.’s (2017) coproduced Barriers to Healthcare Checklist to explore the primary care point of access to social prescribing for different demographic groups across changing contexts using regression analysis. Semi-structured interviews with 21 autistic participants investigated meanings of wellbeing and how autistic individuals self-managed this, and attitudes towards social prescribing as a response to unmet needs. We applied reflexive thematic analysis with a critical realist ontology, as well as the candidacy...
framework which considers relational and systemic aspects of service access (Dixon-Woods et al., 2006; Mackenzie et al., 2013). The research was designed and conducted by a team led by an autistic PhD student.

Results:

Findings suggest that access to social prescribing for autistic adults via referral from health and social care services may be affected by patient and provider evaluations of candidacy, socioeconomic factors and context of service delivery. Self-determination was found to link themes relating to meanings of wellbeing for autistic adults. Social prescribing may promote self-determination through its tailored approach, such as the inclusion of intrinsic interests and connecting people with peers. However, existing models may require adaptations at different stages of the pathway by offering alternative referral routes and additional support engaging with prescriptions for autistic adults. Further evaluation will build on the established findings.

Conclusions:

Findings may enable service commissioners and policymakers to consider whether additional funding could support a discrete social prescribing pathway for autistic adults or upskill existing providers to adapt their practice for autistic adults. The research also adds to the growing literature on peer support and self-determination as important mechanisms for wellbeing in autistic people.

406.336 (Poster) Accuracy of the Screening Tool for Autism in Toddlers (STAT) in the Primary Care Setting

(1)Pediatrics, Indiana University School of Medicine, Indianapolis, IN, (2)Biostatistics, Indiana University School of Medicine, Indianapolis, IN, (3)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN

Background: Community-based models for evaluation of young children at risk for autism spectrum disorder (ASD) may be one solution for reducing diagnostic delays and disparities. However, feasible and accurate observational assessment tools are needed for such evaluation models to be scalable. The Screening Tool for Autism in Toddlers (STAT) is a level-2 ASD observational tool with strong psychometric properties when used by ASD experts, and recent research has provided further evidence for STAT utility with non-specialists across community settings. To date, large-scale community-based studies of STAT accuracy are lacking.

Objectives: To evaluate accuracy of the STAT when used by primary care providers (PCP) across a statewide system for early ASD diagnosis. Specifically, we investigated agreement between STAT outcome and 1) PCP ASD diagnosis, 2) ADOS-2 classification, and 3) expert best-estimate clinical diagnosis of ASD. Finally, we examined clinical characteristics of children who received an inaccurate STAT ASD categorization.

Methods: Early Autism Evaluation (EAE) Hubs have been established in primary care practices across Indiana. EAE Hub PCPs are trained to conduct a standardized ASD evaluation of at-risk children (ages 14-47 months) and participate in a longitudinal learning collaborative. The EAE Hub evaluation includes administration of a DSM-5 focused caregiver interview and administration of the STAT. As part of a larger study of EAE Hub accuracy, 130 children (M=2.6 years; SD=0.6; 76% male; 71% non-Latinx White; 29% other race/ethnicity) from 7 EAE Hubs were evaluated in a follow-up blinded research-grade evaluation conducted by ASD experts (including caregiver DSM-5 ASD interview, Mullen Scales of Early Learning [MSEL], Vineland Adaptive Behavior Scales [Vineland-3], and Autism Diagnostic Observation Schedule [ADOS-2]).

Results: STAT ASD categorization matched EAE Hub PCP diagnosis in 86% of cases (STAT Fail, ASD diagnosis: 75/82; STAT Pass, non-ASD diagnosis: 37/48). STAT ASD categorization matched ADOS-2 ASD classification in 77% of cases (STAT Fail, ADOS-2 ASD: 80/104; STAT Pass, non-ASD outcome: 20/25). STAT ASD classification aligned with expert best-estimate clinical diagnosis in 78% of cases [102/130; true positive (TP)=58%; false positive (FP)=8%; true negative (TN)=20%; false negative (FN)=14%], with sensitivity of 0.81, specificity of 0.72, positive predictive value (PPV) of 0.88, and negative predictive value (NPV) of 0.59. Compared to TP, FN cases (STAT Pass; ASD outcome) were older (p=.005), more likely to identify as non-Latinx White (p=.02), and evidenced higher developmental (MSEL; p<.001) and adaptive (Vineland-3; p<.004) skills and lower ASD symptom severity (ADOS-2; p<.004).

Conclusions: Community-based PCPs trained as part of a statewide longitudinal learning collaborative for ASD evaluation can utilize the STAT to diagnose ASD in most young children. Overall, the STAT shows adequate accuracy characteristics when used by non-specialist PCPs. Our accuracy metrics suggest that, overall, most children who fail the STAT are likely to have ASD; however, children deemed not at-risk on the STAT often require more comprehensive evaluation for accurate diagnosis. Further, children for whom the STAT underclassifies ASD risk show a discrepant clinical profile. Findings have implications for training of non-specialist clinicians, specifically regarding identification of cases requiring referral for specialized ASD evaluation.

406.337 (Poster) In-Vivo and Virtual Reality Training Increases Autism Knowledge and Confidence for Law Enforcement Officers

L. Gardner and J. M. Campbell

(1)Johns Hopkins All Children's Hospital, St. Petersburg, FL, (2)Psychology, Western Carolina University, Cullowhee, NC
Background: Historically, law enforcement officers (LEOs) in the US are not well trained in autism spectrum disorder (ASD; Modell & Mak, 2008). Gardner and colleagues (2019) found the majority of LEOs reported they had no formal training in ASD, despite working in a state that has required ASD-specific training since 2016. Although law enforcement departments throughout the United States may provide autism training, these programs often vary widely in length, format and quality. In considering the ideal training format to increase LEO awareness of ASD, in-person training is considered superior to online training modules. Teagardin and colleagues (2012) provided ASD-related training to LEOs via video. The authors concluded that video training alone is insufficient to train LEOs on how to assess and respond to autistic individuals. Instead of video or online training, in-vivo training is recommended combined with opportunities for role-playing and hands-on activities to supplement training (Gardner et al., 2019). As a prevalent population within our society, an understanding of autism by LEOs is warranted; however, best-practices in training LEOs to increase ASD knowledge remains an under-researched area.

Objectives: The primary author created a training program for LEOs that prepares officers to respond to calls involving autistic individuals. This training includes a three-hour training utilizing in-vivo and virtual reality. LEOs who participated were asked to complete a pre- and post-training questionnaire that assessed knowledge of ASD and confidence in responding to calls with autistic people. The purpose of the present study was to determine if a combination of in-vivo and virtual reality training (a) impacted LEOs knowledge of ASD, and (b) increased confidence in responding to calls.

Methods: Sixty-six (N = 66) LEOs attended two separate training sessions. LEOs were 78.5% male with a mean age of 34.63 years (SD = 6.8) and 8.69 years of law enforcement experience (SD = 7.2). Most LEOs (n = 33; 52.4%) reported receiving prior training in autism. Each participant completed a pre- and post-training questionnaire assessing knowledge of ASD and confidence in responding to calls. Results: All LEOs who responded (n = 62; 94% of the sample) reported the training increased their understanding of autism. Likewise, all LEOs who responded (n = 61; 92% of the sample) reported the training would impact their professional interactions with autistic individuals. Younger LEOs with fewer years of experience reported greater increases in confidence. Increased knowledge and confidence did not differ by gender, previous autism training, or personal relationships with an autistic person.

Conclusions: Combined in-vivo and virtual reality training significantly increased pre- and post-test scores of LEO knowledge of autism and confidence in responding to calls for all participants. Younger LEOs with less experience responded with greater increases in confidence, which may indicate virtual reality as a viable training approach for younger officers. Future research should investigate the long-term impacts of autism training on LEO behavior and call outcomes from the perspective of both LEOs and autistic civilians.

406.338 (Poster) Addressing the Autism Waitlist Crisis: Using Project Echo As a Method of Increasing Diagnosis of ASD in Pediatric Primary Care
K. Casagrande1, A. V. Dahiya1, J. Gerds1, G. Stobbe1 and J. Mancini1, (1)Department of Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (2)University of Washington LEND, Seattle, WA, (3)Seattle Children's Autism Center, Seattle, WA, (4)University of Washington, Seattle, WA

Background: Individuals with autism spectrum disorder (ASD) are at high risk for unmet service needs. This is especially true for diagnostic evaluations, which have long waitlists due to limited access to specialists. Additionally, families in rural and underserved communities may be less able to access specialty care sites due to barriers such as distance and cost. To address this, Washington State initiatives an Autism Center of Excellence (COE) program certifying primary care providers (PCPs) to diagnose ASD and encouraged participation in ECHO Autism Washington: a year-long tele-mentoring program in identification, diagnosis, and management of ASD based on the Project ECHO model. Support was provided by an interdisciplinary team of specialists, including autistic self-advocates.

Objectives: We aim to confirm previous findings that participation in ECHO Autism increases provider confidence and decreases perceived barriers to providing diagnostic and care management support. We examine changes in diagnostic clinical practices and referrals. Qualitative interviews will contextualize how participation in ECHO Autism impacts provider practices.

Methods: Seventy-seven medical providers (23 of 39 Washington counties; 83% urban, 17% rural practice locations) enrolled in one year of ECHO Autism Washington. Information was collected pre-, mid-, and post-ECHO about confidence, perceived barriers, autism diagnostic practice patterns, and self-efficacy via a modified version of the Primary Care Autism Self-Efficacy (PCASE-M) survey. Non-ECHO COE providers served as a convenience sample comparison group. Diagnostic referrals from ECHO providers to Seattle Children’s Autism Center (SCAC) were tracked. Follow-up interviews were conducted with a subset of ECHO providers (n=19) to understand how ECHO influenced practice change and needed implementation supports. Purposive sampling was used to promote diversity of provider roles and location. Interviews were analyzed using emergent thematic analysis.

Results: After one year of ECHO, the number of autism diagnoses given by providers increased significantly (F(1, 65)=7.52, p=.008). Providers who attended more sessions reported making more diagnoses (F(2, 613.26), p=0.045). The average number of SCAC diagnostic referrals from ECHO providers significantly reduced during ECHO (t(43)=4.23, p<.001). ECHO providers reported making significantly more autism diagnoses than non-ECHO providers (t(40)=2.00, p=.05). The total number of reported barriers reduced (F(2, 61)=13.5, p<.001), and PCASE-M ratings increased in all areas, (F(2, 60)=24.21, p<.001), including knowledge of autism diagnostic criteria and...
confident in making independent autism diagnoses. Follow-up interviews indicate providers felt underprepared to diagnose ASD following initial state-level COE certification. Providers valued the ongoing education, case presentations, and supportive ECHO Autism community. They directly attributed increases in their diagnostic practice to their participation in ECHO.

**Conclusions**: ECHO Autism is an effective way to empower PCPs to diagnose autism in their own practices in community settings. Ongoing mentorship and support through ECHO are critical components of success. The ECHO model can be feasibly adapted to diminish the gap in unmet autism diagnostic service needs. Further, increased community capacity for diagnosis can reduce referrals to tertiary care sites and may increase access in rural or underserved communities. This may improve the quality-of-care families receive and increase access to those who face barriers accessing evaluation outside their primary care setting.

### 406.339 (Poster) Improving Healthcare Experiences for Autistic Individuals: A Scoping Review

**H. Harris**, C. Rotman, E. Friedlaender, A. M. Neumeyer, S. Broder-Finger, S. J. Spence, A. Friedman, S. Krauss, L. Weissman and C. Weitzman*, (1)Pediatrics, Developmental Behavioral Pediatrics, Meyer Center for Developmental Pediatrics, Texas Childrens Hospital, Baylor College of Medicine, Houston, TX, (2)Medical Library, Boston Children's Hospital, Boston, MA, (3)Pediatrics. The Children's Hospital of Philadelphia, Philadelphia, PA, (4)Lurie Center for Autism Massachusetts General Hospital, Lexington, MA, (5)UMASS Medical School, Boston, MA, (6)Autism Spectrum Center, Department of Neurology, Boston Children's Hospital, Boston, MA, (7)Developmental and Behavioral Pediatrics, Boston Medical Center, Boston, MA, (8)Boston Medical Center, Boston, MA, (9)Boston Children's Hospital, Boston, MA, (10)Harvard Medical School, Boston, MA

**Background**: Autistic individuals have increased need for accommodations in healthcare settings due to communication challenges, sensory sensitivities, behavioral rigidity and difficulty with transition. While previous literature has assessed some of the caregiver, patient and provider-reported barriers to care for autistic individuals, there has not been a scoping review of the literature on intervention effectiveness, inclusive of all potential healthcare settings.

**Objectives**: We sought to conduct a scoping review of the literature to explore existing studies on improving healthcare experiences for autistic individuals. We were particularly interested in understanding study setting, study design, sample sizes and intervention content.

**Methods**: Literature from January 2005 to October 2020 was reviewed via searches conducted by a medical librarian, using PubMed, EMBASE, CINAHL and PsychINFO. Hand searching was also utilized to capture new, relevant publications. Searches were limited to English-language articles and results were exported to Covidence review software for screening by the study team. Figure 1 summarizes the stages of the review. All abstracts and papers were reviewed by at least 2 authors at every stage.

**Results**: Thirty-eight studies met inclusion criteria and the majority (N=25) were completed in the United States. (Table 1) Dental settings were most common (N=12) followed by psychiatric and procedural settings (N=6 each). There were 3 randomized controlled trials (RCTs) with the majority of studies (N=17) being descriptive (e.g. chart reviews, cohort studies) or survey design (N=7). Interventions most commonly targeted pre-visit planning and preparation (N=13) followed by procedural support and accommodations (N=10). Three studies assessed large system change. The most common outcome assessed was procedural compliance (N=15). A total of 33 of studies (87%) had a sample size 100 or less. Cultural considerations were not addressed in any of included studies and only one study utilized feedback from autistic adults when developing the intervention.

**Conclusions**: Methodologically sound, outcomes-based studies of interventions that improve care of autistic individuals in healthcare settings are limited and contain small samples. Most of the research has been conducted in dental and perioperative based settings, due to the necessity for procedure completion with no studies completed within pediatric inpatient settings. Future work assessing intervention effectiveness must include the feedback of autistic individuals themselves.

### 406.340 (Poster) Assessing Provider-Reported Use of Evidence-Based Early Intervention Practices within Georgia’s State Funded Early Intervention System

**E. Chatson**, H. Davies, B. Demetri, M. Yohannes, N. M. Hendrix and K. Pickard*, (1)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA

**Background**: Naturalistic developmental behavioral interventions (NDBIs) are considered a validated intervention approach for young autistic children and children who have an increased likelihood of being autistic (Schreibman et al., 2015). The use of NDBIs has been popularized through Early Intervention (EI) systems because they facilitate access to services for families with 0-3-year-old children with developmental delays (Aranbarri et al., 2021). Research has shown that NDBIs are used frequently by interventionists (Pickard et al., 2021); however, more research is needed to understand the provider- and system-level factors that influence practices in community-based EI systems and to develop solutions for better implementation methods (Stahmer & Aarons, 2009; Stahmer et al., 2019).
Objectives: Objectives of the current study are: 1) to examine provider-reported use of NDBI within Georgia’s Part C EI system; and 2) to examine the extent to which providers’ background, attitudes, and perceived organizational support predict use of NDBI strategies.

Methods: One hundred EI providers (Mage=47.2 years, SD=12.55) completed a survey including: 1) demographic information including age, gender, disciplinary background, and years of experience working within EI systems and with autistic children; 2) attitudes towards evidence-based practices (EBPs) (Aarons et al., 2009); 3) system-level resources and support to attend training (Lehman et al., 2002); 4) provision of family-centered care (King, King, & Rosenbaum, 2004); 5) delivery of NDBI strategies in their most recent session (Frost et al., 2020); and 6) level of experience with manualized NDBI programs (Frost et al., 2020). Descriptive statistics were used to examine provider reported NDBI use; linear regression models were used to examine factors predicting NDBI use.

Results: During their most recent session, providers reported using 5.74 (SD=2.69) developmental NDBI strategies (D-NDBIs) and 5.77 (SD=2.72) behavioral NDBI strategies (B-NDBIs). When looking at strategy frequency, providers reported verbally responding to the child’s attempts to communicate in about 74% of the session while directing the child to demonstrate new skills in about 46% of the session. D-NDBI and B-NDBI use was significantly predicted by provider openness and appeal to new interventions as well as providers’ self-reported use of family-centered care. The final models explained 35.0% and 31.6% of the variance in D-NDBI (F=4.836, p<0.001) and B-NDBI (F=4.152, p<0.001) use, respectively. Specifically, provider openness to new interventions explained a significant proportion of variance in D-NDBIs (b=0.546, t(70)=4.08, p<0.001) and B-NDBIs (b=0.491, t(70)=3.58, p<0.001).

Conclusions: Preliminary analyses suggest that provider openness to EBPs predicted greater use of D-NDBI and B-NDBI strategies, indicating that provider attitudes towards EBPs are important to consider when implementing interventions. System-level factors did not predict provider use of NDBI strategies. While provider reports offer a deeper understanding of their use of NDBIs, this research lacks the perspectives of children and families who are on the receiving-end of interventions. However, these findings provide insight on factors necessary for successful uptake of NDBIs within EI systems. Future directions include expanding survey measures to include the perspectives of families within EI systems and expanding the administration of provider-report surveys to compare evidence-based intervention implementation across multiple community EI systems.

406.341 (Poster) Autism CanTech!: Overcoming Barriers to Autistic Youth Post-Secondary Education and Employment in the Canadian Digital Economy through Holistic Supports

J. B. Leifso and J. Gauthier, (1)10230 108 Street NW, NorQuest College, Edmonton, AB, Canada, (2)NorQuest College, Edmonton, AB, Canada

Background: Canadian Autistic youth face high levels of unemployment, poverty and barriers in gaining and maintaining employment. Funded in part by the Government of Canada under the Youth Employment and Skills Strategy, Autism CanTech! (ACT!) is a pilot program aimed at studying the outcomes of providing Autistic-centred training and supports for Autistic youth (18-30) and employers. Using the lens of the social model of disability (Oliver 1983; 1990; 2013), ACT! aims to improve the employment outcomes of those with Autism and to ensure employers can foster inclusive work environments. ACT! aims to provide supports for both employers and Autistic youth to gain and maintain employment in the Canadian digital economy.

Objectives: To understand and redress barriers to post-secondary education and employment faced by the Autistic community and discover what supports and environmental factors create inclusive spaces for Autistic learners and workers to thrive within the Canadian digital economy.

Methods: The study focused on acquiring qualitative data, through semi-structured focus groups, interviews and secondary analysis of program evaluation data and outcomes of Autistic participants, ACT! Employer-Partners, their natural supports, and ACT! staff. Data was analyzed through Thorne’s Interpretive Descriptive method and situated within disability justice and labour, Oliver’s Social model of disability and intercultural human resource theories.

Results: Data identified that Autistic individuals experience barriers to accessing post-secondary education and employment (ie. Recruitment process; rigid environments; supervisory instruction; culture, etc.). Autistic individuals also experience “burnout” from ill-suited environments and are not equipped for advocacy. The tailored post-secondary experience, unique supports, and bridging to employment resulted in a 41% employment rate and 12.5% further educational attainment. ACT! dispelled attitudinal barriers within employer-partners and supported them throughout the program with training, and support from the Career Coaches and the ACT! Inclusion and Accessibility Consultant. Autistic workers, much like their neurotypical counterparts, can be successful in a variety of work environments, with strong individual preferences for both in-person and remote work, and an ability to adapt to the technologies provided for task management particularly when employers have been trained and supports are in place to meet their unique needs, provide clear communication, and provide concise task delegation. Removing post-secondary and employment barriers mitigates broader systemic barriers faced by Autistic adults. To fully thrive, Autistic adults also require supports from external society such as access to education, affordable sustained mental health supports, housing, transportation, and community, which can be partially mitigated through sustained employment.
Conclusions: In our study, Autistic learners and workers overall do not require specialized software to complete tasks but rather adequately trained educational and work environments that value inclusion and create processes for equitable approaches to meeting access needs. Employer partners benefit from tailored training in working with Autistic youth, confronting a lack of knowledge regarding the Autistic community. Additional community supports are needed for Autistic workers to thrive including adequate housing, transportation and consistent, sustained mental health supports. More research is needed regarding post-program sustained supports requested from both employers and Autistic youth as well as accessible pathways through post-secondary education.

406.342 (Poster) Autism Spectrum Disorder (ASD) in a Developing Country- Age at Diagnosis and ASD Comorbidities.
P. Bahadursingh¹, K. Morris¹, C. Adolph¹, A. Ali¹, E. Balkaran¹, C. Bissessar¹, V. Chaitram¹, N. Khan¹ and D. Ramsingh¹, (1)University of the West Indies, San Fernando, Trinidad and Tobago, (2)Paediatrics, South West Regional Health Authority, San Fernando, Trinidad and Tobago

Background:

A specialty community paediatric service was initiated in 2011 within a health authority serving a 600,000 population in a developing country. This was the only service in the region providing specialized assessment for children with developmental concerns. In 2011 fifty percent of referrals were for developmental concerns and by 2019 this increased to 90%. The percentage of children seen for ASD annually within the clinics ranged from 25% to 41%.

Objectives:

We sought to determine the ages at first diagnosis for children with ASD and the proportions of children with comorbidities including Attention Deficit Hyperactivity Disorder (ADHD), Learning Difficulty (LD), Global Developmental Delay (GDD), Speech Difficulty, Feeding problems, Obesity, Epilepsy and Sleep onset delay.

Methods:

A Database on Microsoft Excel regarding patients with Autism Spectrum Disorder attending the community pediatric clinics at the health authority was reviewed for the period Sept 2018 to August 2019. The data was analyzed using Microsoft excel spreadsheet.

Results:

The numbers of children seen for ASD steadily increased from 2012 to 2019. 178 children were seen in 2012 and 724 in 2019. The odds of being diagnosed ASD in 2019 was significantly higher compared to 2012 (OR 1.8; 95% CI 1.5-2.1; P < 0.0001).

From September 2018 to August 2019, 83 new patients (71 Male), were diagnosed with ASD. 21(25%) age 2-3yrs, 23(28%) age 3-4yrs, 12 (14%) age 4-5yrs, 22 (27%) age 5-12yrs and 5 (6%) age more than 12yrs. 53% had first diagnosis before the age of 4yrs (median age 46 months). The average age of diagnosis was 62 months. 641 (513 M) had a previous diagnosis of ASD; 507(79%) were more than 5yrs.

Co-morbidities

From September 2018 to August 2019, 114 (15.7%) children with ASD were diagnosed ADHD (98% were more than 5yrs of age). In the more than 5 yrs category 21% were diagnosed with ADHD. 197 (27%) had LD. 122 (16.9%) had GDD. 396 (54%) had speech difficulty. 53 (7.3%) had feeding problems. 24 (3.3%) had epilepsy. 68 (9.4%) were obese or overweight (96% were more than 5yrs). 30 (4.1%) had sleep onset delay.

Conclusions:

Using an approximate 0-19 population of 168,000 for the health authority and an estimated worldwide prevalence of 1% for ASD, approximately 1,680 patients were expected to have ASD. 724 children were seen during 2018 to 2019 which is less than 50% of the expected numbers. It is likely that ASD is still under diagnosed and a prevalence study is needed.

47% had a diagnosis after the age of four years. The average age for first diagnosis was 62 months. A large percentage of children are not being detected between the ages of 2-4 yrs. A national screening program needs to be considered.

In the more than 5 yrs category 21% were diagnosed with ADHD. This is lower compared to international data. Children may need to be more actively assessed for ADHD.
The proportions of children with other co-morbidities were lower compared to international data. A local prevalence study regarding ASD and its comorbidities is required.

**N. Khan**, C. Mirzaian, O. Solomon, A. Deavenport-Saman and L. Yin, (1)Children's Hospital Los Angeles, Los Angeles, CA, (2)Children's Hospital Los Angeles/Keck School of Medicine of USC, Los Angeles, CA

Background: Autism spectrum disorder (ASD) is associated with higher rates of comorbidities and healthcare utilization compared with children of typical neurodevelopment. Disparities by sex and age have been described in the literature before, though findings from cohort and registry studies are at times discordant.

Objectives: To describe the prevalence of ASD, mental health comorbidities, healthcare utilization, and caregiver wellness among children with ASD compared with children with and without other special healthcare needs (SHCN). We also describe differences within the ASD population by age and sex, and before/after the COVID-19 pandemic.

Methods: The National Survey of Children’s Health (NSCH) is a nationally representative survey, the methodology of which is published and publicly available (www.childhealthdata.org). Data includes caregiver report of current ASD along with other SHCN. We analyzed data from 2016-2021 and used multiple logistic regression to test for trends over survey year. We provide point estimates of prevalence and 95% confidence intervals (CI). All analyses accounted for the complex survey design and were conducted using Stata IC/15.1.

Results:

The final sample (n=191,382) represented a population of 60.7 million children ages 3-17 years. The pooled prevalence of ASD was 2.85%, representing 1.7m children. Prevalence per year varied from 2.4% to 3.1%, and there was no significant trend over time (p=0.198). Compared to both children with and without other SHCN, children with ASD were less likely to have excellent/very good general or dental health, along with numerous other comorbidities (Table 1).

The proportions with ASD receiving behavioral treatment or medication over the past 12 months were 58.5% and 25.6%, respectively. There were no significant differences by sex (Table 2). Fewer children ages 11-17y received behavioral therapy and more received medication.

ASD was associated with more mental health services use, unmet need, and frustration in obtaining care compared with those both with and without other SHCN. Among caregivers of those with ASD, 51.5% (48.3 - 54.7%) report sometimes, usually, or always being frustrated with obtaining care, compared with 34.4% (33.3 - 35.4%) among caregivers of other children with SHCN and 12.8% (12.4 - 13.3%) of caregivers of children without SHCN. Children with ASD and other children with SHCN were more likely to have visited an emergency room or needed referrals within the past year.

Caregiver wellbeing and stressors of care were generally worse among those with ASD, with 13.9% reporting their child was “always” harder to care for, compared with 3.9% among other children with SHCN and 0.34% among children without SHCN. Frustration in access to care was associated with worse caregiver wellness. There were no significant differences in caregiver stress by child’s sex or between time periods prior to and during the COVID-19 pandemic.

Conclusions: ASD is associated with high care utilization and unmet need, and inadequate access to care is associated with caregiver stress. High pre-pandemic need did not increase from 2016-2019 to 2020-2021.

**406.344 (Poster) Autism, Ageing, and Social Care**

**M. Stewart**, K. Sang, R. A. Charlton, A. J. Gow, R. Woolrych, M. Dragone, J. Rodgers, J. R. Parr, P. Heslop and C. Stewart, (1)Psychology, Heriot-Watt University, Edinburgh, UNITED KINGDOM, (2)Heriot-Watt University, Edinburgh, United Kingdom, (3)Psychology, Goldsmiths University of London, London, United Kingdom, (4)Psychology, Heriot-Watt University, Edinburgh, United Kingdom, (5)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (6)Northumbria University, Newcastle Upon Tyne, United Kingdom, (7)SWAN: Scottish Women's Autism Network; Scottish Autism, Dunblane; United Kingdom of Great Britain and Northern Ireland

Background: For autistic people, the ageing process may be challenging as their health and social care needs change with age. These changes are likely to intersect with autism-related support needs such as anxiety and difficulties with change and uncertainty, difficulties with executive function, autobiographical memory, and the ability to think about the future \(^{11}\). Autistic community-led ageing priorities identified via scoping sessions, focus groups and literature reviews\(^{12}\) indicate that support needs should include focus on health and wellbeing in ageing; people’s understanding of the ageing process; service planning; relationships and social inclusion; and legal and financial advocacy.
Objectives: To identify the areas of priority and gaps in social care support for older autistic people, identify what healthy ageing looks like for older autistic people, and provide recommendations for social care workers regarding how autistic people may be better supported to thrive as they age.

Methods: We conducted 3 rounds of interviews with autistic people and social care providers (a total of 33 interviews), the first identified priorities, gaps and good practice in social care support, the second focused on healthy ageing, and the third on provision of care within the home. Autistic people aged 50+ were recruited via a range of community organisations and networks, social media, and word of mouth. Social care providers were recruited through organisations, charities, councils, and social media. Ethical approval was granted by the University Ethics committee. Informed consent was gained from all participants before taking part. All interviews were conducted online (due to COVID restrictions), either via text, with video and voice, or just voice depending on participant preference. Interview data are being analysed by reflective thematic analysis (to be completed 01/23)

Results: Early themes are emerging, for instance, participants have raised themes as priorities such as: interaction with the healthcare; Healthy Ageing, Residential Care, and Lifelong Planning; and Training of Professionals. Autistic people reported a lack of understanding and knowledge among professionals relating to how best to work with them as they age. Autistic people reported a sense of fatigue that they have to continually train others in how to work with them. Autistic people reported the disabling effect of an impairment approach and the lack of use of a strengths-based approach and how that influenced engagement. Social care providers reported the need for specialised training in working with intersecting needs.

Conclusions: Older autistic people are not receiving the support they require to thrive. It is important that professionals are adequately trained to both work with autistic people and in working with age-related changes. The medical model can be disabling and othering (make autistic people feel different), it is important that a strengths-based approach is embedded in care.

406.345 (Poster) Barriers and Facilitators to Early Intervention Services: A Study of How Caregivers Access Part C State Systems
Q. O. Wedderburn, K. Rowland and S. R. Edmunds, (1)The University of South Carolina, Atlanta, GA, (2)University of South Carolina, Columbia, SC

Background: The US Individuals with Disabilities Education Act (IDEA) of 1975 established Part C, a mandate for the provision of free, state-administered Early Intervention services for developmentally delayed children aged 0-3. Although autism is not a federally mandated Part C eligibility criterion, more toddlers with autism enter Part C each year. It is unclear how caregivers find and access Part C services for their child in each state, what barriers and facilitators there are to caregivers’ access to Part C information and services, or whether the accessibility of services predict their use. Given the heterogeneity of these systems from state to state, it’s important to consider how states approach the accessibility of Part C services to families of diverse backgrounds.

Objectives:

- To define and measure accessibility metrics of all 50 publicly available Part C state websites.
- To determine whether accessibility and mention of autism varies by state.
- To correlate accessibility with state-by-state Part C service use.

Methods: All data was generated from publicly available state Part C websites and the 2019 federal Office of Special Education Programs (OSEP) Annual Report to Congress. Four constructs measuring accessibility were operationalized and analyzed from Part C websites for all 50 U.S. states: languages offered; information availability and ease of access; convenience of methods for child referral; and website visual appeal and readability. The percentage of children under 3 enrolled in Part C services for each state was extracted from the OSEP report.

Results:
On average, 3% of children under three are enrolled in each state’s Part C system (SD=1.7%), with little variability by population size of state (Figure 1). 48% (N=24) of states included autism or social communication delays in their eligibility criteria. Most state websites (60%; N=30) had translation tools available for more than one language. Several states (78%; N=39) had information on child referral available in one click or less from the Part C home page, and several states (76%; N=38) allow any concerned adult to refer to Part C services. However, the method by which a child can be referred varied across states. Most states did not have online referral forms available (60%; N=30). Lastly, every website was given a visual appeal and readability rating of 1-5 by two independent raters; on average, ratings were moderate to low (M=2.7) and normally distributed with notable variability (SD=1.05).

Correlations between accessibility measures were weak-moderate in size, ranging from r=-0.3 to r=0.36 (Figure 2). Correlation analyses yielded no statistically significant relation between website accessibility and the 2019 state-by-state enrollment of children in Part C services (p’s > 0.05).

Conclusions: While state Part C websites do show promising accessibility (language access, universal referral), there is room for improvement (lack of online referral; website readability; whether autistic children are served). Information accessibility does not appear to affect rate of enrollment, although more recent OSEP data is needed. Future work will create a novel, comprehensive accessibility construct for early intervention government services. Further work will provide insight into diverse caregiver perspectives on how they approach seeking early intervention services for their developmentally delayed and/or autistic children.

406.346 (Poster) Barriers/Enablers for ASD Children for Vision Evaluation Review (BEAVER)

R. A. Coulter, A. Bade', M. Combs', S. Krueger', P. Beegle, B. Zhang, D. Kurani and S. Patel, (1) College of Optometry, Nova Southeastern University, Ft Lauderdale, FL, (2) Optometry, Nova Southeastern University, Fort Lauderdale, FL, (3) Health Professions Library, Nova Southeastern University, Ft Lauderdale, FL, (4) Farquhar Honors College, Nova Southeastern University, Ft Lauderdale, FL

Background: Children with Autism Spectrum Disorder (ASD) are at increased risk for vision and ocular health problems including significant refractive error (particularly astigmatism), strabismus, amblyopia, anisometropia and optic neuropathy. Though at increased risk, ASD children are less likely to complete vision screenings at their pediatrician’s office or school and are less likely to receive comprehensive vision examinations.

Objectives: This review investigates barriers and enablers for vision screenings and vision examinations for ASD children and categorizes those identified by previously defined themes including: challenges associated with autism-related characteristics, challenges experienced by vision care providers, challenges related to the health care system, and challenges experienced by the family, caregiver or household.

Methods: A pre-registered systematic review was conducted (CRD42022344299). Ovid MEDLINE, EMBASE.COM, Web of Science Core Collection (select indexes), ProQuest PsycINFO, ProQuest Dissertations and Theses Global, Cochrane CENTRAL (EBSCO) and CINAHL were searched. In addition, a handsearch of past International Society for Autism Research meeting abstracts was completed. Using the Rayyan platform, titles and abstracts were screened against eligibility criteria. Included were research studies (quantitative or qualitative) in English, published from 1994 or later (correlating with DSM-IV criteria), investigating vision screening or vision examinations in ASD children (<18 years) with a primary population of ASD children, their families or caregivers, vision screening personnel or eye care providers, or support staff or organizations for ASD children. Excluded were literature reviews, systematic reviews, case reports and case series and publications published earlier than 1994. Studies were also excluded if their focus was not specific to children with autism or if it was not possible to extract data pertaining to autistic participants.

Results: 2452 unique publications were identified through the database searches. The handsearch of past International Society for Autism Research meeting abstracts identified 3 more abstracts. Screening of titles and abstracts was completed for 2455 publications. Full text publications were reviewed for 233 articles. Forty-six publications were included; 32 of these focused on visual diagnostic or screening results, 7 investigated challenges associated with autism-related characteristics, 4 investigated eye care provider/vision screener-based issues, and 5 investigated challenges related to organizational issues including those within the health care system. Underway, included articles will be appraised using the Mixed Methods Appraisal Tool (MMAT). Data, from included studies, will be used to construct a data matrix. From the data matrix and MMAT results, a narrative synthesis will be constructed to identify patterns of consistency and divergence.

Conclusions: Barriers and enablers for vision care access for children with autism are present and occur at the patient, provider, family/caregiver and systematic levels. There is a dearth of investigations targeting issues experienced by eye care providers and vision screeners or issues experienced by family, caregiver, or households of ASD children.

406.347 (Poster) Battling the Bottleneck for Autism Spectrum Disorder Diagnosis and Care: Training a Primary Care Community Sample

A. V. Van Hecke, S. A. Lehman, M. Carlson, N. Johnson, K. A. Kotik, L. Jepson and A. Leventhal, (1) Psychology, Marquette University, Milwaukee, WI, (2) Education, Marquette University, Milwaukee, WI, (3) Nursing, Marquette University, Milwaukee, WI, (4) Medical College of Wisconsin, Milwaukee, WI, (5) Next Step Clinic, Milwaukee, WI
Background: Primary Care Practitioners (PCPs) in the US widely do not diagnose ASD (Martinez et al., 2018) and report being uncomfortable with assessing ASD risk (Carbone et al., 2013). Instead, they often refer families to scarce ASD specialty clinics with long waiting lists. This results in delayed identification and access to supports and intervention. Minority children, and children who live in underserved areas, are even more affected, receiving diagnoses less frequently, and years later, than their suburban, white counterparts (Angell et al., 2018; Constantino et al., 2020; Dababnah et al., 2018). Efforts to train PCPs in streamlined ASD diagnosis within Primary Care (PC) are growing (Ahlers et al., 2019; Hine et al., 2018, 2020), but these training programs are not currently widely implemented.

Objectives: The study aimed to replicate the initial findings of Hine and colleagues, via training a novel group of PCPs in streamlined ASD diagnosis of “uncomplicated” (i.e., high screening scores and low comorbidities) toddlers, and extend prior work by including a cohort of Family Navigators (FNs) being trained in ASD co-care coordination, while examining impacts of the training and learning community on knowledge, attitudes, and PC ASD practices.

Methods: PCP (n=9) and FN trainees (n=7) were recruited from a mid-sized midwestern US city and consented utilizing an Internal Review Board-approved protocol. See Table 1 for demographics. PCP and FN trainee participants completed online demographics and an adapted version of the Practice Behavior Questionnaire (PBQ: Hine et al., 2021) pre and immediately post STAT™ (Screening Tool for Autism in Toddlers & Young Children) initial training sessions, and 6 and 12 months later. The adapted PBQ assessed: knowledge of screening/diagnosis of ASD, current practice/intention to diagnose ASD, attitudes on appropriateness of ASD diagnosis in PC, and comfort level with ASD. After STAT™ training, PCPs and FNs participated in a year-long ASD learning community, moderated by an interdisciplinary research/community implementation team. Monthly meetings consisted of education on ASD topics and case consultation.

Results: Data presented here refers to pre and immediately post STAT™ training: additional longitudinal results will be added as available. From pre to post, trainee’s attitudes shifted to rating in-house ASD diagnosis as more appropriate, \( t(8) = -2.27, p = .05 \), Cohen’s \( d = 1.32 \); to feeling more comfortable identifying ASD characteristics, \( t(8) = -2.27, p = .05 \), Cohen’s \( d = 1.32 \); and to being more comfortable having the diagnosis discussion with families, \( t(8) = -5.38, p < .001 \), Cohen’s \( d = 1.05 \). PCP trainees were more likely to endorse attempting an in-house diagnosis vs. referring a patient to a specialist after STAT™ training [Likelihood ratio(1) = 3.86, \( p = .05 \); 40% likely to attempt in-house diagnosis at pre compared to 100% likely at post].

Conclusions: ASD diagnostic and care coordination training improved ASD attitudes, knowledge, and intentions to diagnose/serve families in PC. Examination of longitudinal data from these participants will gauge number of families served and screening to diagnosis lag times. ASD diagnosis and care within PC has potential for improving and streamlining diagnostic flows, especially for marginalized populations who experience inequities in access to ASD care.

406.348 (Poster) Behaviour Therapists’ Confidence, Knowledge, Attitudes, and Practice Experiences with Autistic Youth with and without Mental Health Challenges

M. Charalampospouli, C. Gallant, N. Eddy, K. M. Thomson, B. B. Maddox and J. A. Weiss; (1)Psychology, York University, Toronto, ON, Canada, (2)Applied Disability Studies, Brock University, St. Catharines, ON, Canada, (3)University of North Carolina at Chapel Hill, Carrboro, NC

Background: Behaviour therapists (BTs) play a critical role in supporting the communicative, cognitive, and behavioural needs of autistic children and youth. Although many therapists may not specialize in mental health, they will often encounter autistic clients with mental health challenges in their practice and must take this added experience into account. Little is known, however, about the practice experiences of BTs in supporting autistic clients with mental health challenges.

Objectives: In partnership with Children’s Mental Health Ontario, this study aimed to understand the experiences, perceptions, and training needs of BTs providing services to autistic clients who also present with mental health problems.

Methods: Two-hundred and forty-one Ontario BTs (\( M_{\text{age}} = 35.1; 94.2\% \text{ cis-female}; 80.1\% \text{ White}; 46.4\% \text{ with 10+ years of experience}) completed an anonymous online survey. Participants reported on the proportion of autistic clients with mental health problems on their current caseloads, the proportion with severe/intensive needs, and the most common mental health problems encountered. Participants also completed a single item assessing their confidence in delivering their services (5-point Likert scale; Maddox et al., 2019), a 6-item self-rated knowledge measure related to autism and mental health (5-point Likert scale; Brookman-Frazee et al. 2012; Maddox et al., 2019), three items assessing their organizational resource needs (Zerbo et al., 2015), and five standard semantic differential scales (10-point slider scale; Fishbein & Ajzen, 2010) to assess their attitudes towards delivering their services to autistic clients with and without mental health needs.

Results: On average, BTs reported that autistic clients with mental health problems make up 33.3% (\( SD = 27.1 \)) of their current caseloads and that 42.5% (\( SD = 33.1 \)) of clients with mental health problems have severe/intensive needs. The three most common mental health problems encountered by BTs included anxiety (endorsed by 89.2% of providers), challenging behaviours (88.8%), and obsessive-compulsive and related disorders (51.5%). Wilcoxon signed-ranks tests indicated that therapists’ confidence was lower, \( Z = -12.7, p < .001 \), and organizational resources and support were less adequate, \( p’ s < .001 \), for clients with mental health problems compared to those without.
Similarly, while attitudes were generally positive regarding supporting clients with and without mental health challenges, paired-samples t-tests showed that therapists’ overall attitudes were more positive, \( t(234) = 14.6, p < .001 \), and their knowledge was greater, \( t(240) = 27.2, p < .001 \), for autistic clients without mental health problems compared to autistic clients with mental health problems. Therapists’ confidence, knowledge, and attitudes were all positively correlated among both client groups, \( p’s < .01 \).

Conclusions: Autistic clients with mental health problems make up a considerable proportion of BTs’ caseloads; however, many therapists do not feel as confident or equipped as they do when supporting clients without mental health challenges. Findings suggest a need for targeted training to build BTs’ capacity to support clients who also present with mental health challenges, especially in ways that can address reported gaps in knowledge and confidence.

406.349 (Poster) Building and Sustaining a Neurodevelopmental Disabilities Clinical Translational Core: A Riley Hospital for Children Division of Developmental Medicine Initiative

D. L. Reisinger, A. Paxton, C. James, and E. C. Kurtz-Nelson, (1)Indiana University School of Medicine, Indianapolis, IN, (2)Pediatrics, Indiana University School of Medicine, Indianapolis, IN

Background: While research has advanced our knowledge of and methodologies for evidence-based early diagnosis and intervention for children with autism spectrum disorder (ASD) and neurodevelopmental disabilities (NDDs), this progress has not translated into community clinical practice where the majority of children with NDDs receive services. Further, within the NDD population, there are unique recruitment barriers in comparison to those without disabilities. To address the research-to-practice gap in the field of NDDs, many clinics across the nation, including Riley Hospital for Children, are developing and successfully implementing interdisciplinary clinical core programs that integrate clinical practice with research in addition to building research registries to better advance the field in NDDs.

Objectives: The present study describes our division’s initiative to build a clinical research database and research registry, including current progress, how we shifted our clinic practices to sustain the database, lessons learned, and future directions.

Methods: We developed a clinical research database and research registry utilizing REDCap in an outpatient NDD assessment and treatment clinic for children up through age 18. We worked closely with our IRB to navigate appropriate consenting, including the development of an abbreviated consent form. Prior to all psychology testing appointments, caregivers were emailed a link to complete the online consent form and a standardized intake from to collect background information. Upon the patients completing their clinical visits, providers were emailed a link to upload their evaluation data and diagnoses into REDCap.

Results: We began building the clinical database and research registry in August of 2021. We officially launched the database and registry in May of 2022 for all our psychology evaluation patients. Since our launch, we have collected psychology evaluation data, including cognitive, adaptive, behavioral, and autism-specific measures on 390 patients (71.79% males) between the ages of 1 and 17 years (\( M=5.60, SD=3.45 \)) across our 9 clinical psychologists. The sample included 70.35% White, 15.70% African American/Black, 1.74% Asian, 0.58% American Indiana/Alaskan Native, and 8.14% patients reporting more than one race, with 3.49% of patients choosing not to provide an answer and 6.43% reporting Hispanic ethnicity. Primary diagnoses provided included ASD (53.8%), global developmental delay (17.7%), Other (8.7%), ADHD (5.9%), Intellectual Disability (5.9%), mixed receptive-expressive language disorder (4.1%), anxiety (2.1%), specific learning disability (0.5%), unspecified behavioral disorder (0.5%), no diagnosis (0.5%), and depression (0.3%). Our research registry and database has also received high support from caregivers with 78.2% of patients agreeing to be in the research registry and 82.5% agreeing to have their data included in the clinical database. Updated data and tips for success will be provided at the time of presentation.

Conclusions: Overall, this project has been the first step toward integrating our clinical and research activities to help address the much-needed research-to-practice gap within the field of NDDs. We plan to expand our database to include all clinical service lines offered, including speech, pediatrics, and genetics. We have already modified clinical practices to better serve our patients based on results collected to date and to achieve sustainability with limited funding sources.

406.350 (Poster) COVID-19 Mitigation and Infection Among Children with and without Autism (Ages 5-9 Years) Enrolled in the Study to Explore Early Development Phase 3 (SEED 3), COVID-19 Impact Assessment

R. Fitzgerald, C. Nadler, L. Eck, L. Wiggins, M. S. Durkin, and K. Pazol, (1)Washington University School of Medicine, St. Louis, MO, (2)Children’s Mercy Kansas City, Kansas City, MO, (3)Centers for Disease Control and Prevention, Atlanta, GA, (4)University of Wisconsin-Madison, Madison, WI, (5)Division of Human Development and Disability, CDC, Atlanta, GA

Background: Children with autism spectrum disorder (ASD) or other developmental disabilities (DDs) may be at increased risk for negative outcomes related to COVID-19, in part because of greater healthcare needs that can impact consistent adherence to CDC-recommended COVID-19 mitigation strategies. Children with ASD also may have enhanced difficulty adhering to COVID-19 mitigation efforts due to behavioral, developmental, and sensory differences.
Objectives: The objective of this analysis is to identify and compare barriers for engagement in COVID-19 mitigation strategies, receipt of COVID-19 testing, and COVID-19 infection among three groups of children from the Study to Explore Early Development Phase 3 (SEED3), COVID-19 Impact Assessment: children with ASD, other DDs, and from the general population (POP).

Methods: Caregivers of SEED3 participants (aged 5-9 years) previously classified as ASD, DD, or POP completed a survey between January and June 2021 assessing impacts of COVID-19 during March-December of 2020. Caregivers reported on their child’s difficulty with four specific COVID-19 mitigation strategies (mask wearing, handwashing, physical distancing, and COVID-19 test swabbing), whether they had been tested for COVID-19, and whether their test was positive. Caregivers also completed the Vineland Adaptive Behavior Scales—Third Edition Parent/Caregiver Form (VABS-3) and the Child Behavior Checklist (CBCL) for the study child. Differences in difficulty with mitigation strategies and COVID-19 infection across the three study groups were examined using chi-square tests and logistic regression models, adjusting for child’s race, sex, socioeconomic status, VABS-3 domain scores, and CBCL subscale scores.

Results: In total, 1,027 caregivers completed the COVID-19 Impact Survey (ASD=274, DD=368, POP=385). A greater proportion of ASD versus DD and POP caregivers endorsed that their child experienced difficulties with all four mitigation strategies. Despite similar proportions of study children receiving a COVID-19 test across the three groups (36%-39%), the positivity rates for ASD and DD children were 3 times higher (11% and 13% respectively) than for POP children (4%).

In multivariable logistic regression models, caregivers who endorsed masking difficulty for their child, versus those who did not, had greater odds of being from the ASD than the POP group (adjusted prevalence odds ratio [aPOR]=1.95, 95% confidence intervals [CI] 1.21–3.14). Similarly, caregivers who endorsed physical distancing difficulty for their child, versus those who did not, had greater odds of being from the ASD (aPOR=1.79, 95%CI 1.13–2.84) and DD (aPOR=1.46, 95%CI 1.06–2.01) than the POP group. Study group did not remain a significant predictor in the adjusted hand-washing and nasal swab models.

Conclusions: During the early months of the COVID-19 pandemic, children in the SEED3 ASD and DD groups experienced more difficulty with COVID-19 mitigation activities and had higher COVID-19 positivity rates than general population controls. Children in the ASD group were especially prone to difficulties with masking and physical distancing. These findings highlight additional challenges faced by children with DDs, particularly ASD, and their families during a pandemic that potentially increase their risk for negative health outcomes. Public health measures must consider barriers to mitigation for individuals with disabilities.

M. R. Talbott, S. Dufek and G. S. Young; (1)Psychiatry and Behavioral Sciences; MIND Institute, UC Davis MIND Institute, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences; MIND Institute, University of California, Davis, Sacramento, CA

Background: Parents with early developmental concerns face many barriers when seeking early autism evaluations including long waitlists, provider shortages, and inequities in access to care. Telehealth-based services have the potential to improve families’ support during this pre-diagnostic period, but a key barrier is the lack of validated tools for identifying infants at elevated likelihood of autism in community settings. We have previously demonstrated the feasibility and acceptability of the TEDI, a developmentally-focused telehealth-based assessment for infants ages 6-18 months, in a sample of infants with early developmental concerns (Talbott et al., 2019, 2021). The current study extends this work by examining the rates of autism and other non-typical outcomes in toddlerhood.

Objectives: To conduct longitudinal follow-up assessments of infants with early developmental concerns via telehealth to examine rates of autism and other clinical concerns in toddlerhood.

Methods: Participants included 54 infants (27 female) aged 6-12 months who enrolled in a pilot (n = 11) or subsequent feasibility (n = 43) study developing and testing the TEDI and who participated in at least one TEDI session as infants (M= 10 months). Families lived across more than 20 states, and identified as 79% White, and 9% Hispanic or Latino. Measures completed in the TEDI included the Autism Observation Scale for Infants (AOSI;Bryson et al., 2008) and the ESDM Infant-Toddler Curriculum Checklist (IT-CC; Rogers et al., 2020): Beginning at 30 months, families were asked to participate in a follow-up toddler visit, consisting of a telehealth evaluation using the Tele-ASD-Peds (TAP; Corona et al., 2020, pilot participants) or the TAP and Toddler Autism Symptom Inventory Interview (TASI; Coulter et al., 2021; feasibility study participants). Outcome visits were conducted by Ph.D.-level developmental or clinical psychologists with extensive experience in early identification and diagnosis of autism. These psychologists were naïve to earlier TEDI assessments. Clinical best estimate outcomes included DSM-5 criteria for autism, typical development, or other clinical concerns noted but not formally evaluated (speech-language, ADHD, etc.).

Results: To date, 23 toddlers have completed an outcome visit (15 female, M = 33 months, range 27-38 months). Overall clinical best estimate rates by category were as follows: autism = 7 (30%) other concern = 7 (30%), typical development = 9 (40%). A one-way ANOVA indicated toddlers with autism and other concern outcomes tended to have higher AOSI and lower developmental curriculum
scores at TEDI intake visits compared to toddlers with typical outcomes; AOSI: F(1, 21) = 4.408, p = .048; Curriculum: F(1, 15) = 3.336, p = .088.

Conclusions: In this preliminary study, we found that infants with developmental concerns in the first year of life have high rates of autism and other clinical concerns in toddlerhood. These findings will be strengthened by ongoing and future work with larger samples of infants examining specific predictors of developmental trajectories and outcomes within this population. However, these initial findings suggest that telehealth evaluations of infants’ early development may be one route towards increasing the accessibility of early evaluations for parents with concerns in the first year of life.

406.352 (Poster) Changes in Autistic Adults’ Healthcare Independence during the First Year of Adult Primary Care at a Patient-Centered Specialized Autism Clinic
D. Gilmore, J. M. Hyer and B. N. Hand; (1)The Ohio State University, Columbus, OH, (2)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH

Background: Transitioning from pediatric to adult healthcare is challenging for many autistic individuals due to various interpersonal and systemic barriers. One barrier is that autistic adults tend to need more support with healthcare tasks, like talking to providers or scheduling appointments, than the general population. The Center for Autism Services and Transition (CAST) is a patient-centered primary care clinic aiming to minimize barriers to care for autistic adults. For example, CAST patients are seen by physicians with extensive experience working with autistic adults and may receive modifications to the standard patient workflow (e.g., bypass the waiting room due to sensory sensitivity). Prior work found CAST patients have greater satisfaction with care, continuity of care, and receipt of preventive services than national samples of autistic adults. In this study, we sought to examine whether CAST patients demonstrate increased healthcare independence over time.

Objectives: To quantify healthcare independence among autistic adults during their first year of receiving care through CAST.

Methods: We conducted a prospective longitudinal study. Participants included 27 autistic adults who are their own legal guardian and participated via self-report and 21 family members of autistic adults with a legal guardian who provided proxy-reports. Online surveys were administered upon establishing care at CAST, 6 months later, and 12 months later. Our primary outcome was healthcare independence, measured by the Transition Readiness Assessment Questionnaire total score, which ranges from 1 to 5 where higher scores indicate more healthcare independence. We used generalized linear mixed modeling to examine changes in healthcare independence over time while controlling for baseline: (1) demographic characteristics (i.e., gender, education, age, race); (2) restrictive and repetitive behaviors, measured by the Adult Repetitive Behavior Questionnaire-2A and Repetitive Behavior Scale–Revised; and (3) executive functioning, measured by the Behavior-Rating Inventory of Executive Function–Adult.

Results: Table 1 provides participant characteristics. Autistic adults who participated via self-report tended to have higher baseline healthcare independence (Mean=3.2, SD=0.7) than those whose family members completed the survey (Mean=1.5, SD=0.6). Among autistic adults who participated via self-report, healthcare independence increased significantly from baseline to 12 months (Mean improvement=0.4, 95% CI=0.2-0.6) and from 6 months to 12 months (Mean improvement=0.3, 95% CI=0.1-0.5; Figure 1). Among autistic adults whose family members completed the survey, no significant changes in healthcare independence were observed over time.

Conclusions: Our results, while preliminary, found autistic adults self-reported increased healthcare independence over time while receiving care through CAST, adding to literature demonstrating the effectiveness of patient-centered healthcare for autistic adults. Further work is needed to understand the most significant drivers of increased healthcare independence among autistic adults who are their own legal guardians and identify targeted strategies that may better assist autistic adults with legal guardians, who likely have higher support needs, in increasing their healthcare independence over time.

406.353 (Poster) Changes in Health and Education Services during COVID-19 Among Children Ages 5–9 Years By Disability Status
Background: Physical distancing and lockdown measures during the COVID-19 pandemic were widely associated with loss of health and education services. Effects may have been more pronounced for children with autism spectrum disorder (ASD) due to their increased need for services for co-occurring conditions, reliance on specialty services in both clinic settings and school-based programs, and difficulties using telehealth and remote learning.

Objectives: To assess differences between children with ASD, other developmental disabilities (DDs) and population controls (POP) in 1) disruptions to regular healthcare and specialty services and reasons for difficulties accessing services, and 2) disruptions to school services and supports for remote learning.

Methods: Caregivers of children ages 5–9 years (N=1,027) from six U.S. communities completed a survey during January–June 2021 to assess COVID-19 impacts during March–December 2020. Children were previously classified as having ASD or another DD using standardized diagnostic measures. Caregivers were asked about delays in regular healthcare or specialty services, reasons for difficulties obtaining services, school closures, disruptions to school-based plans and accommodations, and resources for remote learning. Differences were assessed with chi-square tests and modified Poisson regression adjusting for key demographic and socioeconomic variables.

Results: Disruptions to regular healthcare services were common across all groups (58.4%–65.2%). Among children receiving specialty services, disruptions were somewhat more likely for ASD versus DD children and over three times more likely for ASD versus POP children.

The most common reasons for difficulty obtaining services were clinic closures and avoiding COVID-19 transmission, both of which were somewhat more common for ASD versus DD and POP children. ASD children also were somewhat more likely than DD children and 2.5 more times likely than POP children to have difficulties with telehealth; ASD children were 2.5 times more likely than DD children and 6.5 times more likely than POP children to have difficulty wearing a mask.

Across all groups, school closures were common during March–May (88.4%-93.0%) and October–December (71.5%-82.5%). Schools commonly offered live online classes and provided printed and online assignments. Across groups, 76.7% of children always had access to a computer or digital device; this proportion was higher when devices were made available by schools (85.1% vs 70.5%, p<0.001; data not shown).

Children with ASD received online classes less often than children with other DDs (84.3% versus 91.1%, p=0.013). While similar proportions of ASD and DD children had decreased ability to receive school-based accommodations, ASD versus DD children were more likely to have disruptions to special educational plans (50.0% versus 36.2%, p<0.009).

Conclusions: Disruptions to health and education services were common for all children but were more pronounced for children with ASD. Children with ASD were more likely than DD/POP children to have disruptions to specialty services and difficulties with telehealth and mask wearing; in school they were less likely than DD children to be offered online classes and more likely to have disruptions in special education plans. These findings highlight the need to plan for continuity of care for children with ASD during public health emergencies.
Caregivers of children and adolescents with ASD between 19 months and 18 years completed an online survey inquiring about the impact of the COVID-19 pandemic on access to services and their satisfaction with the service delivery formats used (remote, in-person or hybrid) for various services (special education, speech, occupational/physical therapies, ABA, mental health, and medical).

Results:

Preliminary analysis of data from the 4 timepoints across 2020 and 2021 revealed that ASD services had not recovered to a fully in-person format by July 2021 for all service types. Certain service types, namely, special education, ABA, speech therapy, and PT/OT had recovered to in-person formats to a greater extent (% recovery of in-person services=24-46.3%) compared to mental health or medical services (% recovery of in-person services = 15-20%). This was also associated with an increase in parental report of satisfaction with therapeutic services (SLT, PT/OT % improvement in satisfaction = 7.1-7.3%) showing slightly greater improvements compared to mental health and medical services (MH and MED % improvement in satisfaction = 4.6-5.7%). However, the extent of recovery to in-person services (15-46.3%) did not correspond with the increase in parental satisfaction over time (4.6-7.3%).

Conclusions:

In conclusion, in-person format of service delivery increased in the one year after the pandemic; however, full recovery to in-person services was not seen. Parent’s satisfaction with services also varied as a function of service type and delivery format. Further relationships/interactions between service types, delivery formats, parental satisfaction with services, as well as child outcomes will be explored in the final presentation. In conclusion, healthcare services for children with ASD were evolving rapidly during the course of the pandemic and that was associated with parent’s satisfaction with the services received as well as changes in child’s development/ASD symptoms. These findings have important implications for how service delivery formats need to be suited to the type of services offered and directly influence parent’s overall satisfaction about service quality.

406.355 (Poster) Childhood Predictors of Emergency Department Utilization in Adolescents with Developmental Disabilities

Background: Individuals with autism, intellectual disability, and other developmental disabilities visit the ED at a high rate during adolescence compared to typically developing individuals. Frequent utilization of the ED can be an ineffective and inefficient intervention for low acuity, chronic conditions, and behavioral difficulties for families trying to access care for their youth with developmental disabilities. Despite the frequent utilization and recidivism, our knowledge of the late childhood risk factors for adolescent ED utilization is limited. Understanding the risk factors in early life that are related to high ED utilization may lead to the development of targeted interventions for families of children with developmental disabilities.

Objectives: The present study aimed to assess the relationship between biological and environmental factors in late childhood (ages 8-12) and the ED utilization rate during adolescence (ages 13-17) for individuals with autism and/or Intellectual Disability (ID) (n=1848).

Methods: This study utilized longitudinal administrative data from 2000-2015 to assess late childhood (8.0-12.11) factors that are associated with adolescent (13.0-17:11) ED visits among youth with developmental disabilities via generalized linear mixed models with covariate adjustments for gender/sex, IQ score, and qualified for free or reduced lunch at least 50% of the time in public school during ages 8.0-12:11 (as a proxy for socioeconomic status (SES)).

Results: Results showed that Non-Hispanic White individuals, and individuals with ID-only visited the ED more than Hispanic individuals, and individuals with autism. Females had significantly higher adolescent ED incidence rates compared to males irrespective of ID status; however there were no differences in rates between females with ID (+/- autism) vs. without ID (i.e. autism without ID), whereas males with ID +/- autism experienced more adolescent ED visits than males with autism without ID. Individuals with DSS reported maltreatment, psychopharmacological treatment, and low SES in late childhood experienced significantly higher rates of adolescent ED visits. Individuals who visited the ED, were admitted to inpatient hospitalization, and encountered or had direct treatment from DMH in late childhood experienced significantly more ED visits in adolescence as compared to their respective counterparts, regardless of gender/sex, IQ, and low SES.

Conclusions: Overall, individuals with developmental disabilities are at a heightened risk for ED utilization, but nuances exist within these populations that distinguish those with the most risk. Identifying children at highest risk for long-term ED reliance early in life and providing appropriate interventions for behavioral and mental health conditions may equip and empower families to handle difficulties without needing the ED services.
Background: Research indicates that children and youth in remote regions can struggle to receive appropriate mental health care, resulting in poorer outcomes over time (Heflinger et al., 2015; Ivey-Stephenson et al., 2017). These care disparities have been linked to three main types of barriers: the limited availability of services, the low acceptability of seeking mental health care, and the restricted accessibility of services in remote regions (Smalley et al., 2010). Many researchers have also highlighted the challenges encountered by autistic youth and their caregivers when seeking services in rural communities (Young et al., 2019), but little is known specifically regarding autistic clients with co-occurring mental health needs.

Objectives: To compare the knowledge, confidence, and experiences of mental health providers when treating autistic children and adolescents with mental health needs across three regions that vary in remoteness.

Methods: Publicly funded mental health providers (N = 611; M_age = 40.2 years; 83% cis-women; 80.3% White) from across Ontario completed an anonymous survey link assessing their knowledge, confidence, and experiences when treating autistic clients with mental health needs. The Statistics Canada Remoteness Index (RI; Alasia et al., 2017; Subedi et al., 2020) was used to categorize providers into three remoteness categories based on their agency locations: easily accessible (n = 449), accessible (n = 96), and remote (n = 63). Provider knowledge was measured using a 6-item self-reported scale (Brookman-Frazee et al., 2012; Maddox et al., 2019), while provider confidence was assessed using the Therapist Confidence Scale – Autism Spectrum Disorder (TCS-ASD; Cooper et al., 2018) and self-efficacy was measured using a single self-report item (Maddox et al., 2019). Providers were also asked to report on barriers to care and to rate their level of agreement with three statements about their organizations’ resource needs (i.e., provider, caregiver, and client supports; Zerbo et al., 2015). Mean confidence and knowledge ratings were compared across the three remoteness groups using one-way ANOVA’s, while self-efficacy and agreement ratings were compared using Kruskal-Wallis tests. Further, providers’ opened-end barrier responses were examined for group differences in the three barrier themes outlined by Smalley et al. (2010).

Results: No group differences were found in terms of providers’ confidence, knowledge, or self-efficacy; however, providers in the remote group were less likely than those in the accessible and easily accessible groups to agree that their clients’ caregivers have adequate support, H(2) = 7.11, p = .03. Providers from remote regions were also more likely to report barriers to care, χ(2, N = 608) = 46.37, p < .001, particularly in the terms of availability of services, compared to clinicians from more accessible regions.

Conclusions: These results support previous investigations highlighting the challenges experienced by remote caregivers and further underscore the need for additional resources and services in remote regions, particularly those that are tailored to autistic youth with co-occurring mental health needs. In turn, these findings have implications for policies and programs aimed at recruiting specialized health providers to these communities.

Background: The context of teacher education within a rapidly changing world generates challenging questions for teacher educators. With current legislation in England, Finland and Sweden supporting the principle of ‘inclusive education,’ it was surmised that all student teachers would work with pupils on the autism spectrum and therefore need to be prepared to include them in classes. However, it was recognised that perceptions of autism can be negative in the general public (Huw & Jones, 2010; Wood & Freeth, 2016), in media (Jones & Harwood, 2009; Pesonen et al., 2021), and in education (Humphrey & Lewis, 2008).

Objectives: Research (Mosyold & Ohnstad, 2016) has identified that teachers need to reflect on their use of language and consider the ethical implications of describing pupils using normative terms. With this research knowledge it was considered valid to examine the words (vocabulary) used by student teachers’ when asked to provide three words to describe their perceptions about people on the autism spectrum. It was anticipated findings could then be utilised to illustrate to teacher educators how to enhance initial teacher education to aid the advancement of inclusive education. This research also aimed to identify whether differences exist in student teachers’ perceptions towards autism across English, Finnish and Swedish contexts.

Methods: The sample comprised a total of 704 student teachers, with 191 in England, 251 in Finland and 262 studying in Sweden. All participating student teachers completed a survey which utilised a cross-sectional design about their perceptions and experiences of people (including pupils) on the autism spectrum. This presentation focuses on the positive words from the theme which recorded the highest number of responses when participants were asked to write down the first three words that came to mind when thinking about people with
autism. Analysis was carried out using a multi-layered, deductive co-rated coding approach to ensure adequate inter-rater reliability. The content analysis procedure was designed and actioned by the researchers from each of the three nations.

Results: Findings suggest that at least half of the positive words used by student teacher participants from England (52.29%) and Sweden (55.68%) do see positive social abilities and characteristics in people on the autism spectrum. However, when positive learning factors alone are scrutinized these figures fell with English student teachers only recording 13 (12.62%) positive words and Swedish student teachers, 60 (42.25%). In comparison, only 39.23% of words chosen by Finnish student teachers to describe positive social abilities and characteristics were positive, but 78.26% of words were focused on positive learning characteristics. It is therefore posited that cautious connections can be made between the words chosen by student teachers in each of the three nations regarding the positive personality / characteristics of people on the autism spectrum and the nations’ social and political status of teachers, school education and inclusion.

Conclusions: This study suggests that student teachers’ perceptions are influenced by the value and quality of their initial teacher education programmes, and by their nation’s policies of inclusion and the professional status teachers have within society.

406.358 (Poster) Delivering a Pre-Emptive Parent Mediated Intervention Program Online for Infants at High Likelihood for Autism in India – What Helps and What Stands in Our Way?

M. Srikar, R. Raju, S. Srikumar, D. Swaminathan, J. V. S. Kommu and S. S. Meera, (1)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, India, (2)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, (3)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, Bangalore, India, (4)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, INDIA

Background: 40-50% of infant siblings of autistic children are at high familial likelihood (HLASD) to develop delays requiring early intervention. There is prior evidence supporting commencing intervention for these infants prior to formal diagnosis— preemptive intervention (Green et al., 2015). Though there is sizable work supporting online intervention for autistic children, this is the first study to provide preemptive parent-mediated intervention (PPMI) through an online modality— a model conceived during the peak of the COVID-19 pandemic. Understanding facilitators and barriers unique to lower middle-income countries (LMIC) like India catering to HLASD families is important to successfully conduct such a program on a larger scale.

Objectives: Understanding facilitators and barriers to delivering PPMI online for HLASD infants

Methods: Data from 14 parents of HLASD (infant age: 11±1.56 months, 10 Male) receiving intervention as part of a larger ongoing intervention study have been included. A PPMI based on naturalistic-developmental behavioral principles was developed and provided. The PPMI was conducted using video feedback and live demonstration with focus on social communication and language. The PPMI included 15 sessions across 12 weeks delivered through ‘Zoom’. The interventionist took detailed notes after each session. Key facilitators and barriers to PPMI delivered online were identified based on two broad themes emerging from analysis of session notes (n=149 sessions)– theme1: related to use of technology, theme2: related to scheduling sessions.

Results: Key facilitators (table-1) included (1) reimbursement of additional mobile internet recharge packs to attend sessions and transfer large files for video feedback, (2) providing culturally relevant illustrated guides for recording and sharing of videos, (3) accommodating late evening PPMI sessions (latest 10:30PM IST) to ensure (i) no disturbances to routines of both siblings (e.g., sleeping hours of the infant, intervention/school timings of autistic sibling) (ii) availability of both parents or availability of the parent who owns a smartphone supporting Zoom. Barriers included (1) fluctuating network (mobile or wi-fi) due to rains or limited high speed internet causing interruptions during sessions, (2) unavoidable interruptions from either/both siblings (e.g., requesting attention from the parent attending the session, waking up from naps early), (3) travel to hometown/villages during holidays, celebrations during festival season, family events like birthdays/weddings, or spontaneous/unscheduled visits from family members causing rescheduled/missed sessions, (4) health related concerns in siblings/parents (e.g., flu during monsoon) requiring rescheduling of sessions. See table-1 for frequency of occurrence of key barriers. Data collection is ongoing (projected at n=450 sessions by April 2023). Data analysis from feasibility forms and semi structured interviews with 6 families who have completed the PPMI demonstrate preliminary feasibility and acceptability of the PPMI.

Conclusions: Although preliminary, current analyses have offered systematic information on facilitators and barriers that are unique to the culture (e.g., festival season) and the population being catered to (nap time for the infant, routine of the older sibling). These nuanced aspects when incorporated will help tailor make programs that will have an impact on feasibility and acceptability and overall scalability of the current PPMI being researched for the first time in India.

406.359 (Poster) Delivering the Communicationdeall Early Intervention Online – Key Learnings through the Lens of Caregivers and Interventionists

D. Nair, R. Raju and M. Srikar, DBN, ComDEALL, Mumbai, Mumbai, India, (2)National Institute of Mental Health and Neurosciences (NIMHANS), Bangalore, India, (3)National Institute of Mental Health and Neuro Sciences (NIMHANS), Bangalore, India
Background: The Communication DEALL (ComDEALL) Early Intervention program (Karanth et al., 2010) for autistic children is a child centered, in person, structured program offered at multiple centers across India. During COVID-19 lockdown, one of the ComDEALL affiliates, shifted to parent mediated tele-intervention (ComDEALL-PMTI). Globally, there is growing evidence for PMTIs (Parson et al., 2017). However, limited information is available about the caregivers and interventionists perspective on delivering intervention online from a low resource country like India.

Objectives: To gain insights into caregivers and interventionists perspectives on feasibility and acceptability of the ComDEALL-PMTI

Methods: 13 caregivers of autistic children aged between 3-7 years (4.9±1.75 years, 10Male) were recruited from the community between May 2019-October 2022. A multidisciplinary team including speech and occupational therapists, and special educator conducted assessments on ‘Zoom’ using the ComDEALL Developmental Checklist and Dunn’s Sensory Profile. Based on caregivers’ preference, intervention was delivered on WhatsApp, an app culturally more familiar and accessible compared to Zoom. A WhatsApp group was created with caregivers and their interventionists(n=3) to share intervention goals, training videos, training forms and materials from open access sources. One core and one follow up session was conducted each week. The first session explained goals/activities using video modelling (30 mins). The next focused on video feedback (15 mins). Interventionists left voice notes/typed messages for continued support. Feedback on feasibility and acceptability of ComDEALL-PMTI was collected via phone call interviews with caregivers and interventionists. Themes emerging from these interviews were analyzed.

Results: Themes from interviews included (1) modality and (2) method of delivering intervention. Under preferred modality of intervention: three caregivers dropped out of intervention due to personal reasons. Seven (62%) preferred online mode. Reasons included decrease in travel induced stress, more time for family activities, overcoming stigma related to autism. One preferred hybrid mode as they saw merit in both. Two (15%) preferred in person as they missed physical connect. Overtime, one preferred online and the other hybrid. All interventionists preferred hybrid mode. One interventionist found explaining some activities (e.g., sensory play) challenging. Interventionists expressed that one WhatsApp group facilitated interdisciplinary communication and prevented challenges from escalating but often blurred professional and personal times. Under method of intervention: all caregivers reported that video feedback helped understand and practice activities better. However, recording videos was challenging. Continued support through WhatsApp, sharing of materials was appreciated by caregivers. Interventionists reported home videos helped pinpoint areas that caregivers needed help. Understanding the home environment allowed intervention tailored to individual milieu to streamline schedules, ensure child’s access to visuals, incorporate activities into daily routines and use household materials for activities.

Conclusions: ComDEALL early intervention, being delivered online for the first time– the ComDEALL-PMTI, was found both feasible and acceptable by caregivers and interventionists. Although results are based on a small sample of caregivers, they hold promise for further use. If online modification is found efficacious (e.g., RCT design) and the model is used regularly, it will cater to a larger population who have less access to good quality intervention.

406.360 (Poster) Development of a Novel Telemedicine Tool to Reduce Disparities Related to the Identification of Preschool Children with Autism

L. Wagner, A. Vehorn, Z. Warren, A. Lavanderos, L. Corona, A. S. Wei latex, T. E. Foster`, J. Hine and C. Stone`, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (3)Vanderbilt University Medical Center - TRIAD, Nashville, TN, (4)Vanderbilt Kennedy Center, Vanderbilt Kennedy Center, Nashville, TN, (5)Dept of Pediatrics, Division of Developmental Medicine, VKC-TRIAD, Vanderbilt UMC, Nashville, TN, (6)Dept of Pediatrics, Division of Developmental Medicine, VKC-TRIAD, Vanderbilt UMC, Nashville, TN, (7)Treatment and Research Institute for Autism Spectrum Disorders, Vanderbilt University Medical Center - Kennedy Center, Nashville, TN

Background: The COVID-19 pandemic heralded a rapid transition to telemedicine, despite limited resources available to support tele-delivered autism assessment. Two years later, tele-assessment remains a viable, and often desirable, alternative to traditional models of care, with potential to reduce diagnostic delays that disproportionately affect traditionally underserved communities. To optimize use of tele-assessment, the field must commit to a planful, sustainable approach to creating and disseminating telemedicine tools and models. The field of implementation science can support this endeavor, by encouraging stakeholder-informed design and service models tailored to unique contextual factors influencing uptake.

Objectives: This presentation describes the stakeholder-informed co-design process leading to the creation of the TAP-Preschool (TAP-P), a telemedicine-based autism assessment tool for children 36-72 months. We present pilot data on use of the TAP-P, including diagnostic agreement, diagnostic certainty, and clinician and family satisfaction.

Methods: The creation of the TAP-P was informed by (1) application of machine learning models to a large clinical data set of preschoolers with ASD and other developmental concerns (n=914) and (2) focus group feedback on tele-assessment procedures and activities. Specifically, machine learning was used to generate behavioral targets that best distinguish ASD and non-ASD features in preschoolers. Focus groups questions informed by implementation science frameworks were used to identify barriers and facilitators to tele-assessment. Focus groups participants included experts in ASD assessment (n=8), providers from underserved communities (n=7), and parents of preschool children with ASD from traditionally underserved racial/ethnic and linguistic groups (n=9). Focus group themes and machine
learning analyses were used to generate an instrument with distinct assessment tasks and scoring procedures based on a child’s language level (i.e., TAP-P Verbal, TAP-P Non-verbal). The TAP-P was piloted with 29 families, with remote clinicians blind to diagnostic status coaching parents through activities in their homes. Clinicians assigned Likert scores across behavioral domains and rated diagnostic certainty and satisfaction with the TAP-P. Families provided satisfaction ratings.

Results: Participating children (mean age=49 months, range 37-68 months, 79% male) with existing diagnoses of ASD (n=20) or other developmental concerns (n=9) completed preliminary TAP-P procedures. Results indicate that use of the instrument in isolation (i.e., without history or collateral information) yielded accurate classification in 66% of cases. Children with ASD diagnoses received higher TAP-P scores, relative to children with other developmental concerns. Clinician diagnostic accuracy and certainty were higher when confirming existing ASD diagnoses (80% agreement) than when ruling out ASD in children with other developmental concerns (33% agreement). Clinicians universally voiced a need for parent report in addition to the assessment tasks. Future phases of this study will incorporate symptom-focused interviewing. Parents reported high levels of satisfaction with TAP-P procedures.

Conclusions: If successful, this work could help address existing barriers in access to diagnostic evaluations that underlie ongoing health disparities. Utilizing an equity approach to understand the functionality and impact of tele-assessment for preschool children has potential to transform the ASD evaluation process for traditionally underserved populations.

406.361 (Poster) Development of a Patient-Facing Mobile Health App to Track Family Access and Engagement with Early Intervention Services in Underserved Communities

L. Wagner, L. Corona, M. Hooper, N. Khan, A. R. Dixon, A. Lavanderos, N. Sarkar, Z. Zheng, N. Sarkar, and Z. Warren, (1)Division of Developmental Medicine, Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (3)Vanderbilt University, Nashville, TN, (4)VUMC Dept of Pediatrics, Division of Developmental Medicine, Nashville, TN, (5)Vanderbilt University Medical Center - TRIAD, Nashville, TN, (6)Mechanical Engineering; Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN, (7)Yale University, New Haven, CT

Background: Expedient access to early intervention (EI) systems has been identified as a priority for children with autism and other developmental differences. Despite the mandated availability of EI, it remains challenging for families to navigate referral processes and establish services. Such challenges disproportionately impact families from traditionally underserved communities (i.e., families in poverty, racial/ethnic minorities). Mobile health apps have the potential to improve clinical outcomes, increase accessibility to health services, and promote adherence to health-related interventions. Though promising, implementation of apps within routine care is in its infancy, with limited research examining the components of what makes an effective app or how to reach those families most impacted by inequities in healthcare delivery. The purpose of this project was to develop a patient-facing app to track family engagement in EI services through a co-design process involving stakeholder input, informed by the Consolidated Framework for Implementation Research (CFIR).

Objectives: This presentation will discuss the co-design process of a mobile health app, Family on Track (FOT). We will share findings from stakeholder focus groups regarding facilitators and barriers to use, and strategies for integration into routine clinical care.

Methods: Focus groups were comprised of 29 participants across four stakeholder groups, including family members, clinicians and clinic staff, community providers, and experts in diversity and inclusion. Stakeholders were presented with two computer-based versions of a survey to track family engagement with the Part C system, each of which had the potential to be translated into a future app. The two formats differed in the (1) their presentation and user interface, (2) the degree of survey customization, and (3) back-end processes for downloading and interpreting data. CFIR-informed interview questions elicited feedback about implementation within routine care, especially when targeting families from underserved groups. Qualitative coding was completed using a content analysis and predominately deductive approach. Using themes and insights identified via focus groups, we collaborated with the Department of Mechanical Engineering to develop the FOT app.

Results: Qualitative analysis from stakeholder focus groups highlighted a collective desire for increased communication and information about the process of accessing EI services, the ubiquity and potential utility of a mobile app for communication, and recommendations for app features. These themes informed the development of the FOT app and related implementation supports. App features included survey customization based on prior responses, timing and delivery of prompts, and questions related to barriers and service satisfaction. Implementation supports include a visual guide for app installation, resources related to common family questions, and availability of study personnel to guide families through installation and provide support.

Conclusions: Results of this study could support an innovative way for the EI system to communicate and connect with families, providing families with a means through which to communicate their satisfaction and frustration and, through the supporting materials, access the supports they need to be more active participants in their child’s care.
**Background:** Autism and other developmental disabilities exist in every racial/ethnic, cultural, and linguistic group, nonetheless, minoritized children and families experience disparities in access to a timely identification, diagnosis and services (Magaña et al., 2017; Stahmer et al., 2019; Luelmo et al., 2022). California delivers free services (e.g., applied behavioral analysis, speech and language therapy, occupational therapy) to individuals with developmental disabilities throughout the State through a network of independently operated non-profit, community-based organizations called Regional Centers (California Department of Developmental Services, 2022). Throughout the State of California, there are 21 Regional Centers (RC) attempting to provide services to every geographic region and racial/ethnic, and linguistic group throughout the most populated State in the US. The California Department of Developmental Disabilities oversees and provides funding to each independent RC based on the purchase of services (POS) they provide to each family. Annually, each RC is mandated to publish data on expenditures by race/ethnicity, home language, disability, and other variables. This study is an examination of disparities in services access for families with developmental disabilities by race/ethnicity and language in the state of California.

**Objectives:** RQ1: What are the expenditures (i.e., Purchase of services) of Regional Centers statewide by race/ethnicity? RQ2: What are the expenditures of RCs by home language in California? RQ3: Are there any disparities in service expenditures by race/ethnicity and/or home language?

**Methods:** In this study and in collaboration with two community-based organizations, we extracted publicly Purchase of Service (POS) data for fiscal year 2020-2021 for each of the 21 RCs in California. Using descriptive and comparative statistics, we analyzed each RC POS expenditures for each RC by race/ethnicity and language. We then compiled the Statewide data and compared the percentage of the population with the percentage of actual expenditures by race/ethnicity. We continued with the same analytic strategy using language as the variable.

**Results:** Disparities were evident by race/ethnicity. White individuals represented 28% of the population, but received 45% of the actual expenditures across the State. Latinx/Hispanic individuals represented the group with the highest disparity observed. Latinx families represented 40% of the population, but only received 28% of the POS expenditures. Disparities in POS were also evident for Asian, Black, and other ethnicities, but to a lesser degree. (See graph 1). Similarly, English-speaking families represented 77% of the DDS population but obtained 86% of expenditures. Spanish speaking families represented 19% of the population but only obtained 13% of the POS expenditures (see graph 2).

**Conclusions:** Disparities in service access by race/ethnicity persist despite efforts in the field to ameliorate the issue. This is particularly problematic for Latinx, Spanish speaking families (Lopez et al., 2019; Iadarola et al., 2020; Luelmo et al., 2021). This study provides further evidence of this issue. Additionally, this study sheds light on the role of language particularly for Spanish speaking families and provides future directions for intervention development.

**P. Luelmo,** Special Education, San Diego State University, San Diego, CA

**Background:** Evidence-based practices (EBPs) are interventions or occupational practices backed by scientific evidence (Spring, 2007). They are essential for advancing community practices, especially in the field of clinical psychology and developmental disabilities. While creating EBPs is the first step, disseminating them to the community and practitioners who implement them is a critical and often overlooked component. This results in EBPs becoming “stuck in academia” and creates a research-to-practice gap (Rynes et al., 2007). The PEERS® Intervention is an evidence-based social skills curriculum that has been adapted for multiple age groups (Estabilllo et al., 2022) and offers certified training to mental health professionals and educators across the globe. With advances in telehealth and remote services, there may be even wider opportunities for more productive dissemination of EBPs, especially those addressing social skills, relevant to autistic individuals (Kamei & Harriott, 2021). Despite having trained tens of thousands of professionals in PEERS®, little is known about the effectiveness of these dissemination efforts via remote delivery.

**Objectives:** This study aims to explore the feasibility and acceptability of the PEERS® Certified Teleconference by examining participant evaluation data following certified training offered through an online platform.

**Methods:** The current study examined the effectiveness of a three-day PEERS® for Adolescents (Laugeson & Frankel, 2010) Certified Teleconference conducted over Zoom for 289 professionals. Participants included 209 professionals who worked or resided in the U.S., and...
80 professionals from outside the U.S. Among the 242 participants reporting degrees and job titles, 60% had obtained a master’s level degree or higher and all who reported employment worked in a behavioral, educational, or healthcare setting. Trainings were led by UCLA PEERS® Certified Trainers and included approximately 24-hours of intensive instruction in which curriculum content and evidence-based strategies for teaching social skills were reviewed via training videos and presentation of telehealth materials. Participants completed demographic questionnaires and a post-training survey which assessed satisfaction with the training and other domains.

Results: Of the 147 participants who completed post-training forms, 70% reported that the session was above average or excellent in effectiveness, 98% reported at least an above average likelihood for the training impacting their practice, 97% indicated the training was relevant to their work, and 95% indicated at least a good ability to deliver the intervention to their patients. Seventy percent reported average knowledge of the material and field prior to the training, and that number increased to 99.3% post-training. Approximately 88.4% indicated this training advanced their scientific knowledge, and 98% endorsed the training as providing evidence-based medical practice.

Conclusions: Findings suggest that behavioral, educational, and mental health professionals were highly satisfied with the dissemination of the PEERS® for Adolescents certified training via a remote delivery platform, supporting the acceptability and feasibility of the training efforts. With advances in telehealth and remote services, this study demonstrates that there may be even wider opportunities and increased desire for dissemination of EBPs, especially those addressing social skills, relevant to autistic individuals.

406.364 (Poster) Early Intervention Providers’ Perspectives about Referring Children for Autism Evaluations
M. Granovetter, C. Coffield and J. F. Harris, (1)Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, (2)Pediatrics, Rutgers RWJ Medical School, New Brunswick, NJ, (3)Children’s Specialized Hospital, Mountainside, NJ

Background:

Early Intervention (EI) is known to be a crucial service to improve developmental outcomes among children with autism. Newly diagnosed children are increasingly referred into EI programs, as demonstrated by growing numbers of children with autism utilizing EI services. However, no known study examines the perspectives of EI providers about referring a child already receiving EI for an autism evaluation. Prior research shows that EI providers often have reasonable clinical suspicion that children they work with have autism, but do not feel comfortable formally making diagnoses. Previous research does not acknowledge the specific challenges EI providers experience in referring children to pediatricians or specialists for autism evaluations, a gap we aim to address.

Objectives:

We explore the unique experiences of EI providers in referring children for autism evaluations. Specifically, we use semi-structured interviews to investigate the factors that prompt them to make referrals, influence their approach to these conversations with families, and prevent or facilitate raising their concerns.

Methods:

We conducted semi-structured interviews with 14 EI providers in New Jersey. Participants were recruited via email from EI agencies throughout the state. Verbal consent for research participation was received prior to interviews, which were conducted on Zoom and lasted 20-60 minutes. The interview included 13 open-ended questions about their feelings, opinions, and experiences as EI providers, their experiences working with children who may or may not have autism, how they make referrals for autism evaluations, and how they decide to make referrals. Respondents received a gift card for their participation.

Results:

We used inductive thematic analysis to identify four primary themes common to all interviews. First, EI providers have knowledge and understanding about autism and its signs, and therefore can identify if a child should be referred for autism evaluation. Second, systemic and family-centered barriers and facilitators inform whether EI providers make referrals. Barriers include individual EI agencies’ rules about avoiding the word “autism,” waitlists for evaluations, socioeconomic status of families, perceived rapport with families, parents’ reactions to referrals, and families’ variable adherence to recommendations. Facilitators include families mentioning autism before the provider does, developing rapport with families over time, and providers’ personal experiences (for example, their own children’s autism diagnoses). Third, whether providers decide to make referrals, and their reasoning for their choices, is variable; there is no standardized approach to making referrals. Fourth, EI providers do not consider making diagnoses as one of their roles, despite their competence in identifying the signs of autism.

Conclusions:

We have identified aspects of the referral process from EI to autism evaluation that are shared among EI providers. Importantly, we found that the approach EI providers choose to take to make referrals is not guided by the value an autism diagnosis has for a child’s long-term
outcomes, but by systemic and perceived family-centered barriers and facilitators. Understanding the challenges inherent to referring children to autism evaluations may help inform a more standardized model for navigating this complex, but crucial, discussion with families.

406.365 (Poster) Echo Seminars for Interprofessional Collaboration Around Autism
E. Rotheram-Fuller, M. Dixon and N. Scherer, Arizona State University, Tempe, AZ

Background: Children with Autism Spectrum Disorders (ASD) often require supports from a range of professionals with unique expertise, but few professionals have opportunities to experience and practice cross-professional collaboration. Extension for Community Healthcare Outcomes (ECHO) seminars are virtual (zoom-based) meetings that allow professionals across professions and roles (community providers, faculty, students, and related professionals) to gather around one common topic. The model has been used effectively in health care, and includes both a didactic component as well as case consultation and discussion.

Objectives: Examine the potential of ECHO seminars to recruit and engage diverse education and speech-language pathology students and professionals around autism. In addition, participant ratings of seminar quality and impact were also explored.

Methods: An ECHO seminar series was created by faculty in Speech-Language Pathology (SLP) and Special Education. Students, faculty, and community SLPs, educators, and other professionals were targeted to join the ECHO seminars. So far, 11 seminars have been held, but another 5 will be offered before March, 2023. Recruitment of participants included wide dissemination of meeting announcements across university listserves, program alumni, community clinical supervisors, and faculty at other universities in related areas. All attendees were asked to complete surveys at the end of each seminar and rate their impression of the quality of the seminar, as well as how likely they were to change their clinical practice as a result.

Results: Preliminary data suggest that an average of 31.78 people have attended each seminar, with a mix of university faculty, students, and community professionals (predominantly SLPs within school districts, as well as teachers). Case consultation has included cases on a wide range of client ages and presenting challenges and didactic lectures have included topics such as the Cultural Acceptability of ABA Interventions, and Sex Differences in Brain Patterns and Autism. Attendee ratings show high interest in the topics (average rating 4.7/5) and ratings of the quality of the presentations (4.8/5). Sixty-seven percent of attendees also report that they are likely to change their practice as a result of attending the seminars.

Conclusions: ECHO seminars have the potential to bridge interdisciplinary barriers and bring professionals together around common topics in autism. Key considerations, however, are the topics chosen and dissemination methods to draw in attendees. Methods to increase participation from all attendees across disciplines during sessions will also be reviewed.

406.366 (Poster) Educator Attitudes to Inclusion of Children on the Autism Spectrum in Early Childhood Education
J. M. Paynter and N. Barone; (1)School of Applied Psychology, Griffith University, Gold Coast, QLD, AUSTRALIA, (2)Griffith University, Gold Coast, QLD, Australia

Background: Early childhood education and care services provide valuable opportunities for learning, social development, and connection for children from infancy to school age. While the right to inclusion for all children is enshrined philosophically and in law, many families of children on the autism spectrum report experiencing barriers to their children’s inclusion in these early learning environments. Research in education more broadly shows that educator positive attitudes to inclusive education are a key factor for successful inclusion of students on the spectrum at school age. However, there is limited research into the attitudes of educators working in early childhood education and care services which are provided before children start school. Understanding these early attitudes and predictors of attitudes is important to support early success in educational settings, to support child participation, and to support families.

Objectives: Our aim was to understand predictors of attitudes to inclusion of children on the spectrum in early childhood education and care services. Specifically, we sought to explore whether autism knowledge, self-efficacy to work with children on the spectrum, and/or feelings of burnout in educators would significantly predict attitudes.

Methods: Participants included 163 (96.9% female) early childhood educators who completed an online quantitative survey of their attitudes to inclusion (Teacher Attitude to Inclusion Scale), knowledge of autism (Knowledge Subscale, Autism Inclusion Questionnaire), self-efficacy (Autism Self-Efficacy Scale for Teachers), and feelings of burnout (Maslach Burnout Inventory – Educators Survey). Measures selected showed reliability and validity for school settings and were pilot tested for content validity and appropriateness of wording with early childhood educators before administration with minor changes to wording to this context incorporated in the final survey.

Results: More positive attitudes to inclusion were correlated with higher autism knowledge with a medium effect, higher self-efficacy with a medium effect, and lower general and inclusive-education-related burnout with small and large effects respectively. Educators with autism-specific training showed higher self-efficacy, but did not differ from those without training, in attitudes to inclusion. Knowledge,
self-efficacy, and burnout, each contributed unique variance to the prediction of attitudes towards inclusion in a multiple regression, with the overall model also predicting a significant proportion of the variance in attitudes.

Conclusions: Our findings highlight potential avenues to support early childhood educators to build more positive attitudes to inclusion of children on the spectrum, through increasing knowledge of autism and self-efficacy, and reducing feelings of burnout.

406.367 (Poster) Effect of Family Navigation on Engagement in Part C Early Intervention Services Among Children with Increased Likelihood of Autism

E. Feinberg1, M. L. Stransky1, M. Augustyn1, S. Broder-Fingert1, A. Bennett1, C. Weitzman1, J. L. Kuhn1, A. Chir1, H. Cabral2, A. Fenick3, and N. Blum4. (1)Boston University School of Medicine, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)Boston Medical Center, Boston, MA, (4)University of Massachusetts Chan Medical School, Worcester, MA, (5)Children's Hospital of Philadelphia, Philadelphia, PA, (6)Boston Children's Hospital, Boston, MA, (7)Harvard Medical School, Boston, MA, (8)Pediatrics, Boston Medical Center, Boston, MA, (9)Brown University School of Public Health, Providence, RI, (10)Yale University, New Haven, CT

Background: Children in the US who are under 3 years old and have developmental conditions or delays are eligible for Part C Early Intervention (EI) services under the Individuals with Disabilities Education Act. Services include developmental evaluation and support, physical and speech therapies, and social work. EI services have been shown to reduce autism symptoms and promote healthy development among young children. However, EI engagement remains low, particularly among children from structurally marginalized communities.

Objectives: We investigated whether family navigation (FN) improved EI engagement following positive primary care screening for autism compared to conventional care management (CCM).

Methods: We conducted a randomized clinical trial among 339 families of children (ages 15-27 months) who screened as having increased likelihood for autism at eleven urban primary care sites in three cities. Families were randomized to FN or CCM. Families in the FN arm received community-based outreach from a navigator trained to support families’ efforts to overcome structural barriers to autism evaluation and services. EI service records were obtained from state or local agencies. The primary outcome, EI service engagement, was measured as the number of days from randomization to first EI appointment.

Results: EI service records were available for 271 children. The majority of children were publicly insured (222 (81.9%)) and had parents who self-identified as Black, Indigenous, or People of Color (254 (93.7%)); 57 (21.0%) parents spoke a language other than English.

More than half (156 (57.6%)) of children were not EI engaged at study enrollment. A greater proportion of children receiving EI at study enrollment were born premature (No EI: 10%, EI engaged: 18%, p=0.04), had siblings (No EI: 62.8%, EI engaged: 77.2%, p=0.01) and had parents who did not work outside the home (No EI: 43.6%, EI engaged: 57.0%, p=0.03) than their non-engaged peers.

Among the children not EI engaged at study enrollment, 87 (56%) received FN and 69 (44%) received CCM (Table 1). A greater proportion of children receiving FN had public health insurance (p=0.02) and lived in single head-of-household families (p=0.04). Twenty-two (14%) children previously received EI but not within 30 days prior to study enrollment (mean=249.4 days, standard deviation (sd)=198.9).

Children were followed for 100 days after diagnostic ascertainment or until age three. The Kaplan-Meier plot (Figure 1) shows time to EI engagement for the 156 children not engaged at study enrollment. The difference between treatment arms emerges by day 50 and peaks approximately 100 days after study enrollment.

The Cox proportional hazard model, controlling for EI engagement within 30 days before enrollment, parental marital or cohabiting status, and insurance type, clustered on site, showed that families receiving FN were 54% more likely to engage in EI than those receiving CCM (1.54 (95% CI: 1.09-2.19), p=0.02). Sensitivity analyses using a 60-day cut-off for EI services prior to study enrollment and that multiply imputed data on the 68 children for whom EI data was unavailable were consistent with the analysis presented here.

Conclusions: FN improved the likelihood of EI engagement among urban families from marginalized communities.

406.368 (Poster) Embedding Autism Evaluations in Primary Care Decreases Time to Diagnosis

S. Habayeb1, A. Khuu1, X. Marshall1, R. Williams1, E. Eisenman1, A. Hastings1, S. Singh1, M. Lauer1, V. Fuentes1, S. Godovich2, M. Long2, A. Inge3, and L. Godoy3. (1)Children's National Hospital, Washington, DC, (2)Center for Autism Spectrum Disorders, Children's National Hospital, Rockville, MD, (3)Child Health Advocacy Institute, Children's National Hospital, Washington, DC, (4)Center for Autism Spectrum Disorder, Children's National Medical Center, Center for Autism Spectrum Disorders, Rockville, MD
Implementation facilitation serves a vital role in the adoption and use of high-quality, evidence-based practices in community settings, which are often particularly scarce for autistic youth. Facilitators serve the role of overseeing and enabling an agency’s implementation team and implementation process through ongoing interactions and regular meetings, ensuring the team understands and works through the various steps of the implementation framework. The Autism Community Toolkit: Systems to Measure and Adopt Research-Based Treatments (ACT SMART; Drahota et al., 2014) is a five-phase implementation toolkit adapted from the EPIS framework (Exploration, Adoption Decision, Preparation, Implementation, Sustainment; Aarons et al., 2011; Drahota et al., 2021). Each EPIS phase was comprised of steps and activities that facilitate movement within and between phases. In a pilot study on facilitators and barriers to using ACT SMART, qualitative thematic coding revealed that agency implementation teams reported that facilitation was a key factor in enabling successful toolkit use. Specifically, teams valued facilitator responsivity, supportiveness, and flexibility, and valued the role of facilitation meetings in providing accountability for and clarification around the process (Sridhar et al., 2021).

Objectives: Quantitatively evaluate implementation facilitator and implementation team perspectives on the ACT SMART facilitation process.

Methods: Three facilitators (66.6% female, 66.6% with Ph.D., ranging from 21-38 years old) rated the feasibility, utility, and satisfaction with facilitating implementation teams through ACT SMART after each EPIS phase (except sustainment) on five-point Likert scales, where 5 is the strongest rating. Thirteen implementation team members from six community-based autism agencies (4 providing ABA, 1 providing Speech/Language services, 1 delivering both ABA and mental health services) also rated their experiences with the implementation facilitation and their team’s specific facilitator(s) at the end of the study. Ratings were coded to match facilitator ratings and ranged from 1-5, with higher scores indicating more positive experiences with the facilitator and facilitation process from the implementation team’s perspective.

Results: Time between referral and completing a two-day diagnostic evaluation embedded within primary care (M = 98.18 days; SD = 67.28) was significantly shorter than previous standards of care that required referral to a tertiary care center (M = 158.08 days; SD = 85.34), t(136) = -3.83, p < 0.001.

Conclusions: Data suggest that an integrated autism diagnostic clinic in primary care has the potential to significantly reduce time to access autism evaluations which could lead to earlier access to intervention services. The program was successful in addressing the needs of families with limited access to resources based on socioeconomic status or race. Expansion of such programs, which increase provider capacity and provide wraparound services in the medical home, has the potential to decrease racial and socioeconomic inequities in access to autism diagnostic services.

Acknowledgments: This work was supported by the Office of Research and Economic Development at Virginia Tech, the National Institute of Mental Health, and the National Institute of Child Health and Human Development. We thank all participants and the Autism Community Toolkit: Systems to Measure and Adopt Research-Based Treatments (ACT SMART) for their contributions to this project.

J. R. Bertollo, E. A. DeLucia, J. E. Tschida, A. Scarpa, and A. Drahota, Virginia Tech, Blacksburg, VA, Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, Department of Psychology, Michigan State University, East Lansing, MI, Department of Psychology, Virginia Tech, Blacksburg, VA.
Results: Overall, facilitators rated the ACT SMART facilitation process as feasible (mean ratings across phases = 3.9 – 4.0), useful (means = 4.6 – 4.8), and satisfactory (means = 3.9 – 4.6; see Figure 1). Feasibility and utility were comparable across phases; satisfaction decreased slightly in Planning and Implementation phases, but remained positive across timepoints. Likewise, implementation team members rated their ACT SMART facilitator(s) positively on helpfulness and responsiveness and the implementation facilitation process highly on feasibility, satisfaction, and convenience (mean = 4.5).

Conclusions: Facilitation is a crucial part of the implementation process by ensuring that agency implementation teams understand and are accountable for completing the implementation process. Facilitators of the ACT SMART implementation toolkit aim to provide these benefits, while being flexible, supportive, and responsive. Data indicate positive perceptions of ACT SMART facilitation by facilitators themselves and implementation team members, including feasibility, utility, and acceptability. Ongoing qualitative analyses of facilitators’ perspectives expand upon these quantitative data and inform tailoring the facilitation process for future use of the toolkit, with the goal of further increasing the impact of the facilitation process role in the implementation of evidence-based practices.

406.370 (Poster) Evaluation of a Province-Wide ASD Family Service Navigation Program
I. O’Connor, M. Spoelstra, S. Shaw, C. Sawyer, J. E. Tarride, G. Blackhouse, C. Russell and S. Georgiades. (1)McMaster University, Dundas, ON, Canada, (2)Autism Ontario, Toronto, ON, Canada, (3)Department of Health Research Methods, Evidence and Impact & Centre for Health Economics and Policy Analysis, McMaster University, Hamilton, ON, Canada, (4)McMaster University, Hamilton, ON, Canada, (5)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada

Background: Early evidence-based treatment improves long-term and short-term outcomes for autistic children, but timely access is challenging due to long waitlists and complex service landscapes which span educational, medical and social service sectors. Also, low income, minority, and non-native speakers may experience additional post-diagnostic treatment delays, creating service access inequities. Family Service Navigation is an intervention which addresses delays and disparities in health care access by providing caregivers with educational and facilitative services. It is particularly relevant for self-directed funding models of care which allocate government funds directly to families to purchase needed autism treatment services themselves rather than funding regional treatment centres.

Objectives: This study describes Autism Ontario’s province-wide Service Navigation Program (SNP) which was designed to promote timely and equitable access to self-directed funding for autism treatment services for the caregivers of children aged 18 or less with a known or suspected diagnosis of autism. Results of an external evaluation of the SNP are shared including evaluation of program adaptations to cope with pandemic-related restrictions that significantly altered program operation.

Methods: McMaster Autism Research Team, the Offord Centre for Child Studies, and the Centre for Health Economics and Policy Analysis conducted an external evaluation of the SNP using mixed methods. A review of SNP activities was first conducted using administrative data derived from customer service software that documented information such as client demographics, number of clients, contact reasons, and response time. In addition, 16 Service Navigators were surveyed though an online platform to gather staff impressions of program reach, utility and effectiveness. Qualitative analysis of open-ended staff survey responses used an open coding approach whereby responses were grouped into categories and concepts then labelled to search for recurring categories and emergent themes. The qualitative survey data was integrated with program data for convergence and expansion.

Results: From July 1, 2019 to March 31, 2020, 4,046 unique families across Ontario were supported by 18 Service Navigators. Contact reasons included information about provincial autism services (48%), funding specifics (9%) and other topics (33%) such as diagnostic resources, mental health concerns, respite, school, and crisis management. On average 4.2 business days elapsed from completion of a service request form to first contact with the local Navigator. First contact averaged 26 minutes. SNP clients reporting a first language other than English or French (17%) was well in excess of the provincial population base rate (3%). Navigators viewed COVID-19 driven virtual service delivery as effective and extending reach to busy families, those without respite, and those living remotely. Virtual contact posed difficulty when assisting families to complete funding application forms.

Conclusions: Autism Ontario’s Service Navigation Program offered immediate, practical assistance and continued to engage families during the pandemic. Outreach to those who do not fluently speak either official language was a program strength. Key recommendations included establishment of a direct link to diagnostic hubs to expedite SNP contact and evaluation of client satisfaction with navigation using standardized measures while taking into account how satisfaction is influenced by caregiver perceptions of local service availability.

406.371 (Poster) Examining Early Intervention Providers’ Perception of Implementing Parent-Mediated Intervention Models
N. Islam, E. Chatson, B. Demetri, K. Pickard and N. M. Hendrix. (1)Marcus Autism Center, Children’s Healthcare of Atlanta, Atlanta, GA, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (4)Marcus Autism Center, Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA

Background: State funded Early Intervention (EI) programs provide children and families with the necessary tools to navigate autism spectrum disorder and developmental delays by teaching caregivers to implement evidence-based intervention strategies. Parent mediated
interventions (PMIs) are one example of an effective approach in EI (Nevill et al., 2018) that have been the focus of implementation efforts within EI systems (Stahmer et al., 2020). While the effectiveness of PMIs has begun to be established within EI systems, less is known about the EI provider’s experience implementing PMIs, the adaptations they perceive necessary to the programs, and their continued use of these programs outside the scope of research. This study’s aim is to examine EI provider feedback on their experience delivering one of two PMIs and their intentions to sustain the intervention models.

Objectives: Study objectives were to: 1) Examine EI providers’ perspectives on the feasibility and acceptability of delivering one of two PMIs, Project ImPACT (Ingersoll & Dvortcsak, 2019) or Autism Navigator, an online resource platform on autism and relevant; 2) Understand the reach of these programs to children enrolled in EI services; and 3) Examine providers’ intent to sustain the programs following training and implementation efforts.

Methods: Twenty-five providers within Georgia’s state-funded EI system participated in an exit interview after receiving training in either Project ImPACT or Autism Navigator and attending 12-13 weeks of group consultation. All providers identified as female and from diverse disciplinary backgrounds, including special instruction, speech language pathology, and service coordination. The exit interview was semi-structured and questions focused on 1) overall impressions of the relevant training model; 2) how providers decided to deliver the intervention model to and why; 3) whether the intervention was delivered to families on the provider’s caseload in addition to those seen in the context of the research study; 4) the feasibility of learning and implementing Project ImPACT or Autism Navigator; 5) any adaptations made to the intervention; and 6) providers’ intent to sustain the intervention with their future EI families. Thematic analysis was used to summarize primary qualitative themes.

Results: Qualitative analysis is ongoing. Primary themes present in the interviews included providers’ overall satisfaction with both Project ImPACT and Autism Navigator, adaptations made based on family needs and priorities, the number of families who received the interventions and plans for future implementation.

Conclusions: Preliminary results from this study suggests that providers perceive both Project ImPACT and the Autism Navigator feasible to implement although may be adapted in response to specific family circumstances or service delivery models. Importantly, although providers reported delivering both intervention models to many families on their caseload, they also described specific decision they weighed in who they delivered the programs to. Limitations include not having exit interviews from providers that prematurely ended training or did not enroll in training. Continued investigation into the decision-making processes EI providers make when implementing PMIs is needed. Future work is also needed to assess these decision-making processes in providers who choose not to enroll or prematurely drop out of training.

406.372 (Poster) Examining IEP Services for Autistic and Anxious Youth from Diverse Communities: Comparing Services Based on Race, Ethnicity and Gender

A. T. Meyer, K. Pickard, A. Blakeley-Smith, L. Hayutin, C. Middleton, R. E. Boles, N. Reyes and J. Reavert, (1) JFK Partners, University of Colorado School of Medicine, Aurora, CO, (2) Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3) JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (4) University of Colorado Anschutz Medical Campus, Aurora, CO, (5) University of Colorado, AMC, Aurora, CO, (6) Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Autistic children have high rates of anxiety that significantly affect functioning across settings (van Steensel et al., 2011). Yet, many autistic youth are not able to access mental health services in the community due to systemic barriers, and this is particularly true for youth from historically underserved communities (Zuckerman et al., 2017). It is critical to provide school-based supports to these children as their mental health needs can significantly impact access to education. Unfortunately, there has been a history of racial/ethnic disparities in education services and placement for non-autistic students (Skiba et al., 2016). Therefore, it is critical to understand what services (including mental health) autistic youth with anxiety are receiving in schools and whether there are differences in the amount and type of services received based on race or ethnicity. It is also important to examine any differences in IEP designation as educational category often dictates service provision.

Objectives: 1) To examine the IEP designation, time spent in general education and amount and nature of mental health services for students with ASD or suspected ASD and anxiety; and 2) determine if there are differences in these factors by race, ethnicity, or gender.

Methods: Seventy-seven children 8-14 years old (mean age=11.10 years, SD=1.82 years; 77.9% male) with diverse racial and ethnic identities (37.7% POC, 62.3% non-Hispanic white) with autism or suspected autism and anxiety were enrolled in a school-based anxiety program (Facing Your Fears-School Based, FYF-SB). Inclusion criteria: Exceeding clinical threshold on the SCARED (Birmaher et al., 1999), T-scores above 60 on the SRS-2 (Constantino & Gruber, 2021), and estimated IQ above 70. All children had an IEP and presented with clinically significant symptoms of ASD on the SRS-2 (Mean=72.50, SD=10.32).

Results: Results indicated a wide range of services were provided across participants with time in general education ranging from 32% to 100%. Mental health services ranged from no mental health supports to 4 hours per month. However, there were no significant differences in mental health minutes by race, t(69)=1.12 p=.27, or gender, t(69)=-1.09 p=.28, nor were there differences in percentage of time in
In Australia across school contexts, individualized accommodations (or reasonable adjustments) in consultation with the caregivers are required under the 2005 Disability Standards for Education. For students with a diagnosed disability, schools are required to ensure that reasonable adjustments are made to support a student’s participation in a course, program, or use of facilities or services. Despite the requirement for reasonable adjustments being mandated, the process for creating individualized goals is not nationally mandated or standardized, and stakeholders acknowledge the challenge of ensuring this process results in meaningful learning for their students. To address this challenge, the Collaborative Model for Promoting Competence and Success (COMPASS) was adapted for use in Australian schools. Results of a randomized-controlled trial confirmed that students in the COMPASS group demonstrated more growth on individual goals than students in the services as usual group ($t(39) = -9.37, p < .001, d = .65$).

Objectives: This presentation aims to detail (a) how COMPASS was adapted and put into practice by community-based trainers, (b) what the student outcomes result demonstrated, and (c) results from a qualitative analysis of stakeholder feedback.

Methods:

In total, 91 participants including an intervention and services as usual group participated in the trial of COMPASS: consultants ($n = 15$), teachers ($n = 36$), and students and their parents/caregivers ($n = 40$). Adaptations were made before beginning COMPASS with a working group of stakeholders, and participant feedback on COMPASS was sought after completion in multiple formats (e.g., focus groups, interviews, and open-response questions). We adopted a participatory approach throughout the project life cycle, working closely with an autistic research assistant.

Results:

A working group of stakeholders initially provided feedback on how best to adapt COMPASS, and an implementation science framework was used to guide the adaptation process. Following the trial of COMPASS, qualitative analysis of feedback from stakeholders resulted in five themes, which summarized perspectives from parents/caregivers, teachers, and consultants who participated in COMPASS. Overall, participants felt COMPASS was a positive experience implemented in the future. However, certain features of COMPASS were more accepted (e.g., GAS, COMPASS profile) than others (e.g., coaching) due to day-to-day challenges faced by the participants (e.g., time constraints, number of students in a classroom). The implications of COVID-19 will also be discussed, as the study took place in 2021.

Conclusions:

This project replicated an intervention that provided a standardized framework for improving the quality of goals and progress for school-age autistic students, a challenge that has been acknowledged in Australian practice and research for years. The results of this study suggest that COMPASS can be replicated outside of the US, for diverse school contexts through stakeholder input and intentional adaptation. The success of this intervention in improving student individualized outcomes along with the results of this study demonstrating the satisfaction of stakeholders demonstrates the need for a standardized intervention that supports teachers in this critical practice.
Background:
Growing evidence has demonstrated the importance of providing parents with knowledge and skills to better support children with autism. However, there is a shortage of interventions suited for this population (especially for those facing geographical or socioeconomic disparities) that include program targets for challenging behaviors, parental stress, and parental competency.

COMPASS for Hope (C-HOPE) is an adaptation of the Collaborative Model for Promoting Competence and Success (COMPASS; Ruble, Dalrymple, & McGrew, 2012), originally a parent/teacher consultation intervention that improves social, emotional, and learning skills of children with autism in public schools. COMPASS is personalized to each child’s profile and identifies their unique personal and environmental supports and challenges. C-HOPE follows this framework. In an RCT, C-HOPE reduced challenging behaviors and parent stress, and increased parent competency when delivered across modalities (face-to-face; telehealth) to increase accessibility (Kuravackel et al., 2018).

Objectives:
The aim of this study was to test an adaptation of C-HOPE using an asynchronous, web-based, group discussion board and examining if parents reported less challenging child behaviors, lower levels of stress, and higher sense of competency from pre- to post-intervention.

Methods:
Participants were parents/caregivers of children with autism (aged 3-12 years; 27% of color) that displayed challenging behaviors. Participants were randomly assigned to two intervention groups and completed pre- and post-intervention measures.

C-HOPE is a virtually delivered eight-week program (12 hours total) consisting of individual sessions and group discussion boards addressing parental concerns specific to autism, child behavior goals, stress prevention, and caregiver wellness plans. For this adaptation, participants were able to watch training videos, participate in discussion boards with parents, and access training materials via a web-interface (i.e., Canvas) using an asynchronous group discussion board.

Results:
With the smaller sample size (N = 10) an intent-to-treat analysis was used. Paired sample t-tests were conducted to examine our main outcomes with an emphasis on effect sizes.

Challenging Child Behavior. The C-HOPE adaptation showed significant differences in challenging behavior from pre- (M = 146.40, SD = 35.36) to post-intervention (M = 123.10, SD = 28.35); t(9) = 3.05, p = 0.01; with medium (d = 0.50) to large (d = 0.80) effects size on challenging behavior (Cohen’s d = 0.73).

Parent Stress. Significant differences were found in parent stress from pre- (M = 122.60, SD = 25.73) to post-intervention (M = 109.50, SD = 26.47); t(9) = 2.51, p = 0.03; with a medium effect size (d = 0.50).

Parent Sense of Competency. Results did not show a significant difference in parental sense of competence scores from pre- (M = 55.20, SD = 17.59) to post-intervention (M = 50.50, SD = 17.51); t(9) = 1.11, p = 0.30.

Conclusions:
Results suggest that the web-based asynchronous adaptation for C-HOPE can assist parents in reducing challenging behavior of children with autism and decreasing parental stress by utilizing behavior plans, psychoeducational information, and interacting with other parents via virtual intervention modalities. Discussion will focus on the impact telehealth-based intervention services, like C-HOPE, can have on broadening accessibility to at-risk and underserved families.

406.375 (Poster) Examining the Impact of Policy Factors upon Early Autism Diagnosis in Five States: A Qualitative Investigation

D. J. Abate, O. J. Lindly, P. Fuchu, J. L. Kahnri, E. Feinberg, and S. Broder-Fingert, (1) E. K. Shriver Center, E. K. Shriver Center, University of Massachusetts Medical School, Worcester, MA, (2) Health Sciences, Northern Arizona University, Flagstaff, AZ, (3) Boston University School of Medicine, Boston, MA, (4) Pediatrics, Boston Medical Center, Boston, MA, (5) Brown University School of Public Health, Providence, RI, (6) University of Massachusetts Chan Medical School, Worcester, MA

Background: Early diagnosis of autism spectrum disorder (autism) before age three is a public health priority in the United States. Despite this, the Autism and Developmental Disabilities Monitoring Network’s 2018 report discovered that the median age of autism diagnosis in the United States is age 50 months and there is substantial inter-state variability in the average age of autism diagnosis (Maenner et al.,
2021). Examination of state-level policy factors -- defined as laws, regulations, procedures, administrative actions, incentives, or voluntary practices of governments or other institutions (Centers for Disease Control and Prevention, Office of the Associate Director for Policy and Strategy, 2015) -- can elucidate modifiable drivers of early autism diagnosis.

**Objectives:** This study sought to identify policy factors across five states participating in a national autism collaborative (Arizona, California, Connecticut, Massachusetts, and Pennsylvania) that impact access to early autism diagnosis.

**Methods:** We conducted semi-structured interviews by telephone or video conference from February 2021 to June 2022 with a purposive sample of autism and/or state policy experts across Arizona, California, Connecticut, Massachusetts, and Pennsylvania (N = 54). Nominated sampling was used to determine additional key informants in each state. Interviews were audio recorded and then transcribed. Data were coded using a directed content analysis approach in NVivo.

**Results:** The following four themes related to policy factors influencing access to early autism diagnosis across the five states were identified: (1) screening programs and practices often serve as a bridge between parent concerns about a child’s development and early autism diagnosis; (2) early autism evaluation and diagnostic processes remain highly variable within and across states; (3) workforce availability and licensure issues affect early autism diagnosis; and (4) health insurance policy affects the accessibility of early autism diagnosis. Theme 1 identified state-level trends concerning usage of the Modified Checklist for Autism in Toddlers (M-CHAT), the contextual dependency of autism screening tools, and common referral sources for autism evaluation. Theme 2 identified state-level trends in the administration of provisional diagnoses, usage of gold-standard diagnostic tools (e.g., the Autism Diagnostic Observation Schedule, Second Edition), and incidence of autism diagnosis amongst historically underrepresented groups. Theme 3 identified state-level trends in the availability, including geographic disparities, of the workforce able to diagnose autism, along with the implementation of legislation that dictates the categories of health professionals able to diagnose autism (e.g., nurse practitioners). Theme 4 identified state-level trends (e.g., low reimbursement rates, supplemental reimbursement through programs like the Early Periodic Screening, Diagnosis, and Treatment program) influencing the acceptance of Medicaid in accessing autism diagnostic services. Table 1 displays subthemes and illustrative quotations.

**Conclusions:** This study analyzed state-level policy factors influencing early autism diagnosis in the United States. To effectively promote early autism diagnosis across all 50 states, our study’s findings suggest it will be imperative to implement national policies dictating universal developmental surveillance and screening systems, diagnostic assessment standards across service settings, increased workforce capacity, and equitable insurance reimbursement rates and regulations. Such efforts should be oriented toward advancing equity in early autism diagnosis.

406.376 (Poster) Examining the Individualized Education Program Goal Areas of School-Age Autistic Children Using Latent Class Analysis

**M. C. Zajic, J. Gudknecht and N. S. McIntyre, (1)Health & Behavior Studies, Teachers College, Columbia University, New York, NY, (2)Human Development, Teachers College, Columbia University, New York, NY, (3)University of Central Florida, Orlando, FL**

**Background:**Autistic children make up 12% of the children served under the Individuals with Disabilities Education Act and often receive special education services through an Individualized Education Program (IEP). Existing approaches to understanding the IEP goals of autistic children have relied on small samples or focused on narrow goal areas. Approaches are needed to understand if IEP goal areas are heterogeneous among autistic children and if there are multivariate relationships among goal areas that may differ by subgroups of autistic children.

**Objectives:**To examine latent classes of autistic children’s IEP goal areas in academics (reading, writing, math), language, social skills, and behavior.

**Methods:**Data come from an online, national survey of families with a school-age child on the autism spectrum recruited through the Simons Foundation Powering Autism Research for Knowledge initiative. Data were collected as part of a study focused on COVID-19; current data only involve the time period prior to COVID-19 (i.e., 2019 to early 2020 school year). While 811 parents and caregivers completed the survey, this study focuses on the 664 children (82%) who were receiving some form of special education service. Children were predominantly male (80%) and White (73%); half of the sample was eligible for free or reduced-price lunch (49%). Children were distributed across grade levels (K-3 = 32%, 4-6 = 33%, 7-8 = 19%, and 9-12 = 17%) and lived across the United States (Northeast = 21%, Midwest = 26%, South = 33%, West = 21%). Children predominantly attended public school (84%). Parents indicated if their child had an IEP goal (0 = no goal, 1 = at least one goal) in the areas of reading (69%), writing (74%), math (60%), language (75%), social skills (81%), and behavior (58%). We used latent class analysis to examine multivariate patterns of parent responses. Classes were fit sequentially until model estimation failed, and model selection was based on model fit indices as well as theoretical and conceptual support.
**Results:** Though we estimated up to an 8-class solution, model fit statistics (BIC, Bayes Factor, Lo-Mendell-Rubin) endorsed a 3-class solution. Class 1 (*All Goal Areas*; 49%) included children who had a very high likelihood of having goals in all areas (0.81-0.99). Class 2 (*Academic and Language Goals*; 20%) included children who had a high likelihood of having academic (all areas) and language goals (0.68-0.86), some likelihood of having social skills goals (0.51), and a low likelihood of having behavioral goals (0.03). Class 3 (*Social, Behavior, and Language Goals*; 31%) included children who had low likelihoods of having academic (all areas) goals (0.10-0.28), some likelihood of having language goals (0.55) and behavioral goals (0.58), and a high likelihood of having social skills goals (0.78).

**Conclusions:** The IEP goal areas of autistic school-age children are heterogeneous, with findings highlighting the existence of multiple underlying classes. Findings highlight that not all autistic children have the same special education goals. Understanding this heterogeneity is a needed next step to helping researchers and practitioners better meet the diverse needs of autistic children in educational spaces.

---

**406.377 (Poster) Examining the Initial Feasibility and Acceptability of Remote Training in Caregiver Coaching for Part C Providers**

**Background:**

The Division for Early Childhood Education recommends building family capacity through practices like caregiver coaching, however a significant research-to-practice gap remains. Thus, there is a critical need to conduct research with community-based EI-providers to evaluate the feasibility, acceptability and social validity of training providers in evidence-based coaching practices.

**Objectives:**

The current study aims to bridge the research-to-practice gap in caregiver coaching in EI by (1) describing a model of remotely training community-based EI providers in Caregiver-Implemented Reciprocal Imitation Teaching (CI-RIT), a parent-mediated naturalistic developmental behavioral intervention (NDBI), and (2) examining providers’ perceptions of the initial effectiveness, feasibility, and acceptability of the model.

**Methods:**

This study is part of an ongoing, multisite randomized controlled trial of the effectiveness of CI-RIT in Part C Early Intervention (EI). Our sample includes 35 EI providers, who were 40.81 years old on average (SD = 9.66). The majority of the providers were white (80%), identified as female (91.4%), and had a Master’s degree (85.7%)(Table 1). Training in CI-RIT includes the following remote training components: (1) completion of self-directed online modules, (2) 12-hour synchronous virtual workshop, and (3) 2-4 role plays in which providers conduct full-length CI-RIT lessons. Immediately post-workshop, providers completed a workshop satisfaction survey containing 3 items rated on a 7-point scale, with higher scores signifying higher satisfaction. They also rated the usefulness of the workshop components (e.g., slides, small group activities) on a 5-point scale, with higher scores indicating higher usefulness. Finally, the providers reported on their perceived CI-RIT self-efficacy with a measure containing 7 items scored on a 7-point scale (1 = “not at all confident,” 7 = “completely confident”). Three months post-training, providers were asked to complete the self-efficacy measure again along with an 18-item social validity scale, a 9-item usability scale, and a 3-item intervention material usefulness scale, rating items on a 7-point Likert scale with higher scores indicating higher social validity, usability, or usefulness.

**Results:**

Providers reported high satisfaction with the workshop content (M = 5.87, SD = 2.03) and the workshop training components (M = 4.72, SD = 0.35). They reported high self-efficacy scores following the workshop (M = 5.78, SD = 0.57), and reported that CI-RIT had high social validity (M = 5.76, SD = 1.25). Preliminary analyses with the first five participants to complete time two data collection, three months post-training, indicates the providers had high self-efficacy (M = 6.62, SD = 0.40), and they perceived the intervention to have high usability (M = 5.62, SD = 0.68), and useful materials (M = 6.27, SD = 1.30). See Table 2 for measure descriptives.

**Conclusions:**

This preliminary evaluation of EI providers’ perceptions of remote CI-RIT training are promising as providers rated high satisfaction and usefulness of the virtual workshop and high feelings of self-efficacy. Further, providers rated the intervention and accompanying materials as having high social validity and usability. Providers’ high sense of self-efficacy demonstrates the potential benefits of an entirely remote training model, an important consideration for broader implementation of caregiver coaching in EI.
Factors Contributing to Caregiver Satisfaction with Autism Spectrum Disorder Evaluation Feedback in the United States

K. Stetinova and R. D. Rieske, (1) Nationwide Children's Hospital, Westerville, OH, (2) Idaho State University, Pocatello, ID

Background: The current study investigated caregiver experiences with autism spectrum disorder (ASD) evaluation feedback process and factors contributing to caregiver satisfaction. Past literature suggested that caregivers often feel distressed during the feedback session and report dissatisfaction with the provided information. Additionally, some clinicians reported experiencing discomfort when breaking "bad news" to the family and feeling that they do not have sufficient training in this area. These findings are not surprising given the limited number of updated, evidence-based clinical guidelines specific to ASD feedback delivery.

Objectives: The study aimed to evaluate whether factors such as family demographics, diagnostic processes, provider characteristics, and level of emotional distress are associated with caregiver satisfaction with ASD feedback. Given the gaps in the extant literature, the secondary goal was to report on details such as the session length, session participants, and elements included in the feedback process as recalled by the caregivers, intending to elucidate common practices across providers in the United States.

Methods: Caregivers of children previously diagnosed with ASD could participate in the study through an online survey developed by the researchers. The survey was inspired by the Autism Treatment Network feedback guide from 2012, aiming to collect both quantitative and qualitative information about caregiver experiences. The survey was advertised through social media, parenting groups, and US clinics specializing in neurodevelopmental disorders. The study included responses from 268 caregivers across 45 US states.

Results: All predicted covariates (i.e., time since diagnosis, child's and caregiver's age, child's and caregiver's gender, and caregiver's relationship to child) were not significantly related to caregiver feedback satisfaction. The results of multiple regression (F(14, 211) = 45.23, p < .001) indicated that waitlist length and an emotional distress count were negatively associated with feedback satisfaction, while the perceived provider advocacy and the value of caregiver's input showed a positive relationship with the outcome variable. There was not a significant relationship between the feedback satisfaction and demographic factors such as location within provider-shortage area and racial/ethnic minority status, which often act as barriers to health care access. The average satisfaction rate was 71%, which is higher than in past literature, but only 24% of caregivers felt as if they were provided with time to think/process emotions during the session. The most common emotions experienced by the caregivers were sadness, anxiety, acceptance, and relief.

Conclusions: The findings suggest that caregivers who experience strong emotions during the session may still be satisfied with the feedback. Furthermore, the results highlight the importance of continuous efforts to decrease the waitlist time for ASD evaluation as well as the need to put greater emphasis on advocacy and the value of the caregiver input rather than the sensitivity with which the diagnosis is shared. Lastly, through the recognition of factors related to caregiver satisfaction, the study was able to shed more light on clients' wants and needs, which may help inform the development of professional guidelines for feedback delivery in the future.

Females with High Autistic Traits Who Identify As Autistic Are Less Likely to Receive a Diagnosis of Autism.

B. M. Alty, M. Brosnan, A. Russell, and M. Adamou, (1) University of Bath, Bath, United Kingdom, (2) Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3) Psychology/Centre for Applied Autism Research, University of Bath, Bath, UNITED KINGDOM, (4) swyt, Wakefield, United Kingdom

Background: Adults seeking diagnostic assessment for autism can be disappointed if the outcome of the assessment is not in line with their expectations. This may be particularly true for adults who identify strongly with autism prior to assessment. There is lack of research on this topic although adults not receiving a diagnosis may account for 50% of diagnostic clinic attendees in the U.K. Screening tools, including autism trait measures are frequently used by clinics to manage diagnostic services, despite the lack of specificity reported.

Objectives: To investigate differences in pre-assessment autism identification and autistic traits in adults attending autism diagnostic clinics who do and do not receive an autism diagnosis.

Methods: Participants were a consecutive sample of adults attending for autism assessment in a UK NHS service between June 2021 and August 2022. 109 referrals (50 male, 59 female, mean age = 33 years, SD=11, range=18-61) who attended clinic received a diagnostic outcome by September 2022. Participants completed the Autism Social Identity Questionnaire (ASIQ, Cooper et al., 2018) and the Autism Spectrum Quotient (AQ50, Ruzich et al., 2015) prior to clinic attendance.

Results:
Of the 109 referrals, 92 (84%) did not receive a diagnosis of autism (no-ASD) and 17 (16%) did (ASD). A MANCOVA analysis explored the impact of outcome (ASD or no-ASD) and sex (male or female) on ASIQ and AQ, controlling for age. There was a significant main effect of sex on AQ50 with females scoring higher than males (39 vs 34: F(1,103)=5.23, p=.024). There was also a significant interaction between sex and diagnostic outcome on ASIQ – males who received a diagnosis (ASD) and females who did not receive a diagnosis (no-ASD) both identified more strongly with Autism prior to clinic attendance, (F(1,103)=6.54, p=.012; see Figure). All other main effects and interactions were not significant (all p>.2). There was a non-significant correlation between AQ50 and ASIQ scores (r(98)=.10, p=.31, controlling for sex, outcome and age).

Conclusions:

This study identified a very low diagnostic rate of autism (16%) for adults attending a UK service when compared with previous UK-based research (70%, Wilson et al., 2016). Cohort differences may account for such variability between UK services, but this warrants further investigation. Females reported significantly higher levels of autistic traits than males prior to assessment. This sex difference is not consistent with sex differences in the general population or autistic populations (Ruzich et al., 2015). Autism traits did not significantly impact on diagnostic outcome, consistent with previous research. These data highlight a group with high levels of autistic traits who did not receive a diagnosis of autism. Finally, males who received a diagnosis of autism and females who did not receive a diagnosis of autism identified most strongly with an autism identity prior to clinic attendance. This suggests sex-specific effects relating to autism identity and formal autism diagnosis.

406.380 (Poster) From Point of First Concern to Follow up after Diagnosis: Enhancing Care in the Medical Home for Patients with Autism Spectrum Disorder

Background:

Primary care providers (PCPs) are expected to help families navigate next steps after an ASD diagnosis. However, PCPs often do not receive sufficient training in providing follow-up care, parents report inadequate guidance related to next steps, and care coordination for ASD is often inconsistent and disjointed within primary care settings.

Objectives:

To evaluate the impact of an ASD pathway that includes streamlined/embedded assessment and routine PCP follow-up after ASD diagnosis within a busy academic medicine clinic.

Methods:

Our study population consisted of children aged <48 months receiving care in a large primary care clinic that includes 83 residents, 9 nurse practitioners, 17 attending faculty pediatricians, and two embedded psychologists. Children who were identified through standard screening protocols were referred to an embedded provider for tiered evaluation. If diagnosed with ASD, children were automatically scheduled for follow-up with their PCP. To increase access, families were given the option to have either visit via telehealth. For the follow-up visit, PCPs were trained in the use of the novel note template and order smart set that integrated best practices, including discussion of genetic testing, referrals for therapy, discussion of co-occurring concerns, and smart phrases to provide educational and practical resources for families. Extracting data from the electronic health record (EHR), we tracked ASD-specific appointments and provider actions in response to ASD concerns. Baseline data were extracted from the EHR for the 12 months prior to intervention. Our team used monthly Plan-Do-Study-Act (PDSA) Cycles to monitor intervention outcomes and overall improvement related to wait times for ASD diagnosis, latency to follow up visits, and use of EHR templates designed to guide and track clinical practices. Additionally, REDCap surveys were sent to PCPs to assess satisfaction and template usability.

Results:

Median wait time between initial referral and diagnosis during the project period was 32 days. In the 12 months prior to intervention, 71 patients received an ASD diagnosis with a mean of only 21% receiving an ASD-specific follow-up visit (median 53 day wait). In the 13 months following project launch, 119 children received a diagnosis of ASD with a majority (89%) receiving ASD-specific follow-up (median 47 day wait). Providers used the note template 73% of the time, providing ASD-specific guidance and resources to caregivers. Genetics testing was discussed with 67% of patients seen after ASD diagnosis (increase from 13% baseline) and testing was consented to and/or obtained by 43%. REDCap surveys indicated a high degree of usability with the template, high satisfaction with the new system, and high agreement that the follow-up protocol helped providers “better follow best-practice guidelines for general ASD care.”
Conclusions:

Results demonstrate sustained improvement with children receiving a timely ASD diagnosis as well as a significant increase in PCP follow-up visits. Clinical decision-making templates embedded within the EHR led to important practice change, with PCPs reporting feeling more equipped to discuss evidence-based care and resources. Next steps include ongoing data collection and system-wide dissemination of model to increase efficient and evidence-based management for children with ASD.

406.381 (Poster) Gender-Based Analysis of Educational Outcomes for Kindergarten-to-Grade 12 Students with Autism Spectrum Disorder in British Columbia, Canada

J. L. Baumbusch, J. E. V. Lloyd, and V. C. Fong, (1)School of Nursing, University of British Columbia, Vancouver, BC, Canada, (2)School of Nursing, The University of British Columbia, Vancouver, BC, Canada, (3)The University of British Columbia, Burnaby, BC, Canada

Background: Autism spectrum disorder (ASD), hereafter referred to as autism, is a neurodevelopmental disability characterized by differences in social communication and interaction, as well as restricted and repetitive interests, activities, and behaviors (APA, 2013). Autism is diagnosed three to four times more often in boys than girls (Baio et al., 2018; Loomes, Hull, & Mandy, 2017) and girls tend to be diagnosed later than boys are (Kavanaugh, 2021). This gender bias in diagnosis is attributed to factors such as camouflaging, which involves copying or masking personality traits or behaviors to adjust or “fit in” to their social environment (Lai & Baron-Cohen, 2015). As a result, autism in girls is more likely to go undetected and remain undiagnosed. The delay or absence of a formal diagnosis has implications related to accessing specialized supports and services. During their formative education in elementary and high school, gender differences, particularly recognition of autism among girls, may have serious implications with respect to educational outcomes.

Objectives: We seek to investigate the educational journeys of students who received an ASD designation from Kindergarten to Grade 12, and to conduct gender-based analyses to explore how gender may influence these journeys over time. (Note: Students must have a formal autism diagnosis to obtain this designation.)

Methods: This is a secondary analysis of student-level data regularly collected by the Ministry of Education and Child Care in British Columbia, Canada. The working sample consists of students from eight annual cohorts who began Kindergarten between the 1999/2000 and 2006/2007 school years (inclusive), and follows them forward in time to when they should ideally have reached Grade 12 or equivalent, up to and including the 2018/2019 school year. Specific outcomes explored are: grade-to-grade transition paces, consistency of designation across school years, time to initial designation, high school completion credentials, and rates of school completion.

Results: The sample consists of 4,287 students with an ASD designation: 3,547 (82.7%) boys and 740 (17.3%) girls. Preliminary findings show that almost half (46%) of students began school with an ASD designation, versus 22% who were designated for the first time after being in school for five or more years. Over half of the students (56%) proceeded through school at a typical pace (one grade level per year). The majority of students (84%) completed high school with some type of credential (in BC, there are three types of high school completion credentials).

Conclusions: Results demonstrate that more boys than girls obtain an ASD designation, which reflects rates in the general population. Moreover, there are gender-based differences in educational outcomes that could contribute to inequities in supports among students. Our study also highlights the value of longitudinal, population-level data in conducting gender-based analyses in autism research.

406.382 (Poster) General Education Teachers Knowledge of Autism in Low-Income and Under-Resourced Settings

M. Dean and Y. Chang, (1)Education, 2013, Camarillo, CA, (2)Department of Special Education & Counseling, California State University Los Angeles, Los Angeles, CA

Background:

The dramatic increase of autistic students being educated in inclusive settings (Biao, 2014) places a growing responsibility on general educators to implement autistic students’ individual education programs (IEP; Bines & Lei, 2011). Yet many general educators have limited knowledge about autism, or evidence-based interventions to support these students (Connor & Ferri, 2007; de Boer et al., 2011). Teachers in low-income or under-resourced settings report limited time for collaboration and lack of school-wide support as barriers to the effective inclusion of autistic students (Iadarola et al., 2015).

Objectives:

The current study examined general education teachers’ knowledge and understanding of autism using The Autism Awareness Survey (Heidgerken et al., 2005; Tipton & Blacher, 2013).
Methods:

The study included 173 general education teachers across different grade levels (preschool=3, TK/K= 20, 1st-5th grade= 67, 6th-8th grade= 38, 9th-12th grade= 45). Approximately 80% (n=139) of the teachers were female and the teachers’ average age was 47.65 years (SD= 24.23 years). The teachers also ranged in their years of experience (M= 16.17 years, SD= 9.35 years). Teachers were from 28 different school districts in the Southwestern region of the United States and 76% of the teachers (n=132) worked in Title I schools.

Teachers completed The Autism Awareness Survey (Heidgerken et al., 2005; Tipton & Blacher, 2013) online through Qualtrics. The survey consisted of 14 statements of beliefs about autism, and participants were asked to rate these statements on a 0-4 scale (Disagree, Agree, Somewhat Disagree, Neutral, Somewhat Agree, and Agree). For analyses, the items were translated to a 5-point correctness scale. For statements that were true, the scoring would range from agree=4 to disagree=0. For statements that were not true, the scoring would be reversed, ranging from agree=0 to disagree=4. The total correct score for the 14 items could range from 0 to 56. The items are also divided into three categories: correct, incorrect, and neutral.

Results:

The total correct score for the 14 items ranges from 28 to 56, with the mean of 41.28 (SD= 6.81). The three statements were the highest correct responses were: 1) There is one intervention that works for all children with autism (94.71%), 2) Children with autism can grow up to live independently (97.67%), and 3) There is a cure for autism (88.24%). The three items with the highest incorrect responses were: 1) Changing a child’s diet will lessen the severity of autism symptoms (32.35%), 2) Autism a developmental disorder (30.18%), and 3) Autism is an emotional disorder (30.23%).

Conclusions:

This study contributes to existing research by focusing on general education teachers’ knowledge of autism. Findings corroborate previous research that identified similar patterns of correct and incorrect knowledge of autism among university faculty (Tipton and Blacher, 2013). Results highlight areas of professional development about autism and evidence-based interventions that are needed to mitigate misinformation among general educators who teach in socioeconomically diverse and under-resourced settings.

406.383 (Poster) Homelessness and Autism in Women

Background: Emerging evidence suggests that autistic people are more likely to experience homelessness, and that their homelessness experiences may be different compared to non-autistic people; autistic individuals also report facing additional challenges to resolving their homelessness (Kargas et al., 2019). Homelessness is the result of a multitude of inter-related factors including unemployment, relationship breakdown, lack of social support systems, and mental health conditions (Fazel et al., 2014).Unfortunately, many of these circumstances disproportionally impact autistic individuals. From the limited data that exists, the prevalence of autism in homeless populations has been estimated to be over 12% (Churchard et al., 2019). Despite this, there is limited research on the link between autism and homelessness, and how to best provide services that could prevent or shorten periods of homelessness in this population. These gaps are particularly acute for autistic women, whose experiences of homelessness are often distinct from men’s, and who are an under-represented, but often vulnerable due to high rates of violence and stigmatisation (Bretherton & Pleave, 2018).

Objectives: We aimed to: 1) map gaps in knowledge and practice in the area of homelessness and autism in women; 2) identify priority areas for research; 3) develop recommendations for how to implement novel research and practice in this area.

Methods: We adopted principles of participatory research (Fletcher-Watson et al., 2019) and designed a series of co-production workshops around Freire’s (1970) framework for generating open dialogue and creative listening to generate new ideas. An interdisciplinary group of 26 stakeholders took part, of which six identified as autistic. Participant-researchers were purposively sampled to ensure expertise and representation from a diverse range of stakeholders, and specifically included individuals with lived experience of homelessness, autistic representatives, researchers, homelessness and domestic violence charity representatives, service providers, health professionals and Commissioners (many attendees fitted into multiple categories). Five attendees had experience of homelessness, and three female attendees identified as being autistic and with personal experience of homelessness. All participant-researchers were asked to agree to a set of principles designed to encourage inclusivity and open, active discussion. Each workshop began with narratives from different stakeholders,
followed by facilitated break-out discussion sessions, which were purposely chosen to include a mix of stakeholders in each group. A plenary session at the end of each workshop consolidated discussions, and reached consensus on priority agenda setting.

Results: Two areas of research priority were identified: to map the prevalence and demographics of autistic women experiencing homelessness; and to delineate risk and protective factors for homelessness. Priority areas for improving provision of support included: staff training to improve communication, awareness of autism and building trust with service providers; and recommendations for practical provision of support by services.

Conclusions: Future research is critical to increase our knowledge of pathways leading to homelessness for autistic women, and barriers to engaging with homelessness and social services. We then need to use this knowledge to develop new ways of delivering targeted and inclusive support for autistic women, which could prevent or shorten periods of homelessness.

406.384 (Poster) How Can We Improve Timeliness and Quality of Autism Diagnostic Assessment: Findings and Recommendations from a Realist Evaluation (RE-ASCeD) of Autism Service Delivery in the UK.

W. Farr*, S. McGrevey*, S. Wigham*, V. J. Abrahamson*, P. M. Wilson*, J. R. Parr* and I. A. Male, (1) Sussex Community NHS Trust, Haywards Heath, United Kingdom, (2) Research, Sussex Community NHS Foundation Trust, Haywards Heath, United Kingdom, (3) Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, UNITED KINGDOM, (4) University of Kent, Canterbury, United Kingdom, (5) Centre for Health Service Studies, University of Kent, Canterbury, United Kingdom, (6) Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (7) Mid Sussex Child Development Team, Sussex Community National Health Service Foundation Trust, Haywards Heath, United Kingdom

Background:

Referral rates for autism diagnostic assessment in children doubled between 2015 - 2019 (Parr et. al, INSAR 2021) and continue to rise. Teams have experienced growing waiting lists, with families experiencing longer times to complete diagnostic assessment.

Objectives:

To examine autism diagnostic service delivery models in the UK National Health Service to determine which approaches have potential to improve quality and timeliness of diagnosis.

Methods:

This abstract is focused on qualitative analysis of interviews of clinicians, referrers and commissioners (n = 69), and children and young people (n = 20), and focus groups with parents (n = 36), with questions designed in line with realist thinking to determine “what works, for whom, when and under what circumstances”, based in six centres: two Child Adolescent Mental Health Services (CAMHS), two Child Development Teams (CDTs), two integrated CAMHS/CDTs. Teams were selected from prior survey (N=128) of services across the UK NHS, who self-reported meeting NICE Quality Standards for autism assessment. The study also included rapid realist literature review, a survey of current national practice, consensus events, and following realist methodology, developed recommendations to improve practice iteratively.

Results:

Interviews with professionals, parents, and young people revealed frustrations with the system, for example the need to better support families throughout the process and not be left on their own to “fall off a cliff” post diagnosis. Seven key themes were identified where the child and family journey to diagnosis could be improved. Some of the key recommendations are presented by theme, below:

1. **Recognition by potential referrers**
   - Develop system-wide recognition of autism, including training targeted at HVs, GPs, nursery and school staff.

2. **Referral process**
   - Develop better information gathering tools that enable professionals and parents to describe the child effectively.

3. **Service organisation**
   - Co-existing conditions should be diagnosed under a neurodevelopmental umbrella.
• Support and intervention should be available throughout assessment process, not just post diagnosis.

4. **Skill mix**

• Staffing should be based on competency, rather than job title, and be responsive to diagnostic complexity.

5. **Assessment**

• Digital technology may be used judiciously, but, where possible, face to face contact should be an integral part of the assessment.
• Assessment should recognise child’s strengths and needs as well as diagnosis

6. **Report and feedback**

• With parental consent, summary reports should be directly shared with schools.

7. **Training and service development/evaluation.**

• Need to train more staff across core disciplines of MDT and widen pool of autism diagnostic practitioners.

Conclusions:

The results point to areas of good practice and potential solutions that could help to meet increasing demand, and the challenges of under resourcing, increasing case complexity and staff retention and recruitment. Some recommendations focus beyond the diagnostic teams, for example improving recognition by primary care professionals to reduce length of time to obtain a referral. Diagnostic teams could introduce greater flexibility with a tailored approach to assessment, e.g. for children with clear signs of Autism, and adoption of a neurodevelopmental approach that recognises a child’s strengths and needs, and co existing conditions alongside Autism diagnosis.

A. M. Angell1, S. Datta1, G. Luo1, C. Parchment1, E. Shoemaker1, and T. Reistetter1, (1)Mrs. T. H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Department of Biostatistics, University of Florida, Gainesville, FL, (3)Keck School of Medicine, University of Southern California, Los Angeles, CA, (4)Department of Child and Adolescent Psychiatry, Los Angeles County+USC Medical Center (LAC+USC), Los Angeles, CA, (5)Department of Occupational Therapy, University of Texas Health San Antonio, San Antonio, TX

Background: Community-based therapeutic services, such as occupational, physical, speech, and behavior therapy, are often considered ‘autism-related services.’ Although they may play a role in important developmental and work-related outcomes, such as promoting community and occupational participation, and reducing the risk of acute psychiatric care utilization, there is some evidence that access to these services decreases with age. Much of existing research, however, utilizes 10+ years old data or relies on patient or caregiver report, or includes only specific age groups.

Objectives: We aim to address these gaps by examining contemporary age-related patterns of therapeutic service utilization for the Florida autistic population across the lifespan. We hypothesized that therapeutic service utilization decreases with age.

Methods: This retrospective observational study is a secondary analysis of Medicaid claims from the OneFlorida Data Trust. We defined therapeutic utilization as the number of ambulatory visits with a provider specialty code for occupational therapy (OT), speech therapy (ST), physical therapy (PT), or behavior therapy (BT). We included patients ages 3 to 64 with an autism spectrum disorder diagnosis (ICD-9: 299.0, 299.1, 299.8, 299.9; ICD-10: F84.0, F84.2, F84.3, F84.5, F84.8, F84.9), with at least one therapeutic service claim during the measurement period (2012-2019). Our final sample was N=20,356 patients. With age and time (measurement year) as the independent variables (covariates sex, race, ethnicity, urbanicity, and therapy type), and therapeutic service utilization as the dependent variable, we constructed a zero-inflated mixed effect model with a random effect on patient ID to account for within-subject correlation, using the glmmTMB package in R.

Results: Holding all other independent variables fixed, therapeutic service utilization decreased with age (β=-0.014, p<0.0001), but the total utilization increased over time (β=0.009, p<0.001). There was also a significant difference between white and nonwhite patients’ utilization (β=0.102, p<0.0001), and a significant difference between Hispanic/Latino and non-Hispanic/non-Latino patients’ utilization (β=0.118, p<0.0001). Specifically, white patients’ utilization was 1.11 times that of non-white patients, and non-Hispanic/non-Latino patients’ utilization was 0.89 times that of Hispanic/Latino patients. Patients in urban areas had significantly higher utilization than those in
non-urban areas at a less significant level ($\beta^e=0.125$, $p<0.05$). There were also significant differences between therapy types: OT and PT were significantly less utilized compared to BT ($\beta^e=-2.598$, $p<0.0001$ and $\beta^e=-0.145$, $p<0.0001$, respectively), and ST was significantly more utilized than BT ($\beta^e=0.168$, $p<0.0001$).

Conclusions: Among the OneFlorida autistic population, therapeutic service utilization decreased with age but increased over time. We identified disparities by race and urbanicity. Surprisingly, Hispanic/Latino patients had significantly higher utilization, suggesting that the Florida Hispanic/Latino population may be gaining equitable access to Medicaid services. It could suggest, however, that non-Hispanic/non-Latino patients are accessing therapeutic services through other systems, i.e., school and private insurance. Finally, ST has the highest utilization, and OT and PT the lowest. More research is needed to identify barriers to receipt of therapeutic services at specific ages, in order to promote equitable access to services that can support community participation.

R. E. Mitre, V. Nanclares-Nogues, E. Boaglio, D. A. Broccolo, C. Franco, M. V. Peralta, V. Pollo, M. B. Raimundo, K. Sohl, N. Santamaria, M. Pena and M. Porto, (1)Fundación Neurodiversidad, Rosario, Argentina, (2)Child Health, ECHO Autism Communities, University of Wisconsin, Columbus, WI, (3)Fundacion Neurodiversidad, Rosario, Argentina, (4)Fundacion Neurodiversidad, rosario, Argentina, (5)ECHO Autism Communities, Child Health, Columbia, MO, (6)Holland Bloorview Bloorview Kids Rehabilitation Hospital, Bloorview Research Institute, Canada, Toronto, ON, Canada

Background: Several investigations have determined that deficits in clinical skills and specific knowledge of health professionals contribute to difficulties and limitations in the timing and quality of the provision of primary care services for people with autism and their families (Dillenburger et al., 2016; Harrison, Slane, Hoang, & Campbell, 2017). The lack of knowledge about autism and best practices guidelines leads many professionals to carry out inconsistent clinical practices and provide inefficient care (Heidgerken et al., 2005). Moreover, in developing countries like Argentina, there are other gaps related to the economic cost and language barriers related to autism training and the structurally unequal healthcare systems (Paula et al., 2020; Kleinman, 2009; Demyttenaere et al., 2004). The Extension for Community Healthcare Outcomes (ECHO) Autism model is a movement to de-monopolize knowledge and expand local capacity to bridge many of those gaps. Creating access to high-quality specialists in local communities has proven to be a feasible and effective way to increase local capacity for best-practice medical care for people with autism (Mazurek et al., 2017; Mazurek et al., 2020; Sohl, Mazurek, & Brown, 2017).

Objectives: To assess the effect of an ECHO Autism program implementation on the level of knowledge, perceived self-efficacy, and practice patterns of healthcare professionals. 

Methods: 29 participants -registered from 18 of the 23 provinces in Argentina-participated in 8 monthly 90-minute telementoring ECHO-clinics during 2021. Each meeting consisted of a de-identified case presentation by a community clinician participant and a brief didactic presentation by content experts to address specific knowledge gaps. A mixed-method evaluation was conducted using a battery of self-administered questionnaires before and after participation in the 8 ECHO clinics. A socio-demographic questionnaire, the Knowledge Questionnaire on Childhood Autism among Health Care Workers (KCAHW), a Perceived Self-Efficacy and Autism Questionnaire and the Clinical Behavior Patterns Questionnaire were administered, along with a survey to assess participants’ level of satisfaction.

Results: After the model implementation, a significant increase was observed between pre- and post-test in the three areas. As for the knowledge level, the mean score of correct answers in the KCAHW was 12.21 ($\pm$ 2.09) in the pre-test, and 16.28 ($\pm$ 1.89) in the post-test, out of a total of 19. The perceived self-efficacy, with an initial total score of 2135 (59%), increased to 2606 (72%), reflecting an improvement of 13%. As for the practice patterns, 92.11% reported experiencing modifications, 85% stated that their practice competencies became adequate or very good, and 79.9% informed the clinics improved their ability to care for autistic people. Furthermore, the participants’ average level of satisfaction was over 80% for all the clinics.

Conclusions: The results suggest that the ECHO Autism program improved access to best-practice care training for clinicians in under-resourced areas of Argentina. Its implementation seems to have improved the participant’s knowledge levels, perceived self-efficacy, and practice patterns. Although much research is still needed, these results seem consistent with previous findings (Mazurek et al., 2017; Mazurek et al., 2020; Sohl, Mazurek, & Brown, 2017).

**406.387 (Poster)** Impacts of the COVID-19 Pandemic on Adaptive Functioning and Behavioral Problems Among Preschool Children with ASD: A Pre-Post Study

Background: Public health measures initiated in the Spring of 2020 to control the spread of SARS-CoV-2 disrupted many aspects of child and family life. Cross-sectional surveys have found children with autism spectrum disorder (ASD) experienced significant disruptions to
their therapies, school, and daily routines. Some studies have reported evidence of both positive and negative impacts of the pandemic on the functioning and behavior of children with ASD as perceived by parents. To our knowledge, no longitudinal studies of children with ASD compare standardized measures of adaptive functioning and emotional and behavioral problems obtained shortly before the pandemic to those re-administered during the pandemic.

Objectives: To investigate changes in adaptive functioning (as measured by the Vineland Adaptive Behavior Scales; VABS) and behavioral problems (as measured by the Child Behavior Checklist; CBCL) for children with ASD using measurements obtained prior to and during the COVID-19 pandemic and associated service disruptions.

Methods: Study participants included 274 children with ASD enrolled in the Study to Explore Early Development (SEED), a multi-site case-control study of preschool-aged children within six communities in the United States. ASD determination was based on the Autism Diagnostic Interview-Revised (ADI-R) and Autism Diagnostic Observation Schedule (ADOS). Between September 2017 and March 2020, parent-reported measures of adaptive functioning and behavioral problems were obtained using the VABS and CBCL, respectively, and served as pre-pandemic baseline measurements. Repeat VABS and CBCL measures, as well as a parent questionnaire on impacts of the pandemic, were obtained between January and July 2021. Multivariable linear regression models were created for each of the VABS domains and CBCL scores measured to assess pre-post differences adjusting for covariates.

Results: The impact of the pandemic on adaptive functioning scores varied by sub-domain, with statistically significant increases in Daily Living (5.5, 95% CI: 4.1, 6.9) and Socialization (2.3, 95% CI: 1.1, 3.5) and decreases in Communication (-4.2, 95% CI: -5.5, -2.9) domain scores. Adjusted linear regression models showed significantly lower mean composite VABS scores for those who reported losing specialty services (70.7, 95% CI: 68.9, 72.5) compared to those who did not (74.6, 95% CI: 71.9, 77.3). Mean CBCL scores decreased (Total Problems score difference -3.2, 95% CI: -4.2, -2.1), indicating a decline in behavioral problems during the pandemic. After adjustment, we found those who received telehealth services during the pandemic had a greater decline in behavioral problems compared (59.4, 95% CI: 57.3, 61.4) to those who did not (61.8, 95% CI: 59.5, 64.2).

Conclusions: Understanding the impacts of the COVID-19 pandemic and associated disruptions in access to services on communication and other domains of adaptive functioning and emotional and behavioral problems in children with ASD is essential to allow preparedness for future public health emergencies and limit service disruptions. For young children with ASD, these disruptions may be especially detrimental given the importance and benefits of early interventions and treatments. However, more time at home with caregivers may also result in increased application of daily living and social interaction skills, or increased recognition of these skills by caregivers.

406.388 (Poster) Implementation and Efficacy of Stress-Reduction Interventions for Parents of Preschoolers with ASD across in-Person and Virtual Modalities
C. L. Neece, R. M. Fenning, and H. Morrell, (1)Psychology, Loma Linda University, Loma Linda, CA, (2)Psychological Science, Claremont McKenna College, Claremont, CA

Background: Parents of children with autism spectrum disorder (ASD) experience heightened parenting stress (e.g., Hayes & Watson, 2013) and challenges are exacerbated for underrepresented families. High levels of parenting stress have been associated with negative consequences for parent mental and physical health (e.g., Allik et al., 2006; Rao & Beidel, 2009), and elevated levels of child behavior problems in youth with ASD (Rodriguez et al., 2019). Nevertheless, parenting stress has rarely been addressed directly in interventions for families of children with ASD, and even less so in underserved populations where clinical needs are greater.

Objectives: Utilizing data from a randomized controlled trial (RCT), we evaluated feasibility, acceptability, and efficacy of Mindfulness-Based Stress Reduction (MBSR) relative to Psychoeducational Support (PE) for parents of preschoolers with ASD. We also compared metrics for in-person and virtual modalities following our pivot to telepsychology in response to COVID-19.

Methods: Participants included 117 diverse parents of preschoolers with ASD (ages 3-5 years, 78.63% racial/ethnic minority) who were part of the Stress-reduction Techniques for Enhancing Parenting Skills (STEPS) Project, an NIH-funded RCT. Parents were randomly assigned to receive the MBSR (N=59) intervention or the PE active comparator (N=58). Parents and their children with ASD participated in assessments at baseline, immediately post-intervention, as well as 6- and 12-months post-intervention. Interventions were delivered in-person (MBSR-IP=32, PE=34) or online (MBSR-VT=27, PE-VT=24). The primary outcome, parenting stress, was a latent variable comprised of three measures; the Parental Distress subscale of the Parenting Stress Index-Fourth Edition, Short Form (PSI4-SF; Abidin, 1995), the Negative Impact scale of the Family Impact Questionnaire (FIQ; Donenberg & Baker, 1993), and the Intensity subscale of the Parenting Daily Hassles questionnaire (PDH; Crnic & Greenberg, 1990).

Results: There were no significant differences by intervention group or modality in baseline variables or in rates of attrition. Most parents who participated in treatment attended at least half the sessions (MBSR-IP=69%, MBSR-VT=92%, PE-IP=82%, PE-VT=100%) and attendance was significantly better virtually than in-person (MBSR r=2.40, p<.05; PE r=3.84, p<.001). Parents recommended/strongly recommended the program (96.6%); there were no satisfaction differences by intervention type or modality.
Intention-to-treat analyses using a two-level linear growth curve model with latent outcomes tested whether parenting stress decreased over time and whether rate of change differed by intervention type or modality. Parenting stress decreased significantly for both groups ($\gamma_{11}=$ -2.448, $p<.001$), but MBSR resulted in greater stress reduction than did PE ($\gamma_{11}=-2.243$, $p<.05$). Subsequent models testing the interaction between intervention modality and change in parenting stress over time, as well as a three-way interaction between intervention type, modality, and change in parenting stress over time were non-significant indicating that change in parenting stress did not depend on modality, nor did it depend on the interaction between intervention type and modality.

Conclusions: Our RCT revealed the feasibility, acceptability, and efficacy of MBSR for addressing a critical clinical need in underrepresented families of young children with ASD. Evidence of improved attendance and similar efficacy of virtual delivery underscores the potential viability and utility of this modality for outreach to underserved families.

406.389 (Poster) Advancing Access to Best Practice Care in Latin America: Implementation of the Extension for Community Healthcare Outcomes (ECHO) Autism Model to Equip Clinicians with Evidence-Based Knowledge and Training

V. Nanclares-Nogues, N. E. Granana, R. E. Mitre, L. Siervo Briones, M. Maharin and K. Sohl, (1)Child Health, ECHO Autism Communities, University of Missouri, Columbia, MO, (2)Servicio de Neurologia Infantil, Hospital Durand, CABA, Argentina, (3)Fundación Neurodiversidad, Rosario, Argentina, (4)Fundación Apoyo Autismo Chile EPAA, Viña del Mar, Chile, (5)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (6)ECHO Autism Communities, Child Health, Columbia, MO

Background: As part of a multi-country effort, Paula and colleagues (2020) identified issues faced by families affected by ASD throughout Latin American countries, where long wait lists were identified as one of the most prevalent concerns. The current project was developed to test an innovative model for training community clinicians in best-practice care for ASD using the Extension for Community Healthcare Outcomes (ECHO) framework. Three different sites in Argentina and Chile launched their ECHO Autism programs between 2020 and 2021, focusing on screening and identification of ASD and developmental differences and management of co-occurring conditions.

Objectives: To determine feasibility of the ECHO Autism model within Latin American populations. This paper shares the experience of three ECHO Autism replication programs and their impact on community clinicians throughout the region.

Methods: Each ECHO Autism program ran in cohorts of 8 sessions per year. Sessions occurred once per month for 90 minutes, where community clinicians presented de-identified cases to an ECHO Autism expert hub team for feedback and guidance, followed by a brief didactic presentation to address specific knowledge gaps. Participants joined each ECHO Autism program from all over the hub-team country, as well as neighboring countries. Pre- and post-surveys were sent to the participants. ECHO Autism: PROTECTEA started in March 2020, with two cohorts now completed and analyzed. ECHO Autism: Neurodiversidad and ECHO Apoyo Autismo Chile started in 2021 and the data represent the results of their first cohort.

Results: ECHO Autism: PROTECTEA (Buenos Aires, Argentina) averaged 115 clinicians per session, from 58 centers across the country in addition to centers in Chile, Ecuador, and Peru. Results showed statistically significant increases in the use of standardized screening or formal testing after participation in the program (from 50% of clinicians using no assessment tools or simple clinical observation, to almost 90% of participants reporting use of standardized testing and screening measures post-ECHO Autism program). ECHO Autism: Neurodiversidad (Santa Fe, Argentina) averaged 30 clinicians per session. Results showed that participants showed great improvements in measured knowledge of autism, with an average score of 12.21 ± 2.09 in the presurvey and an average score of 16.28 ± 1.89 in the post-survey score ($t(29)=2.04; p=0.00$), as well as increases in self-efficacy, rating themselves as feeling $3=\text{a little confident} (32\%)$ and $4=\text{confident} (39\%)$ at first; while, in the post-test, the most significant response was $5=\text{very confident} (51\%)$. ECHO Apoyo Autismo Chile (Chile) averaged 30 participants per session. Participants rated their satisfaction and applicability of the information received as very high, with most respondents falling in the $4=\text{applicable} (35\%)$ or $5=\text{very applicable} (54\%)$ range.

Conclusions: The ECHO Autism model has demonstrated to be an effective model to approach autism care and address one of the main barriers identified by families, namely prompt access to assessment and best-practice care in under resourced areas of Latin America. The results of these programs suggest that it can be an effective model for advancing access to evidence-based knowledge, and thus increase access to best-practice care in low resource communities.

406.390 (Poster) Addressing Gaps in Care through the Extension for Community Healthcare Outcomes (ECHO) Autism: Psychology Program in Missouri and Beyond

V. Nanclares-Nogues, A. Brewer Curran, M. Odum, N. E. Granana, M. Maharin, K. Boles and K. Sohl, (1)Child Health, ECHO Autism Communities, University of Missouri, Columbia, MO, (2)Department of Child Health, Thompson Center for Autism, Columbia, MO, (3)ECHO Autism Communities, University of Missouri, School of Medicine, Columbia, MO, (4)Servicio de Neurologia Infantil, Hospital Durand, CABA, Argentina, (5)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (6)Child Health, University of Missouri, Columbia, MO, (7)ECHO Autism Communities, Child Health, Columbia, MO

Background: In recent decades we have seen a global rise in the prevalence of autism spectrum disorders (ASD), with an insufficient number of professionals trained to meet this demand. The combination of complex assessments, along with a rise in the prevalence of ASD,
has led to significantly long wait times for diagnostic evaluations. In addition, people with autism and their families are often left without the follow-up care needed to address their ongoing needs. The ECHO Autism: Psychology Program was developed in Missouri in 2018 to address these gaps, training and supporting community-based psychologists to provide best-practice autism diagnostic evaluations and follow-up care. This model was replicated in Argentina, training and supporting clinicians and psychologists in advanced diagnostic practices using best-practice guidelines.

Objectives: Increase capacity of clinicians in underserved areas who can provide high-quality, best-practice autism evaluations for patients of all ages by bolstering clinician self-efficacy to utilize gold-standard tools.

Methods: Community clinicians (i.e., psychologists, physicians) who participate in the program complete a three-day Autism Diagnostic Observation Schedule–Second Edition (ADOS-2) clinical training before they participate in 90-minute ECHO Autism virtual sessions held twice monthly. Sessions include a de-identified case-presentation by one program participant, which leads to a rich case discussion and a brief didactic that reinforces specific knowledge (e.g., diagnostic interviewing skills, differential diagnosis, management of co-occurring conditions, etc.). After demonstrating an increase in knowledge and self-efficacy across 31 participants in the US, the model was replicated in Argentina with adaptations due to funding limitations, including hosting sessions monthly and being unable to provide ADOS-2 clinical training. Sessions continued to follow the ECHO Autism: Psychology model as described above.

Pre- and post-surveys were completed by participants in the US and Argentina to rate their confidence in understanding, detecting, and diagnosing ASD. Measures such as location, years in practice, number of people with autism seen in their practice, knowledge, and self-efficacy in diagnosing and providing follow-up care were gathered to determine program effectiveness.

Results: The flagship program in Missouri recruited psychologists across the state, with a focus on underserved areas. Program participants joined from 18 different counties, with 65% of the psychologists in Missouri within 30 miles of an ECHO Autism trained primary care clinician (Figure 1). Results showed 25% growth rate across all domains of self-efficacy measured, with the most significant growth in ADOS-2 administration, coding, and interpretation (136% growth rate). The ECHO Autism: PROTECTEA program in Argentina averaged 115 clinicians per session, from 58 centers across the country (Figure 2). Analysis of pre-post surveys showed significant increases in the use of standardized screening or formal testing, from 50% of clinicians using simple clinical observation, to almost 90% reporting use of standardized testing and screening measures at post.

Conclusions: ECHO Autism: Psychology is an effective program that has demonstrated successful replication, increasing best-practice autism care in low resource areas in the US and beyond. In both the US and Argentina, clinicians find the sessions highly valuable, with increases in self-efficacy, knowledge, and development of referral networks to support their practices.

Background: Health care transition (HCT) services help adolescents prepare for a smooth transition to adult care, ensure insurance retention, and promote adolescents’ independent management of their health care and life needs. Lack of HCT services can result in negative outcomes such as unmet needs, over-medicated, and loss of decision-making authority. Less than 15% of autistic young adults receive HCT services. This is a significant disparity compared to young adults with other special health care needs. Further, HCT readiness assessments are a part of HCT services but there are no self-reported HCT readiness measures that address the unique needs of the autistic young adult population.

Objectives: This study used a mixed-methods approach to develop a holistic self-reported measure of HCT readiness for autistic young adults called the Health-Related Independence Self-Report (HRI-SR).

Methods: A previously developed caregiver-reported Health-Related Independence (HRI-CR) measure was revised based on a two-step data collection process with autistic young adults. First, autistic young adults took part in individual interviews to assess the constructs and sub-topics included in the HRI-CR. Cognitive interviews were then conducted to assess the survey structure, question-wording, and online usability. Both individual and cognitive interviews were conducted until data saturation was identified. A validation study comparing the HRI-SR to the gold standard (STARx) and other validated measures is underway (completion date March 2023).
Results: The analysis of the individual interviews (n=5) identified high needs for HCT services and a desire for an HCT readiness measure that young adults could complete independently or with minimal support. All six constructs within the HRI-CR measure were highly rated by all participants. The highest-ranked constructs were 1) Knowledge of Physical and Mental Health Conditions, 2) Medication and Illness Management, and 3) Safety. Major themes within the qualitative data included: reliance on caregiver assistance, desire for independence with some support, lack of provider engagement, and need for skills to fully participate in a health care clinic visit.

Similarly, autistic young adults participating in the cognitive interviews (n=10) endorsed all six of the constructs currently included in the HRI-SR measure. Participants provided extensive feedback on how questions and answer choices should be worded. Participants also discussed how they thought about each question and how they picked an answer. This information was used to make terms and descriptions more concrete and improve the clarity and readability of questions. Member checking was used to ensure the accuracy of results and measurement changes.

Conclusions: The development of the HRI-SR measure was a comprehensive and iterative process utilizing the lived experiences of stakeholders. Autistic young adults were very supportive of the development of this and additional self-reported measures. Autistic young adults identified themes that can help enhance healthcare provider engagement, promote independence, and improve the frequency and quality of HCT services provided.

426.347 (Poster) Indigenous Autism in Canada: A Scoping Review

G. Bruno, T. Chan; L. Zwaigenbaum and D. B. Nicholas, (1) Pediatrics, University of Alberta, Edmonton, AB, Canada, (2) University of Toronto, Toronto, ON, Canada, (3) Autism Research Centre, University of Alberta, Edmonton, AB, Canada, (4) University of Calgary, Edmonton, AB, Canada

Background: Autism spectrum disorder (ASD) is characterized by difficulties with communication, differences in social communication, as well as restricted repetitive behaviors and interests. It is widely recognized that ASD occurs in all populations, including Indigenous populations. The prevalence of ASD in Indigenous communities is currently unknown and there is minimal academic literature on lived experience related to ASD in cultural contexts.

Objectives: Our goal was to scan all the academic and grey literature as it pertains to ASD and Indigenous peoples in Canada. Our aim was to capture what is conveyed in the literature as it pertains to the following research questions: Overall, what is known about ASD in Indigenous communities in Canada?; what are the experiences of ASD in Indigenous communities across Canada?; what research has been conducted on the prevalence of ASD in Indigenous communities in Canada?; What supports for ASD are offered in Indigenous communities in Canada?

Methods: We conducted a scoping review to capture the breadth and nature of the literature on ASD and Indigenous communities in Canada. Scoping reviews are used to identify the types of available evidence in each field; to examine how research is conducted on a certain topic or field; to identify and analyze knowledge gaps. In this review, we collaboratively defined concepts and outcomes in an iterative fashion to ensure comprehensive inclusion and relevance of the literature reviewed. We further applied Harfield’s Indigenous Quality Appraisal Tool (QAT) to all original research articles to assess quality of health information from an Indigenous perspective. Finally, we brought the review to the Autism Society of Alberta (Canada) Indigenous Relations Circle and asked them to provide feedback which included perspectives of Indigenous autistics, Indigenous caregivers, and non-Indigenous service providers.

Results: The initial database search yielded 207 articles, and after removing 128 duplicates, 84 articles remained. Two authors independently screened out 50 articles. From the 34 remaining sources, the authors excluded 10 through full-text review as they did not meet the inclusion criteria. Thus, a total of 24 articles met inclusion criteria for this scoping review. The main finding was the lack of literature as it pertains to ASD in Indigenous communities and how the lack of evidence is a main concern of those who work in this field. Other identified themes included the need for more Indigenous-led primary research, routine misdiagnosis of Fetal Alcohol Spectrum Disorder (FASD), lack of funding and resources, and the problematic use of the deficit oriented medical model. Most articles also scored better on the QAT and the ones that scored better were written within the past 5 years and had substantial Indigenous input.

Conclusions: This scoping review indicates the critical need for research that is focussed on autism and Indigenous peoples in Canada. The literature that does exist does not adequately provide a picture of that realities of autism in Indigenous communities. Finally, the review showed that the lack of Indigenous led research on autism is an urgent priority for Indigenous communities and families in Canada.

426.348 (Poster) Intervention Plan Quality Matters: Providing Feedback on Planned Adaptations for Personalized Evidence-Based Practices in Compass

L. N. Ogle, L. A. Ruble, A. M. Love and B. Garman-McClaine, (1) Department of Special Education, Ball State University, Muncie, IN, (2) Special Education, Ball State University, Louisville, KY, (3) Aspect Research Centre for Autism Practice, Autism Spectrum Australia (Aspect), Melbourne, VIC, Australia, (4) Indiana University, Bloomington, IN
Background:

Developing high quality educational programming individualized to the social emotional learning (SEL) needs of students with autism remains a challenge for teachers despite the widespread dissemination of evidence-based practices (EBPs) (Odom et al., 2022). COMPASS supports teachers and caregivers in identifying SEL goals and developing intervention plans using EBPs individualized to the student’s personal/environmental strengths and challenges with teacher and caregiver input (Ruble et al., 2022). This study comes from a larger study of developing and testing a training package for COMPASS (Ogle et al., 2022; Ruble et al., 2022) and focuses on an area where trainees faced the most difficulty - developing high quality intervention plans.

Objectives:

To improve the fidelity of intervention plans developed in COMPASS, the Intervention Plan Quality Scale (IPQS) was developed and validated with other fidelity measures to provide consistent, targeted feedback to consultant trainees (CTs).

Methods:

Participants included nine school based CTs who each implemented COMPASS to up to four different students with autism (n = 28) in collaboration with the student’s special education teacher (n = 28) and caregiver (n = 28) for a total of 93 participants. All students were diagnosed with autism and receiving special education services under the category of autism. All CTs were White women (M = 37 years old, SD = 7.96) who had an average of 10 years (SD = 6.31) consultation experience. The Intervention Plan Quality Scale (IPQS), a 16-item yes-no checklist completed by the researchers and CTs, was developed and tested to assess the evidence-based principles of a high-quality intervention plan (e.g., SMART goals, teaching sequence utilizing EBPs, plans for generalization). Criterion validity of the IPQS was established with other measures of COMPASS fidelity including a measure of the CT’s adherence (25-items, yes-no, KR-20 = 0.72) and quality of delivery (27-item, yes-no, KR-20 = 0.86) in implementing the consultation, as well as the teacher’s adherence to the intervention plan (0-4 scale, 4 = 76-100% elements observed).

Results:

The IPQS had acceptable reliability (KR-20 = .72) and interrater reliability (percent agreement = 94%). The percentage of elements identified from the IPQS averaged 52% for their first consultation and reached 75% by the fourth. Unlike the other skill domains that required one session to achieve adequate fidelity, four sessions were required for intervention plan development. Further, there was a significant difference in researcher (M = 62.51, SD = 18.35) vs. consultant self-report (M = 77.88, SD = 13.043) ratings of the IPQS; t (23) = 4.99, p = .001. This difference was highest the first feedback sessions (28%) but decreased to a 2% difference by the fourth session. Scores from the IPQS were positively correlated with the consultant’s adherence to the COMPASS consultation protocol, quality of delivery, and teacher adherence to the intervention plans at the final coaching session (see Table 1).

Conclusions:

The IPQS shows promise as measure of high-quality intervention plans in COMPASS as it demonstrates acceptable reliability and validity. Further, the IPQS may be helpful for dissemination efforts more broadly.

426.349 (Poster) Investigating South African Practitioners’ Educational Practices and Knowledge of Early Childhood Development in Children Aged 3 Months to 2 Years

A. A. De Souza1, A. Pedro2, G. Filgueiras3 and C. de Beer2, (1)308 Marillac Hall, University of Missouri Saint Louis, St Louis, MO, (2)University of Western Cape, Cape Town, South Africa, (3)Universidade Estadual de Londrina, Londrina, Brazil

Background: Olusanya et al., (2016) estimated that 95% of children worldwide who present with some type of disability, including autism, live in low- and middle-income countries. Whitehouse et al. (2021) showed that preventative interventions strategies implemented by caregivers with children younger than 1 year old of age reduced the rate of expected autism diagnosis. In low- and middle-income countries, it is common for infants to spend most of their waking time in daycare centers (Gromanda et al., 2020). Thus, it is important for daycare educators to identify children at risk of developmental disabilities and to promote a context that fosters infants’ milestone development.

Objectives: The objective of this project was to conduct a training needs assessment for educators caring for children between the ages of 3 months to 2 years from low- to middle-income areas in the Cape Town, South Africa. Specifically, we aimed to identify educators’ knowledge and level of confidence in describing young children developmental milestones and age-appropriate activities in daycare centers.
Methods: We utilized a mixed methods approach to identify educators’ knowledge of early childhood developmental milestones and educational activities. First, we conducted an online survey (adapted from Banerjee & Luckner, 2013) containing questions related to educators’ demographic information, knowledge of young children’s developmental milestones and age-appropriate activities. Next, we conducted a face-to-face interview to draw on participants’ in-depth experiences and their subjective accounts on the topic. A total of 253 early-childhood educators from various childcare facilities from low- to middle-income areas in Cape Town completed the online survey. From this sample, 45 participants completed the interview. Sample sizes were determined by the broader integrative perspective which balances the qualitative consideration of favoring a small sample (N= 45-50; Dworkin, 2012) for conducting in-depth qualitative analysis, against that of quantitative considerations of generalizing from a larger sample (N= 251; Creswell, 2017). We analyzed survey data using descriptive statistics such as measures of central tendency (e.g. mean, median), and interview data using Braun and Clark’s (2006, 2013) six steps of thematic analysis.

Results: Data collected from both the survey and interview showed the majority of participants working directly with young children have little to no confidence in listing the developmental milestones and describing classroom strategies to promote these milestones. The qualitative analysis revealed four related themes: (a) Educators’ knowledge of developmental milestones; (b) educators’ perceived skills of an effective educator; (c) strategies employed to foster children’s development; and (d) perceived characteristics of a healthy educational environment for child development.

Conclusions: The lack of knowledge of developmental milestones and age-appropriate educational activities might negatively impact the rate by which young children at risk of autism are referred for evaluation and specialized services. Of great importance is the development of training programs which prepare educators to identify developmental delays and promote an educational environment that is rich and stimulating. Based on these results, we plan to develop a training program to prepare early childhood educators to recognize expected children’s developmental milestones and to implement age-appropriate activities in the classroom.

K. Sengupta* and S. K. Mahadik, (1)Ummeed Child Development Center, Mumbai, Maharashtra, India, (2)Ummeed Child Development Center, Mumbai, India

Background: The COVID-19 pandemic and the resultant lockdown forced autism services, including parent-mediated interventions (PMIs) to pivot to an online mode globally. In India, during the first year of lockdown, we piloted an online version of UPPA- a culturally adapted version of Project ImPACT (Ingersoll & Dvortcsak, 2010) which is an evidence-based, parent-mediated naturalistic-developmental behavioral intervention model. Initial data revealed satisfactory levels of feasibility and acceptability as the synchronous-online model increased accessibility for those in remote locations and with caregiving responsibilities at home. However, lack of face-to-face contact and technological issues impeding facilitatory coaching by the therapists led to parental recommendations for a blended model. As the lockdown eased, we implemented a hybrid group model of Project ImPACT. Providers who conduct the PMI have had to customize to novel delivery modes with their inherent strengths and challenges.

Objectives: To report on providers’ perspectives of the acceptability and feasibility of a hybrid mode of delivery of Project ImPACT in community settings. Methods: A hybrid model was utilized to deliver Project ImPACT, which included twelve group sessions (1.5 hours) delivered online on Zoom and six individualized parental coaching sessions (1 hour each), which parents could opt for either remotely or in person at our clinic in ... over a duration of 6 weeks. Six providers with clinical experience ranging from 3-7 years and prior experience in delivering the PMI conducted the group and individualized coaching sessions with the families. Qualitative data was collected from the providers (n=6) and supervisors (n=2) through in-depth interviews conducted by a trained interviewer, using an interview guide with open-ended questions about the process of delivery of the PMI. Audio recordings were transcribed, all data was coded using principles of thematic analysis, and themes were identified inductively.

Results: Between January 2021 to October 2022, a total of caregivers of 96 children (age 2-6 years) participated across six cohorts of the PMI, including both online (n=41) and in-person center-based coaching sessions (n=39), with a drop-out rate of 15.7%. The themes identified included Increased satisfaction due to Greater Access to care for Families (in under-resourced areas, ease and flexibility of access with lesser need for childcare, more family members could attend) and Greater Connection with children and families (during in-person coaching sessions). Themes also highlighted challenges around Frustration with Increased Drop-out and Feelings of Disengagement with Parents (engagement in online group sessions perceived as low as compared to in-person or completely online models). Additionally, data from supervisors revealed Logistical Challenges and Resource Allocation as difficulties, with the need to manage both online and in-person services simultaneously and synchronously.

Conclusions: Though promising, the hybrid delivery mode has its challenges. While some barriers were specific to the post-pandemic reopening phase, others are more systemic and will need to be addressed to make this model feasible and sustainable for both care recipients and care providers. Future directions of study include caregiver perspectives of hybrid care models and examining clinical outcomes for children to explore effectiveness.

426.351 (Poster) It’s Time to Improve and Systematize How We Document Autism Care in Our Medical Records. 
Z. M. Wong1, A. Bennett2, L. Dowd1, J. Dudley1, M. Gerdes2, W. Guthrie3, M. Schoenberg4, K. E. Wallis4 and J. S. Miller4, (1)Center for Autism Research, Children’s Hospital of Philadelphia, Philadelphia, PA, (2)Sidney Kimmel Medical College, Thomas Jefferson University,
Background: The electronic health record (EHR) system has vast potential in service use tracking, care coordination, and population-based research for children with autism. However, research on the reliability and validity of EHR documentation for autism diagnosis and care is scarce.

Objectives: To investigate the reliability of diagnostic and service documentation within one healthcare system and, for variables with high reliability, examine potential disparities in care.

Methods: Participants were drawn from a cohort who received at least one well-child primary care visit between 16 and 26 months of age across our pediatric health system between 2011 and 2019 (n=23,015). Children were considered to have autism if the diagnosis appeared more than once in their EHR (i.e. in a visit diagnosis or problem list) or was made by an autism specialist. Of the 731 children with autism, 217 were randomly selected for further review.

Manual chart reviews identified any reference to referrals, diagnoses, or interventions (both general and autism-specific) from encounter notes, direct evaluation reports, or scanned external documents. If dates were not explicitly reported, they were estimated with consensus from the study team. Each chart review took at least 30 minutes. The presence of documentation and dates were compared across sex, race, insurance type, and diagnostic provider using chi-square tests. Inter-rater reliability (IR) analyses were performed on 31 records with IRs for dates calculated within a 3-month window. Data that was both present and reliable (>80%) was further analyzed and compared across similar subgroups.

Results: Documentation was both highly present and highly reliable (>90%) for general intervention referrals and autism diagnoses including diagnostic provider and diagnostic measures used (Table 1). Documentation that general intervention was received also frequently present (95.4%). Type of general intervention received and date of autism diagnosis had relatively high IR (83.9% for both).

Experiencing variables that were both highly present and highly reliable, we found that most children received some type of general intervention prior to their autism diagnosis (Table 2). Those who received county-provided Early Intervention prior to their autism diagnosis also received an earlier diagnosis (p=0.029). However, Black and Medicaid covered children were less likely to have received general interventions before a diagnosis (p=0.039 for both) or to receive their diagnosis from a developmental behavioral pediatrician (p=0.014 and 0.010, respectively). Additional differences in care by provider type and patient demographics will be discussed.

Conclusions: Autism diagnoses and general intervention services could be located with time-intensive manual chart review. Unfortunately, documentation on type and timing of autism-specific services was very limited. Systematizing basic autism documentation presents an extraordinary opportunity to improve individual care coordination, implement quality improvement initiatives, and conduct population-level research on early diagnosis, intervention, and disparities.

426.352 (Poster) Learning Social Skills Online and on the Spectrum: Evidence from the Telehealth Adaptation of PEERS® for Young Adults

Background: Autistic young adults exhibit differences in social communication (APA, 2013), which can contribute to social isolation, loneliness, and mental health symptomatology (Orsmond et al., 2013; Schiltz et al., 2021). Effective social skills interventions are essential to mitigating these negative sequelae and empowering autistic people to achieve their social goals. As one of the only evidence-based social skills treatments for this population, PEERS® for Young Adults (Laugeson et al., 2012; McVey et al., 2016) meets a critical need and has been adapted for telehealth in response to the COVID-19 pandemic. Though evidence suggests that outcomes following other PEERS® programs are similar across in-person and telehealth modalities (Estabillo et al., 2022), the effectiveness of telehealth implementation of PEERS® for Young Adults has not yet been empirically established. To do so is essential given indications that telehealth activities are here to stay (Bestsennyy et al., 2021; Dorn, 2021).

Objectives: This paper aims to examine effectiveness of PEERS® for Young Adults implemented via telehealth and to compare treatment response to the original in-person modality.
Methods: Participants included 58 autistic young adults \( (M_{age}=21.97, SD=4.32) \) who completed PEERS® for Young Adults via telehealth between 2020 and 2022 and a comparison pre-pandemic group of 89 autistic young adults \( (M_{age}=23.09, SD=4.74) \). PEERS® for Young Adults is a 16-week caregiver-assisted curriculum that teaches skills related to friendships, handling conflict, and dating etiquette. Young adults and their caregivers completed measures of social functioning pre- and post-intervention, including the: Social Responsiveness Scale, 2nd Edition (SRS-2; Constantino & Gruber, 2012), Social Skills Improvement System (SSIS; Gresham & Elliott, 2008), Empathy Quotient (EQ; Baron-Cohen & Wheelwright, 2004), Social Anxiety Scale (SAS; La Greca, 1998), Social Emotional Loneliness Scale for Adults (SELSA; DiTommaso & Spinner, 1993), and the Test of Young Adult Social Skills (TYASSK; Laugeson, 2015).

Results: Following PEERS® for Young Adults via telehealth, young adults significantly improved on all outcomes, \( ps<.05 \). When comparing baseline differences between telehealth and in-person groups, young adults in the telehealth group were rated as having significantly higher social skills on the SSIS at baseline, \( p=.003 \). Including baseline SSIS Social Skills as a covariate, two MANOVAs were conducted comparing in-person to telehealth outcomes for caregiver- and self-reported outcomes, respectively. No significant differences emerged on caregiver-reported outcomes, \( F(5,85)=0.41, p=.84 \). The MANOVA for self-reported outcomes was significant, \( F(4,81)=2.79, p=.032 \). Post-hoc analyses indicated that this effect was driven solely by differences on the TYASSK, \( p=.014 \), such that the in-person group showed greater increases in knowledge of the social skills taught in PEERS® \( (M_{change}=8.57) \) than the telehealth group \( (M_{change}=6.02) \).

Conclusions: Results indicate that telehealth PEERS® for Young Adults is an effective intervention for autistic adults. Slight benefits of in-person implementation on knowledge of the social skills taught in PEERS® may be due to unique distractions present on telehealth (e.g., adequate internet access, family members in home, administration location) interfering with encoding and recall. Overall, these findings lay a strong foundation for continued telehealth implementation, expanding accessibility of evidence-based social skills treatment and reducing barriers impacting service access and utilization.

426.353 (Poster) Making Feedback Feasible: Improving the Efficiency of Performance Feedback of Compass Trainers

M. B. Hoffman, L. N. Ogle, R. D. Stayton, and L. A. Ruble, (1)Ball State University, Muncie, IN, (2)Department of Special Education, Ball State University, Muncie, IN, (3)Special Education, Ball State University, Louisville, KY

Background:

Depending availability of accessible evidence-based practices (EBPs) in autism, a research-to-practice gap persists (Knight et al., 2019). Implementing EBPs in community settings has been hindered by the absence of frameworks for effective intervention implementation that maintains fidelity. The Replicating Effective Programs (REP) framework addresses this research-to-practice gap by outlining mechanisms (i.e., training and package refinement as a component to maintenance and evolution) for feasibility packaging interventions for community-based settings without compromising effectiveness (Kilbourne et al., 2007).

The COMPASS is an evidence-based consultation and teacher coaching intervention that has been successfully implemented by community-based consultants (Ruble et al., 2022). For COMPASS to be disseminated beyond the developers, critical elements (e.g., fidelity assessment/feedback) must be able to be transferred feasibly to schools with limited resources.

Objectives:

Using the REP framework, we will describe a process for increasing the feasibility of fidelity feedback to consultant trainees (CTs) in community settings.

Methods:

To ensure implementation fidelity for COMPASS, trainers prepared feedback sessions by reviewing a three-hour audio recording of the initial consultation. Recognizing the need for feasible feedback and training for future dissemination, we applied an iterative data-driven, two-phase refinement process to reduce the amount of time required while maintaining COMPASS fidelity.

Original Measures. Consultant adherence to the COMPASS protocol was evaluated using a 25-item, yes-no checklist. Assessment of intervention plan adherence included a 16-item, yes-no checklist following the consultation that evaluated CT adherence to the evidenced-based principles for intervention plan development. To appraise the quality of delivery, initial consultation process skills were assessed using a 35-item yes-no checklist gauging communicative skills across the consultation.

Phase I: Initial Assessment Using Time-Sampling Procedure. Timestamps for content review of audiotapes were selected for the COMPASS introduction/closing, and development of the social goal and intervention plan. The written intervention plan and a 30-minute sample of a COMPASS consultation audio recording were rated for fidelity using the original measures. Interrater reliability between RAs and the primary coder was calculated. Rating differences necessitated further item clarifications and elimination of redundancies in items across the measures.
Phase II. Refinement and Testing of Fidelity Measures. After refining the feedback process, the primary rater and RAs evaluated the 30-min audio sample and intervention plan using the abridged fidelity measures from Phase I. Measures refinement continued until attaining 80% interrater reliability.

Results:

The refinement process reduced the measures by 56.0% for consultation adherence and 65.7% for process skills. The amount of audio that the trainer had to evaluate was reduced by 80%, from 3 hours to 30 min. Final interrater agreements for measures of adherence, intervention plan quality, and process skills were 97.0%, 90.2%, and 94.0%, respectively. Most importantly, agreement between the original and abridged measures of adherence, intervention plan quality, and process skills were 89.7%, 81.8%, and 83.3%, respectively

Conclusions:

Findings suggest the time-sampling procedure and abridged fidelity protocol can reliably capture COMPASS fidelity that maintains fidelity captured by original and time-consuming assessment. Feasible and effective feedback is essential for the future maintenance and evolution of COMPASS in schools.

426.354 (Poster) Maximizing Clinical Data Utility: Parent and Clinician Preferences for Caregiver-Reported Data Collection and Access

D. Coury1, D. S. Murray2, L. Cole3, J. S. Anixt4, E. M. Butter5, A. Karpur6, V. Vasudevan7, A. Fedele8, L. Latten9 and W. Cornell10,

(1)Developmental-Behavioral Pediatrics, Nationwide Children’s Hospital, Columbus, OH, (2)Science, Autism Speaks, Boston, MA,

Background:

Academic health professionals participating in learning health networks collect data for research to inform clinical decision-making and for Quality Improvement (QI). While clinical data is collected as part of routine care, caregiver or patient-reported outcome (PRO) data are critically important for understanding the priorities and needs of the patient and family. PRO data are typically not part of the clinical care process and alternate collection methods are often needed. The Autism Care Network (ACNet), an autism learning health network, supports a large patient registry which includes PRO data provided by caregivers. An understanding of the priorities of patient registry consumers (clinicians, researchers, and patients / families) is needed to create a data system that ideally meets their needs and can support QI to improve patient outcomes.

Objectives:

To optimize collection and use of PRO data in order to improve a) clinician decision-making, b) symptom monitoring, and c) population level care practices and research.

Methods:

Surveys were completed by 93 caregivers and 167 clinician/researchers participating in ACNet to better understand current use of PRO data and priorities. Survey content was developed by a workgroup of network leadership, family partners and two data analysts with expertise in survey design. Clinician survey questions addressed the scope of data collected, demographics, experience with current registry data, and factors to increase future use of registry data. Caregiver surveys were similar with revised demographic questions and emphasis on use of their family member’s health information. Surveys were disseminated by email to all network clinicians and members of site family partner committees. One-on-one interviews of select clinicians and parents were conducted for more detailed feedback.

Results:

60% of caregivers reported having received behavioral data from their health provider in the past. 90% of caregivers felt that behavior data would help them understand their child’s behavior, 88% felt data would help with medication decisions, and 97% felt data would be helpful in assessing efficacy of behavioral interventions.

Among data access options, 72% of caregivers preferred an online portal while 59% prefer their autism care provider’s electronic medical record. Caregivers indicated willingness to complete surveys longitudinally regarding their children’s behavior, as long as the behavioral assessments correlated with their child’s specific areas of difficulty. Priorities for clinicians included easy access to the data (83.7%), a meaningful connection to clinical outcomes (80.7%), measures that can demonstrate change in symptoms over time (75.6%), and measures
that are easy for families to complete (80.0%). Both groups recommend addition of measures assessing parenting stress and social determinants of health.

Conclusions:

Consideration of end-user priorities can improve patient registry data collection, analysis and utilization. Families are more willing to participate if they can receive direct benefit by accessing their own data or clinicians use data to optimize clinical care. PRO data collection could be accelerated by providing clinicians access to data displayed in meaningful ways that aid in care decision making.

426.355  (Poster)  Mechanisms for National Change Towards Neurodiversity Affirming Practice in Health and Education Services in Scotland

M. Rutherford1, D. Maciver1, L. Johnston1, M. Boilson2, M. Murray4 and E. Curnow2, (1)National Autism Implementation Team, School of Health Sciences, Queen Margaret University Drive, Musselburgh, Edinburgh, United Kingdom, (2)National Autism Implementation Team, School of Health Sciences, Queen Margaret University, Edinburgh, United Kingdom, (3)NHS Fife, Fife, United Kingdom, (4)School of Health Sciences, Queen Margaret University, Edinburgh, United Kingdom

Background:

Implementing the changes we wish to see to improve the lives of autistic people and other neurominorities on a national level is extremely challenging. Neurodivergent people, including autistic people, often wait too long for assessment and receive inadequate support in educational and health settings. The National Autism Implementation Team (NAIT) was funded by the Scottish Government to establish a national quality improvement approach and performed against the backdrop of significant focus on autism and related needs, and strong messages from stakeholders on improvement requirements. The NAIT programme was designed to improve Scottish healthcare pathways and educational experiences, aiming to improve quality of life, participation and access to employment and education with a renewed focus on outcomes valued by autistic people. Clinicians, education professionals and researchers developed and led the programme, with active involvement of stakeholders, including Government representatives and people with lived experience. The work of NAIT has included a multi-year, multi-phase national programme of training, practice development, education, dissemination, and facilitation of change.

Objectives:

This conference presentation will report how the NAIT programme was planned, delivered, and received over four years, and provides an analysis of the ‘active ingredients’ of this complex intervention.

Methods:

Complex interventions research requires a pluralistic evidence base so multiple methods are required. An analysis was completed drawing on the Medical Research Council (MRC) Framework for developing and evaluating complex interventions and realist evaluation analytic methods. Data and analytic procedures included a review of programme documents, consultation with programme leaders, and consultation with professional stakeholders with a high degree of involvement in NAIT activities and change. The analysis led to the identification of a NAIT ‘programme theory’ expressed through a realist matrix of ‘contexts’ (C), ‘mechanisms’ (M), and ‘outcomes’ (O). Autistic people have been included in the development of the research and in the NAIT team.

Results:

NAIT principles towards facilitating neurodiversity affirming practice, activities, resources and key interventions were identified. Sixteen ‘context’ factors (factors which favour or disfavour the activation of mechanisms) were identified. Three clusters of ‘mechanisms’ (processes underpinning changes in outcomes or ‘active ingredients’ of the NAIT programme) were identified at Macro level (two mechanisms), Practitioner level (seven mechanisms) and Institutional level (four mechanisms). Seventeen outcome areas were identified. The role of NAIT is to provide support to enable practitioners across sectors to develop improved practices. This research was focused on national practice changes associated with NAIT, and to understand the impacts of NAIT in this ‘audience’ which is professional staff.

Conclusions:

The research has resulted in a clearer and more replicable programme theory that can be used by others with similar aims. This work illustrates the value of NAIT and realist methodologies as a tool for other policymakers, practitioners, and researchers.

426.356  (Poster)  Medical Staff Training for Hospitalized Patients with Autism Spectrum Disorder and Behavioral Health Needs

E. Klinepeter1,2, K. Gibbs3, J. Choate2, T. Nelson Hall2, D. Wells2 and C. Massrey3, (1)Baylor College of Medicine / Texas Children’s Hospital, Houston, TX, (2)Texas Children’s Hospital, Houston, TX, (3)Baylor College of Medicine, Houston, TX
Background: Estimates suggest children with Autism Spectrum Disorder (ASD) are six times more likely to be hospitalized for behavioral health needs (e.g., aggression, self-injury, and tantrums) and incur 12.4 times greater hospitalization costs than for typically-developing children. Further, children with ASD are at increased risk of restraint usage while hospitalized, and staff report lack of knowledge and comfort in caring for autistic patients. To address these needs, research on medical staff education is warranted. To date, some preliminary research exists on medical staff educational programs regarding ASD characteristics, behavior management strategies, and strategies for partnering with families. However, further development of an in-depth, cost-effective education curriculum that targets a variety of types of hospital staff members is needed.

Objectives: The purpose of this study was to 1) describe a medical staff education curriculum on caring for patients with ASD and behavioral health needs, and 2) evaluate effectiveness of the curriculum on increasing staff’s knowledge and confidence in providing care.

Methods: A team that included a pediatric psychologist, nurse educators and leaders, and neurodevelopmental disability residents designed a six-part, module-based training series. Module topics included: 1) ASD characteristics and family engagement, 2) risk factors for challenging behavior, 3) functions of behavior, 4) preventative measures, 5) calming techniques, and 6) a two-part, interactive case study. Pre- and post-survey questions and knowledge-based questions were embedded across modules and designed to assess changes in the knowledge and confidence of participants. The curriculum was introduced in a step-wise manner across hospital units and departments based on clinical need. All staff who completed the training were offered the option to consent for data use as part of the study.

Results: A total of 138 staff members consented to data use. Staff members included nurses, advanced practice providers, personal care assistants, sitters, and other ancillary staff (e.g., occupational therapists, speech-language therapists, social workers, child life specialists). The Wilcoxon signed rank test was used to compare participants’ ratings before and after completing the curriculum. All item scores increased significantly as a result of the intervention. See Table 1 for detailed scores.

Conclusions: This study describes an educational curriculum that was designed and implemented to increase the knowledge and confidence of medical staff members in providing care to patients with ASD and behavioral health needs. In particular, preliminary data suggest that interactive, module-based education about ASD, why challenging behavior occurs, and strategies for managing behavior can be effective in increasing knowledge and confidence of a wide variety of staff members in a comprehensive and cost-effective manner. In turn, this offers the potential for additional, long-term practice improvements. Currently, work on follow-up educational strategies continues at our organization to ensure maintenance of educational gains and translation to practice.

426.357 (Poster) Moderating Effects of Family Income on the Relationship between Racial and Pragmatic Barriers to Treatment and Parental Stress  

Background: Historically, Black caregivers of autistic children face barriers when accessing treatment and diagnostic services (Pearson & Meadan, 2018). Prior research has illuminated the prominence of pragmatic (e.g., treatment cost, long waitlist) and racial barriers (e.g. racial microaggressions, autism stigma) Black caregivers experience as they navigate diagnostic and treatment services, with less research focusing on the impact of barriers experienced on caregiver stress (Broder-Fingert et al., 2020; Stahmer et al., 2019). Considering the pronounced intersection of poverty, equity, and its impact on youth mental health (Castro-Ramirez et al., 2021), it is important to understand how the relationship between barriers and parental stress is further impacted by family income among Black caregivers of autistic youth.

Objectives: The study was conducted to examine the relationship between practical barriers, racial barriers to treatment, and parental stress; and to investigate if caregiver income acts as a moderating variable in this relationship.

Methods: In this study, participants were a sample of Black caregivers of youth ages 0-21 years with ASD (N = 101). Bootstrap moderation analyses were used via PROCESS 4.0 in SPSS (Hayes, 2022) to examine if family income moderated the relationship between pragmatic barriers to treatment (measured by the Barriers to Treatment Participation Scale), racial barriers to treatment (measured by the Racial Barriers to Treatment Scale), and parental stress (measured by the Parental Stress Scale). Family income was fairly equally distributed among the participants.
Results: Individually, perceived pragmatic barriers to treatment predicted parental stress ($\beta = .2439$, $t(101) = 2.53$, $p = .001$). Similarly, perceived racial barriers to treatment predicted parental stress ($\beta = .2602$, $t(101) = 2.29$, $p = .025$). The results showed that family income did not significantly moderate the relationship between pragmatic barriers to treatment and parental stress. However, the results revealed that family income significantly moderated the relationship between racial barriers to treatment and parental stress ($\beta = -0.55$, $t(101) = -2.36$, $p = .021$). As racial barriers increased for families who earn $81,000-$100,000, parental stress remained unchanged; but as racial barriers increased in families who made less than $20,000, parental stress increased.

Conclusions: The results of the analysis suggest that caregivers who experience practical and racial barriers are more likely to experience parental stress. The relationship between racial barriers and parental stress may be less impactful for families with greater financial resources. This may be attributed to associations between income health literacy, and access to resources (Aylward et al., 2021). The results highlight the continued influence structural barriers have on maintaining disparities among Black families of autistic children. Further discussion and future directions will be presented on the poster.

426.358 (Poster) Neighborhood Deprivation Is Associated with Autism Symptom Severity and Internalizing Problems Among Youth with Autism

M. Johnson, E. E. Long and L. Carpenter, Medical University of South Carolina, Charleston, SC

Background: Children living in socioeconomically disadvantaged areas are less likely to be diagnosed with autism spectrum disorder (ASD) than those living in higher SES areas within the US. However, population-based studies in Sweden have found that lower SES is associated with an increased risk of ASD, suggesting that lower rates of diagnoses observed in the US may be attributable to barriers to accessing diagnostic evaluations. Additionally, research suggests that individuals with ASD are approximately four times more likely to experience depression compared to the general population and about 40% have had at least one comorbid anxiety disorder diagnosed. Evidence indicates that lower SES confers risk for internalizing problems, including anxiety and depression, among typically-developing children. However, the impact of socioeconomic disadvantage on symptoms of anxiety and depression among youth with ASD is less understood. Likewise, while there is some evidence to suggest that factors often associated with disadvantage including low parental education predict anxiety and depression in children with ASD, it appears other factors of impoverished communities such as employment, income, and housing quality have not yet been explored.

Objectives: The current study investigated whether living in a socioeconomic disadvantaged area is associated with ASD symptom severity and/or symptoms of anxiety and depression among youth with autism.

Methods: Participants included 7061 children with ASD aged 6 to 17 years (M=10.68, SD=3.28; 77% male) with available Area Deprivation Index (ADI) data from the Simons Powering Autism Research for Knowledge (SPARK) database. Autism symptom severity was assessed using the Social Communication Questionnaire (parent report). The Child Behavior Checklist (parent report) was used to assess symptoms of anxiety and depression. The ADI uses factors including income, education, employment, and housing quality to create nationwide percentile rankings of participants’ neighborhoods, where a neighborhood ranking of 1 indicates the lowest level of disadvantage and a ranking of 100 indicates the highest level.

Results: ADI was associated with autism symptom severity ($r=.12, p<.001$); children in areas of higher disadvantage also had greater levels of autism symptom severity. ADI also was associated with anxiety symptoms ($r=.08$) and depression symptoms ($r=.10$) among youth with autism ($p$’s<.001), such that children in more disadvantaged neighborhoods also experienced more symptoms of depression and anxiety.

Conclusions: The present study demonstrates that, like their typically-developing peers, youth with ASD living in neighborhoods characterized by greater levels of disadvantage are at elevated risk for experiencing anxiety and depression. As youth with ASD are already at heightened risk for internalizing outcomes, those with lower SES represent a uniquely vulnerable population. Further, neighborhood disadvantage was associated with increased autism severity, highlighting the importance of reducing barriers to accessing diagnostic services and intervention.

426.359 (Poster) Neurodiversity of the AIMS-2-Trials Research Network: Clinical and Self Diagnosis, Disclosure and Personal Links to Autism

Background:
Research teams need to reflect their surrounding society, and the proportion of autistic researchers in the autism research field has the potential of bridging science and communities. As a working example, we present the multi-national AIMS-2-TRIALS research network (aimed at biomarker discovery and interventions) - whose diversity has not yet been quantified.

Objectives:

For the first time, we seek quantitative insights in the representation of clinically/self-diagnosed autistic across researchers’ professional categories, personal links to autistic people, and whether diagnostic status impacts mental health.

Methods:

An online multiple-choice questionnaire set-up on Redcap was sent via internal newsletter, with 124 anonymised complete respondents across 14 countries. For selected variables (see Figure 1A; in bold, selected/aggregated variables/levels), we used (1) Fisher Exact tests to investigate associations between diagnostic status and seniority (advanced/mid vs early career, and advanced/mid vs early career vs support staff, whose odds ratio were calculated via logit binomial regression) (2) logit binomial regression to test the effect of having an autistic family member, autistic friends, other neurodevelopmental conditions and autistic acquaintances on diagnostic status (3) two-stage least square regression to test the effect of diagnostic status on mental health.

Results:

23% (29) responded that they are clinically/self-diagnosed (see Figure 1B) and 26% (32) that they have another neurodevelopmental condition. 35% (44) had an autistic family member, 68% (84) autistic friends and 90% (113) autistic acquaintances. 50% of the clinically diagnosed declared that they disclosed to their superior, while all self-diagnosed (24) did not declare whether they had.

Having a clinical/self-diagnosis was associated with being in early career, with higher odds compared to advanced/mid-career (OR = 4.48, 95% CI = 1.20-25.22, p-value = 0.01; Figure 2A). Further, clinical/self-diagnosis was associated with being support staff as compared to early, mid-advanced career (p-value = 0.0004; OR compared to mid-advanced career = 10.57, SE = 2.36, p-value = 0.06).

Among the personal links to neurodiversity, having autistic kin (OR = 19.15, SE = 2.18, p-value = 0.0001) and coexisting neurodevelopmental conditions (OR = 8.96, SE = 1.83, p-value = 0.0002) significantly predicted clinical/self-diagnosis.

Having a clinical/self-diagnosis increased the odds of mental health issues (OR = 5.82, SE = 1.63, p-value = 0.0003), but seniority made it less likely (OR = 1.91, SE = 1.39, p-value = 0.05).

Conclusions:

A leading network of autism researchers was found to include 50% of neurodivergent researchers, and with personal links to autistic people (kin 40%, friends 68%). Self-diagnosed people did not declare whether they disclosed this information; further investigation could clarify whether this links to stigma, perception of self vs clinical diagnosis, and knowledge of disclosure modalities. Lower seniority and close personal links to autism were associated with diagnosis, suggesting autistic people may not reach directorial roles. Diagnosis was associated with mental health issues, but the protective instrumental effect of seniority suggests that one’s job may foster discovery of one’s needs.

426.360  (Poster) Pandemic-Related Interruptions to Early Identification and Intervention

S. Hurwitz, D. Myers and Y. S. Chiang, (1)Special Education, Indiana University - Bloomington, Bloomington, IN, (2)Indiana University Bloomington, Bloomington, IN

Background:

The COVID-19 pandemic disrupted educational systems for young students with autism. Child Find services, eligibility evaluations, and enrollment into special education were suspended or delayed due to closures and/or social distancing requirements that made administering traditional assessments difficult. Even the students who had already received a diagnosis had limited access to educational facilities when many specialized preschool programs were closed. Some families chose to delay entry into kindergarten rather than begin school under such uncertain circumstances. This caused many students with autism to miss out on the early intervention and early school-aged services that they would have received during normal times.

Objectives:
The purpose of this study is to assess the changes in the proportions of autistic students identified and enrolled in preschool and early school-aged classrooms during the pandemic. This information is a key first step in order to evaluate the level of interruption of services these students experienced and provide a baseline to follow the long-term educational impacts.

**Methods:**

Using four years of administrative data from a school district in Indiana, we compared the number of students with autism enrolled in prek/kindergarten/1st grade each year from 2018 to 2022. Data on the total number of students with disabilities was also examined, to discern if children with autism were disproportionately impacted by the pandemic compared to other students in special education. The district is a large, urban, and serves 16,000 students/year, approximately 3,000 of whom with disabilities (18%). It is racially and ethnically diverse (37% Black, 27% White, 24% Hispanic, and 10% multiracial). About 10% of the student body are English language learners, and most students (65%) come from economically disadvantaged households. Data was extracted from the District’s Ed-Fi Operational Data Store (ODS) that houses the Student Information System (SIS) data in a standardized format.

**Results:**

There was a precipitous drop in special education identification during the pandemic. Only one student with autism was enrolled in the district’s preschool programs during the 2020-2021 pandemic school year. The number rebounded last year (2021-2022 school year) with 45 new students with autism enrolled. A similar drop and rebound occurred for overall numbers of students with disabilities. In preK and K-1 classrooms across the district there were 685 students in special education before the pandemic, during there were 393, and post pandemic the number returned to 680 students.

**Conclusions:**

This study shows that young students with autism were not identified or enrolled in specialized education during the pandemic. Although there was nearly 50% drop in enrollment for all students with disabilities in prek-1 during the 2020-2021 school year, those with autism appear to have been significantly more impacted. There are likely to be ongoing ramifications for these students who effectively missed out on a year of services. Even for students who attended school in 2020-2021, their social skills goals were often removed from their IEPs due to social distancing requirements (authors, 2022) which has ongoing impacts to their interactions and social behavior.

426.361 (Poster) Pilot Feasibility Study of Clinical Implementation of a Sustainable Telehealth Assessment Model for Autism Spectrum Disorder

E. M. Kryszak1,2, C. M. Albright1, K. G. Stephenson1, C. E. Murphy1, A. Newmeyer1, T. R. Hollingsworth1, C. Rice1, D. F. Michalec1,2 and E. M. Butte1,2; (1) Nationwide Children’s Hospital, Columbus, OH, (2) The Ohio State University, Columbus, OH, (3) Developmental Assessment Program, Nationwide Children’s Hospital, Columbus, OH, (4) Nationwide Childrens Hospital/Ohio State University, Columbus, OH

**Background:** Innovative assessment models for autism spectrum disorder (ASD) can increase access to services (Zwaigenbaum & Warren, 2020). The COVID-19 pandemic necessitated creating novel telehealth assessment models to continue to serve the needs of families. However, more data is needed to determine whether these new models can be integrated long-term into pre-pandemic assessment models to improve access to care for those with barriers related to geographical location, need for additional childcare, transportation, and other factors. Sustaining and continuing to improve telehealth assessment methods has the potential to increase agility during future adverse events limiting access to in-clinic services.

**Objectives:** Develop and implement a sustainable telehealth assessment model for ASD that would be equivalent to in-clinic services and improve access to care for families with possible barriers.

**Methods:** An interdisciplinary team of psychology, developmental pediatrics, and speech therapy providers from a development assessment center at a large US children’s hospital convened for eight meetings over five months to transition a telehealth assessment model for children ages 3 and under created during the COVID-19 pandemic into a sustainable model integrated into existing in-clinic services. Factors considered for sustainability included equivalency to existing services, need for services to increase access of care, demand for telehealth services post-pandemic, staffing, and licensing and billing for telehealth vs. in-clinic services. A triaging protocol was created with input from intake clinicians to identify families with possible access barriers that could be addressed by telehealth. Basic demographic data (e.g., distance from clinic, insurance status, social determinants of health), attendance to evaluation appointment, final diagnoses, and Childhood Autism Rating Scale, second edition (CARS-2) scores were collected through chart review for children referred for telehealth (n=33) and in-clinic interdisciplinary evaluations (n=148) between December 2021 and August 2022. Data on reason for referral to telehealth services was also collected. T-tests and Fisher exact tests were used to test for group differences.

**Results:** Feasibility analyses determined that the initial telehealth model was reasonably equivalent to current in-clinic assessment services in terms of interdisciplinary evaluation processes and time billed. The initial stream of referrals has steadily filled two interdisciplinary centers.
telehealth evaluation slots per week for the last five months. Families were referred for telehealth services most often due to distance from clinic (70%), childcare needs (20%), and general family stress (20%). Children seen in telehealth evaluations did not differ from those seen in-clinic on social determinants of health, insurance type, rural location, age at referral, and CARS-2 scores (all \( p > 0.05 \)). A diagnosis of ASD was given more frequently in the telehealth group than the in-clinic group (\( p = 0.04 \)).

**Conclusions:** Initial results indicate a continued small but sustainable demand for telehealth services that can address possible barriers to care. Results indicate both models are serving an equivalent population, although those seen by telehealth were more likely to be diagnosed with ASD. It is possible intake clinicians referred to telehealth when more confident in initial ASD symptoms, although further data is needed. Next steps include addressing barriers allowing for sustainable telehealth services for older children.

426.362 (Poster) Post-Diagnosis Support for Autistic Adults: Context, Positive and Negative Experiences and Proposed Solutions to Address Gaps in Service Provision. A Qualitative Study

S. Wigham, A. Fisher-Rogers, A. LeCouteur, B. Ingham\(^{1,2,3}\), C. Wilson\(^1\), P. Welsh\(^1\), R. Lees\(^1\), O. McConnell\(^1\), A. Neddyalkova\(^1\), L. Nicholson\(^1\) and J. R. Parr\(^1\), (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, UNITED KINGDOM, (2)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (3)Cumbria, Northumberland, Tyne & Wear NHS FT, Newcastle upon Tyne, (4)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

**Background:** Research shows there are few support services and specific gaps in provision for people following a diagnosis of autism in adulthood. Most findings focus on deficits in provision with little emphasis on positive experiences and solutions.

**Objectives:** We aimed to (i) examine experiences of receiving/providing an autism diagnosis in adulthood as context to any support services that may be required (ii) explore positive experiences and solutions to address gaps in post-autism diagnosis support services provision in the context of (iii) perceived gaps and limitations in support service provision.

**Methods:** Autistic adults, relatives and clinicians recruited from the ASC-UK adult autism cohort (https://research.ncl.ac.uk/adultautismspectrum) were surveyed about recent experiences of UK adult post-autism diagnosis support services within 12-months following the diagnostic assessment. Thematic analysis of verbatim survey content using a semantic approach was undertaken. To ensure high quality data analysis, the following methods were employed: comparing key characteristics of autistic adult survey participants (responders) with non-responders; data double-coding; and data from the stakeholder groups were triangulated to provide multiple perspectives on common and divergent views.

**Results:** 343 autistic adults, 45 relatives and 35 clinicians completed parallel surveys. Five super-ordinate themes were defined. **Theme 1: Reorientation to self and others after diagnosis** with two subthemes: Inter-personal and Intra-personal changes experienced ["...my social anxieties...subsided once diagnosed. I was able to reduce my anxiety meds’ autistic adult"]. **Theme 2: Examples of effective/acceptable support available:** One autistic adult said: ‘For me, it was really important to get a job coach, to support me with ensuring reasonable adjustments at work’. Another autistic adult said ‘with my diagnosis report, the psychologist included a page to give to my work to say “these are the things I struggle with, and what you can do to help me”’. **Theme 3: Characteristics of effective/acceptable support** comprised three subthemes: psychoeducation, support for families/carers [’My wife and I attended parallel courses. Myself for those diagnosed with autism, and my wife for those who were ‘carers’. It was helpful’] and personalisation [’My diagnosis letter was in my birthing notes and helped me have an infinitely better birthing experience. I had my own room after the birth and not thrown onto a ward with even more crying babies (total sensory overload meltdown situation first time around without knowing why) autistic adult’]. **Theme 4: Organisational factors facilitating effective/acceptable support** focussed on good connections with other services and community-based support [’My counsellor was brilliant and helped me gain some confidence back and accept my diagnosis’: autistic adult]. **Theme 5:** considered Context including perceived gaps in support/services available and how to fill them: ‘post-diagnostic materials [web-based] that could be shared’[’because I don’t live in the city where the service is’].

**Conclusions:** Involving perspectives of relevant stakeholders and building on their direct positive experiences and recommendations can constructively inform development of effective support services for autistic adults in the future. Those commissioning and providing post-diagnostic support can use these examples of support that led to positive change to enhance their post diagnostic support provision.

426.363 (Poster) Predicted Rate of Having a High-Cost Chronic Condition Among Adults with Intellectual Disability and/or Autism Spectrum Disorder By Disability Benefit Status

C. Rice, B. Barger\(^1\), Q. Cheng\(^2\) and T. W. Benevides\(^3\), (1)Division of Human Development and Disability, Centers for Disease Control and Prevention, Atlanta, GA, (2)Georgia State University, Atlanta, GA, (3)Centers for Disease Control and Prevention, Atlanta, GA, (4)Institute of Public and Preventive Health, Augusta University, Augusta, GA

**Background:** Adults with intellectual and developmental disabilities (IDD) face complicated systems to qualify and receive disability benefits in the United States. The way in which disability is measured and defined varies across local, state, and federal programs. The Social Security Disability Insurance (SSDI) program provides a monetary benefit for basic needs based on inability to work and Federal disability determination standards. Individuals \(<65\) years qualifying for SSDI are eligible for Medicare to support healthcare services after a 24-month wait. U.S. states have different disability-related standards to qualify for Medicaid service-based benefits not dependent on
income. Individuals can qualify for both Federal and State disability. Understanding factors associated with receiving disability benefits can inform efforts to improve access to essential disability supports.

Objectives: This study evaluated the association between presence of a co-occurring chronic condition and receipt of disability benefits among adults 18-64 years with Intellectual Disability (ID) and/or Autism Spectrum Disorder (ASD) who qualified for federal (SSDI and Medicare) and/or state (Medicaid-only).

Methods: We used the Medicare-Medicaid Linked Enrollees Analytic Data Source (MMLEADS,v2), which includes chronic condition variables. The denominator (n=850,616) were beneficiaries 18-64 years with ASD and/or ID receiving Federal SSDI+Medicare and/or State-based Medicaid (on the basis of disability). The numerator represented adults with Federal (n=355,505) or State-only (n=495,111) disability by ASD and/or ID status. 92.47% of the Federal+ group (n=328,737) are dually-eligible for Federal and State disability benefits. Chronic conditions included: depression, epilepsy, Alzheimers, diabetes, arthritis, obesity, cancer, and heart disease (myocardial infarct, hypertension). Descriptive statistics and logistic regressions adjusting for age, gender, race/ethnicity, ID-status, U.S. Census region, and rurality were conducted.

Results: There were 850,616 beneficiaries in the MMLEADS and, of those, 41.79% qualified for Federal benefits. The top chronic conditions were depression, heart disease, and epilepsy. Those with Federal disability, regardless of DD, had 2.47 greater odds of having depression (95%CI: 2.44-2.50), 1.48 greater odds of having heart disease (CI:1.46-1.50), and 1.02 greater odds of having epilepsy (CI:1.01-1.03). Having a Federal disability determination was associated with greater odds of having any chronic condition (OR=1.60, CI:1.58-1.61). However, the strength of this association was based on age and disability type. The predictive probability of a chronic condition on receiving Federal benefits varied most in the youngest age group and least in the oldest age group (Figure 1). Autistic adults with ID were more likely than those without ID or with ID-only to have a chronic condition in both the Federal + and State Only disability eligibility groups.

Conclusions: Those with Federal benefits were significantly more likely to have chronic conditions that those with State benefits. Almost 50% of young autistic adults with ID who qualify for Federal disability benefits also had chronic health conditions requiring coordinated, effective care for mental (e.g. depression) and physical (e.g. heart disease) chronic conditions. Discontinuous services and lack of a consistent way to determine disability across states and federal systems hamper care and likely result in disparities in access to care. Implications for public health and disability services will be discussed.

426.364 (Poster) Predictors of Early Intervention Referral after a Positive Developmental Screen in Community Primary Care Clinics

M. Solgi1, C. Calub1, A. Feryn1, E. Fombonne2, C. Matushak3, A. Bush4 and K. Zuckerman5, (1)General Pediatrics, Oregon Health and Science University, Portland, OR, (2)Department of Psychology, Oregon Health and Science University, Portland, PA, (3)Biostatistics and Design Program, Oregon Health and Science University, Portland, OR, (4)Department of Psychiatry, Oregon Health & Science University, Portland, OR, (5)Oregon Pediatric Society, Portland, OR, (6)Help Me Grow, Providence Swindells Center, Portland, OR, (7)Division of General Pediatrics, Oregon Health & Science University, Portland, OR

Background:

Primary care physicians (PCPs) may rely on clinical judgement rather than screening test scores in making referral decisions for children with autism and other developmental disabilities (DD).

Objectives:

This study investigated which patient and screening test factors predict a PCP’s Early Intervention (EI) referral after a positive Modified Checklist for Autism in Toddlers, Revised (MCHAT-R) or Ages and Stages Questionnaires (ASQ-3) screening test result.

Methods:

Child developmental screening test results and EI referral decisions were collected via medical record review of 1,864 15-, 18- 24- and 30-month well-child checks conducted at 7 community primary care clinics in 4 Oregon counties, in 2020-2021. We tested the association of receipt of EI referral with screening test scores and child demographic data (sex, language, race/ethnicity), using binary logistic regression. ASQ-3 domains and overall ASQ and MCHAT-RF scores were considered separately.

Results:

59% of of children with MCHAT-RF ≥3, and 47% of children with ASQ-3 ≥ 2 received EI referrals. 41% were not referred even after receiving an ASQ-3 cumulative score ≥ 5. Multivariable analyses showed that M-CHAT-RF score, ASQ overall score, and all ASQ domain scores except Problem Solving, predicted EI referral. The Communication domain accounted for the most variance in predicting EI referral.
Predictors of Repeat Hospitalizations for Behavioral Health in Children with Autism

A. Pavlov and N. Nuhu, Marcus Autism Center, Atlanta, GA

Background:
Children with autism spectrum disorders (ASD) require more visits to the Emergency Department (ED) than typically developing children. For children with ASD, aspects of their diagnosis also make them particularly ill-suited to the ED environment. As a result, outcomes for these patients are generally poor, with longer lengths of stay, increased likelihood of repeat admissions for crisis intervention, and more invasive forms of medical care, such as restraint or inpatient hospitalization. Repeat hospitalizations are particularly problematic as it can...

Predictors of Participation in Autism Evidence-Based Practice Training within an Early Intervention System

B. Demetri, E. Chatson, H. Davies, M. Yohannes, A. Buck, D. H. Balser, N. M. Hendrix and K. Pickard, (1)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA

Background: Early access to autism evidenced-based practices (EBPs) has been shown to support autistic children’s developmental trajectories and improve quality of life (Mason et al., 2018). To help foster early access to autism intervention, there is a growing interest in delivering Naturalistic Developmental Behavioral Interventions (NDBIs) in Early Intervention (EI) systems, which serve as a natural entry point to services for children aged 0-3 years with developmental delays. Research shows that EI providers who participate in NDBI training can increase their fidelity to these models (Rogers et al., 2022; Stahmer et al., 2020). However, not all providers complete implementation initiatives; further, limited research has examined provider- and system-level factors that predict the extent to which providers participate in NDBI training.

Objectives: The objectives of this study are to examine: (1) factors that predict the uptake of autism EBPs within Georgia’s EI system; (2) factors that predict EI providers’ perceptions of feasibility and acceptability of autism EBPs; and (3) how providers deliver autism EBPs after training.

Methods: Preliminary data is available for 57 EI providers, although data collection is ongoing. Providers participated in one of two NDBI training opportunities: (1) Project ImPACT, an evidence-based parent-mediated intervention (Ingersoll and Dvortcsak, 2019); or (2) the Autism Navigator, an online platform providing information on autism and evidence-based strategies for supporting autistic toddlers. Prior to training for either program, providers completed measures of (1) demographic information; (2) attitudes towards evidence-based practices; and (3) perceived level of support to attend training and consultation. Following training, all providers participated in group consultation for one hour per week over 12-weeks and completed measures of feasibility, acceptability, and intervention delivery. Linear and logistic regression models were used to examine predictors of EI provider participation in NDBI training. Descriptive statistics were used to examine delivery of autism intervention following training.

Results: 91.1% of providers agreed that they learned new skills by attending professional training in the last year. However, 60.0% agreed, to at least a moderate extent, that clinical experience outweighs manualized interventions. Results from a binary logistic regression model predicting autism NDBI training completion are displayed in Table 1. Both NDBI training opportunities, Project ImPACT and the Autism Navigator, predicted training completion above and beyond provider attitudes, perceived level of training support, and years of experience. Of the EI providers who completed training (n=40) and consultation (n=37), 54.8% indicated delivering either Autism Navigator or Project ImPACT to several additional families on their caseload.

Conclusions: Preliminary findings suggest that specific NDBI training content and structure may impact provider engagement within EI systems. Although data collection is ongoing, these findings provide insight into training processes by which NDBIs can be translated into the EI system and the barriers and factors that influence their use by EI providers. This information may allow for the development of implementation strategies and training methods in partnership with EI providers that support provider use of NDBI models and, in turn, family access to evidence-based early intervention treatment.

Predictors of Repeat Hospitalizations for Behavioral Health in Children with Autism

A. Pavlov, Marcus Autism Center, Atlanta, GA

Background:
Invasive forms of medical care, such as restraint or inpatient hospitalization. Repeat hospitalizations are particularly problematic as it can...

Conclusions:
Screening test and clinical thresholds for EI referral differ substantially. The majority of children who are at high risk for developmental concerns or autism are not receiving EI referrals from PCPs. Girls and children with problem solving challenges are least likely to be referred. These findings may help inform physician training on developmental and autism screening in primary care.

Predictors of Participation in Autism Evidence-Based Practice Training within an Early Intervention System

B. Demetri, E. Chatson, H. Davies, M. Yohannes, A. Buck, D. H. Balser, N. M. Hendrix and K. Pickard, (1)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA

Background: Early access to autism evidenced-based practices (EBPs) has been shown to support autistic children’s developmental trajectories and improve quality of life (Mason et al., 2018). To help foster early access to autism intervention, there is a growing interest in delivering Naturalistic Developmental Behavioral Interventions (NDBIs) in Early Intervention (EI) systems, which serve as a natural entry point to services for children aged 0-3 years with developmental delays. Research shows that EI providers who participate in NDBI training can increase their fidelity to these models (Rogers et al., 2022; Stahmer et al., 2020). However, not all providers complete implementation initiatives; further, limited research has examined provider- and system-level factors that predict the extent to which providers participate in NDBI training.

Objectives: The objectives of this study are to examine: (1) factors that predict the uptake of autism EBPs within Georgia’s EI system; (2) factors that predict EI providers’ perceptions of feasibility and acceptability of autism EBPs; and (3) how providers deliver autism EBPs after training.

Methods: Preliminary data is available for 57 EI providers, although data collection is ongoing. Providers participated in one of two NDBI training opportunities: (1) Project ImPACT, an evidence-based parent-mediated intervention (Ingersoll and Dvortcsak, 2019); or (2) the Autism Navigator, an online platform providing information on autism and evidence-based strategies for supporting autistic toddlers. Prior to training for either program, providers completed measures of (1) demographic information; (2) attitudes towards evidence-based practices; and (3) perceived level of support to attend training and consultation. Descriptive statistics were used to examine delivery of autism intervention following training.

Results: 91.1% of providers agreed that they learned new skills by attending professional training in the last year. However, 60.0% agreed, to at least a moderate extent, that clinical experience outweighs manualized interventions. Results from a binary logistic regression model predicting autism NDBI training completion are displayed in Table 1. Both NDBI training opportunities, Project ImPACT and the Autism Navigator, predicted training completion above and beyond provider attitudes, perceived level of training support, and years of experience.

Conclusions: Preliminary findings suggest that specific NDBI training content and structure may impact provider engagement within EI systems. Although data collection is ongoing, these findings provide insight into training processes by which NDBIs can be translated into the EI system and the barriers and factors that influence their use by EI providers. This information may allow for the development of implementation strategies and training methods in partnership with EI providers that support provider use of NDBI models and, in turn, family access to evidence-based early intervention treatment.
overwhelm hospital systems and ultimately indicates a failure in stabilization and a mismatch between patient need and available crisis services.

The available literature has primarily compared hospital admissions for children with ASD to those of their neurotypical peers and largely focuses on those admitted for primary medical or co-morbid psychiatric chief complaints (e.g., GI issues, seizures, suicidality, depression). To date, the authors are unaware of a study comparing children with ASD who are admitted once to those who present more than once for a primary behavioral health chief complaint to look at the unique factors within the population.

Understanding what variables contribute to the risk for readmission to the ED for children with ASD for behavioral health complaints can help us better identify these patients, equip hospital emergency rooms to meet the census, and more aggressively match intervention to their unique needs.

Objectives:

This study aims to examine predictors of repeat hospitalizations for behavioral health chief complaints in a cohort of children diagnosed with ASD. The study examined variables hypothesized to predict return rate including age, sex, height, weight, restraint, and length of stay.

Methods:

This study is a retrospective chart review of all patients diagnosed with ASD who presented to one of three ED between 1/01/2019 – 12/31/2019 for a chief complaint of a behavioral health concern. Encounters from the patient’s electronic medical record system were coded for all relevant variables associated with the participant’s ED admission. A total of 213 encounters were coded.

Results:

A total of 146 unique patients presented to the ED in 2019 (15 females, 131 males). Of those patients, 37 patients (25.34%) were admitted more than once (M = 3, Range 2 - 12) during the twelve-month period examined. A linear regression using a generalized linear model with number of visits as a continuous variable, where the true number of visits was used as the outcome, was used to analyze the data. Results indicated that age, weight, BMI, and medical restraint did not predict readmissions to the ED while length of stay (p = .007) and physical restraint (p < .001) did predict readmission to the ED.

Conclusions:

Children with ASD are at an increased likelihood for admission to the ED for behavioral health concerns. Understanding what variables contribute to the risk for readmission to the ED for children with ASD can better equip medical providers and hospital emergency rooms to meet the census and needs of this population.

**426.367 (Poster) Primary Care Provider Perspectives on Autism Screening: A Multi-Methods Study of Barriers to Equitable Referral**

Background: The goal of detecting and intervening early for autism spectrum disorder (ASD) remains elusive. Guidelines for screening in pediatric primary care and early referral for interventions and diagnostic assessment are well established (including from the American Academy of Pediatrics, AAP). However, adherence is inconsistent, contributing to delays as well as racial, ethnic, and socio-economic disparities in diagnosis and care.

Objectives: To identify barriers to equitable screening and referral after a positive ASD screen for young children in pediatric primary care.

Methods: Multi-method data were collected within a large academic pediatric primary care network with high rates of screening [>86% of all 16-26-month-old children screened at least once with the Modified Checklist for Autism in Toddlers with Follow-Up (M-CHAT/F) between 2018 and 2021]. Primary care network providers completed a survey and interview about their knowledge, intentions, and experiences with ASD screening and referral. Surveys included a measure of intentions’ regarding reporting positive screening results and referring children with positive screens to interventions and for ASD evaluation. We summarized survey results descriptively. Interviews were recorded, transcribed, coded, and analyzed thematically.

Results: A total of 69 providers responded to the survey (317 invited; response rate, 21.7%), including 58 attending physicians (76.3%) and 11 advanced practice nurses; most (91.3%) were female. Most (68.1%) providers reported having 15 minutes or less allotted for well-child
visits. Few providers reported receiving additional training in ASD (n=10, 14.5%) such as continuing education or conference participation. Knowledge about ASD screening recommendations from the AAP varied: 97.1% of respondents correctly identified 18 months as an AAP-recommended age of screening, and fewer correctly identified 24 months (79.7%) or whenever there is a concern raised (62.3%). Regarding recommended actions after a positive screen, 78.3-84.1% correctly identified each possible action after a medium or high-risk screen.

Providers reported strong attitudes toward and normative pressure to discuss screening results (Figure 1, panel A) and refer children after a positive screen (Figure 1, panels B & C). However, there was greater variability in their reported self-efficacy to discuss screening results and refer for evaluation (Figure 1, panels A & C).

Qualitative interviews with 39 of the surveyed providers helped elucidate barriers to screening and referral (Table 1). Providers reported that the biggest barriers they face are lack of training, time during visits, and available referral resources. These barriers discourage them from referring all but the most “severe” cases, and instead encourage them to “wait and see.”

Conclusions: We identified deficits in provider knowledge about ASD screening and referral; additional education is needed. Additionally, there are gaps between provider intentions and actions regarding referral after a positive screen. Barriers to screening and referral include lack of referral sources and frustration at not having resources to offer families after a positive screen.

Limitations include a low response rate, although non-respondents might have even lower interest or engagement in ASD screening processes, and lack of generalizability to non-academic practices. Ongoing work includes gathering family perspectives to identify acceptable strategies to improve screening and referral processes.

426.368 (Poster) Promoting Interdisciplinary Preventive Care for Cardiovascular Disease (CVD) with the Autism Spectrum Disorder Population: A Scoping Review

K. Aranha and G. Ferreira, (1)OT Department, University of St. Augustine Health Sciences, Austin, TX, (2)PT department, USAH HS, Austin, TX

Background: The purpose of this investigation is to: 1) examine the implications of cardiovascular health with children and adolescents with ASD, and 2) make a case for the inclusion of motor deficits (MD) in clinical guidelines for the treatment of ASD. CVD is the leading cause of mortality in the ASD population. Eighty to ninety percent of children with ASD have motor deficits. Evidence also suggests MDs are a precursor to social and cognitive dysfunction, limiting engagement in play and occupations. Based on the DSM V manual criteria for diagnosis of ASD, clinical guidelines for treatment fail to account for motor dysfunction. However, the implication for cardiovascular health is a significant issue that is preventable with the timely treatment of motor deficits. The dynamical systems theory provides the underpinnings to explore the implications of cardiovascular health and quality of life of this population.

Objectives: 1. Understanding clinical presentations that are not otherwise included in the Diagnostic and Statistical Manual V criteria for ASD.

2. Increase the understanding of the correlation between motor deficits and cardiovascular disease in the ASD population.

3. Advocate for interprofessional collaboration to provide patient-centered and preventative care.

Methods: A scoping review, consisting of an extensive database search, includes CINHAL, PUBMED, EMBASE, and Cochrane. Inclusion criteria used: Ages: 1 month to 20 years, English articles published 2010 onwards, and studies examining physical health and cardiovascular health with ASD, and exclusion criteria included: comorbidities of learning and language disorders, cerebral palsy, and seizure disorders.

Results: Children born with cardiac issues are more likely to have ASD. MDs with this population limit the ability to meet environmental demands in the classroom, playground, social interactions, and a press for mastery. A lack of optimal motor skills development limits the potential to transition into adulthood with a good quality of life. Chronic disorders such as obesity present in this population increase the likelihood of CVD. MDs and obesity in this population necessitate early interdisciplinary intervention to promote age-appropriate engagement in play and ADLs at home, at school/playground, and in the community and prevent the incidence of CVD in this population.

Conclusions: Cardiovascular health has significant implications for health and quality of life for this population. Therefore, the inclusion of motor deficits in the clinical guidelines is recommended.

426.369 (Poster) Promoting Wellbeing in Autistic Youth and Adults through a Positive Focus on Sexuality and Gender Diversity: Education, Clinical Practice, Research, and Policy Recommendations
J. Dewinter1, M. L. Massolo1, M. Giwa Onaiwu1, R. Caplan1, E. Van Beneden1 and A. I. van der Miesen1, (1)GGzE, Eindhoven, Netherlands, (2)Tilburg School of Social and Behavioral Sciences - Tranzo, Scientific Centre for Care and Wellbeing, Tilburg University, Tilburg, Netherlands, (3)Division of Research, Kaiser Permanente Division of Research, Oakland, CA, (4)Advocacy Without Borders, Houston, TX, (5)Brandeis University, Heller School for Social Policy and Management, Waltham, MA, (6)LAVA (Autistic Adults’ Reading and Advisory Group), Vilvoorde, Belgium, (7)Child- and Adolescent Psychiatry, VU University Medical Center, Amsterdam, Netherlands

Background:

Sexuality is part of children and adolescents’ development and an important part of life. Studies conducted over the past 40 years revealed that autistic adolescents and adults too often lack tailored and comprehensive sexuality education and accessible information. In addition, attention to sexuality in healthcare remains limited. Also, more autistic adults identify as LGBTIQ+ or enjoy non-heteronormative sexuality or intimate relationships and therefore may face additional marginalization and stress, impacting their mental health. Until now, recommendations for supporting sexual health and wellbeing in autistic individuals are lacking.

Objectives:

Using a community based participatory approach, this project aimed to develop consensus recommendations for education, clinical practice, research, and policy to promote sexual wellbeing, with attention to the needs of sexual and gender diverse individuals, and make them available to a broad audience.

Methods:

The project was initiated and conducted by a core group (3 autistic, 3 non-autistic; researchers, clinicians and self-advocates) in close collaboration with an international group of 21 leading autistic and non-autistic experts in the field of autism, sexuality and gender diversity with a background in research, clinical practice, and self- and parent advocacy. In a first online expert meeting in May 2022, the experts provided input to create a set of recommendations, through the Nominal Group Technique. In a second phase, a call was put to autism communities across the world to complete an online survey, to rate the initial 11 policy recommendations and provide feedback. Survey results and their implications were discussed in a second online expert meeting in August 2022.

Results:

Based on the input from the expert meeting, a set of 11 recommendations was developed, grouped in four themes: 1) better education and information about sexuality and gender identity, 2) promoting supportive and inclusive communities, 3) building capacity to offer better sexuality, gender diversity, and health related services for autistic people and 4) sexuality and gender diversity research and meaningful inclusion of the autistic community. In total, 493 participants completed the survey (353 autistic adults, 140 non-autistic family members and professionals). They were a diverse group in terms of role (e.g., autistic adult, parent, professional), country, sex assigned at birth, gender identity, sexual attraction, living situation and type of sexuality education, although people living in Western countries were overrepresented.

High agreement between autistic and non-autistic participants resulted in the selection of eight recommendations. Three recommendations, relating to promoting supportive and inclusive communities were rated just below the threshold. Feedback and responses to an open question were analyzed and revealed additional specifications but no new recommendations.

Conclusions:

Experts and the community agreed on a set of eight consensus recommendations for education, clinical practice, research, and broader policy to promote and support sexual health and wellbeing in autistic individuals across the lifespan. These recommendations are crucial next steps to improve wellbeing of the autism community, describing different approaches to promote wellbeing that can be adjusted to the local situation. Experts and participants in the global South should be specifically targeted in future initiatives.

426.370 (Poster) Providing Telehealth Support for Caregivers of Autistic Children Using a Mobile App

A. V. Dahiya1 and A. Scarpa3, (1)Department of Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (2)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Department of Psychology, Virginia Tech, Blacksburg, VA

Background: Autism spectrum disorder (ASD) presents with challenges for caregivers and providers while impacting a child’s developmental trajectory across several domains, including behavior challenges. Unfortunately, due to limited access and affordability of care, especially during the pandemic or other situations that require people to stay at home, in-person services are not always feasible. Rural or underserved communities face additional barriers, such as geographic isolation and lack of autism-specific resources. Accessibility
of autism treatment may be expanded through telehealth supports, such as mobile applications. When implementing these supports for autistic children, decreasing child problem behaviors while improving caregiver stress, knowledge, and competence is crucial. Providing a telehealth platform for caregivers of autistic children may help improve the accessibility of autism services.

**Objectives:** The objective was to conduct a pilot study of a behavior consultation mobile application, *Treks*, to improve telehealth support for caregivers of autistic children. This study aimed to investigate: (1) the feasibility of the mobile application by examining attrition, compliance, ease of use, and appropriateness of *Treks*, and (2) the preliminary benefits on caregiver and child outcomes following use of *Treks*.

**Methods:** Participants included 26 caregivers (*n* = 2) of autistic children (3-13 years), who were randomly assigned to a one-session telehealth parent-training consultation with 1) the enhancement of the *Treks* app over the course of one month (TH; *n* = 14) or 2) with access to mobile resources comparable to *Treks* for one month (CC; *n* = 12). They were then administered measures at baseline (T1), pre-*Treks* (T2), and post-*Treks* (T3) to assess changes in caregiver stress, knowledge, competence, and child behaviors. Metrics were also calculated to understand acceptability, appropriateness, and feasibility of *Treks* as well as satisfaction, fidelity, and compliance.

**Results:** Findings revealed that *Treks* was received positively across groups, ranging from moderate to high satisfaction. Feasibility questionnaires showed moderate to high ratings of acceptability, appropriateness, and feasibility of *Treks*. Participants provided positive feedback on the structure and content of *Treks* with others raising some concerns related to technical issues (e.g., getting signed out of the app). In terms of preliminary efficacy, there was a significant improvement in TH participants from T2 to T3, specifically showing significant mean decreases in child behaviors and caregiver stress and increases in caregiver knowledge and competency. Results from CC participants showed a nonsignificant trend towards improvement across outcome measures, with a significant increase in caregiver knowledge from T2 to T3.

**Conclusions:** Findings revealed feasible outcomes and brief support of this telehealth application. The implementation of *Treks* should continue to be examined, as it has the potential to improve caregiver and child outcomes when delivered as a consultation or supplement to full treatment. Families of autistic children experience varying levels of stress, and the addition of mobile telehealth services can provide necessary and accessible supplemental support. This project increased accessibility of services to rural families of autistic children during the height of the pandemic, and future research will continue to examine the use of *Treks* across transdiagnostic settings in under-resourced populations.

**426.371 (Poster) Qualitative Insights into Improvement of Primary Healthcare for People with Autism: A Delphi-Study**

**Background:** People with an autism spectrum diagnosis (ASD) often experience a range of barriers in accessing healthcare (Mason et al., 2019; Nicolaidis et al., 2015; Walsh et al., 2020). In addition, they have an increased morbidity and mortality risk (Croen et al., 2015; Hirvikoski et al., 2016). Since providing (access to) appropriate healthcare is a main task of general practitioners (GPs), improvement of primary healthcare for autistic people is a necessity (Raymaker et al., 2017, Walsh et al., 2021). In order to improve primary healthcare, useful and feasible recommendations for general practice, based on both the needs of primary healthcare providers (HCPs) and autistic people, are needed (Gilmore et al., 2022; Walsh et al., 2021).

**Objectives:** Therefore, the aim of this study was to evaluate barriers and identify recommendations to improve primary healthcare for autistic people, based on both the needs of autistic adults and primary healthcare providers (HCPs).

**Methods:** This study was developed within the Dutch Academic Workplace Autism (*Academische Werkplaats Autisme*), which is a collaborative effort of autistic (advocacy) organizations, clinical institutions, and academic institutions with the aim to improve the lives and health of the autistic population based on outcomes of co-created academic research. The project-team for this specific study consisted of different HCPs, researchers, and members with lived experience (i.e., autistic adults and parents of an autistic child). In Figure 1, the qualitative study design (preparatory phase and Delphi-study) was summarized. In the preparatory phase, we performed semi-structured interviews (with 11 adults: parents of autistic people and HCPs) to evaluate what type of barriers are present for autistic people in Dutch healthcare. To summarize these interview-results, a thematic analysis was executed. Next, in the Delphi-study, a panel of 21 autistic adults and 20 primary HCPs (10 GPs and 10 GP-nurses/-psychologists) participated. Barriers in primary healthcare for autistic people were rated regarding negative impact and suggested recommendations were assessed based on usefulness and feasibility.

**Results:** In the interviews, 20 barriers in Dutch healthcare for autistic people were identified: barriers related to HCPs, barriers related to autistic traits, and barriers related to the healthcare system and the social support system. In the Delphi-study, primary HCPs rated the negative impact of most barriers in primary healthcare relatively lower than the autistic participants. This Delphi-study resulted in 22 recommendations to improve primary healthcare for people with ASD: focused on primary HCPs (i.e., education enriched with input from
people with lived experience), on the social network and organization (i.e., related to more continuity in care), and on autistic people (i.e., recommendations to improve preparation for a GP appointment).

**Conclusions:** Primary HCPs underestimate the negative impact of barriers in primary healthcare for autistic people. With use of the Delphi-method, useful and feasible recommendations to improve primary healthcare for autistic people were identified, based on the needs of autistic adults and primary HCPs. The Dutch Academic Workplace Autism will publish an informational leaflet including these recommendations in a visual overview for primary HCPs and autistic people.

426.372 (Poster) Quality and Accessibility of Written Development Assessment Reports Provided to Caregivers in a Publicly Funded Child Developmental Assessment Service

**A. J. Guastella**, K. A. Boulton, A. Hodge, N. Ong, N. Silove and D. C. Coghill, (1)Brain and Mind Centre and Children's Hospital Westmead, Sydney, NSW, Australia, (2)Brain and Mind Centre, Children’s Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (3)Sydney Children's Hospital Network, Sydney, NSW, Australia, (4)University of Sydney, Sydney, Australia, (5)University of Melbourne, Melbourne, VIC, Australia

**Background:**

Despite long wait times, public pediatric developmental assessment services remain crucial for assessment of vulnerable children. Assessment represents a critical opportunity to guide the placement of supports to improve functioning and developmental trajectories. There is, however, a lack of research examining how services conduct assessments, synthesize results, and provide reports to families.

**Objectives:** Reports were evaluated for whether they 1) addressed caregiver perceived needs, 2) used available data to provide appropriate information about child needs, 3) provided recommendations that were actionable and specific to needs, 4) had appropriate readability levels and 5) followed existing autism assessment guidelines.

**Methods:** This study retrospectively examined 85 reports provided to caregivers at a developmental assessment service. A report extraction checklist was developed to determine whether reports followed developed criteria.

**Results:** Findings showed clinicians were more focused on autism diagnostic needs while caregivers were more focused on transdiagnostic needs. Recommendations related to autism diagnoses were specific and actionable, but rarely addressed transdiagnostic needs or comorbidities (e.g., cognitive impairments, mental health). For instance, only 13% of reports contained recommendations for conditions other than ASD, despite 61% of the population receiving two or more diagnoses. Reports largely followed autism guidelines, but the language used was more complex for families than recommended.

**Conclusions:** While developmental assessment services reviewed conducted a high quality multi-disciplinary assessment that largely followed recommendations and existing guidelines, areas of improvement were noted. Some of these areas reflect challenges of assessment for practice internationally. Recommendations for future practice are provided.

426.373 (Poster) Racial, Ethnic, and Language Disparities in Healthcare Services Utilization in Children Diagnosed with Autism: Five-Year Follow-up after Diagnosis

**Y. L. Chen**, A. Botticello and H. Genova, (1)Occupational Therapy, Kessler Foundation, New York, NY, (2)Kessler Foundation, East Hanover, NJ

**Background:**

Children with autism require timely and ongoing healthcare services to support their health and developmental needs. However, children with autism from Black, Hispanic, and non-English speaking backgrounds children with autism with low English proficiency receive fewer autism health services compared to non-Hispanic White and English-speaking children, placing them at risk for poor health and development. Insufficient service receipt early in life may lead to increased service needs in later childhood or adolescence, a little is known about the longitudinal trends and cumulative gaps in health service utilization among children with autism from disadvantaged backgrounds.

**Objectives:**

To explore the racial/ethnic and language disparities cumulative healthcare service utilization in children with diagnosed with an autism spectrum disorder (ASD) over a five-year period.

**Methods:**
We identified a patient cohort (N=287, aged between 0-17) who were diagnosed with ASD and classified as Autism or Autism Spectrum by the Autism Diagnostic Observation Schedule or Autism Diagnostic Interview-Revised in 2014 at the major pediatric healthcare system in New Jersey, USA. Data on the patients’ five-year service utilization (2014-2019) and demographic information were extracted from electronic medical records. Healthcare services are defined as the total number of outpatient clinic visits made to a primary care pediatrician or specialty care provider in neurodevelopmental pediatrics, neurology, psychiatry, psychology, speech/occupational/physical therapy, nutrition, and audiology. Healthcare utilization was compared by age group, sex, race/ethnicity, and preferred language for medical communication.

Results:

Table 1 presents participant demographics and service utilization summary. Of the 286 identified children, 144 were non-Hispanic White and 142 were of minority race and/or ethnicity (60 Hispanic, 39 non-Hispanic Black, 15 Asian or Pacific Islander, 1 American Indian/Alaskan, and 22 other or multiple races). Thirty-four children preferred communication in a language other than English; the majority communicated in Spanish (n=29). Compared to non-Hispanic White children, minority children in this sample had an earlier diagnosis age and more frequent use of therapy services (e.g., psychology, speech-language/ occupational/ physical therapy, applied behavioral analysis, nutrition, or auditory). Poisson regression models showed that minority children in this sample received more physician and therapeutic services five years after the diagnosis after adjusting for age and sex (Table 2).

Conclusions: Contrary to our hypothesis and the literature, the findings showed greater cumulative service utilization among children with autism from historically disadvantaged backgrounds. This may suggest the need to examine the role of other relevant covariates such as clinical severity, co-occurring developmental disability, and insurance type (private or public). These covariates will be included in the final analysis for the presentation. Additionally, we will further explore the trend of service utilization over the five years in order to understand group differences in treatment for autism.

Background: Families with a child with autism spectrum disorder (ASD) who live in rural communities face many barriers to receiving care, including diagnostic and treatment services (Antezana et al., 2017). Traditional ASD research has defined rurality by the rural county definition, but counties often vastly differ by size and urban counties can include rural areas (Coburn et al., 2007). An alternate way to define rurality is by census tracts via a measure called the Rural-Urban Commuting Areas (RUCA; Morrill, Cromartie, & Hart, 1999). RUCA further divides rurality into a more precise definition (e.g., Urban, Large Rural, Small/Isolated Rural) and has found individuals living in small and isolated rural must travel farther to receive their treatment across different medical conditions (Caldwell, Ford, Wallace, Wang, & Takahashi, 2016).

Objectives: This study aimed to clarify rural healthcare disparities in ASD by analyzing precisely defined rural geographic regions for children referred for an ASD evaluation. By exploring the information gathered from ASD diagnostic visits, we can more accurately inform future research that aims to address access to quality care in the communities that need assistance the most. We predicted that families from rural communities would be from more socioeconomically disadvantaged areas, display greater severity of symptoms (therefore prompting the referral), and have less access to services.

Methods: The participants for this study were from a database composed of preschool children referred and clinically evaluated for an ASD diagnosis at a tertiary diagnostic clinic in the southeastern United States between 2010-2019. Participants’ home addresses were coded via RUCA conventions (e.g., Urban, Large Rural, Small/Isolated Rural). Preschoolers were defined as children who were under 5 years of age by the time of their ASD evaluation. Socioeconomic disadvantage was defined by the Area Deprivation Index (ADI), ASD symptom severity was defined by the ADOS Comparison Score, and access to services was defined by caregiver-report of number of service providers. A one-way ANOVA of the RUCA groups was conducted with the variables of interest.

Results: Participants included 350 individuals (73% male; M_age= 3.36 years, SD= 0.70) and 60% were diagnosed with ASD. Children from rural communities lived in more socioeconomically disadvantaged areas, (Urban [N=246] M=68.77, Large Rural [N=73] M= 79.38, Small/Isolated Rural [N=31] M= 79.42, F=10.534, p<.001), but did not differ in ASD severity or number of service providers (Table 1).

Conclusions: Preliminary results demonstrated that our rural families live in more disadvantaged communities than our urban families, indicating that rural communities would benefit from further public health interventions. However, current results should be interpreted with caution since children referred to tertiary care clinics are usually connected to multiple service providers before being referred. Additionally, these cases usually reflect difficult diagnostic questions, and this sample may not include children who are diagnosed by the primary care provider, potentially impacting severity differences. Therefore, analyses are ongoing to explore subdomain ASD severity differences, language, and adaptive differences to further elucidate potential geographic healthcare disparities (Table 2). Future studies
should utilize population-based sampling to better represent the experiences of rural families.

426.375 (Poster) School Absenteeism in Children and Adolescents on the Autism Spectrum – a Scoping Review

**V. Nordin**, A. Lindbladh, M. Palmgren, S. Bolte and U. Jonsson, (1)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (2)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden

Background: Education is a basic human right, preparing children and adolescents for future life and active citizenship. Globally, an estimated 258 million children and adolescents were out of school in 2018. School absenteeism is a heterogeneous phenomenon, with a range of potential adverse long-term consequences for the individual and the society at large. Recent population-based studies clearly suggest that children and adolescents on the autism spectrum are absent from school more days than their peers. However, the full scope of the literature on this topic has not yet been synthesized.

Objectives: The aim of this scoping review was to provide a comprehensive overview of all research to date on all forms of absence from school in children and adolescents on the autism spectrum, with a view to present a historical and cross-cultural perspective on the field, outline major themes from this body of research, and identify important gaps in the literature.

Methods: Five relevant databases (Cochrane, Medline, Psychinfo, Web of Science Core Collection, and ERIC) were searched systematically from inception to February 2022. Study selection was conducted independently by two review authors. Information pertaining to study characteristics (year of publication, country, diagnosis, age span, gender distribution, design, and research question, and definitions of absence) and quantitative and qualitative data related to absenteeism was extracted. Overarching themes in the accumulated body of research were identified and synthesized narratively.

Results: After removal of duplicates, 4,940 records were screened. From these, 529 full-text documents were assessed for eligibility. A total of 36 eligible reports from 32 distinct studies were identified. All studies were conducted in high-income countries, and 27 were published in the last decade. Three major themes were covered by the literature: occurrence, contextual factors, and interventions. The results of several studies, including some large-scale population-based studies, clearly suggest that autistic children and adolescents are at increased risk of chronic school absenteeism. Bullying and psychiatric comorbidities were identified as major risk factors. There were no conclusive results concerning the effect of inclusive education on school attendance, and authors underscored the need to distinguish placement in mainstream classes from real participation (e.g., time for instruction as well as time spent with peers). The few available studies on targeted interventions were based on small numbers of participants, but some promising results were reported.

Conclusions: School absenteeism is a major challenge for autistic children and adolescents and their families, often arising in a context of other developmental, health-related, and psychosocial problems. There is a need for larger and more robust studies on early detection and intervention. More research is also needed on the mechanisms leading to and maintaining school absenteeism in this specific group of students. It is also important to shed more light on the situation in low- and middle-income countries.Awaiting more research, schools should adapt well-researched pedagogical strategies and make necessary accommodations in the learning environment to promote school attendance among children and adolescents on the autism spectrum.

426.376 (Poster) Simulation-Based Education for Teaching Aggression Management Skills to Health Care Providers in the Acute Health Care Setting: A Systematic Review

**M. J. Mitchell**, A. Brignell, C. Bernie, F. Newall and K. Williams, (1)Department of Paediatrics, Monash University Department of Paediatrics, Melbourne, Australia, (2)Monash University, Clayton, VIC, Australia, (3)Southern Cross University, Gold Coast, QLD, Australia, (4)Royal Children’s Hospital; The University of Melbourne, Melbourne, Australia, (5)Monash University Department of Paediatrics, Clayton, VIC, Australia

Background: Aggression demonstrated by patients in acute care hospitals is frequent and costly with nurses working in emergency departments and paediatrics at high risk of experiencing patient violence. Behavioural emergencies caused by young people in paediatric hospitals are sufficiently frequent to require prioritisation as a global child health hazard. Children with additional needs, including autism, account for nearly half of all incidents in one Australian tertiary hospital. In addition, data is emerging in Australia that children presenting to emergency departments for behavioural crises have increased during prolonged periods of lockdown of the Covid-19 pandemic. The healthcare costs of behavioural emergencies are high with injuries to patients, families and staff, reduced work attendance and health care presentations also common. Acute care staff are often not trained or confident in the prevention or management of aggression or high-risk behaviours. Specifically, paediatric clinicians report a lack of knowledge and understanding of children and young people with a history of aggression and complex communication needs who are at high risk for aggressive and externalising behaviours. A range of training modalities have been described for acute care staff, including didactic lectures, written and web-based learning modules and simulation-based education. Simulation-based education has been found to be superior to traditional clinical medical education for clinical skill acquisition and is gaining acceptance as a training method for teaching skills in managing clinical aggression.
Objectives: The aim of this systematic review was to assess the effectiveness of simulation-based training for increasing de-escalation knowledge, skills and behaviour of staff working in the acute care setting. A broad search was conducted as there were insufficient publications about autism-specific simulation interventions.

Methods: We designed, registered and published a study protocol for a systematic review of studies evaluating simulation-based training for the management of patients with aggression in the acute health care setting. Comprehensive searches were conducted in PubMed, MEDLINE, PsycINFO, CINAHL and The Cochrane Library. Two reviewers independently screened all records, extracted data and assessed risk of bias. The primary outcomes included patient outcomes, quality of care, and adverse effects. Secondary outcomes included workplace resource use, healthcare provider related outcomes, knowledge (de-escalation techniques), performance, attitudes, and satisfaction. A narrative synthesis was performed for included studies.

Results: Our search strategy yielded 16099 records with 101 undergoing full text review following abstract screening. Nineteen studies met inclusion criteria and were included in this review. Three studies were RCTs with the remainder pre-/post-test cohort design. All but one study combined simulation-based education with at least one other training modality. There was substantial variation of interventions and outcome measures used in included studies, thus a narrative synthesis of results was performed.

Conclusions: Simulation-based education is an acceptable training format for teaching acute health care staff how to manage clinical aggression and has positive impacts on knowledge and self-reported confidence. However, there is a lack of information about the magnitude of these positive effects and impact on patient outcomes. The findings are of relevance to autistic children, providing an opportunity to reduce harm during their hospital presentations and admissions.

426.377 (Poster) Support in Daily Living for Young Adults with Neurodevelopmental Conditions in Sweden: A Qualitative Description of Current Practice
M. Löthberg, T. Hirvikoski, S. J. Girdler, S. Bolte and U. Jonsson, (1)Center of Neurodevelopmental Disorders (KIND); Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Habilitation & Health, Stockholm County Council, Stockholm, Sweden, (3)School of Allied Health, Curtin University, Bentley, Western Australia, Australia, (4)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (5)Karolinska Institutet, Stockholm, Sweden

Background: The transition to adulthood is a phase where young people are increasingly expected to navigate life themselves, adapt to societal roles and expectations, and eventually achieve milestones such as leaving their parental home, completing their education, or finding a job. In Sweden, young adults with neurodevelopmental conditions are increasingly receiving a practical, educational, and social support service called housing support. This service aims to enhance the individual’s autonomy and ability to manage their everyday life, within the home and community. However, no detailed guidance is currently available on how this support should be delivered.

Objectives: A better understanding of current practice is needed, to guide policy and practice toward an equal and efficient provision of support. This study aimed to provide a qualitative description of support workers’ views on housing support services delivered to young adults (age 18 to 29) diagnosed with autism and/or ADHD.

Methods: In-depth interviews were conducted with 34 housing support workers from 22 municipalities, differing in size and geographic location, across 19 Swedish regions. An open-ended interview guide comprised questions focusing on the support workers’ perceptions of support needs, support delivery, and factors influencing the support for this specific target group. Follow-up questions regarding the impact of the COVID-19 pandemic were also included. An inductive qualitative content analysis approach was used, in which meaning units were identified, labeled with codes, and grouped into subcategories, categories, and main categories.

Results: The interviews depicted a complex service, subject to organizational aspects (roles responsibilities, availability, and allocation), the joint effort of multiple key players (the young adult, relatives, support workers), and the diverse and heterogeneous nature of the core components (finding common ground for work, establishing productive collaboration, and specific skills/methods used). Current practice was partly determined by organizational needs (e.g., staffing, working hours, and means of transport), without fully considering the specific needs of the target group. Similarly, while general strategies such as motivational interviewing were used, no tailored approach for the target group was described. The support workers also found it challenging to be supportive without being directive, and to incorporate the young adult’s objectives and self-determination in the support provision. While service delivery clearly was disrupted by the COVID-19 pandemic, this sometimes led to new insights that may be utilized in the future development of housing support.

Conclusions: Findings raised important questions regarding how housing support should be organized and delivered to strike the right balance between providing necessary supports and promoting autonomy, meeting the target group’s specific needs across the various stages of transition, and providing an equitable service across municipalities. Increased standardization of service elements and detailed guidelines at a national or regional level will likely be key tools in translating best practices and evidence into a sustainable model of housing support for neurodivergent young adults.

426.379 (Poster) The Association of Family Characteristics and Clinicians’ Use of Caregiver Coaching in Early Intervention
Results: The questionnaire items were shown to be invariant across participants from both degrees and specialties at the configural, metric, and strict levels. Pre-service teachers showed generally positive attitudes towards inclusion, especially in relation to its benefits for students with ASC. Subsequently, invariance between groups was tested according to degree (pre-primary educators vs. primary teachers). Finally, latent means were compared between groups. Adequate alpha ordinal and McDonald’s omega reliability indices were obtained (ordinal α = .88, ωt = .92).

Methods: A total of 350 pre-service teachers (287 women) between 18 and 52 years of age (M = 20.99, SD = 3.68) were surveyed using an adaptation of the Attitudes of Regular Educators toward the Inclusion of Students with Autism Spectrum Disorder questionnaire. The analytic process was carried out in three phases. First, the internal structure of the questionnaire was tested by confirmatory factor analysis on the polychoric correlations matrix between items and three factors were identified that explain 52 % of the common variance: beliefs, benefits, and training for the inclusion of students with ASC. Subsequently, invariance between groups was tested according to degree (pre-primary educators vs. primary school teachers) and specialisation (special educational teachers vs. primary teachers). Finally, latent means were compared between groups. Adequate alpha ordinal and McDonald’s omega reliability indices were obtained (ordinal α = .88, ωt = .92).

Results: The questionnaire items were shown to be invariant across participants from both degrees and specialties at the configural, metric, scalar, and strict levels. Pre-service teachers showed generally positive attitudes towards inclusion, especially in relation to its benefits for

Background: Autistic children of color and of lower socioeconomic status (SES) often do not receive the same quality care as do their white or higher SES peers (Mandell et al., 2002; Mandell et al., 2007; Begeer et al., 2009). Qualitative studies find that community clinicians may choose not to coach caregivers from minoritized backgrounds in using evidence-based interventions (EBI) (Tomczuk et al., 2022). To date, however, no quantitative studies have examined whether family characteristics affect whether clinicians coach caregivers.

Objectives: We assessed if clinicians, trained in an evidence-based, caregiver-mediated intervention, differed in their implementation of the intervention as a function of family income, education, race, ethnicity, or primary language.

Methods: Family characteristics such as caregiver education, race, and ethnicity, income-to-needs ratio (King et al., 2020), and household language were collected as part of a community-based caregiver-mediated pilot randomized trial of an EBI, Project ImPACT (Ingersoll & Dvortcsak, 2009), in partnership with community agencies serving infants and toddlers with autism. Sixty families were recruited and randomized to three conditions: (1) Project ImPACT 4 hours/week (n = 19), (2) Project ImPACT 1 hour/week (n = 23), (3) Control (n = 18). Family SES characteristics included: caregiver education, race, and ethnicity; income-to-needs ratio; and household language. Two outcome measures were used to assess clinicians use of Project ImPACT: Project ImPACT Coaching Fidelity Checklist (for conditions 1 and 2; Ingersoll & Dvortcsak, 2009) and Parent Empowerment and Coaching in Early Intervention Fidelity Checklist (PEACE; Pellecchia et al., 2020). We used multiple linear regression to estimate associations between each SES characteristics and the two fidelity measures, controlling for condition and total intervention time.

Results: Overall fidelity to ImPACT (M = 57 on a 100-point scale, SD = 22) and coaching strategies was low. Family SES in this sample was very low, with 50% of families (n = 30) reporting household incomes under $20,000 USD; over 41% of mothers (n = 25) reported having education less than or equal to a high school education; and over half of fathers (n = 33) reported having less than or equal to a high school education. No family SES characteristics were statistically significantly associated with clinicians’ ImPACT fidelity (p > 0.05). ImPACT Fidelity was higher among clinicians coaching families that spoke non-English languages than clinicians coaching families that spoke English only (p = 0.04; Figure 1).

Conclusions: In contrast to the one qualitative study in this area, we found that family characteristics were not associated with use of one evidence-based practice, and only caregivers’ language was associated with the extent to which the clinician coached the caregiver. Two limitations hamper interpretation of findings: 1) intervention fidelity was, on average, low, and 2) families’ income was very low. The limited variability in these two constructs may have limited our ability to observe an association. Future studies should assess these associations in samples with greater variation in SES. In the interim, future efforts should address structural burdens faced by marginalized communities to successfully implement EBIs.

Background: Pre-service teacher attitudes toward the inclusion of children with Autism into Mainstream Schools

Objectives: The aim of this research was to understand these attitudes to improve the design of training programs for pre-service teachers in higher education.

Methods: A total of 350 pre-service teachers (287 women) between 18 and 52 years of age (M = 20.99, SD = 3.68) were surveyed using an adaptation of the Attitudes of Pre-Service Teachers Toward the Inclusion of Children with Autism into Mainstream Schools questionnaire. The analytic process was carried out in three phases. First, the internal structure of the questionnaire was tested by confirmatory factor analysis on the polychoric correlations matrix between items and three factors were identified that explain 52 % of the common variance: beliefs, benefits, and training for the inclusion of students with ASC. Subsequently, invariance between groups was tested according to degree (pre-primary educators vs. primary school teachers) and specialisation (special educational teachers vs. primary teachers). Finally, latent means were compared between groups. Adequate alpha ordinal and McDonald’s omega reliability indices were obtained (ordinal α = .88, ωt = .92).

Results: The questionnaire items were shown to be invariant across participants from both degrees and specialties at the configural, metric, scalar, and strict levels. Pre-service teachers showed generally positive attitudes towards inclusion, especially in relation to its benefits for...
Background: Currently there are few formalized supports for families and caregivers of autistic youth in navigating sexuality, changing bodies, and other issues related to puberty and adolescence (e.g., Pugliese et al., 2020). There is also evidence of disparities in access to more formal sex education supports for autistic youth (Holmes et al., 2020) and these supports may neglect important topics for autistic individuals (e.g., sensory needs, gender diversity, social safety; Hannah & Stagg, 2016). While parents are often their child’s first sexuality educator, many parents report feeling underprepared and lacking support in having these discussions with their children (e.g., Blakeley-Smith & Nichols, 2009). As such, it is important to consider parent-led sexual health interventions for caregivers of autistic youth in order to mitigate the risk of averse sexual health outcomes and support overall well-being of autistic individuals.

Objectives: (1) Evaluate the initial acceptability and feasibility of a novel parent-led sexual health program and (2) Evaluate changes in knowledge of core content, parent self-efficacy in discussing issues related to sexuality with their child, and expected outcomes of discussing sexual health topics with their child.

Methods: Two separate groups of parents of autistic youth (ages 10-13 and 14-18, respectively) were recruited to participate in the Birds & Bees pilot program. Eligible parents attended a 90 minute telehealth group for 8 weeks (see Table 1 for content areas). Participants completed the Parent Knowledge Questionnaire, the Parent Self-Efficacy Scale (PSES; DiLorio et al. 2006) and the Parenting Outcome Expectancy Scale (POES; DiLorio et al. 2001) pre- and post-treatment. Parents also provided feedback regarding overall acceptability of the program. The first cohort of parents consisted of mothers (N=4; mean age= 39 years) who had cisgender autistic sons (N=2) and daughters (N=2) (mean child age= 10.5 years). Six parents have been recruited to begin cohort 2, which is anticipated to end in December 2022.

Results: Preliminary results indicate that acceptability for the Birds & Bees program was high on the parent feedback form, with all participants endorsing that they strongly agreed or agreed with their overall satisfaction and perceived helpfulness of the program. Parent knowledge was high both pre- and post-treatment, yielding medium effect sizes following the intervention, Cohen’s d = .55 (-0.93 - 3.75). Parent self-efficacy also demonstrated positive initial effects, Cohen’s d = .50 (-1.67-3.36) as did parent outcome expectations, Cohen’s d = .68 (-0.85-3.54). See table 2 for additional details. Full results including both cohorts are forthcoming.

Conclusions: Overall, the Birds & Bees pilot program demonstrates promising initial acceptability and changes in outcomes for parents of autistic youth. Parents found the group to be helpful and displayed positive trends in their content knowledge, self-efficacy and outcome expectancies in serving as sexuality educators to their children. Implications of these results illustrate the positive impact of an innovative parent-led sexual health program for caregivers of autistic youth. Limitations include the small sample size, which limits the ability to measure more robust changes pre and post intervention.
Objectives: The objective of the study was to evaluate the convergent validity of the RITA-T.

Methods: Our sample comprised 100 children aged between 18 and 36 months referred to a diagnostic clinic for an assessment of ASD or global developmental delay (GDD). The M-CHAT, the RITA-T and the Autism Diagnostic Observation Scale, Second Edition (ADOS-2) were administered as part of the diagnostic evaluation process. Descriptive and statistic analyses were performed (e.g. means, standard deviation, min/max, correlations).

Results: The data collected indicate that the RITA-T is able to discriminate children with ASD from children without characteristics associated with this developmental disorder. In addition, this tool correlates positively with the (ADOS-2).

Conclusions: Based on the results of this study and previous studies, the RITA-T could help optimize a service pathway by identifying children with ASD symptoms earlier.

Background:

Recognition of autistic doctors is a recent phenomenon. Little research exists on their experience in the medical profession. This study aims to fill that gap.

Objectives:

Describe the professional experiences of autistic doctors, identify key areas of need, and highlight priorities in research.

Methods:

A cross-sectional survey, adapted from an autistic school staff survey, was delivered via Facebook and WhatsApp to an online, invite-only group of over 550 autistic doctors. Participants provided quantitative and qualitative data on topics including disclosure, mental health, career outcomes, and beliefs about autism.

Results:

We received 225 responses from autistic doctors. See Table 1 for demographics. 64% had a formal diagnosis of autism, with 6% diagnosed in childhood. The mean age of formal diagnosis was 36 (range 3 – 61, median 36.5).

Most respondents were currently working as doctors (82%). Most common specialties were general practice / family medicine (31%), followed by psychiatry (18%) and anaesthesiology (11%). Some previously worked as doctors but were not currently practising (14%) or never worked as doctors (4%). Almost half of those working had completed specialty training (46%), 40% were current trainees. Of those with a childhood diagnosis, seven were currently working as doctors with one yet to start.

Of the 80% who responded, 73% agreed that that “being autistic helps me in my work as a doctor” while only 10% disagreed. However, 62% reported that being autistic was also a disadvantage in the workplace. Advantages cited included attention to detail, increased empathy and connection with patients, diligence, and pattern recognition.

80% reported having worked with another doctor they suspected was autistic, but only 22% had a colleague they knew was autistic. Having never worked with another potentially autistic doctor was significantly associated with having considered suicide. Most preferred “autistic doctors” (64%) rather than “doctor with autism” (18%) or “doctor on the autistic spectrum” (28%). Most considered autism as a difference (83%); a majority also considered it a disability (52%) or an identity (54%). Just 13% considered autism a disorder, but of those who did, twice as many had attempted suicide (p=0.019, 43% vs 21%). Considering autism a disorder was significantly associated with preference for the term “doctors with autism” (P<0.001).

Half had engaged in self-harm (49%), 77% had considered suicide, and 24% had attempted suicide. Only 6 respondents were openly autistic in all workplace settings and 29% had not disclosed to anyone at work. 46% had requested adjustments in the workplace. Changes sought included more manageable workloads, ability to be open about being autistic, changes to the work environment, and flexibility from
empowers. Of those who asked for adjustments, only 49% had them implemented. Negative mental health outcomes were associated with requesting adjustments and particularly with requesting and not receiving those adjustments.

Conclusions:

Many autistic doctors are thriving in medicine and bring important strengths. However, our results suggest they experience significant workplace barriers which may lead to negative employment and mental health outcomes. Research and practice changes are required to facilitate equitable access for autistic healthcare providers.

**426.384 (Poster)** The Impact of the COVID-19 Pandemic on Mental Health and Coping of Parents Raising a Child with Autism Spectrum Disorder

Background: The COVID-19 pandemic abruptly disrupted family life. Families were impacted by unemployment, and loss of childcare supports, in-person social interactions, and educational/clinical services. Several studies have reported pronounced mental health impacts on parents raising a child with a disability, including those who have a child with autism spectrum disorder (ASD). Few, if any, studies have evaluated differences in parental coping strategies between neurodevelopmental groups (i.e., ASD and other developmental disabilities (DDs)) and the role these strategies play in improving parental mental health during the pandemic.

Objectives: The objectives of this study were to: 1) evaluate the differences in parental mental health across three child disability status groups (ASD, DD), and population controls (POP); 2) evaluate differences in parental engagement in coping strategies during the pandemic across the three child disability status groups; and 3) examine the relationship between engagement in parental coping strategies and parental mental health.

Methods: Data were gathered from the Study to Explore Early Development, a large multi-site U.S. case-control study of ASD and other DDs in young children. In the summer of 2020, data from a custom online survey were collected from participants measuring: a) parental mental health (comprised of 4 items from standardized questionnaires: depression, anxiety, loneliness, and trauma-related symptoms); and b) parental coping skills (a checklist of 9 activities, such as meditation and spending time outdoors) that were practiced in response to perceived stress during COVID-19. Bivariate (ANOVA, Chi-Square) and linear regression models were employed in the analyses. Tukey’s Honestly Significant Difference Test was used for post-hoc comparisons.

Results: A total of N = 1019 parents, 98% of which were biological mothers, of children in the ASD (n = 269), DD (n = 366), and POP (n = 384) groups were included in this study. There were significant differences in mental health among the three groups (F = 7.29, p < .001), with parents of children in the POP group (m = 22.94, sd = 7.69) having significantly better mental health (higher scores are worse) than parents of children in the ASD (m = 25.35, sd = 8.67) and DD (m = 24.35, sd = 8.15) groups. There were also significant differences in parental coping between the three groups (F = 18.53, p < .001), with parents of ASD children (m = 4.08, sd = 1.90) engaging in significantly fewer coping strategies than those in the DD (m = 4.87, sd = 1.86) and POP (m = 4.86, sd = 1.77) groups. However, parental coping was not associated with parental mental health (t = 1.01, p = 0.32).

Conclusions: Our findings show parents of children with a neurodevelopmental disability experienced worse mental health than those raising a child without a neurodevelopmental disability during the COVID-19 pandemic. While coping skills were lower among the ASD group, it was not associated with parental mental health. Further research is needed to understand the best strategies to improve the well-being of parents of children with ASD, and those with other DD, in the current and future pandemics.

**426.385 (Poster)** The Pediatric Care Network Autism Program at Children’s Hospital Colorado: Educating and Supporting Primary Care Providers to Expedite Identification and Care of Autistic Youth

E. M. Coan, R. E. Boles, L. Hayutin, C. Middleton, S. Mattie, R. Wilson, J. Thomas and D. Swain, (1) Pediatrics, Children’s Hospital Colorado, Aurora, CO, (2) University of Colorado - Anschutz Medical Campus, Aurora, CO, (3) University of Colorado Anschutz Medical Campus, Aurora, CO, (4) Children’s Hospital Colorado, Aurora, CO, (5) Developmental Pediatrics, University of Colorado Childrens Hospital Colorado, Aurora, CO, (6) Psychiatry, Weill Cornell Medicine, New York Presbyterian Hospital, White Plains, NY

Background: Families seeking specialist evaluations for autism spectrum disorder (ASD) face long delays. There is an increasing need for medical and mental health professionals to accurately assess and support families with ASD concerns (Hyman et al., 2020). Primary care
providers (PCPs) are often the first line of referral for children with developmental delays but have reported inadequate training and lack of confidence related to diagnosing ASD and supporting their healthcare needs (Self et al. 2015). Although programs have been developed to increase PCP knowledge and confidence in ASD diagnosis (Mazurek et al., 2019), few training initiatives exist within the state of Colorado. The Children’s Hospital Colorado’s Pediatric Care Network (PCN) Autism Program was developed to address this need, partnering with community PCPs to coordinate physician trainings and ultimately create an expedited assessment model, which leverages telehealth and consultation practices, to better serve families efficiently and comprehensively.

Objectives: This pilot feasibility study (1) assessed PCP satisfaction and changes in knowledge, confidence and practice post training; and (2) explored preliminary outcomes of patients seen through an expedited telehealth consultation clinic.

Methods: 163 PCPs across 19 practices and 16 counties completed the 4-hour PCN Autism Program training provided by clinical psychologists. Post-training surveys were administered to assess provider knowledge, confidence, satisfaction and practice changes. Paired samples t-tests analyzed retrospective review of pre- and post-training changes. In phase 1, PCPs were trained to conduct ASD-specific developmental histories that accompanied their referral to an expedited list for comprehensive assessment with the clinical psychologist. In phase 2, a telehealth consultation model was introduced that used the PCP’s developmental history to identify patients who might require fewer face-to-face hours for an evaluation. Patients seen in Phases 1 and 2 (n=188 and 16, respectively) ranged in age from 2 to 20 years. Chi-square analyses were used to compare patient characteristics across groups requiring more vs. less face-to-face contact hours.

Results: A subset of PCPs (n=43; 33%) completed post-training surveys. PCPs reported increased confidence and knowledge regarding ASD identification and care, as well as high rates of acceptability and satisfaction with the educational materials (see Figure 1). Significant increases were seen in frequency of PCP’s concern for ASD (t[38]=-3.38, p=.002) and frequency of consultations with hospital specialists (t[38]=3.16, p=.003). In phase 2, the average face-to-face time with families was 5.2 hours (SD=2.1), compared to the 8-hour standard in the comprehensive evaluation model. Those requiring 4 or fewer hours of direct contact (n=7, 43.8%) were more likely to have a sibling with ASD (X2(1,16)=3.88, p=.049) and carry a provisional or educational diagnosis from a community provider (X2(1,16)=8.9, p=.003). PCP identification of suspected diagnosis (n=12) was confirmed in 100% of the cases seen by the clinical psychologist.

Conclusions: The PCN Autism Program is an innovative approach for improving the knowledge and confidence of PCPs in supporting families of autistic youth. Our pilot consultation model also suggests that information provided by the PCP may help predict which patients need fewer hours with specialists, resulting in increased efficiency for both specialists and patients.

426.386 (Poster) The Perspective of Autism Spectrum Disorders Caregivers about COVID-19 Lockdown: Repercussions in the Brazilian Population

Background:

The COVID-19 lockdown has posed new challenges for individuals with autism spectrum disorder (ASD), including school and services suspension, besides reductions in support with different consequences around the world.

Objectives:

To explore the caregivers’ perspectives on the repercussions of the COVID-19 lockdown on people with ASD in different age groups in Brazil, and to investigate the association between services suspension and changes in ASD behaviors.

Methods:

This cross-sectional exploratory study is part of a multicenter project undertaken by the eighth Latin American countries represented in the REAL collaboration. A convenience sample of 158 caregivers of people with ASD completed the survey in Brazil between June and August 2020. The survey comprises nine sections concerning: general data on the person with ASD; educational attainment before and during the pandemic; home situation during the pandemic; treatments and support at the start of the pandemic; behavioral changes due to sheltering-in-place; going out behaviors; treatment and support during the pandemic and; main concerns during lockdown. Data analysis included central tendency and frequency calculations and inter-group comparisons were made using chi-square tests.
Results:

The ASD sample was comprised of 81% (n = 128) males and divided into three age groups: 1) Early Childhood (n = 47, age 6 years or younger); 2) School-age (n = 97, ages 7 to 18 years) and 3) Adults (n = 13, age >= 19 years). Considering the total sample, 80.3% of the subjects reported that only left the house for essential errands or work; 14% had the school activities suspended and from those who continued with school activities, 62.5% accepted partially or without problems the educational changes. Most caregivers reported “a major” or “some” regression in problems with sleep (63.1%), attention (61.2%), food intake (61.8%), irritability (76.4%) and anxiety (74.5%). When comparing between age groups, the school-age group refused to attend school online more than the rest of ages ($X^2 = 16.4, p = 0.03$). Likewise, the school-age group presented the greatest regression in depressive symptoms ($X^2 = 16.4, p = 0.03$) and attention ($X^2 = 17.7, p = 0.02$). Services suspension occurred for 60.5% of the individuals. Fisher tests associated the increase of attention deficits ($p = 0.04$) as a function of the suspension of services received by people with ASD; no significant increase in internalizing or externalizing symptoms were found in this association.

Conclusions:

Service suspension in Brazil had a negative impact on different domains of the development of children with ASD, including their mental health. The school-age children seem to be the ones who bear the most consequences regarding depressive symptoms and inattention.

426.387  (Poster) The Role of Lived Experience: Autism Identification Among Children with Autistic Older Siblings

G. Liu, L. Kong, E. H. Dennis and M. J. Murray, (1)Public Health Sciences, Penn State University College of Medicine, Hershey, PA, (2)Department of Psychiatry/Division of Autism Services, Penn State University College of Medicine, Hershey, PA

Background: Autism Spectrum Disorder (ASD) is highly inheritable. About 10% of younger siblings of those with Autism are likely to have ASD as well. However, little known is about the age of initial ASD identification among children with autistic older siblings.

Objectives: This study used a large, national healthcare claims database of a privately insured population in the US to investigate the age at initial identification of ASD among children with autistic older siblings as compared to those without autistic older siblings.

Methods: Using the 2005-2020 MarketScan® database, we identified children with ASD based on the diagnose codes, ICD-9: 299.xx and ICD-10: F84.xx. Children who enrolled in the database within one year after birth and had initial diagnosis of ASD before age 8 were included in the study. We defined siblings as those in the same family with £10 years difference in age. Our study cohort was divided into three mutually exclusive groups: ASD children with (1) at least one autistic older sibling; (2) no autistic older sibling(s); (3) no older sibling(s). The age at initial identification of ASD was compared among these three groups, in conjunction with gender, geographic region (by US census region and state), residency (urban vs. rural), type of insurance (HMO, PPO, other types), and year of birth. Descriptive analyses and multivariable regressions were performed to examine the impact of having autistic older sibling(s) on age at initial identification of ASD, among other potential risk factors/confounders.

Results: Our study cohort consisted of 66,726 unique individuals with ASD (Table 1), with 78.3% males and an average length of enrollment in the database of 6.4 (sd: 3.7) years. Among them, 3,615 (5.4%) had an older autistic sibling; 29,514 (38.8%) had no older autistic sibling(s); and 37,197 (55.8%) had no older siblings. Autistic children with older autistic siblings were on average diagnosed at younger ages (mean: 36.8 months, std: 17.0, median: 33), compared to those with only non-autistic older siblings (52.4, 31.9; 42), and those with no older siblings (49.9, 29.5, 41). This pattern was consistent geographically across the US (Figure 1), but there were significant variations among the states. Multivariable regression, having adjusted for gender, year of birth, census region, type of insurance and urban vs. rural residency, showed that, autistic children with autistic older siblings were identified 10.8 months earlier than children with only non-autistic older siblings; and 9.7 months earlier than children with no older siblings (p-values<0.0001). In addition, being male, born in later years, having a PPO plan, and living in urban areas were associated with earlier diagnosis of autism.

Conclusions: Our results show that autistic children with older autistic siblings were identified at an earlier age nationally, but large regional variations were noted. Future studies are warranted to examine the multi-level factors attributed for these differences including potential enhanced family and/or primary care provider sensitivity to development differences.

426.388  (Poster) Title: Teachers’ Perception of Autistic Students: Associations with the Quality of Student-Teacher Relationships and Students’ Socio-Emotional Adjustment

K. Joseph, L. Andoni, L. P. Thammathorn, S. Yang, J. Blacher and A. Eisenhower, (1)Department of Psychology, University of Massachusetts Boston, Boston, MA, (2)Department of Psychology, University of Massachusetts, Boston, Boston, MA, (3)School of Education, University of California, Riverside, Riverside, CA
Background: Autistic adolescents and adults reflecting on their early school experiences have noted that teachers often viewed them from a deficit-based rather than a strengths-based lens (Cohen et al., 2022). The way teachers view students may impact the quality of student-teacher relationships (STRs), which influences students’ emotional and behavioral outcomes (Murray & Zvoch, 2011).

Objectives: To examine teachers’ perceptions of their autistic students (positive, negative, neutral) based on their open-ended descriptions of these students. Further, to examine associations between these perceptions and teachers’ ratings of the quality of their STR and the students’ adjustment.

Methods: This pilot study includes 26 K-2 general education teachers (88.5% female; 53.8% White; 84.0% with Master’s degree; 88.0% without professional training in autism) with at least one autistic student in their classroom. To assess teachers’ perceptions, we coded written responses to the following question: “...take a moment to think about your autistic student...add a few words or word phrases that describe your student...” Responses were coded as positive (e.g., “lovable”), negative or focused on difficulties (e.g., “difficult peer interactions”), or neutral (e.g., “hyper focused on his interests”). The proportion of positive, neutral, or negative descriptions was calculated as well as the ratio of positive to negative descriptions. Teachers rated their students’ socio-emotional adjustment using the Social, Academic, and Emotional Behavior Risk Screener (SAEBRS) and completed the Student Teacher Relationship Scale (STRS) as a measure of their perception of their STR. We examined associations between teachers’ open-ended descriptions and quantitative ratings of STR quality and student socio-emotional adjustment.

Results: Teachers made more negative (M=3.27) than positive (M=2.12) or neutral (M=0.58) descriptions. A greater proportion of positive perceptions was associated with higher STR quality ($r=.47$, $p<.05$) while a greater proportion of negative perceptions was associated with lower STR quality ($r=.57$, $p<.01$). Similarly, a greater ratio of positive to negative perceptions was associated with greater STR quality ($r=.48$, $p<.05$) and teachers with more positive perceptions of their autistic students showed lower student-teacher conflict ($r=-.48$, $p<.05$) and teachers with more negative perceptions showed greater student-teacher conflict ($r=.58$, $p<.01$). The number of neutral perceptions was not associated with STR quality. In regards to students’ socio-emotional adjustment, we found that greater proportion of positive perceptions was associated with better adjustment ($r=.42$, $p<.05$) while greater negative perceptions was associated with lower adjustment ($r=-.54$, $p<.01$).

Conclusions: Our analysis showed that teachers held slightly more negative than positive perceptions of their autistic students. Further, we found that the way teachers view their autistic students may relate to the quality of relationships they form and is associated with students’ socio-emotional adjustment. These perceptions of autistic students may relate to teachers’ attitudes about autism in general, thus underscoring the importance of helping teachers develop affirming attitudes toward autism. Our findings are limited by a reliance on teacher report for STR quality and student socio-emotional adjustment; future research should include observation or child-report measures.

426.389 (Poster) Trained Primary Care Providers Can Diagnose Clear Autism in Toddlers after Screening

Background: With the shortage of autism specialists, it is important to build diagnostic capacity among non-specialist providers when possible. Building capacity specifically for primary care diagnosis in toddlers builds upon the momentum of both early universal autism screening and the common primary care practice of referring families for early intervention. If done effectively, it can reduce the age of diagnosis for this subset of children, support earlier intervention, and reduce the number of families waiting for a specialist diagnostic evaluation.

Objectives: To measure diagnostic outcomes and patient and provider satisfaction after an autism diagnostic evaluation by a primary care provider trained in early autism diagnosis (a PCP Champion).

Methods: Four primary care providers (PCP Champions) in two city primary care practices were trained in identification and documentation of autism using the Screening Tool for Autism in Toddlers and Young Children (STAT) and the Childhood Autism Rating Scale-2 (CARS2). Clinicians within the PCP Champions’ practices referred children who scored 7 or greater (high-likelihood) on the Modified Checklist for Autism in Toddlers (M-CHAT) for a 45-60-minute evaluation with a PCP Champion, followed by a 30-minute feedback session one week later. Children with clear features of autism and who met full diagnostic criteria were given a diagnosis and referred to community-based interventions. Children who did not clearly meet criteria for autism were referred to the Developmental and Behavioral Pediatrics (DBP) specialty program for a specialist evaluation. PCP Champions met twice monthly with autism diagnostic specialists to discuss complex cases, documentation, billing, and community resources.

Variables studied include rate of autism diagnosis, rate of referral for specialist evaluation, average age of diagnosis, connection to autism intervention services, and patient/provider satisfaction.

Results: To date, over our 6-month service, PCP Champions diagnosed 57 of 75 children with autism (76%). Eighteen children (24%) were referred to DBP for further evaluation; 3 received autism diagnoses with DBP and 15 are pending evaluation. The average age at evaluation
was 27.52 months (n=75, 17-41 months). So far, 39 primary clinicians have referred children for this service. The service is ongoing and updated results will be presented, including satisfaction survey results from the parents, referring providers, and PCP Champions.

Conclusions: With an investment in training four providers on the STAT, CARS2, and consultation hours twice per month, PCP Champions have served as a very early diagnostic resource for 39 primary care clinicians over a 6-month period and were able to diagnose approximately ¼ of patients who scored as high-lielihood on the M-CHAT. This has resulted in a timely diagnosis for these children with clear autism and provides a benchmark for the amount of capacity building needed to serve the subset of children with high likelihood scores at screening. It represents one small step in expanding capacity to meet the diagnostic needs of autistic individuals at different points across the lifespan.

426.390 (Poster) Training for University Staff Who Work with Autistic Students

E. Jenks and F. Sedgewick, University of Bristol, Bristol, United Kingdom

Background: Autistic students currently make up ~2.4% of the UK university student population. These students are particularly vulnerable to stressors within a university environment and are more likely to experience poor mental health than their non-autistic peers. Despite this, there is a lack of tailored support for autistic students at university.

Objectives: The current project assesses a training course, co-created with autistic students, staff, and relevant experts, for university staff who work directly with autistic students (e.g. personal tutors, disability support staff, careers advisors). The programme focused on debunking stereotypes, educating about the autistic experience at university, and highlighting the differences in mental health presentation between autistic and non-autistic individuals. It also aimed to provide practical strategies and tips for these staff members to help make interactions with autistic students as accessible and beneficial as possible. The full course was conducted online over the course of five weeks (1-2 hours per week), with a shorter, half-day session (3 hours) provided for staff who could not attend the longer version. In total, 74 staff from three UK universities completed the training (42 full course, 32 half day).

Methods: The Autism Stigma and Knowledge Questionnaire (ASK-Q; Harrison et al., 2017) was administered before and after the training, to examine changes in trainees’ understanding and acceptance of autism and autistic people. Post-training interviews and surveys were also conducted with trainees, covering the impact the training has had on their perceptions of autism, the strategies they found beneficial, and how they will use the materials in future.

Results: There were no statistically significant differences between pre- and post-training scores on the ASK-Q, likely due to ceiling effects as pre-training scores were high for both courses. Thematic analysis of the participant interviews identified four themes: developing nuanced, in-depth knowledge of autism; feasibility and acceptability of the training; implications for practice; and the benefit of hearing autistic voices.

Conclusions: Although ceiling effects meant there were no changes to participant’s knowledge about autism and autistic people statistically, the qualitative data reveals the extensive benefits they gained from taking part in the training programmes. Scoring highly on the ASK-Q did not mean that people could not learn important new information and profit from the course. This more nuanced understanding of autism, and especially the links to and impact on student mental health, led to practical changes in their approach going forwards. Listening to and learning from autistic people was seen as particularly important, highlighting the value of co-production in this realm. Our results also highlight the need for alternative assessment measures for evaluating training effectiveness, as reliance on the quantitative results alone would have missed the subtler, but impactful, changes our participants experienced in the perspectives and practice. This has important implications for professional practice in a variety of contexts, both within higher education and more broadly.

426.391 (Poster) Understanding Information Sharing and Parent Experiences of Latinx Families to Accessing ASD Care within a Family Navigation Model

A. Lavanderos, A. Miceli, A. S. Weitlauf, N. Harris, E. Rogers, M. West, F. V. Alzhyri and Z. Warren, (1)Vanderbilt University Medical Center - TRIAD, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (5)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN

Background: Children with autism from ethnically and linguistically diverse backgrounds face numerous barriers to accessing care, particularly Latinx families (Coffield et al., 2021; Zuckerman et al., 2018). In 2019, our team established a statewide Family Navigation Network to connect underserved families to community resources and services. To better understand family utilization of our navigation model and barriers to care encountered after diagnosis, we examined contact notes for 243 Latinx caregivers of children with or at risk of ASD.

Objectives: We qualitatively coded contact notes from care navigation phone calls after clinic appointments for 243 Latinx caregivers of children with diagnosed or suspected autism in order to better understand unique caregiver needs, experiences, and service support surrounding autism diagnosis.
Methods: Families were referred for navigation by a primary care provider or state early intervention provider. Participants included 102 English-speaking and 141 Spanish-speaking Latinx caregivers (94.7% female) of children aged 15 months to 7 years (27.6% female). Navigators contacted families before and after diagnosis to offer resources and listen to caregiver concerns. Contact notes were logged in a REDCap database and input into Dedoose, a qualitative data coding program. Notes were coded through an iterative, ongoing process that yielded three broad content domains: Parent Needs, Parent Experiences, and Service Access. Although the Parent Needs domain included resources that Navigators shared with families, the latter two categories comprised information spontaneously shared by caregivers with navigators during calls.

Results: Mean age at point of referral was 33.6 months (sd: 18.9 months). Families lived in 30 different Tennessee counties, 14 of which are medically underserved areas (46.7%), 11 of which have medically underserved populations (36.7%), and 16 of which are rural (53.3%). Navigators shared information about at least one resource with 73.3% of families. The resources shared most often were handouts on commonly requested topics such as toilet training (28.4%), online educational videos (24.7%), caregiver training workshops (24.7%), school services (22.7%), and a partnering statewide disability support agency (21.4%). As navigators shared resource information, families in turn shared about their experiences. Almost half of caregivers (46%) shared their own questions, feelings, and experiences with the navigation team; 18.1% expressed anxiety, 15.2% expressed knowledge or lack thereof of autism, and 9.9% expressed confusion. Almost half (42.4%) of families reported at least one barrier to care, such as language (8.6%), economic difficulties (8.2%), and technology (7.8%) (Table 1).

Conclusions: Qualitative analysis of contact notes with Latinx families provided insight into caregiver needs and experiences before and after receiving an autism diagnosis for their children. Navigators shared resources with nearly three quarters of families. Families also shared information about their lived experiences with navigators, highlighting the reciprocal relationship of family navigation. Future research should continue to investigate how navigation models can support Latinx families.

426.392 (Poster) Understanding Practice Gaps Among Pediatric Providers for Autism Spectrum Disorder

Background:
Autism spectrum disorder (ASD) is a neurodevelopmental disability that is characterized by persistent deficits in social communication and the presence of repetitive and restricted behaviors. The need for early diagnosis of ASD is critical, as early intervention has been associated with reduced impairments in intellectual, behavioral, and functional abilities. Yet several challenges continue to be associated with early diagnosis, including a lack of parental awareness of symptoms, patient race and household income, and low confidence among clinicians in recognizing ASD due to the heterogeneity of symptoms.[Bishop-Fitzpatrick 2017; Durkin 2017; Zwaigenbaum 2015] Several effective interventions are also available for patients with ASD, and have been associated with improved long-term outcomes.[Hyman 2020] Despite this, pediatricians and other primary care providers have shown low levels of confidence in providing care for children with ASD.[Carbone 2013]

Objectives:
Therefore, understanding clinical practice gaps for clinicians related to the diagnosis and management of ASD can inform the development of education and tools to improve clinician knowledge, competence, and clinical practices.

Methods:
A survey instrument containing 30 multiple choice, knowledge and case-based questions was used to assess participants’ knowledge, attitudes, and confidence in the management of ASD. The survey was available online to US physicians without monetary compensation or charge. Respondent confidentiality was maintained, and the responses were de-identified and aggregated prior to analyses. Data were collected from September 10, 2021 to October 28, 2021.

Results:
In total, 187 general pediatricians, 149 child and adolescent psychiatrists, and 50 neurodevelopmental pediatricians completed all assessment questions. The results demonstrated gaps in the following areas:

Correct Response (%)

Results:
In total, 187 general pediatricians, 149 child and adolescent psychiatrists, and 50 neurodevelopmental pediatricians completed all assessment questions. The results demonstrated gaps in the following areas:

Correct Response (%)
Background: The current crisis in access to autism specialists has amplified existing health equity issues in autism care, resulting in even longer delays in diagnosis and connection to treatment for children coming from under-resourced communities (Kanne & Bishop, 2021; Yingling & Bell, 2019). This has heightened the focus on accessible providers, such as pediatricians and generalists in behavioral health, to manage autism care needs. Yet, these providers report that lack of autism-related knowledge impacts their confidence and willingness to care for children with autism-related concerns (Fenikile et al., 2010). As such, understanding healthcare provider needs and barriers associated with providing competent autism care is critical to improving equitable access to services. To date, insights into provider needs has been largely based on survey data. Our project aimed to extend this literature through analysis of the utilization of our ECHO Autism program at Children’s National, which has been successful in engaging over 400 community providers from primary care, medical and behavioral health disciplines, and early care/educational settings in the DC metro area since 2020.

Objectives: To characterize the needs of providers seeking autism training and supports through analysis of de-identified case-based presentation data obtained through ECHO Autism clinics.

Methods: ECHO Autism programs offer an innovative approach to improving equitable access to healthcare services for autistic individuals and their families by enhancing capacity in the existing medical and behavioral healthcare workforce (Mazurek et al., 2017). Consistent with the ECHO Autism model, we used Zoom to hold virtual “clinics” to provide mentorship and a shared learning forum among a multidisciplinary “hub” of autism specialists and community providers (“spokes”). Clinics ran in 6-month sessions on a bimonthly basis and consisted of case presentations with discussion, and autism-specific didactics. No-cost continuing education credits were provided for attendees and incentive pay was offered for participation in research surveys.

Study data collected included case presentation characteristics such as consult reasons, insurance status, and outcome recommendations. To characterize provider needs, referral reasons were categorized into 13 classifications (See Table 1) and independently coded by two raters with strong inter-rater reliability (87% agreement).

Results: Preliminary results based on de-identified case presentation data from 67 participants indicated utilization of our ECHO program was primarily driven by support needs specific to diagnostic clarification of autism and treatment plan development (see Table 1). Available demographic information indicated at least 68% of cases involved public insurance. Additionally, community providers were offered an average of 6.8 recommendations per case, representing needs from multiple disciplines (e.g., psychology, speech-language pathology, social work, psychiatry, genetics).

Conclusions: This dataset offers an ecologically valid analysis of provider needs and barriers to managing autism concerns without referral to specialty settings, extending the literature which has been largely based on self-report survey data. Our data specifies primary support needs in autism related to identification/diagnostic clarification and outlining next steps for families. Additionally, our outcome recommendation data highlights the complexities of needs in autism and critical role of multidisciplinary frameworks in autism, particularly for providers not practicing in multidisciplinary settings.
Background: Families of young children with autism spectrum disorder (ASD) experience barriers to accessing diagnostic evaluations and evidence-based early intervention services, especially those in under-resourced communities. Many families rely on their state’s Part C early intervention system for these services, but there is variability in service providers’ knowledge and experience with screening and assessment tools for ASD, use of evidence-based intervention strategies, and access to ASD-specific professional development tools and resources. The application of telemedicine to Part C service delivery increases access to services for families and offers a unique opportunity for Part C service providers to participate in diagnostic evaluations, specialty intervention services, and virtual learning opportunities to enhance their knowledge of both evaluation and intervention approaches.

Objectives: We will present outcome data from the development and expansion of a telemedicine service delivery model targeting increased access to early identification and intervention services in under-resourced communities. Key components of this model include a community of practice (COP) for Part C early intervention providers and a telediagnostic evaluation process mediated by the family’s developmental therapist (DT). This project builds on a model that already has served over 1000 families through both traditional and telemedicine models of service delivery since 2014. This expansion focuses on feasibility and acceptability of (1) the DT-mediated telediagnostic consultation and (2) use of COPs to promote knowledge and utilization of evidence-based screening and intervention strategies.

Methods: Participants included 92 Part C providers (across 17 agencies) and 97 families of children <36 months of age showing early indicators of ASD. Providers participated in a one-time training focused on the TELE-ASD-PEDS (TAP), a play-based telehealth evaluation tool. Providers then participated in ongoing monthly COPs focused on evidence-based practices for supporting caregivers. Providers referred children for telediagnostic evaluation and helped facilitate the telediagnostic evaluations by collecting medical/developmental background, actively participating in the telediagnostic evaluation, and providing support to caregivers following the evaluation. We assessed caregiver and provider satisfaction with the telediagnostic model as well as provider satisfaction with COPs.

Results: Caregivers (N=97) were satisfied with the telediagnostic evaluation process (0=strongly disagree,5=strongly agree; mean = 4.59) as were providers (N=92, mean = 4.89). Most providers reported they would recommend the model to other families (93% “strongly agree”). Results also showed that caregivers were satisfied with DT involvement (see Table 1) with providers reporting positive service-related outcomes (see Table 2). After participating in COPs, 92% of providers reported “good” or “excellent” knowledge of ASD to share with others.

Conclusions: These results offer several potential benefits to engaging Part C service providers in both COPs and telediagnostic visits with families. This includes increasing providers’ knowledge of the characteristics of ASD, comfort in talking to families about ASD, and knowledge of evidence-based intervention strategies. Other benefits include increasing caregivers’ comfort with the evaluation process and access to support following the evaluation. Ongoing data collection and analysis will allow for further evaluation of these models to address sustainability and further expansion.

Background: Public health restrictions related to the COVID-19 pandemic challenged clinical programs to find alternatives to usual practices. For extended periods, in-person assessments were not possible, and thus other strategies were needed to maintain access to autism diagnosis. The TELE-ASD-PEDS, developed by Warren and colleagues provided proof of principle that observing a child’s interactions with their caregiver within their home environment could inform ASD diagnoses (Corona et al., 2020). Because the TELE-ASD-PEDS was designed to assess children younger than 36 months, our group developed the Autism Assessment for Preschoolers with Language Element Sequence (AAPLES) to further inform assessment of older preschool children, including those with more advanced language skills. Open access resources for family members administering assessment activities in the home, and the clinician directing the assessment virtually are available online (bit.ly/AAPLES). The AAPLES was introduced at a regional diagnostic assessment program in Alberta, Canada in January 2021.
Objectives:
To evaluate the feasibility of clinical assessment that included the AAPLES, including parents’ and clinicians’ confidence in the diagnostic process.

Methods:
Participants included 10 clinicians (developmental pediatricians and psychologists) and parents of the initial 68 children (aged 39-73 months; male: 73.5%; White ethnicity: 36.8%) who were assessed using the AAPLES, as well as a developmental and medical history. Clinicians rated their confidence in their diagnostic impression (ratings of DSM-5 criteria for ASD, informed by the child’s social-communication, play and other behavioral features observed during the AAPLES) on a 4-point Likert scale (from Completely Uncertain to Completely Certain). Parents also rated their confidence on a 4-point Likert scale (from Not Confident to Very Confident) in the diagnostic process and completed a questionnaire about the assessment experience. Exploratory analysis of factors influencing parent confidence were explored by correlations with family demographics and parents’ questionnaire responses, using Pearson’s rho for non-parametric data.

Results:
Of the 68 children who were assessed, 48 (70.6%) were diagnosed with ASD and 6 (8.9%) were felt not to have ASD. For 14 (20.6%) the clinician was uncertain. Overall, 48 of 59 parents (81.4%) were confident or very confident in the assessment findings, whether or not child diagnosed with ASD. Parental confidence level was not related to diagnosis ($X^2(9) = 2.37, p = .99$), nor ethnicity ($X^2(24) = 23.33, p = .50$), or household income ($X^2(30) = 37.53, p = .16$). Parental confidence level was positively related to self-report on being respected as experts and how the AAPLES activities allowed their child to show their skills, based on correlations with questionnaire items.

Conclusions:
Virtual assessments that included the AAPLES supported clinicians to confidently determine whether or not diagnostic criteria for ASD were met in about 80% of this sample of clinically referred children. Parents’ expressed high levels of confidence in the process. Although further evaluation of agreement with in-person assessment is needed, virtual assessment appears to be a viable option to support preschool ASD diagnosis.

426.396 (Poster) What Autistic Adults Want from Post-Diagnostic Support
M. Freeth, S. Crowson and D. Poole, (1)Psychology Department, The University of Sheffield, Sheffield, United Kingdom, (2)Psychology, University of Sheffield, Sheffield, United Kingdom, (3)University of Sheffield, Sheffield, United Kingdom

Background:
Knowledge and understanding of how autistic adults are best supported following an autism diagnosis in adulthood is poor and the post-diagnostic support available varies greatly. There is widespread recognition that post-diagnostic support for autistic adults requires improvement but there is a lack of consensus on what exactly this should involve. Traditionally, post-diagnostic support services have been designed and commissioned by non-autistic professionals. This risks services not meeting the needs of the individuals they are trying to serve. Considering the perspectives of autistic adults, and establishing whether there is consensus on what post-diagnostic support should involve, is therefore essential to designing optimal post-diagnostic support services.

Objectives:
To identify what autistic adults in the UK think post-diagnostic support should involve. The aim of this study was to provide a bank of consensus priorities, ranked in order of agreement, that can inform future service design.

Methods:
Initial statements were co-produced via a workshop involving 10 autistic adults diagnosed in the UK within the last 10 years. These statements were then presented to a larger cohort of autistic adults and modified further via a series of online questionnaires in a three-round modified Delphi study.

Forty autistic adults completed all three rounds of the modified Delphi study (21 Female; 11 Male; 5 Non-binary; 1 Gender non-conforming; 1 Questioning*, 1 Prefer not to say). The ethnicity of the participants was 0 Black; 1 Asian; 32 White; 4 Mixed-heritage; 1 Arab*, 2 Prefer not to say. Sixteen identified as LGBTQ+, 20 identified as non-LGBTQ+, 4 Preferred not to say. *Categories added by participants.
In each questionnaire round autistic adults were asked what post-diagnostic support should involve. Delphi allows for an understanding of which views are consistently held by community members. Final questionnaire items were organised into six topics: (1) delivery of support; (2) emotional and psychological support; (3) person-centred support; (4) supporting relationships; (5) practical support; and (6) support understanding autism.

Results:

One hundred and fifty-three priorities were identified and, of these, 30 reached or exceeded the consensus threshold of >80% of respondents being in agreement or strong agreement that the item describes an important element of post-diagnostic support. The top items were: Access to professionals with specialist up-to-date training on autism; Help with self-empowerment; Includes support to process the impact of a late diagnosis; Help with autistic fatigue; Access to mental health professionals with specialist knowledge of autism; My support plan would take into account my coexisting conditions (if appropriate); Support takes into account my communication and contact preferences; The option to access support immediately post-diagnosis.

Conclusions:

This study provides consensus-driven guidance on key priorities for post-diagnostic support for autistic adults. It is clear that a holistic approach involving knowledgeable professionals who can help individuals to process the meaning of their diagnosis and enhance self-empowerment would be valued. Broadening a traditional understanding of experts within Delphi studies beyond those with clinical expertise to include those with lived experience is a step towards delivering inclusion in autism research and provides an important evidence-base for service design.

426.397 (Poster) What Factors Help or Hinder Autistic Adults’ Experiences with Therapies and Health Services?: A Qualitative Study

C. L. McIntyre, T. Q. Boucher, V. Ly, N. E. Scheerer, P. Hood, H. Aime and G. Iarocci, (1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Wilfrid Laurier University, Waterloo, ON, Canada

Background: Autistic people experience mental health problems at significantly higher rates than the general population (Lai et al., 2019). They also face barriers accessing needed therapies/services to support their mental and physical health (Adams & Young, 2020). Those that do access therapies/services report that they fail to meet their needs (Nicolaidis et al., 2013). Considering the high rates of mental health problems, accessible therapies/services that meet autistic people’s needs are essential. There is some knowledge about autistic adults’ experiences with therapies/services, yet less is known about their subjective experiences with accessing these services.

Objectives: This study aimed to analyze autistic adults’ experiences with therapies/health services as reported by autistic people themselves.

Methods: Participants were 53 autistic adults between the ages of 18 and 67 years ($M_{age}=33.38$, $SD=11.15$; 58.5% women). Most participants were white (77.3%), had a post-secondary degree (52.8%), and had a mental health (90.6%) or medical (71.7%) condition. Participants reported the specific therapies/health services they were previously or currently involved in and how many hours they spend per month participating in each therapy/health service. Participants answered an open-ended prompt asking them to describe their overall experiences with these therapies/health services, asking them to highlight their positive and negative experiences. Thematic analysis was conducted following the framework of Braun and Clarke (2006).

Results: Two core themes were identified: 1) Factors that Help and 2) Factors that Hinder. Five subthemes were identified for Factors that Help: 1) therapies/health services for autistic and disabled people are available/accessible, 2) reduced symptom severity/improved quality of life, 3) personal attitudes towards therapies/health services (e.g., viewing a specific therapy/health service as effective), 4) interpersonal support (e.g., family, teachers, peers), and 5) therapist/provider characteristics (e.g., patience, validation, collaboration, or knowledge of autism/neurodiversity). Six subthemes were identified for Factors that Hinder: 1) lack of/no resources/services for autistic and disabled people (e.g., inaccessible), 2) no changes in symptom severity/quality of life, 3) adverse physical side effects (e.g., medication dependence), 4) adverse psychological side effects (e.g., PTSD, stigmatization), 5) lack of interpersonal support (e.g., family, teachers, peers), and 6) therapist/provider characteristics (e.g., lack of patience, validation, collaboration, or knowledge of autism/neurodiversity).

Conclusions: The findings reveal the unique factors that either promote or hinder autistic adults’ positive experiences with therapies/health services. The findings can inform therapies/health services for autistic adults to ensure that appropriate supports are available that meet their needs. Therapists who are accepting, validating, collaborative, and have knowledge about autism/neurodiversity can facilitate a more accessible therapeutic environment. Thus, more training opportunities on autism/neurodiversity that are informed by autistic people’s experiences should be developed and made available for service providers. This can help refine service provision to be more effective and, in turn, promote better mental health outcomes for autistic people. A strength of this study was gathering information directly from autistic adults in their own words. A limitation is that participants were predominantly white, women, and had a post-secondary degree. Future research should include more gender diverse and culturally and economically varied samples.
Background: Universal developmental surveillance of infants and toddlers is the best practice for the early detection of autism; though, inequitable access to early identification is evident globally. Previous research has identified differences in the rates and likelihood of autism between racial, ethnic, and socioeconomic groups, with evidence indicating that maternal factors are also influential in autism prevalence rates (Becerra et al., 2014). However, there is a dearth of literature examining potential differences in engagement in early autism identification research between different ethnic groups and rates of autism in comparison to the wider community.

Objectives: To understand the relationships between child ethnicity and maternal demographics and engagement in early autism identification research and autism prevalence.

Methods: This is a retrospective analysis of data from the Social Attention and Communication Surveillance-Revised study (SACS-R; Barbaro et al., 2022). Conducted in Melbourne, Australia, 126 maternal and child health (MCH) nurses from eight local government areas (LGAs) monitored 13,511 infants and toddlers aged 11-30 months for the early signs of autism. MCH nurses used the SACS-R tool during 12-, 18-, 24- month health checks and the Social Attention and Communication Surveillance Preschool (SACS-PR) at the 42-month health checks. Children who were identified with a “high likelihood” of autism were offered a free developmental assessment by the study team. In this study, we compared participating children’s ethnicity background (European, Non-European, and Mixed) and maternal educational attainment, language(s) spoken at home, socioeconomic status, and autism incidence with that of the greater population from the family’s home LGA, using 2016 census data (Australian Bureau of Statistics, 2020).

Results: 523 children were referred for a free developmental assessment. Of the 357 (68.26%) children who attended the assessment, 95.2% (n = 340) had maternal ethnicity data available. Overall, there was no difference between the proportion of participating mothers who were born overseas and the proportion of residents of the relevant LGAs who were born overseas. No differences were observed between maternal ethnicity groups for maternal education and annual family income. However, differences between child ethnicity groups were observed for maternal employment status, with non-European children (n = 41, 48.8%) more likely to have mothers in current employment compared to those in the European (n = 113, 46.9%), and Mixed-Ethnicity (n = 6, 40.0%) groups (p=0.025). Multilingualism was significantly higher in children of non-European ethnicity (n=49, 58.3%, p=0.000) compared to children of Mixed or European ethnicity. Of the participating children, 257 (75.6%) received a diagnosis of autism, with the remaining 183 (24.4%) children having developmental and/or language delays. Autism prevalence was higher in non-European children (n = 69, 82.1%) compared to those in the European (n = 181, 75.1%), and Mixed-Ethnicity (n = 7, 46.7%) groups (p=0.012).

Conclusions: Research engagement was associated with the child’s diagnosis of autism, multilingualism, and maternal employment status and not maternal country of birth, maternal education attainment, or family income.

Objectives: To explore how autistic children experienced telehealth OT during the pandemic, through the narratives of their parents and treating OTs.

Methods: This secondary analysis is part of a larger qualitative study that investigated how clinic administrators, OTs, and parents of autistic children experienced the sudden shift to telehealth OT during the pandemic. For this secondary analysis, we attempt to address a limitation of the larger study, namely, that the perspectives of the autistic children themselves were not collected directly. We utilized semi-structured narrative interviews with 10 participants (6 OTs and 4 parents of autistic children) who were initially recruited from 3 Los Angeles area pediatric community-based clinics. Interviews took place between April and November 2021. For this secondary analysis, an autistic team member (first author) coded the transcripts using Braun and Clarke’s (2006) thematic analysis (theoretical, semantic, essentialist/realistic approach), using a narrative approach of keeping stories intact. We looked for parent and OT stories about the children’s experiences (observed behaviors, and expressed emotions and perspectives). To increase rigor and social validity, we discussed the codes with other autistic coauthors, and resolved all differences.
Results: We found 3 major themes: 1) Adjusting to Telehealth; 2) Challenges with Telehealth and; 3) Benefits of Telehealth. Participants described that autistic child clients underwent varying processes to adapt to the transition from in-person to virtual OT. Common challenges included disruption to their previous routines, confusion with the technological interface, difficulty focusing on virtual therapy, and regression in some therapeutic goals and/or developmental milestones. Common benefits that clients experienced included developing greater autonomy, feeling increased comfort within their home environment, and receiving greater therapeutic involvement from caregivers. For example, some children appeared to feel empowered to indicate when they needed a break, e.g., by shutting the laptop (compared to in-person treatment where they were unable to leave the physical space). The safety of the home setting seemed to facilitate greater therapeutic gains, such as being able to explore more foods alongside the beloved family dog. Despite the barriers, children successfully adapted to telehealth during the pandemic, and their experiences were overall positive.

Conclusions: This secondary analysis of a larger qualitative study aims to correct the tendency in autism research to exclude the direct experiences of autistic children. Although a noted limitation is that the parents’ and OTs’ perceptions are not an exact proxy, they provide a starting point in understanding how the children experienced telehealth OT. Findings are relevant for policy efforts to provide accessible means of service delivery for autistic children, such as having choices between in-person and telehealth.

426.400 (Poster) “Leery of Diagnosis:” Expert Interviews Describe Barriers to Autism Support in Underserved Metro Atlanta Communities
M. Bonnett, M. Berman, M. South, (1)Epidemiology, Emory University, Atlanta, GA, (2)Psychology & Neuroscience, Emory Autism Center, Decatur, GA, (3)Psychology & Neuroscience, Emory University School of Medicine, Atlanta, GA

Background: Consistent with overall public health estimates, children in the Metropolitan Atlanta (USA) area inequitably have access to autism diagnostic and support services. A delay in identification can have significant impacts on intervention and outcomes for the child and can exacerbate social, racial, and economic inequities. Many of these children spend a significant amount of their day in childcare services, but to our knowledge, no studies currently exist that have sought the perspective of childcare professionals on the barriers that interfere with obtaining evaluation or treatment for autism in young children.

Objectives: To investigate causes of delay or deterrence from autism evaluation or support services in children under 5, in underserved communities in the Atlanta Metro Area. This study also sought to identify potential solutions to these barriers from the perspective of experienced childcare directors.

Methods: A series of interviews were conducted with experienced childcare directors (n=11) specifically working in underserved neighborhoods across the Atlanta Metro region. Participants were identified through the Georgia Department of Early Care and Learning childcare registry and recruited by phone or email, and were sampled from private, school-based, and Head Start daycares. Qualitative analysis of trends was conducted using NVIVO. Participants filled out a brief demographic survey then answered questions about the following topics: barriers preventing equitable evaluation and diagnostic access, barriers preventing equitable support service access, factors on which children are differentially affected by these barriers, and what potential solutions may address these concerns.

Results: Saturation was generally reached after 6 interviews except for additional ideas from an outlier daycare from a more rural area. All 11 childcare directors (100%) mentioned parental resistance or denial as a significant factor influencing equitable access to evaluation. Limited caretaker knowledge and lack of healthcare provider recognition or referral were cited by 8 directors (76%). Among barriers to accessing autism services, proximity of services to families was cited most commonly (82%) followed by caretaker knowledge about services available (76%). When asked about factors common to children impacted more severely by these barriers, directors had less of a consensus. Directors most mentioned that black children were more likely to be impacted (64%) while Hispanic ethnicity was not considered to be a barrier. Many solutions were suggested to address these barriers, with nearly all directors (91%) stating that having diagnostic or supportive services available in the childcare setting where the children spend their days would be beneficial and a strong majority suggesting parental education and support as a viable solution (82%).

Conclusions: Childcare directors had considerable insight into families’ experience with the autism assessment and support process. They identified known factors but also suggested additional influences contributing to the enduring disparities seen in the Atlanta Metro area, and many actionable solutions. Education and support to overcome parental resistance, as well as local availability for evaluation and supportive services, should be a primary focus among policy makers.

426.401 (Poster) An Interpretive Phenomenological Analysis of the Experiences of Autistic Psychiatrists: “If We Can't Recognize Ourselves, How Can We Diagnose Autistic Patients Accurately?”
M. Doherty, N. Chown, N. Martin and S. Shaw, (1)Neuroscience, Brighton & Sussex Medical School, Brighton, United Kingdom, (2)Anaesthesia, Our Lady's Hospital, Navan, Ireland, (3)London South Bank University, London, United Kingdom, (4)Brighton & Sussex Medical School, Brighton, United Kingdom

Background:
Recognition of autistic physicians is a recent phenomenon and open disclosure remains rare. Insights from autistic physicians in all specialties, but particularly psychiatry, have potential to reframe our understanding of autism and improve healthcare outcomes for autistic people.

Autistic Doctors International (ADI) is a peer support and advocacy group for autistic doctors. Psychiatrists are the most over-represented specialty in ADI, second only to general practitioners in term of numbers. Psychiatrists are among the least likely to either pursue a formal diagnosis or to disclose a diagnosis of autism.

Objectives:

We investigated the perspectives of autistic psychiatrists, with a particular focus on decisions relating to or experiences of disclosure.

Methods:

As an autistic-led research team, we conducted a qualitative study. Interpretive phenomenological analysis (IPA) was used. IPA is a qualitative research methodology with an idiographic focus, which seeks to understand how participants make sense of their own experiences. It is particularly well suited to insider researchers.

Purposive sampling was employed. Participants were members of “ADI Psych”, a subgroup of Autistic Doctors International for autistic psychiatrists. Loosely structured interviews were conducted online and recordings transcribed verbatim.

Results:

Eight participants took part: six consultant psychiatrists and two specialty doctors. Ages ranged from mid 30s to late 70s. Two identified as male, six as female. All lived in UK, predominantly in England. Four were child psychiatrists, four worked in adult services including liaison & old age psychiatry. Seven were in current practice at the time of the study and one was retired. Two participants had a formal autism diagnosis received in adulthood, one had a childhood PDD-NOS diagnosis and self-identified as autistic as an adult, and the remaining 5 self-identified as autistic. None were openly autistic in all settings.

Analysis resulted in 6 group experiential themes and 28 individual subthemes. See table 1 for selected themes and illustrative quotes.

Themes include the journey to autistic identity, considerations around pursuing formal autism diagnosis, cultural barriers to disclosure within psychiatry, perceptions of autism, and stigma. Insights into autistic people as patients, current autism services and autism research were explored along with the personal cost of making change.

“You read all those papers about... autistic people having no empathy and no theory of mind... is that really me? So, if it's not me, does that mean that I'm not actually autistic or... this paper is actually very wrong... which one is it? There's a lot of... cognitive dissonance going on” (Lisa, autistic psychiatrist, diagnosed aged 5).

Conclusions:

Analysis of autistic psychiatrists’ perspectives on the nature of autism, mental health for autistic people and autism services highlights various avenues for research and to improve services and outcomes for autistic people in psychiatry whether as service user or service provider. However, the potential for such insights to benefit research and clinical practice as well as the autistic community more directly remains untapped because of barriers to disclosure. Self-recognition and disclosure by autistic psychiatrists may be facilitated by re-framing the traditional deficit-based view of autism towards a neurodiversity-affirmative approach.

426.402  (Poster) Client Insurance Status, Service Setting, and Autism Service Provider-Reported Use of Parent Coaching Strategies

J. E. Tschida¹, A. Sridhar¹, A. Drahota¹, C. M. Kerns¹ and L. Moskowitz¹, 1)Department of Psychology, Michigan State University, East Lansing, MI, (2)Child and Adolescent Services Research Center (CASRC), San Diego, CA, (3)University of British Columbia, Vancouver, BC, Canada, (4)Department of Psychology, St. John’s University, Queens, NY

Background:

Parent coaching occurs when service providers use modeling and corrective feedback to teach parents to use intervention strategies (Kerns et al., 2019). For autistic youth, parent coaching is a cost-effective evidence-based practice (EBP) that improves social communication skills, reduces challenging behaviors, and lessens parental stress (Minjarez et al., 2020; Steinbrenner et al., 2020). Despite this potential, limited information exists regarding which factors influence the use of parent coaching within community-based settings where autistic
children receive care. This study examined contextual factors influencing provider-reported use of parent coaching with autistic youth and their families in community-based settings.

Objectives:

Determine the degree to which client insurance statuses, service settings, and their interactions predict provider-reported frequency of parent coaching use with autistic youth.

Methods:

Participants: 480 community-based behavioral, educational, medical, mental health, allied health, and other providers delivering services to autistic youth (7-22 years old) with social difficulties, externalizing behaviors, and/or anxiety.

Measure: A large-scale online survey was utilized to collect:

a) Client insurance statuses (i.e., school district, out of pocket/private pay, private insurance, public insurance, state-funded disability services, other)

b) Settings where providers deliver services (i.e., private practice, community mental health outpatient clinic, hospital/medical school outpatient clinic, specialized school for autistic children/other developmental disabilities (DD), specialized classroom for autistic children/other DD, outpatient clinic associated with a research center, other)

c) Provider-reported frequency of parent coaching (i.e., modeling intervention techniques, parent practice, and corrective feedback) use rated on a Likert scale, ranging from 1 (not at all) to 4 (very commonly)

Data Analytic Approach: Moderated multiple regression analyses determined the degree to which client insurance statuses, service settings, and their interactions predicted provider-reported frequency of parent coaching use with autistic youth. An a priori power analysis indicated a required sample size of N=469 to achieve 80% power for detecting a small effect, at a significance criterion of $\alpha=.05$. Client insurance statuses and service settings were each given a yes/no answer by providers (coded: 0=no, 1=yes) and provider-reported frequency of parent coaching use was averaged across indication of use for addressing anxiety, externalizing behaviors, and social skills.

Results:

On average, providers indicated occasional to common use of parent coaching. Main effects of client insurance statuses, service settings, and their interactions explained approximately 11.4% of variance in frequency of parent coaching use $[F(34,425)=2.12, MSe=.829, p<.001]$. Significant interactions were found between private insurance and private practice as well as school district insurance and private practice. Highest frequencies of parent coaching use were associated with delivering services in private practice and accepting private health insurance or school district insurance (Figure 1).

Conclusions:

While parent coaching is an EBP with proposed benefits of cost-effectiveness and outcome improvement, these findings highlight potential contextual factors influencing provider-reported use. Notably, private practice and accepting private insurance was associated with most frequent use. Given that most autistic children receive care in community settings, these findings reinforce the need for implementation strategies to ensure more frequent parent coaching use in broader settings when appropriate.
Objectives: The purpose of this study is to examine perceptions of EI providers on facilitators and barriers of providing culturally responsive EI to marginalized families.

Methods: We conducted a qualitative study using semi-structured individual interviews with 15 EI providers of varying professions across eight different states. Most of these EI providers reported working in the families’ homes, and the target children for the purpose of this interview either had a diagnosis of autism or suspected of being autistic. The interview questions were developed based on the Exploration, Preparation, Implementation, Sustainment (EPIS) implementation science framework, and the data were analyzed across different levels (i.e., individual, organization, and system). All interviews were conducted online in English.

Results: The interview data revealed several reported determinants (i.e., facilitators and barriers). These determinants were reported across the three levels, including individual, organization, and state. Facilitators on the individual level included: (a) providers’ own efforts to take on extra responsibilities, (b) using online translation tools, and (c) cultural self-efficacy. On the organization level, reported facilitators included (a) promoting interdisciplinary collaborations, (b) hiring culturally and linguistically diverse EI workforce, and (c) cultivating long-term relationships with interpreters. No system-level facilitators were reported. In terms of barriers on the individual level, providers reported (a) cultural clash between providers and families, (b) their own limited cultural awareness, and (c) independent contractors not having any organizational obligations, such as training. On the organization level, the barriers included (a) not providing relevant PD, (b) limited organizational infrastructure for training, (c) not enough interpreters or enough session time with interpreters, and (d) interpreters’ lack of content knowledge. On the system level, providers reported barriers of (a) no professional development (PD) on cultural diversity, and (b) not prioritizing working with marginalized families.

Conclusions: EI providers reported limited PD related to providing culturally responsive EI, and that they mostly rely on their own ability to seek out additional PD opportunities to learn about cultural diversity or the client’s culture and that they learn “on the job”. This indicates the needs for more accessible PD that targets increasing providers’ capacity to work with marginalized families. More implementation research needs to examine how providers are supported to provide more culturally responsive EI.

426.404 (Poster) The Use of Compass to Address EBP Disparities for Rural Children with Autism

R. D. Stayton, L. N. Ogle, L. A. Ruble and J. H. McGrew, (1)Ball State University, Muncie, IN, (2)Department of Special Education, Ball State University, Muncie, IN, (3)Special Education, Ball State University, Louisville, KY, (4)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN

Background: The Collaborative Model for Competence and Success (COMPASS) is a comprehensive consultation and coaching intervention that has been shown in three randomized controlled trials (RCTs) to improve the social emotional learning (SEL) outcomes for students with autism regardless of age and autism severity. In rural areas, there is a trend of less availability and access to evidence-based practices (EBPs) for autism (Scarpa et al., 2020), and consultation interventions such as COMPASS can address this critical need for high-quality intervention. Barriers that individuals with autism and their families face in rural communities include increased distance from autism resources, lower socio-economic status, higher unemployment rates, lower parental education level, and less knowledge of autism (Antezana et al., 2017). These barriers interfere with access to high-quality early intervention (Noyes-Grosser et al., 2018). Families of children with autism who receive support report better family outcomes, including a greater understanding of their child, better advocacy skills, and knowledge of how to access services (Wicks et al., 2021).

Objectives: The purpose of this study was to test the hypothesis that there is no difference in student goal attainment outcomes in COMPASS for rural vs. non-rural students.

Methods: Data from two randomized controlled trials and a pre-post test of COMPASS delivered by school consultants were analyzed by geographic location to evaluate students’ IEP goal progress following COMPASS intervention (n = 56). Student ages ranged from 3 to 12 (M = 6.79), 82.7% of students were male and 17.3% were female; 36.9% of students attended rural schools and 63.1% of students attended non-rural schools. Individualized goals and intervention plans were collaboratively identified and developed for students using the COMPASS Profile completed independently by the caregiver and teacher about the students’ strengths and challenges in various domains (e.g., social communication skills, independent learning skills, sensory interests and challenges, etc.). Student outcomes were assessed using goal attainment scaling (GAS) using a five-point rating: -2 = present levels of performance, 0 = expected performance, +2 = much more progress than expected (AUTHOR, 2012). A paired samples t-test will be used to compare rural and non-rural student GAS outcomes.

Results: All students who received COMPASS demonstrated a significant increase in goal attainment across all three goal domains of social, communication, and learning skills, t(62) = 15.808, p = <.001, d = 1.09. As hypothesized, there were no significant differences in student GAS outcomes between rural and non-rural students, t(54) = -.500, p = .619, d = 1.09.

Conclusions: Students with autism and their families in rural communities face distinct barriers to accessing high-quality, evidence-based intervention. COMPASS offers a potential solution for bridging this gap through consultation and coaching support provided by trained school-based consultants to reduce the impact of disparities in evidence-based autism support for rural communities.
Background:
Caregiver-teacher alliance is an important building block to foster student success. Caregiver-teacher alliance can be defined as shared communication, investment, and concern for a child. Improved caregiver-teacher alliance leads to positive outcomes for children, specifically behavior and transition outcomes. Improved alliance additionally benefits caregivers by helping them feel more involved in educational decisions (Garbacz & McIntyre, 2015; Hampden-Thompson & Galindo, 2017; Thijs & Eilbracht, 2012).

Objectives:
We evaluated the association between caregiver and teacher ratings of alliance and child goal progress after receiving COMPASS when delivered by community-based COMPASS-trained consultants. Additionally, we sought to examine if increased caregiver or teacher-reported alliance related to caregiver and teacher ratings of goal progress.

Methods:
Participants included 28 triads consisting of a special education teacher, a student with autism from the teacher’s caseload, and the student’s caregiver(s). There were twelve total COMPASS consultants, all White females ranging in age from 24 to 60 years. Eighty percent of students were white, 6% Black, 3% Multiracial, and 10% did not report race. Almost half (46%) reported an annual income of less than 50K. Students ranged from 4-13 years old (84% male; 16% female), with a mean age of 7.39 (SD = 2.7). Most teachers were female (83.9%) and white (90.3%); the average number of years teaching was 11.14 (SD = 8.14). There were twelve total COMPASS consultants, all White females ranging in age from 24 to 60 years. COMPASS trainees had an average of 12.2 (SD - 7.03) years of consultation experience.

A within-subjects pre-post design was applied to study the impact of COMPASS on parent teacher alliance and child goal attainment outcomes. We examined change in teacher/caregiver alliance before and after completing COMPASS and child goal progress reported by the caregiver and teacher. Measures included the Parent-Teacher Alliance Questionnaire, a 20-item measure (1 ‘strongly disagree’ to 5 ‘strongly agree’) completed by caregiver and teacher. Caregivers and teachers reported goal progress using a single-item Likert scale (1 ‘none at all’ to 5 ‘a great deal’).

The impact of COMPASS on caregiver and teacher-reported alliance was examined using paired samples t-tests, one-tailed due to the directionality of our hypothesis. Pearson correlations were used to determine associations between caregiver and teacher-reported alliance and goal progress.

Results:
Both caregiver- \( t(22) =1.62, \ p=0.05; \ d = 0.425 \) and teacher- \( t(24)= 3.11, \ p< .01; \ d = 0.537 \) reported alliance increased following COMPASS intervention. Analysis of Pearson correlations between caregiver and teacher-reported alliance with teacher and caregiver-reported goal progress revealed a significant correlation between caregiver-reported alliance and caregiver ratings of goal outcomes \( r = 0.463; \ p = .026 \). However, the correlation between teacher-reported alliance and teacher ratings of goal outcomes was not significant \( r = 0.329, \ p = .906 \).

Conclusions:
COMPASS may enhance alliance between teachers and caregivers. Caregivers who report higher alliance with teachers also perceived better outcomes for their children. Although not originally intended to target caregiver-teacher relationships, COMPASS appears to have collateral effects in caregivers that may enhance child outcomes.
Challenges with emotion regulation (ER) are common and disruptive to the lives of autistic individuals and their families. Research on neurotypical children makes clear that parents play a critical role in children’s ER development, yet research examining parent-child emotional dynamics in families of autistic children is lacking. The present panel brings together four talks aimed at exploring how parents’ and autistic children’s behaviors and experiences around emotions relate to one another in childhood. The first presentation examines how child ER mediates the relationship between parent ER and child internalizing and externalizing problems. The second presentation reports on how various aspect of parenting (gentle guidance, scaffolding, involvement, and reinforcement) relate to children’s observed ER in both dyadic and independent regulation challenges. The third presentation explores the relationship between parent responses to child negative emotions and various child characteristics, including child ER. And finally, the fourth presentation reports on results of an intervention aimed at reducing parenting stress in parents of young autistic children, with downstream effects on child ER. Together, these four presentations demonstrate the importance of exploring parent-child dynamics around ER, with implications for identifying targets for interventions to meaningfully improve quality of life for autistic children and their families.

214.001 (Panel Discussion) Evaluating the Influence of Caregiver Emotion Regulation on Child Emotion Regulation and Behavioral Challenges in Autistic Toddlers

D. Swain,*, S. Constant, N. Cristallo and S. H. Kim, (1)Psychiatry, Weill Cornell Medicine, New York Presbyterian Hospital, White Plains, NY, (2)Pediatrics, University of Colorado Denver - School of Medicine/Children’s Hospital Colorado, Aurora, CO, (3)Psychiatry, Center for Autism and the Developing Brain at Weill Cornell Medical College, White Plains, NY, (4)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, Korea, Republic of (South)

Background: Caregivers play a critical role in the development of child emotion regulation (ER), which encapsulates one’s ability to modulate emotional reactions to environmental demands. Although challenges in ER in autistic youth are well documented (Beck et al., 2020), there are limited studies examining the influence of parent factors on child ER use. Similarly, child ER has been shown to contribute to behavioral problems and emerging findings suggest that child ER may mediate the relationship between caregiver ER and child behavioral problems in a community sample (Crespo et al., 2017); however, results have yet to be replicated in young autistic children.

Objectives:

1. Examine the direct association between caregiver and child ER in toddlers with ASD.
2. Explore the association between caregiver ER and children’s internalizing and externalizing symptoms as well as the mediating role of child ER.

Methods:

Participants included 64 toddlers with ASD (28.1% female, 25% Hispanic, M_age= 32.81 months) and their caregivers (85.9% mothers, M_age= 37.96 years). Parents completed self-report measures of ER strategies (cognitive reappraisal and expressive suppression from Emotion Regulation Questionnaire) and parent report measure of child ER (Flexibility Index from the BRIEF-Preschool Version) and challenging behaviors (Child Behavior Checklist). For aim 1, a regression predicting child ER was run with parent predictor variables (cognitive reappraisal and suppression) and covariates. Baseline correlations revealed no significant correlations between caregiver or child age, child non-verbal IQ and child ER; however, fathers reported significantly higher rates of expressive suppression coping (p<.01) and thus, caregiver gender was included as a covariate in the regression. For aim 2, the PROCESS Macro Model 4 (Hayes, 2013) was used to test whether caregiver ER strategies were indirectly related to child behavior problem outcomes via associations with children’s ER.

Results:

Less than 33% of participants were identified as having clinical levels of ER difficulties (n=12, 18.8%), externalizing (n=14, 21.9%) and internalizing challenges (n=11, 17.2%). After controlling for caregiver gender, caregiver cognitive reappraisal (β=-.29, p=.02) and suppression (β=-.39, p<.01) were significant predictors of child ER difficulties, such that less cognitive reappraisal and more suppression strategy use corresponded with higher child ER difficulties. For all mediation models run, no direct or indirect effects were significant such that caregiver ER strategy use did not correspond with child internalizing or externalizing difficulties and child ER did not play a mediating role.

Conclusions:

The current study provides preliminary evidence regarding the importance of caregiver ER strategy use in the context of ER development in young autistic youth. Because caregivers are often active participants and providers of treatment techniques, especially for preschoolers, future treatment models targeting child ER may benefit from measuring and providing support for adaptive caregiver ER. Interestingly our findings did not find support for a direct effect of caregiver ER on child internalizing or externalizing problems. Nonsignificant findings may indicate a delayed onset of such behaviors, small sample size, or limited heterogeneity in variables of interest.
214.002 (Panel Discussion) Differential Relations between Parenting and Emotion Regulation in Children with ASD across Dyadic and Independent Contexts

J. K. Baker and R. M. Fenning*, (1)Center for Autism; Dept. of Child & Adolescent Studies, California State University, Fullerton, Fullerton, CA, (2)Psychological Science, Claremont McKenna College, Claremont, CA

Background: Children with ASD exhibit considerable difficulties with emotion regulation which, in turn, greatly impair functioning. Several intrinsic correlates of dysregulation have been identified in these children, including core symptom level and parasympathetic nervous system functioning (Baker et al., 2022). The search for potential environmental influences has been less fruitful, with parental co-regulatory scaffolding relating to children’s concurrent but not independent regulation (Fenning et al., 2018). Although some tentative cross-sectional evidence exists for emergent internalization of parental co-regulatory support as these children enter adolescence (Baker et al., 2019), the identification of additional and earlier support mechanisms is a critical precursor to effective psychosocial intervention.

Objectives: The current study examined several different aspects of positive parenting (involvement, reinforcement, gentle guidance, and scaffolding) as correlates of observed regulation in children with ASD, as measured in both parent-child and independent regulatory contexts. Methods: A sample of 77 children (79% male) with ASD aged 6 to 10 years participated in frustrating laboratory tasks with and without their primary caregivers, and the caregivers completed a parenting questionnaire. Children were diverse with regard to ethnicity (35% Caucasian, non-Hispanic), socioeconomic status, ASD symptom level and cognitive functioning (IQ range 47-121). Emotion regulation was coded from videotape and included dimensions outlined by Cole et al. (1994; dyadic ICC=.92; independent ICC=.91, see Baker et al., 2022). Parental scaffolding was coded during the dyadic task using a system validated with families of children with ASD that included motivational, emotional, and technical support (Baker et al., 2018; 2019; ICC=.73). Maternal gentle guidance was coded from an additional parent-child clean-up compliance task (Kochanska et al., 2001; ICC=.93), and both parental involvement (alpha=.81) and parental reinforcement (positive parenting scale=.72) were obtained through parent report on the Alabama Parenting Questionnaire.

Results: No child characteristics or demographic factors related to both the parenting and regulation variables. Differential relations were observed between parenting and children’s regulation when considered across contexts, with laboratory coded parent-child interaction (scaffolding and gentle guidance) correlated with children’s dyadic regulation (r=.23 and r=.24, respectively, p<.05), and parents’ reports of their overall involvement (e.g., transporting children, playing games together, attempts at communication, collaborating on plans) relating to children’s observed independent regulation, r=.32, p=0.01, over and above children’s age, IQ, and ASD symptom level, beta=.29, p=.02. Scaffolding and gentle guidance were not significantly correlated with each other. Conclusions: Findings suggest that intentional co-regulatory parenting behavior (e.g., scaffolding, gentle guidance for compliance) may relate to children’s regulatory behavior in the presence of the parent, but this potential influence does not appear to translate to children’s independent regulation by middle childhood. In contrast, children’s independent regulation appears correlated with parents’ report of their level of involvement with their children. Although direction of effects cannot be determined, these findings suggest the possibility that remaining broadly involved and engaged with children with ASD may promote their development of regulatory competence.

214.003 (Panel Discussion) Predictors of Parent Responses to Child Negative Emotions in Parents of Young Autistic Children

J. B. Northrup, K. E. Szkoda, K. T. MacKenzie, A. G. Hartman and C. A. Mazefsky*, (1)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)University of Pittsburgh Medican, Pittsburgh, PA, (3)Department of Psychiatry, University of Pittsburgh Department of Medicine, Pittsburgh, PA, (4)University of Pittsburgh, Pittsburgh, PA

Background: The preschool years mark a significant period in emotional development during which parents play a critical role (Eisenberg et al., 1998). How parents respond to their child in times of distress has an impact on emotional competence and emotion regulation development (Davidov & Grusec, 2006; Fabes et al., 2002). At the same time, children’s cognitive, verbal, emotional, and behavioral challenges likely impact how parent’s respond to them. Given vast heterogeneity amongst autistic children in intellectual and verbal ability, autism symptom severity, and emotion dysregulation, we aimed to understand how child characteristics relate to parent responses to child distress.

Objectives: Examine how child age, biological sex, parental education, intellectual disability, verbal ability, autism symptom severity, and emotion dysregulation predict parents’ a) supportive (i.e., encouraging and helping responses); b) unsupportive (i.e., discouraging and minimizing responses); and c) personal distress responses to their autistic child’s negative emotions.

Methods: Participants were 674 parents (94.4% mothers) of 2- to 5-year-olds (mean age = 4.6 years; 76% male) who participated in an online study. Parents provided demographic and descriptive information and completed several questionnaires, including: 1) the Coping with Children’s Negative Emotions Scale (CCNES), a self-report measure of parental response to child negative emotions; and 2) the Emotion Dysregulation Inventory-Young Child (EDI-YC), a parent report measure of child emotion dysregulation with two subscales: Reactivity and Dysphoria. These two measures and their subscales are described in detail in Table 1. In addition, parents filled out the Social Communication Questionnaire (SCQ), a measure of autism symptom severity, and reported on the child’s verbal ability (five categories ranging from fluent to nonverbal and presence of intellectual disability (ID)).

We ran three linear regressions predicting parents’ 1) Supportive Response Score; 2) Unsupportive Response Score; and 3) Distress Response Score. Predictor variables included age, sex, parent education, ID, verbal ability, SCQ scores, EDI-Reactivity Scores, and EDI-Dysphoria Scores.
**Results:** Results are presented in Table 2. Presence of ID predicted more supportive and less distressed responses. Higher SCQ scores predicted less unsupportive and less distressed responses. Higher emotional reactivity predicted more supportive responses, whereas higher levels of dysphoria predicted less supportive, more unsupportive, and more distressed responses.

**Conclusions:** Results suggest that, in general, parents of autistic children endorse less distress, more helping/encouraging, and less discouraging/minimizing in response to their children’s negative emotion when their child has higher support needs (e.g., presence of ID, higher autism symptom severity, and more emotional reactivity). However, autistic children’s level of dysphoria—characterized by low positive affect, anhedonia, and sadness—was predictive of less helping/encouraging, more discouraging/minimizing, and more distressed parental responses. Autistic children who struggle with the upregulation of positive emotion may not elicit as much positive support from parents, perhaps because their needs are not as clear as children with high reactivity (e.g., outbursts and tantrums).

**Methods:** Participants included 117 diverse parents of preschoolers with ASD (ages 3-5 years, 78.63% racial/ethnic minority) who were part of the NIH-funded Stress-reduction Techniques for Enhancing Parenting Skills (STEPS) Project. Parents were randomly assigned to receive Mindfulness-Based Stress Reduction (MBSR; n=59) or Psychoeducational Support (PE; n=58). Due to COVID-19, our final cohort (n=51; 44%) participated online. Parents reported on parenting stress and child emotion dysregulation at baseline, immediately post-intervention, and 6- and 12-months post-intervention. Parenting stress was indexed by the Parenting Stress Index-Fourth Edition, Short Form Parental Distress subscale (PSI-4-SF; Abidin, 1995). Parent-reported child emotion dysregulation was indexed by the Emotion Dysregulation Index-Young Child Reactivity score (EDI) and by the Emotion Regulation Checklist Lability/Negativity (ERC).

**Results:** There were no significant intervention-group differences in demographics, parenting stress, or child dysregulation at baseline. However, cohort (in-person/virtual) was included as a covariate due to associations with change in the EDI, with in-person groups reporting greater reduction in child reactivity than virtual groups ($\gamma_{10}=-2.37$, $p<.05$). Two-level linear growth curve models examined whether parent-reported child emotion dysregulation indices changed over time, whether change in child dysregulation differed by intervention group, and whether change in parenting stress over the course of intervention predicted change in child dysregulation.

Both indices of child dysregulation significantly decreased over time (EDI $\gamma_{10}=-2.63$, $p<.001$; ERC $\gamma_{10}=-2.76$, $p<.05$), but degree of change did not differ by intervention group. Change in parenting stress predicted change in child dysregulation (EDI $\gamma_{20}=2.9$, $p<.05$; ERC $\gamma_{20}=.21$, $p<.001$), indicating significant covariation. Notably, change in parenting stress accounted for change in parent-reported child lability/negativity (ERC), but change in child reactivity (EDI) remained significant even after controlling for the contributions of parenting stress.

**Conclusions:** Parents participating in stress-reduction interventions reported significant decreases in child dysregulation over time, with comparable effects for MBSR and PE. Evidence that reduced parenting stress predicted improvement in parent-reported child dysregulation suggests important mediational processes that may be tied to intervention-altered parent perceptions or behavior. Future analyses will incorporate additional measures of parenting behavior to examine proximal factors that may underlie change in child regulatory functioning in our diverse sample.
School is a place where children meet peers, socialize, and make friends, which contributes to their sense of belonging. However, many autistic children have difficulties attending school on a daily basis, and especially to participate in different kinds of social activities outside the classroom, such as their breaktime. In this session, we show how autistic children experience their school environment at different levels, via a multi-method, interdisciplinary approach including Psychology, Psychiatry, Computer Science, and Architecture. What factors contribute or hinder social participation? Taking into account individual (autistic) differences in needs and capacities, and addressing these in the social, cultural, and physical environment help to create a school climate that welcomes all children, in which diversity is valued and appreciated. The first presentation addresses the extent to which autistic pupils participate in school activities. Through a national survey, factors related to the pupils and school are discussed. The second and third presentations focus on autistic pupils’ social connections in school. Peer interactions on schoolyards are captured during recess via new wearable sensing technologies and combined with children’s self-reports. Lastly, we discuss strategies for enhancing social inclusion of autistic pupils in schools, by showing a systematic review on school-based interventions.

226.001 (Panel Discussion) School Participation of Autistic Youths: The Influence of School, Family, and Youth Factors

Background: School-aged youths have a basic human right to participate in educational and recreational activities inside the classroom and on the school grounds. Compared to non-autistic youths, autistic youths have much higher rates of school absenteeism (Adams, 2021). Also, when they attend school, they are less involved in educational and social activities (Kaljaca et al., 2019; Keen et al., 2021; Ratcliff et al., 2018). Traditionally, autistic youths have often been held accountable for the exclusion they experience (Edery et al., 2016; Keating & Louise, 2020). Recently, there has been a paradigm shift, showing an increasing emphasis on the role of environment in creating difficulties that autistic people experience (Dargue et al., 2021).

Objectives: The present study aimed to investigate autistic youths’ school participation and predictors of school participation on a school, family, and youth level, using data from a national survey conducted in the Netherlands. In addition to the often-considered individual factors of autistic youths such as age and level of autistic traits, we examined how the two important environmental settings (i.e., school and family) could affect autistic youths’ school participation.

Methods: In the Netherlands, children begin primary school from the age of 4 years and start the secondary education from the age of 12 years. The sample of this study included 200 autistic youths, aged between 4 and 16 years (Mage = 12.23 years, SDage = 2.93 years). Their parents filled in questionnaires online, reporting the age and autistic traits of their child, the extent to which their child participated in school activities, and the extent to which their child experienced barriers in the physical and social environment at school. In addition, parents reported their own educational levels and evaluated their perceived efficacy in supporting their child’s school life.

Results: Multiple linear regression analyses revealed that a higher level of autistic traits and greater barriers in the social and physical environment of school predicted a lower level of school participation of autistic youths. Among the predictors, barriers in the physical environment of school had the strongest negative association with autistic youths’ school participation. No associations were found between family factors (i.e., parents’ education levels and perceived self-efficacy) and autistic youths’ school participation.

Conclusions: This study provided new empirical evidence on the role of school environment in predicting autistic youths’ school participation. Noteworthy, our findings indicate that barriers in the school environment could have stronger impacts on autistic youths’ participation than youths’ personal factors or family factors. This highlights the importance of modifying the school environment, to make it more accommodating for autistic youths’ needs and to create a safe space where autistic youths can learn and participate.

226.002 (Panel Discussion) Social Connectedness in Autistic and Non-Autistic Pupils: Preliminary Findings

Background: In schools, autistic students often report to be less connected with their (non-autistic) peers, which indicates that they are more peripheral in classroom social networks. On the playgrounds, autistic students are also observed to have fewer social interactions with peers, participate in fewer joint activities, and spend more time on solitary activities instead. Despite these observations, autistic pupils do express a desire for social interactions and connections with others.
Objectives: This study aims to examine social connectedness reported by autistic and non-autistic pupils and their playground social connectedness during recess. The objectives of this study are twofold. First, the level of social connectedness in autistic and non-autistic pupils is examined and compared. Second, the relationship between self-report and playground social connectedness is examined, and the extent to which the two groups differ in this regard is explored.

Methods: Autistic pupils (N = 47, 5 girls and 42 boys) and their non-autistic classmates (N = 52, 29 girls and 23 boys) aged 8 to 14 years from two special schools in the Netherlands were recruited. Participants completed self-report questionnaires on social connectedness (i.e., peer acceptance and peer closeness centrality). Additionally, participants wore proximity sensors on the playground to measure playground social connectedness (i.e., total time spent in interactions, number of interacting partners, and playground closeness centrality). This modern sensing technology allows unobtrusively monitoring children’s face-to-face interaction during recess.

Results: Results showed no group differences in self-report or playground social connectedness. Higher levels of peer closeness centrality were related to more interacting partners during recess only in non-autistic pupils. No other significant correlations and group differences in correlational strength were noted.

Conclusions: The present study used self-report questionnaires and sensing technologies to examine social connectedness in autistic and non-autistic children. In this study, social connectedness appears comparable in the two groups. Yet, different from non-autistic pupils, autistic pupils’ social connectedness on the playground does not correspond with the self-report social connectedness. This highlights the importance to consider peer interaction during unstructured time when studying autistic pupils’ social relationship in school. Moreover, the study was conducted in special schools, where pupils with diverse special needs attend, and where more specialized personnel and knowledge are available to better guide and support them. Such individual differences are important to address when aiming for an inclusive school climate, also in special schools. Future study is suggested to further investigate social connectedness of autistic pupils in mainstream schools, and how to identify and translate strategies – that are developed in special schools – for implementation in mainstream schools.

226.003 (Panel Discussion) Social Connectedness and Loneliness in School for Autistic and Non-Autistic Children

C. Rieffe1,2, Y. T. Tsour1, M. Nasri1, B. LI, E. M. Blijd-Hoogwys2, M. Baratchi3, A. Koutamanis1, (1)Leiden University, Social and Behavioral Sciences, Leiden, Netherlands, (2)Faculty of Electrical Engineering, Mathematics and Computer Science, University of Twente, Enschede, Netherlands, (3)Institute of Education, University College London, London, United Kingdom, (4)Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (5)Leiden-Delft-Erasmus Centre for BOLD Cities, Leiden University, Leiden, Netherlands, (6)Leiden Institute of Advanced Computer Science (LIACS), Leiden University, Leiden, Netherlands, (7)Faculty of Architecture & the Built Environment, Delft University of Technology, Delft, Netherlands

Background: Compared to non-autistic pupils, autistic pupils are often reported to be less socially connected in school: they make and receive fewer social initiations, are less often seen as “someone to hang out with”, engage in fewer reciprocal friendships, and more often spend time alone during recess (e.g., Chamberlain et al., 2007; Kasari et al., 2011). Moreover, recent studies show that when entering into adolescence, autistic pupils experience more loneliness in school than non-autistic pupils, which contradicts the traditional view that autistic pupils lack the desire to build social connections.

Objectives: While peer interaction is an essential part of most children’s school life, what remains underexplored is how autistic children feel about their social connections. Thus, this study aimed to understand the individual differences in how social connectedness is construed, both between and within groups of autistic and non-autistic pupils, using a multi-method approach including self-reports, peer reports, and wearable sensors.

Methods: Participants included 47 autistic children (5 girls, 42 boys) and 52 non-autistic classmates (29 girls, 23 boys) from two special education primary schools (Mage = 10.84 years, SD = 1.21). Regarding social connectedness in school, peer reports were used to measure (i) reciprocated friendships and (ii) centrality in their playmate networks; wearable proximity sensors (Radio Frequency Identification Devices, RFID) were worn by pupils on playgrounds during school recess to measure (iii) total time spent in face-to-face peer interactions, (iv) number of different interaction partners, and (v) centrality in playground social networks. To evaluate how they felt about their social connectedness, feelings of loneliness in school was measured by the self-reported Children’s Loneliness Scale (Maes et al., 2015).

Results: Compared to non-autistic pupils, autistic pupils had fewer reciprocated friendships (U = 1528.0, p (one-tail) = .001). Yet, the two research groups showed similar total time in interaction, number of interaction partners, playmate/playground centrality, and levels of loneliness in school. Higher levels of playmate centrality were related to lower levels of loneliness only in autistic children (rho = -.36, p (one-tail) = .002). Longer time in interaction during recess was related to lower levels of loneliness only in non-autistic children (rho = -.39, p (one-tail) < .001).

Conclusions: Autistic and non-autistic children may construe their loneliness in school differently, finding different features of social connections valuable. For these autistic children, feelings of loneliness may go beyond face-to-face interactions. Being accepted as part of a
peer group was key. Understanding relevant differences in the social needs of children could lead to more effective design for a welcoming school climate.

226.004 (Panel Discussion) School-Based Interventions for Increasing Autistic Pupils' Social Inclusion in Mainstream Schools: A Systematic Review

Background: School is an important environment for children to socialize with their peers and make friends, through which they also learn the social skills that prepare them for adulthood, such as how to negotiate and collaborate (Veiga et al., 2017). Moreover, peer interaction is crucial for children’s sense of belonging to their school (Allen et al., 2021), which also contributes to psychosocial wellbeing in later life (Palikara et al., 2021; Tian et al., 2016). Yet, many autistic children face challenges when joining an interaction with peers (Brewster & Coleyshaw, 2010; Kasari et al., 2011), are often excluded or ignored by non-autistic peers (Dean et al., 2014; De Boer & Pijl, 2016), and the physical environment could be too overstimulating for them to comfortably participate in social activities (Bailey & Baker, 2020). Special considerations are thus needed to make schools a more welcoming place for autistic children.

Objectives: In this study, articles on school-based interventions for enhancing autistic pupils’ social inclusion in primary and secondary mainstream schools were systematically reviewed. Included interventions had to target at least one level of the school environment: i.e., the autistic child, the peers, the staff, and/or the physical environment, and assessed autistic pupils’ quantity and/or quality of social participation as an outcome measure.

Methods: The PRISMA Checklist was used to guide the review process (Moher et al., 2009). A search was conducted in April 2021 using four electronic databases and via manual search of reference lists of the retrieved studies. The studies included had to involve autistic participants in primary or secondary mainstream schools, a school-based intervention implemented at one of the four levels of the school environment for improving social inclusion of autistic pupils, a group design or a single-subject design that allows for testing the effect of the intervention, and a “strong” or “adequate” methodological quality rating (Reichow et al., 2008). The screening and eligibility check were conducted by two individual coders.

Results: A total of 56 studies met the inclusion criteria. Findings of these studies showed that interventions at child-level improved accessibility of school and social activities for autistic pupils, whereas interventions at peer-level enhanced their integration. Interventions in the physical environment improved autistic pupils’ responses to peers, but it was uncertain if this was reciprocal.

Conclusions: A holistic strategy interconnecting different levels of the school environment, moving focus from individual children’s capacities to modifying the larger context, seems to enhance better social inclusion of autistic children in regular schools.

ORAL SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR

312 - Eye Gaze & Eye Tracking

Moderator: Matthew Goodwin, Northeastern University, Boston, MA

312.001 (Oral) Characterising Eye Tracking Social Functioning Subgroups with EEG, Structural and Functional MRI

L. Mason, E. Jones, C. Moessnang, C. M. Pretzsch, and C. Ecker, (1)Forensic and Neurodevelopmental Sciences, CBCD, Birkbeck, University of London, London, UK, (2)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (3)Department of Psychiatry and Psychotherapy, Central Institute of Mental Health, University of Heidelberg, Mannheim, Germany, (4)Forensic and Neurodevelopmental Sciences, IoPPN King’s College London, London, United Kingdom, (5)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe University, Frankfurt am Main, Frankfurt, Germany

Background: Eye tracking indices of social attention, such a looking time to faces, often differ in autistic people relative to neurotypical controls. There is, however, much overlap in distributions of these measures, and little consensus on the cognitive, social and neurobiological mechanisms that underly them.

Objectives: 1) To stratify participants by eye tracking indices of social attention, and 2) To use EEG, fMRI and genetic data to characterise these subgroups.
Methods: We collected eye tracking data from autistic (N=393) and neurotypical (N=270) participants aged 6-30 years whilst they watched a naturalistic social video and aggregated proportion of attention to the faces within 250ms bins across the time course of the video. We then performed a PCA across these time courses, and selected all components explaining > 1% variance. We ran a Gaussian mixture model clustering approach on the loadings and selected the optimal number of clusters based on BIC score. We then characterised these clusters by 1) clinical variables (ADOS, ADI); 2) P1 and N170 ERP amplitude and latency to upright faces; 3) MRI cortical thickness and surface area; 4) fMRI activation to faces.

Results: The PCA decomposition revealed 23 components that each explained more than 1% of variance (total: 73% cumulative variance). GMM clustering revealed an optimum number of clusters of four (BIC = 12380.2), revealing a cluster of participants with low face looking throughout (Low Face); a cluster with initially moderate face looking that declined over time (Declining Moderate Face); a cluster with initially high face looking that again declined over time (Declining High Face); and a cluster with sustained high face looking (High Face). Clusters differed on:

1. **Clinical variables:** High Face lookers had a lower proportion of autistic people than other groups and within the ASD group showed higher IQ, fewer symptoms, and stronger adaptive skills. In contrast, Low Face lookers showed the most pronounced symptoms, the lowest IQ and the poorest adaptive function. Variation between clusters was stronger for the ADI than the ADOS.
2. **EEG P1 and N170:** Both the parietal (P7/8) P1 and N170 differed by cluster membership in the autistic group (P1: F(3, 472)=3.62, p=0.013; N170: F(3, 472)=3.64, p=0.013, but not in the NT group (F’s<2.36, p’s>.072).
3. **Structural MRI:** Cluster membership had a significant effect on surface area including a) right superior parietal cortex, precuneus cortex, inferior parietal cortex, and isthmus cingulate cortex; b) right lingual gyrus and isthmus-cingulate cortex; and c) left postcentral gyrus, superior parietal cortex, and supramarginal gyrus (all p’s<.001).
4. **fMRI:** Face looking associated with amygdala habituation to faces (R=-0.107, p<.001).

Conclusions: We demonstrate data-driven subgroups stratified by the dynamics of social attention, and describe neurobiological differences in these subgroups in terms of brain structure, function and electrophysiology. Together, these data suggest that low-cost, non-invasive eye tracking technology can be used to acquire clinically, genetically and biologically meaningful markers of social function in autism.
Conclusions: These findings expand upon existing research by suggesting that autistic people—beyond solitary social simulations—demonstrate significantly less socially directed gaze and achieve less mutual eye contact during dyadic, naturalistic conversations than their neurotypical peers. This work is also novel in terms of its direct, granular sampling of behavior and focus on both members of a social dyad. Future directions for this research include using these manual annotations to inform the development of computational tools for automatic quantification of social gaze patterns during conversations.

312.003 (Oral) Differing Predictive Strategies in Toddlers with and without Autism Underlie Rhythm of Social Engagement

N. R. Fram, C. Alviar, Y. Wang, S. Chawla, L. A. Edwards, W. Jones and M. D. Lense, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Marcus Autism Center, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA

Background:

Rhythm is an important mechanism for scaffolding social behavior. Impairments in rhythm, including in social timing/coordination, in autism are increasingly examined in light of models of predictive coding (Sinha et al., 2014). We previously demonstrated that during child-directed singing, typically developing (TD) and autistic toddlers use predictable rhythms to modulate their eye gaze, increasing attention to a singer’s eyes on metrically strong beats (Chawla et al., 2021). Here we extend this work to assess predictive processes underlying time-locked attention to the eyes when engaged by child-directed singing of varying predictability.

Objectives:

Investigate how different models of temporal prediction hypothesized to be linked to autism manifest in the timing of eye-looking to unpredictable child-directed singing.

Methods:

Eye movements of toddlers 18-36 months old (ASD: n=31; TD: n=39) were tracked while watching videos of child-directed singing. Songs were presented in original, temporally predictable versions and experimentally-manipulated versions in which rhythms were jittered to disrupt predictability. We used peristimulus time histograms (PSTHs) and peak phase (where a phase of 0 is perfect alignment) to assess rhythmically entrained eye gaze to actual beat timing and for beat times predicted by two models of temporal prediction corresponding to two prevailing hypotheses of prediction impairments in autism: a linear regression of all previous beat times, representing the slow-updating theory; and the average of all previous beat inter-onset intervals, representing the high-precision hypothesis (Figure 1). We measured time-locking of eye-looking using permutation testing of peristimulus time histograms (PSTHs) and assessed the angular concentration of phase terms using the Rayleigh test of uniformity (i.e., metric of response consistency).

Results:

During original, unjittered (temporally predictable) singing, TD and autistic toddlers exhibited increased eye-looking time-locked to the beats (Figure 2a,e), though phase of eye-looking was more uniform in TD (R=0.55, p<0.001) than autism (R=0.31, p=0.06). During the jittered, disrupted predictability singing, magnitude of time-locked eye-looking to actual beat times was substantially reduced in both groups (Figure 2b,f) though continued to exhibit significant phase uniformity in TD (R=0.49, p<0.001) but not autistic (R=0.24, p=0.19) toddlers. Notably, when comparing time-locked eye-looking to beat times predicted by the two models in the jittered condition, TD toddlers showed no preference between the models (Figure 2c,d) while autistic toddlers showed significantly stronger phase synchronization of eye-looking in the regression (slow-updating) model (R=0.52, p<0.001) (Figure 2) but no use of the average IOI (high precision) model (Figure 2g,h). In autism, the regression model better predicted eye-looking timing than actual beat times.

Conclusions:

Rhythmic predictability may serve as a structuring mechanism to help children coordinate their behavior to important moments of social-communicative signaling. When presented with unpredictable social stimuli, TD and autistic toddlers use different approaches to time their eye-looking. While TD toddlers appear to show flexibility in use of predictive strategies, enabling them to accommodate unpredictable cueing, autistic toddlers consistently use a slow-updating model that makes then less able to adapt to cues in the actual stimulus. Results have implications for use of rhythmic predictability during natural interactions to scaffold social behavior.

312.004 (Oral) Deconstructing Slower Latency to Faces during Visual Exploration in School-Age Children with ASD: Results from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)

Background:

Prior work has identified slower latency of first look-towards-faces (LTF) in autistic children compared to controls on an eye-tracking (ET) visual exploration task (1). However, it is unclear whether this is due to increased perseveration on non-social objects prior to first look-towards-faces or decreased attentional prioritization towards faces. Furthermore, it is unclear whether visual exploration strategies associate with clinical and neural profiles.

Objectives:

To test, via between-group modeling, whether increased non-social perseveration or decreased social stimuli prioritization better accounts for slower latency of first look-towards-faces; and to investigate relationships between visual exploration variables and 1) clinical characterization, and 2) EEG signal features related to face processing.

Methods:

Participants included 399 6-11-year-old children (ASD: n=280, male=215; TD: n=119, male=83) from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT) Main Study Timepoint 1. Stimuli comprised static arrays of five objects including one face. Non-social perseveration and decreased social stimuli prioritization were tested, respectively, by linear model testing of group differences on two variables: 1) Average time spent looking at each object prior to first look-to-face (Time per Object Prior - TpOP); and 2) How many objects were looked at (including repeats and central fixation) before the child first looked at the face (Look Number Face - LNF).

Associations in the ASD group between clinical variables (ADOS 2 Social Affect, Vineland-3 Socialization & Communication, NEPSY-II Memory for Faces), EEG variables (right posterior temporal P100 amplitude and N170 latency in response to static images of faces (2,3)), and LTF, TpOP, and LNF were assessed using non-parametric Spearman’s rank correlation coefficients partialing for age, IQ, and data quality (4).

Results:

Group differences were observed on LNF (F=16.40, p<.0001), but not TpOP (F=0.013, p=.91). Children with ASD looked at more objects before the face (2.95, 95%CI [2.87, 3.04]) compared to TD children (2.66, [2.55, 2.77]) (t(385)=4.05, p=.0001). Both LTF and LNF were negatively correlated with Vineland-3 Socialization Scaled Score (p<.05, Figure 1). LNF was negatively correlated with NEPSY-II Memory for Faces (p<0.01, Figure 1). A negative correlation was observed between right posterior temporal P100 amplitude and both LTF and LNF (Figure 2) with increased P100 amplitude associated with earlier looks to faces and fewer looks to nonsocial objects before first look-to-face.

Conclusions:

Results support the decreased attentional prioritization towards faces hypothesis in the ASD group, but not the non-social perseveration hypothesis. Negative correlations between LTF/LNF and social communication variables align with prior findings (5) and suggest attentional prioritization for faces may index clinically meaningful variation. Negative correlations between right-side posterior temporal P100 amplitude, which may represent level of neural activation/use of neural resources in attention to meaningful stimuli (6), and LTF/LNF suggests coupled variance between neural mechanisms and attentional strategies that may underlie and reflect differences in social motivation and response to social rewards in children with ASD.

**Background:**

Investigative interviews are likely to present significant challenges to those on the autism spectrum. Social and cognitive differences associated with autism as well as a lack of autism-specific suspect interview methods suggest unique vulnerabilities for autistic suspects at interview. Relatively, behavioural and communication differences mean that autistic people may also be more likely to be perceived as deceptive. These two issues have substantial implications for the efficacy and fairness of police suspect interviews with autistic adults.

**Objectives:**

We aimed to investigate how verbal, paraverbal and nonverbal cues associated with deception are presented by autistic adults during mock-police interviews. In Study 1, we aimed to establish if (and how) autistic adults’ truthful and deceptive accounts differ from those of non-autistic controls. We predicted that autistic adults’ deceptive accounts would present more pronounced verbal cues to deception (i.e., greater inconsistencies, sparser accounts) than those of non-autistic adults. We also expected that autistic adults’ truthful accounts would more frequently display verbal deception cues than neurotypical adults’ truthful accounts. We also anticipated that autistic suspects would experience the investigative interview as more challenging than non-autistic suspects. In Study 2, we aimed to identify which verbal, paraverbal and nonverbal behavioural cues are most commonly reported by observers who (incorrectly) perceive truthful autistic mock-suspects as deceptive.

**Methods:**

In Study 1, 32 autistic and 33 (age and IQ-matched) non-autistic adults either undertook a simulated ‘criminal’ or ‘non-criminal’ task in a novel virtual environment. Participants were then instructed that they were to be interviewed as a lead ‘suspect’ in the mock-offence. ‘Criminal’ participants were instructed to lie and ‘non-criminal’ participants were instructed to tell the truth. All interviews were video recorded and transcribed to produce quantitative verbal cues. In Study 2, 70 lay rater participants (unaware of autism diagnosis) viewed a video of an autistic mock-suspect from Study 1 (providing a truthful account) and judged whether they were lying or telling the truth.

**Results:**

In Study 1, innocent autistic mock-suspects reported fewer details that would support their innocence ($t(30) = -2.075, p = .023, d = -.735$), although both autistic and non-autistic mock-suspects reported similar levels of investigation-relevant information and statement-evidence consistency (all $ps > .079$). In post-interview questionnaires, autistic mock-suspects self-reported greater difficulty understanding interview questions, higher anxiety, and perceived the interview as less supportive than non-autistic participants (all $ps < .040$). In Study 2, lay raters who judged the mock-suspect as deceptive based this evaluation upon verbal, paraverbal and nonverbal cues associated with deception, many of which are autism-common behaviours and relevant to the difficulties experienced by autistic participants during the mock-suspect interviews.

**Conclusions:**

Our findings show that investigative interviews are more socially and cognitively demanding for autistic mock-suspects than non-autistic controls. As such, a range of verbal, paraverbal and nonverbal cues associated with deception are displayed by autistic mock-suspects even when truthful. The development of autism-focused suspect interview techniques is therefore crucial to resolve the (interrelated) issues of interviewee welfare and provision of best evidence.

</table>
Background: One common aspect of Autism is difficulty with social interactions. The Double Empathy Problem Hypothesis (DEPH) argues that autistic-related social difficulties may be due to differences in communication styles between autistic and neurotypical individuals that diverge throughout development. This hypothesis is supported by findings that interactions between two autistic individuals are deemed more comfortable than those between autistic-neurotypical dyads. Are differences in social communication styles between autistic and non-autistic persons related to the degree of shared neural processes during interactions?

Objectives: We used an fNIRS hyperscanning paradigm to examine whether the degree of neural synchrony between interacting pairs with varying levels of autistic traits is associated with the Double Empathy Problem.

Methods: Participants (N=14, data collection ongoing) were classified as having high (H) or low (L) levels of autistic traits, based on Autism-spectrum Quotient scores. These classifications were then used to create H-H, H-L, and L-L pairs. Brain activity was then recorded simultaneously from both participants with fNIRS using a 45-channel montage during social interactions. Activity was recorded from the temporo-parietal junction (TPJ) and prefrontal cortex (PFC). Functional connectivity measures were used to examine synchrony patterns within groups for each of four social interaction conditions.

Results: Synchrony patterns differed based on dyad, story, and communication type. For instance, we found fewer synchronous connections in both TPJ and PFC for the non-ToM story in L-L dyads (p<.05); more TPJ connections during the non-ToM story and more PFC connections during the ToM story in the L-H group (p<.05); and many connections in TPJ (lateralized to the right hemisphere) and PFC for both ToM and non-ToM stories in the H-H group (p<.05; Figure 1). We also found synchronous connections of greater significance during non-ToM discussion for the L-L group (p<.05); right lateralized TPJ synchrony during non-ToM story discussion, and left lateralized TPJ synchrony during ToM story discussion for the L-H group (p<.05). Conversely, synchrony was lateralized to the left TPJ during non-ToM discussion and the right TPJ for ToM discussion for the H-H group (p<.05; Figure 2). All p-values were FDR corrected.

Conclusions: We used fNIRS hyperscanning to assess real-world interactions across dyads with varying degrees of autistic traits, to test the DEPH. While all groups had significant inter-brain synchrony in PFC and TPJ, patterns of synchrony differed based autistic traits, and the presence of ToM elements during story listening and conversation. Pairs with low autistic traits appear most synchronized in general, and dyads with high autistic traits appear to have more synchrony than pairs differing in autistic trait expression in PFC. Our results suggest that matched dyads have more shared neural processing likely contributing to quality of interaction, supporting the DEPH.

313.003 (Oral) Loneliness in Daily-Life in Neurodevelopmental Disorders

Background: Being alone (*i.e.* aloneness) can lead to loneliness, a negative emotional experience, but can also be enjoyed. It is not yet clear whether individuals with autism spectrum disorders (ASD) like being alone or feel lonely. However, this is a crucial distinction that needs to be understood, as social interaction difficulties are at the heart of the autism phenotype. Recently, we began to address this question by studying social interactions with the Ecological Momentary Assessment (EMA), an ecological methodology that enables repeated assessments in the flow of daily-life. The main results showed an intact social motivation but more isolation and rejection feeling in a non-social context compared to typically developing individuals (TD) and to individuals with 22q11.2 deletion syndrome (22q11DS), a genetic syndrome that has frequently been described as mimicking the social difficulties of ASD. Therefore, loneliness appears to be an aspect of the social phenotype in ASD that requires further investigation. In addition, loneliness has been described as a predictor of mental health is therefore a critical topic to study.

Objectives: This study aims to better characterize loneliness in individuals with neurodevelopmental disorders using a combination of ecological (EMA) and classical (questionnaires) measures, as well as its association with emotional reactivity and mental health.

Methods: One hundred and sixty-seven participants (79 females, 88 males) aged 12-30 years old were included in the study: 48 individuals with ASD, 54 22q11DS carriers and 65 TD. All participants were assessed with EMA during 6 days 8 times a day using the RealLife smartphone app. The items assessed positive and negative affects, loneliness and the subjective experience of aloneness. Reactivity to loneliness was measured as an increased in negative affects and a decrease in positive affects in response to loneliness. Paper-pencil questionnaires were used to assess positive and negative attitude toward aloneness (“trait” loneliness) as well as symptoms of mental health difficulties.
Results: There was no difference between the groups in terms of loneliness, and all participants reported feeling more lonely when alone than in the company of others. However, at the within-person level, the variance of loneliness was significantly different between groups, with higher variance in participants with ASD than among 22q11DS carriers and TD, as well as among participants with 22q11DS compared to TD. On emotional reactivity in response to loneliness, there was a stronger negative reactivity in participants with ASD compared to 22q11DS, as well as a stronger positive reactivity in ASD and TD participants compared to 22q11DS. On “trait” loneliness, participants with 22q11DS and ASD expressed greater affinity toward being alone than TD, and participants with ASD expressed lower aversion toward being alone than TD. However, loneliness in daily-life was not associated with trait loneliness in any group. Finally, no association between loneliness and mental health was observed.

Conclusions: This study opens up new avenues on the topic of loneliness, both state and trait, as well as its relationship with emotional reactivity and mental health in neurodevelopmental disorders and may have an impact on the care of these individuals.

313.004 (Oral) Non-Autistic Observers Both Detect and Demonstrate the Double Empathy Problem When Evaluating Interactions between Autistic and Non-Autistic Adults

D. R. Jones, M. Bola, R. A. Ackerman, K. King and N. J. Sasson, (1)The University of Texas at Dallas, Richardson, TX, (2)Department of Psychology, University of Stirling, Stirling, United Kingdom, (3)The University of Texas at Arlington, Arlington, TX, (4)University of Texas at Dallas, Richardson, TX

Background: Autistic adults often experience more successful and enjoyable interactions with autistic compared to non-autistic (NA) partners (Crompton et al., 2020; Morrison et al., 2020). This is consistent with a “double empathy” framework (Milton, 2012), which suggests that social interaction difficulties in autism are not inherent deficits but instead occur selectively with NA partners.

Objectives: This study examines how NA observers evaluate interactions between two autistic people relative to interactions between two NA people and mixed (A-NA) interactions.

Methods: One hundred and two NA adult observers viewed recordings of 42 autistic and 44 NA male participants interacting in one of three dyadic conditions: mixed (one autistic, one NA), both NA, or both autistic, and provided evaluations of character traits and interaction outcomes. Observers were not made aware of the composition of dyads. Multilevel modeling with REML was used to compare the effects of diagnosis and dyad composition on ratings both across and within dyads.

To determine whether observers could accurately predict participants’ assessments of their interactions, observers also estimated how each dyad member would evaluate the interaction and their partner. These ratings were compared to dyad members’ actual ratings using the Truth and Bias model, which assesses both the similarity between ratings (i.e. accuracy), and the directional bias (i.e. degree of over- or under-estimation).

Results: Overall, NA-NA interactions and participants were rated most positively. Observers perceived mixed interactions between autistic and NA adults as the least successful overall, with NA-NA dyads rated more positively than A-NA dyads on enjoyment (p < .001), smoothness (p < .001), awkwardness (p = .017), and intimacy (p = .043), and more positively than A-A dyads on enjoyment (p < .001) and smoothness (p = .004). However, observer ratings of NA-NA dyads did not differ significantly from ratings of A-A dyads on awkwardness (p = .254) or perceived intimacy (p = .979) between conversational partners. Observers also detected significantly more disclosure from autistic participants when interacting with an autistic relative to an NA partner (p = .008), and NA participants when interacting with an NA relative to an autistic partner (p < .001). NA observers rated autistic participants significantly worse than how their partners rated them within the interaction, and underestimated ratings to a greater degree than for NA participants on attractiveness, trustworthiness, likeability, and intelligence (p = .001). Observers also underestimated autistic participants’ social interest in their partners to a greater degree than for NA participants (p = .01).

Conclusions: Collectively, these findings indicate that NA adults both detect and demonstrate aspects of the double empathy problem during their observations of social interactions involving autistic people. They noticed that mixed interactions were less successful than those between two autistic or two NA partners, yet they also were less accurate at estimating how autistic participants felt about their partners relative to NA participants, suggesting that NA observers are poor at deciphering autistic signals of social interest. If extrapolated to real-world environments, this finding could translate into misperceiving autistic peoples’ desire for social inclusion and interaction.

POSTER SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR

418 - Social Cognition and Social Behavior I

418.341 (Poster) Lying to the like-Minded: Is It Easier to Spot Deception in Someone of the Same Neurotype?

I. Chowdhury, A. Hamilton and S. J. White, (1)University College London, London, United Kingdom, (2)University of Surrey, Guildford, United Kingdom, (3)University College London, London, UNITED KINGDOM
Background: The double empathy problem (DEP) in autism suggests that the socio-communicative difficulties faced by autistic people are not just because of atypical cognition in autism, but due to a breakdown in reciprocity and mutual understanding between autistic and non-autistic people. This is evidenced by the comparable success of autistic-only and non-autistic-only communication chains, but not mixed chains. Autistic participants are also more successful at attributing mental states to animated triangles created by other autistic people than they are for animations by non-autistic people, while the opposite is true for non-autistic participants.

Objectives: The current study investigated if the DEP extended to non-verbal deception, as autistic individuals find deception detection difficult but have only ever been tested on deception detection from non-autistic agents.

Methods: 103 autistic and 104 non-autistic adults of comparable age and ability watched 3-second non-verbal videos of both autistic and non-autistic agents lifting boxes, sometimes faking the weight of the box. Participants judged how fake the lift was on a scale of 1 (real) to 5 (pretend). Participants were aware that there were both autistic and non-autistic agents in the videos, but the neurotype of individual agents was not disclosed. It was hypothesised that participants would be better at distinguishing between pretend and real lifts for neurotype-congruent agents, i.e. autistic participants would detect deceit better from autistic agents, and non-autistic participants would detect deceit better from non-autistic agents.

Results: Both autistic (Figure 1a) and non-autistic participants (Figure 1b) were able to distinguish between real and pretend lifts, although autistic participants did so to a lesser extent. Both groups were better at distinguishing between real and pretend lifts from autistic agents than non-autistic agents. In comparison to non-autistic agents, autistic agents were judged to be more deceptive for pretend lifts by all participants, whereas for real lifts, autistic agents were judged to be more deceptive only by non-autistic participants, but not by autistic participants.

Conclusions: In line with past findings, autistic individuals in this study showed weaker deception detection ability. Both groups were better at detecting deception from autistic agents, which does not support the DEP; this could be because autistic agents reveal more deception cues. Additionally, findings here are consistent with past literature that suggest autistic individuals are perceived less favourably—notably, here autistic agents were considered to be deceptive by non-autistic participants even when they were being genuine. As these judgements were made on the basis of short, non-verbal videos with no indication of the agents’ neurotype, this must be due to some fundamentally different characteristic of autistic individuals, such as the way they move, that paints them in a negative light. This has far-reaching consequences for how autistic individuals are perceived in their day-to-day lives: such as in interpersonal relationships; or more worryingly, in high-stakes situations such as criminal investigations.

418.342 (Poster) A Novel End-to-End Dual-Camera System for Eye Gaze Synchrony Assessment during Face-to-Face Interaction

M. Thorsson, M. Galazka; J. Åsberg Johnels; and N. Hadjikhani. (1)Gillberg Neuropsychiatry Centre, Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (2)Gillberg Neuropsychiatry Centre, Department of Neuroscience and Physiology, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (3)Section of Speech and Language Pathology, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (4)MGH, Martinos Center for Biomedical Imaging, Harvard Medical School, Charlestown, MA, Sweden

Background: Quantification of face-to-face interaction has the potential to inform much about interpersonal communication. Current commercial, glint-dependent solutions suffer from several disadvantages and limitations when applied to examine face-to-face interaction. These include data loss, the inconvenience of using wearables, and/or the need for several cameras to capture each person. Here we present a novel eye-tracking solution, consisting of a dual-camera system used in conjunction with an individually optimized deep-learning approach that aims to overcome at least some of these limitations (setup displayed in Figure 1).

Objectives: To investigate if a dual-camera system used in conjunction with deep learning-based eye-tracking can be used to accurately classify gaze at specific facial areas and capture subtle differences in gaze synchrony in face-to-face interaction.

Methods: The present proof-of-concept study consisted of two experiments using a convenience sample of 8 healthy individuals (4 females; between 23 – 44 years) and the experimenter (male; 26 years). In Exp. 1, we examined the accuracy of the deep learning-based eye-tracking methodology using a 9-point calibration similar to those currently used in monitor-based eye trackers. In Exp. 2 the experimenter and a participant sat across from each other and each listened to a pre-recorded verbal instruction (60 5-second trials) directing them to look either at the left eye, right eye, mouth or just outside their partner’s face.

Results: The data show that our system, using deep learning methodology, can accurately classify the gaze location within different areas of the face of two interlocutors and capture subtle differences in interpersonal gaze synchrony between two individuals in a close-to-natural face-to-face interaction. The median rate of correct gaze classification was 89.54% across participants and conditions. Four separate Friedman tests confirmed that there were significant differences in the median prediction rate in each of the conditions Q (df = 3, n = 8) ≤ 14.55, p ≤ .002 (Figure 2).
Background: Compared to the general population autistic individuals report disproportionate rates of mental illness and suicidality. Evidence suggests that autistic core social deficits result in atypical social behaviours that inhibit social connection. This subsequently leads to fewer social connections, which are known to decrease loneliness and depression. Differences in autistic social behaviour are often perceived by others to portray a lack of desire for social relationships. This has led to the development of Social Motivation theory (SMt), which proposes that autistic individuals find socialisation less motivating due to a deficient social reward system. Consequently, autistic individuals have fewer social interactions, which reduces opportunities to learn and develop competent social communication skills. However, many autistic individuals camouflage to enhance social competency in the pursuit of socially desired outcomes. Camouflaging is highly reliant on observing others’ social behaviour and practicing these skills through social interactions. Yet, camouflaging can be inefficient and unsuccessful, which subsequently often negatively impacts mental health and wellbeing. Thus, SMt requires closer examination, particularly with attention to camouflaging.

Objectives: To synthesise empirical evidence of camouflaging autistic symptoms to obtain desired social relationships in autistic adolescents and adults.

Methods: Systematic searching of three databases yielded 1281 records. After duplicate deletion, 1029 records were screened for inclusion. Exclusions left 70 full texts of which nine qualitative studies met inclusion criteria and were retained.

Results: Camouflaging was a major theme in the socialisation experience for autistic adolescents and adults. The desire for social connection and acceptance was prevalent, and camouflaging was the main strategy used to pursue these outcomes, although not the most preferred strategy. For most, camouflaging was exhausting, isolating, often ineffective, and a challenge to one’s social authenticity, which negatively impacted their mental health.

Conclusions: Camouflaging is an extremely taxing, yet highly prevalent strategy used by autistic adolescents and adults to obtain social connection. Its use exemplifies the importance of social connection to autistic individuals. We need to understand more about individual differences in social motivation in autism, the strategies used to obtain social connection, and how to support them to achieve this endeavour.

Background: Recent studies have reported abnormal processing of happy expressions in children with ASD. For example, Kim et al. (2015) found reduced tendency to approach to positive social-emotional events in children with ASD. Further, Sepeta et al. (2012) suggested reduced sensitivity to positive and rewarding stimuli in children with ASD. Despite recent findings on abnormal social reward processing in ASD, to our knowledge, deficits in emotion recognition processing for positive expressions have not been reported in ASD. As happy emotion is considered to have social rewarding values, here we examined processing of happy emotional expressions in children with ASD using dynamic facial stimuli.

Objectives: The purpose of this study is to discover emotion recognition functions in children with ASD. We expected to find less sensitive processing to detect happy expressions in children with ASD possibly due to their abnormal reward sensitivity.

Methods: Eleven children with ASD (aged 6-12) and 12 age and gender matched typically developing controls (TD) performed a dynamic facial emotion recognition (DFER) task. The DFER task consisted of 72 video clips of faces. Each face gradually changed its emotion from neutral to full expression of one of six basic emotions (happiness, sadness, fear, disgust, anger, or surprise). Participants were asked to watch the video clip and make their choice among the six emotion labels as soon as they noticed emotion. The children were asked to respond twice: the first choice was made within 10 second of the video clip, and the second choice was made after the video clip stopped. The sensitivity of emotion recognition was defined as reaction times of the correct response of the first choice. The accuracy of emotion recognition was defined as accurate response rates of the second choice.

Conclusions: Our data show that this novel dual-camera system can accurately classify gaze location within different areas of the face of two interlocutors, effectively addressing some of the limitations of the current commercial solutions. In addition, the proposed approach allows to quantify subtle differences in interpersonal gaze synchrony between two individuals during a natural face-to-face interaction.
Results: Data from fear expression were excluded for further analyses since the accuracies were below the chance level for both groups. For the accuracy data, 2 (group) * 5 (emotion) repeated measures of ANOVA was conducted to examine emotion recognition dysfunctions in ASD. Results revealed a significant interaction effect between emotion and group ($F(1, 20)=4.94, p<.05$), after controlling for effects of full-scale IQ. Post-hoc analyses confirmed that children with ASD showed significantly lower performance to detect disgust emotion compared to TD ($t(15.42)=-2.56, p<.05$). The same series of analyses were conducted for the sensitivity data. Results showed a significant interaction between emotion and group ($F(1, 20)=8.62, p<.05$), revealing lower sensitivity to detect happiness in the ASD compared to the TD group ($t(21)=2.74, p<.05$).

Conclusions: Overall, we demonstrate differentiated facial emotion recognition processing in children with ASD depending on the valence of the expression. Specifically, children with ASD showed impaired processing to accurately detect negative emotion (i.e., disgust) in line with previous findings on ASD. Here, we also report a novel finding that children with ASD are less sensitive to detect the happiness expression. The lower sensitivity to detect happiness in ASD may be related to the abnormal reward processing and reward sensitivity of children with ASD, which can contribute to their abnormal social cognitive functions.

418.345 (Poster) Academic Interactions between Autistic University Students and Their Instructors: What Can We Learn from Autistic and Neurodivergent Instructors?

J. Ballantine, School of Linguistics and Language Studies, Carleton University, Ottawa, ON, Canada

Background: Autistic students are increasingly enrolling at universities worldwide. However, most university instructors are non-autistic and may be unaware of autistic students' lived experiences of learning and socializing. Research concerning the academic interactions (verbal and written) between autistic university students and their instructors is limited. Using Milton's (2012) Double Empathy Problem and selected rhetorical concepts from applied linguistics and discourse studies, we explore the nature of the interactions between both autistic and non-autistic instructors as they work together with autistic students in university settings in North America and Australia.

Objectives: By learning more about the social and academic interactions between autistic students and their instructors, especially in comparing similarities and differences between interactions when they are between two autistic people (i.e., an autistic student and autistic professor) and when they are across neurotypes (i.e., an autistic student and a non-autistic professor), we aim to identify key features of such interactions which support autistic university students to gain equitable access to learning and participation in knowledge creation at university.

Methods: This PhD doctoral project was participatory in nature in that a group of autistic graduate university students advised us through several stages of the methods; however, we were not able to attain the gold standard of participatory research (co-production from start to finish). Nevertheless, using semi-structured interviews, we interviewed 10 autistic and non-autistic instructors about their interactions with autistic university students. To analyze our qualitative data, we used a six-step reflexive thematic analysis (Braun and Clarke) to generate our themes and sub-themes with input from the advisory group.

Results: We found important differences in the ways that different instructors structure, teach, and assess outcomes for their courses depending on if they are neurodivergent, have had exposure to neurodivergent (or autistic) people, if they are not neurodivergent and yet are empathic to different styles of interaction and learning, and if they are not neurodivergent, but have limited exposure and understanding of autism.

Conclusions: We conclude that autistic and otherwise neurodivergent instructors, and non-neurodivergent instructors with personal experience interacting with autistic university students have important experiences and strategies to share with university instructors who have not encountered autistic and otherwise neurodivergent students before. These include both attitudinal and specific pedagogical strategies which will provide autistic university students with equitable access to learning and knowledge creation in university settings. We also find that use of rhetorical concepts together with the Double Empathy Problem is useful in elucidating the nature of misunderstandings between autistic university students and their instructors.

418.346 (Poster) Are Autistic Teens Better at Predicting Preferences of Autistic Peers?

S. Cahalan1, S. Block2, A. Clawson3, K. Frolichs4, C. Korn5 and G. Rosenblau1, (1)Autism and Neurodevelopmental Disorders Institute, The George Washington University, Washington, DC, (2)Department of Psychological and Brain Sciences, The George Washington University, Washington, DC, (3)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (4)Section Social Neuroscience, Department of General Psychiatry, University of Heidelberg, Heidelberg, Germany, (5)Institute for Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Learning about others is a crucial prerequisite for successful social interactions. Typically developing (TD) adults rely on feedback and prior knowledge about similar people to learn about someone new. Autistic adolescents rely on their own preferences to learn about TD peers (Rosenblau et al. 2021), potentially because autistic individuals do not integrate information from social feedback during learning, as hypothesized by the hypo-prior account of autism. Alternatively, autistic individuals could have more social knowledge about autistic people and use this during learning.
Objectives: We had TD young adults and autistic adolescents learn about TD vs. autistic adolescents and manipulated how similar learning profiles were to the average adolescent in both diagnostic groups. We expected TD adults to have developed representations of average TD population preferences as reflected in greater predictive accuracy when learning about the average TD adolescent as compared to a TD adolescent with less average preferences or autistic adolescents. Given our prediction that autistic people have more knowledge about autistic peers, we expected autistic adolescents to have greater predictive accuracy when learning about autistic profiles, yet still use their own preferences during learning.

Methods: TD adults (N = 94) and autistic adolescents (N = 101) rated two TD adolescents’ preferences for 60 items and received trial-by-trial feedback. Separate samples of TD adults (N = 97) and autistic adolescents (N = 119) completed the same task for two autistic adolescents. To test participants’ reliance on average preferences, one presented profile was very similar to the average preference profile in each diagnostic group (a TD person similar to the mean TD profile, i.e. mean profile), while the other was maximally dissimilar (odd profile). Learning was quantified by change in prediction errors (PEs) i.e., the difference between participants’ ratings and subsequent feedback. Lower PEs reflect higher task accuracy. Average population preferences were based on self-preference ratings from TD adults (N=307) and autistic adolescents (N=285). Groups were sex-matched for direct comparisons and age was entered as a model regressor.

Results: As predicted, PEs were smallest when TD participants learned about the TD mean profile, higher for the TD odd profile, highest and indiscriminate for the autistic mean and odd profiles. Contrary to our predictions, autistic adolescents’ PEs were lower for the TD vs. ASD profiles. Both groups learned about the mean and odd autistic profiles – the conditions with highest PEs across groups. When comparing the groups’ reliance on feedback, own, and mean-preferences, feedback was a significant regressor for preference ratings across groups. A condition by mean preference interaction suggested participants relied on mean preferences when learning about TD adolescents. A group by own preference interaction suggested autistic adolescents relied more on their own preferences during the task.

Conclusions: Autistic adolescents are more accurate at predicting the preferences of TD adolescents. While both TD and ASD groups reduced PEs over time and relied on feedback to make preference ratings, autistic adolescents relied more on their own preferences across conditions. In future analyses, a well-validated computational modeling framework will test nuanced differences in social learning strategies between groups.

418.347 (Poster) Assessment of Multiple Facets of Social Connection Among Autistic Adults: Development of the Connections with Others Scale – Autistic Version (CWOS-AV)

Background: Social connectedness, the perception that one is close and connected to other people, is an established protective factor against mental health disorders. Yet, the social motivation theory of autism poses the misconception that autism represents an “extreme case of diminished social motivation.” This theory stands in stark contrast to the earlier work of numerous researchers, all of whom suggested that humans, in general, have an intrinsic motivation and need to connect with others (Baumeister & Leary, 1995; Deci & Ryan, 1985; Maslow, 1954). Work by self-advocates have also highlighted the inaccuracy of this stigmatizing notion, with work from den Houting (2020) on the toll of social isolation emphasizing an inherent preference for social connection. Building upon the research and voices of autistic individuals, research is needed to advance the understanding of the extent to which autistic individuals are motivated to socially connect. Despite this need, limited measures exist to assess levels of motivation, desire, and value associated with connecting with others (i.e., social connection) among adults, particularly autistic adults.

Objectives: This study aims to develop a measure to assess facets of social connection that is valid among autistic adults. A secondary aim is to use this measure to examine the extent to which autistic adults are motivated, desire, and value connection with others, compared to non-autistic adults.

Methods: The sample consisted of 200 participants recruited online (autistic sample M age = 35.9, SD=12.6; non-autistic sample M age = 41.7, SD=18.8). Half of the sample self-reported a diagnosis of autism. Participants completed an initial set of 35 items to assess the desire, value, enjoyment, and motivation to connect with others and provided feedback on these items. Exploratory factor analyses (EFA) were conducted using 50 participants. Confirmatory factor analyses using the remaining 50 participants were then performed.

Results: A four-factor model was produced by the EFA. Item reduction resulted in the development of the 8 item Connections With Others Scale – Autistic Version (CWOS-AV). The scale includes factors for value, similarity, sociable, and member. The CWOS-AV had a comparative fit index of 0.980, a standardized root mean square residual of 0.064, and a root mean square error of approximation of 0.097 (90%CI=0.000-0.184; p=.205). Using a comparison group of 100 non-autistic individuals, autistic participants had significantly greater CWOS-AV scores compared to non-autistic participants (t(195)=3.39; p <.001).

Conclusions: The CWOS-AV was developed to facilitate measurement of social motivation, desire, and value among autistic individuals. This measure will allow for greater ability to assess numerous facets of social connection, resulting in improved ability to produce research that clarifies theories and describes psychological phenomenon. Additionally, autistic participants had significantly greater scores on the
CWOS-AV, demonstrating higher levels of motivation, desire, enjoyment, and value associated with connecting with others. This provides clear evidence in contradiction with the social motivation theory. This, coupled with theoretical work on the human need to connect, suggests that the social motivation theory of autism cannot be generalized to all autistic people, or even most autistic people.

**418.348** (Poster) Associations between Antipsychotic Use, Severity of Challenging Behaviors, and General Attention Assessed Via Eye Tracking: An Exploratory Investigation from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)

**Background:** Prior work has found that autistic children taking antipsychotics display a trend toward greater overall cognitive and socio-adaptive impairments. Little is known, however, about associations between antipsychotic use and attentional processes which may covary with behavioral issues. The current project explores whether antipsychotic use has a similar outcome effect on measures of social attention using eye-tracking (ET).

**Objectives:** To examine how the use of antipsyhcotics, the severity of challenging behaviors, and their possible interaction in autistic children is associated with differences in general attention to ET stimuli.

**Methods:** Data from 280 participants (M=215, F=65) aged 6-11 years with ASD, including N=20 participants using antipsychotics, were acquired from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT). Medications were classified by category and examined alongside behavioral features using standardized clinical measures including the Aberrant Behavior Checklist, 2nd Edition (ABC-2). Percentage of valid data acquired via ET (%Valid) was fit in a linear mixed model as a function of Medication use {No Antipsychotics, Antipsychotics}, ABC Raw Scores, their interaction, and an age-control-covariate.

**Results:** ANOVA revealed no main ABC Raw Score effect (p=.837), a marginal Medication effect (p=.068), significant Age effect (p<.001), and an ABC x Medication interaction (p=.008). Children on antipsychotics showed a positive relationship between ABC and %Valid (10-point ABC increase associated with 1.97% [95%CI: -0.33%, 2.52%] %Valid increase), whereas children not on antipsychotics showed a negative relationship (-0.94% [95% CI: -.485%, -1.396%]). At the highest ABC, children on antipsychotics showed lower %Valid (76.1% [95% CI: 65.3%, 86.9%]) compared to children not on antipsychotics (90.8% [95% CI: 88.4%, 93.2%], p=.009), whereas at the highest ABC, children on antipsychotics showed higher %Valid (92.2% [95% CI: 80.4%, 100%]) compared to children not on antipsychotics (77.0% [95% CI: 72.2%, 81.7%], p=.019) (Table 1).

**Conclusions:** These exploratory results suggest that antipsychotic use is associated with higher attention to stimuli for autistic children with high ABC scores and lower attention for those with low ABC scores. The most prescribed antipsychotic within this group was risperidone, an FDA-approved drug for reducing irritability in 5- to 16-year-olds with autism shown to also treat aggression, hyperactivity, and stereotypy. There are several possible (not necessarily mutually exclusive) directionals to consider for these associations: high ABC scores in children on antipsychotics may be associated with greater levels of irritability and less with attention issues compared to children with high ABC scores not taking antipsychotics; low ABC scores in children on antipsychotics may reflect antipsychotic responders with side effect profiles including lethargy and drowsiness associated with decreased ET data collection; antipsychotic use could improve general attention for children with persistently elevated ABC scores. Further analyses could investigate subdomains of the ABC measure individually, i.e., irritability, social withdrawal, stereotypic behavior, hyperactivity, etc. to hone our understanding of its relationship to attention. These results merit further exploration into eye-tracking as a potential lens to help disentangle our understanding of the effect of medication use on attention in autistic children.

**418.349** (Poster) Associations of Emotion Dysregulation and Autonomic Responses during an Emotion Regulation Task in Adolescents with and without Autism

_H. T. Chiu, I. Ip, F. N. Y. Ching and S. W. H. Wong, (1)Department of Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)Laboratory for Brain and Education, The Chinese University of Hong Kong, Hong Kong, Hong Kong

CWOS-AV, demonstrating higher levels of motivation, desire, enjoyment, and value associated with connecting with others. This provides clear evidence in contradiction with the social motivation theory. This, coupled with theoretical work on the human need to connect, suggests that the social motivation theory of autism cannot be generalized to all autistic people, or even most autistic people.
Background: Emotion regulation (ER) deficits are increasingly seen as a factor underlying mental health problems in autistic individuals. Physiological regulatory processes in the autonomic nervous system (ANS) is closely related to the ability for effective ER. Studies of resting autonomic activity in autism have reported mixed results, with between-group findings of hyperarousal, hypoarousal or null effects (Arora et al., 2021). As such, capturing the individual differences in autonomic changes during emotional processing may be a helpful approach to examine links between emotion dysregulation and ANS functioning. However, to date, no study has measured autonomic indices during task-based measures of emotion reactivity and effortful ER strategy use in autistic individuals.

Objectives: To investigate whether emotion dysregulation in adolescents with and without autism is associated with autonomic responses during ER in a laboratory task.

Methods: Twenty adolescents with autism (male = 70.0%, \(M_{\text{age}} = 16.4, SD = 1.30\)) and thirty-four without autism (male = 26.5%, \(M_{\text{age}} = 16.4, SD = 2.13\)) completed a short ER strategy training (i.e., reappraisal) at the lab and were then administered an ER task. In the task, blocks of negative and neutral images were presented. Prior to each block, participants viewed a strategy prompt that indicated either “Look” or “Decrease”. When prompted to “Look”, participants looked at the images and responded naturally. When asked to “Decrease”, participants used the ER strategy to decrease any negative emotions aroused by the negative images. After each block, participants rated their degree of negative emotion (from 1 = “very weak” to 4 = “very strong”). The task had 3 conditions: Decrease Negative, Look Negative, and Look Neutral.

Task-related physiological responses, including beat-by-beat heart rate (HR) and skin conductance (SC) measures were recorded continuously throughout the ER task. Physiological changes in emotion reactivity were reflected in difference scores between Look Negative and Look Neutral conditions. While physiological changes in emotion regulation were reflected in difference scores between Look Negative and Decrease Negative conditions.

All participants completed the Autism Quotient (AQ), while participants’ caregiver or parents completed the 7-item Reactivity Short Form from the Emotion Dysregulation Inventory (EDI). The scale measures rapidly escalating and intense negative affect, with higher scores reflecting higher emotion dysregulation.

Results: Correlational analysis in the combined sample of participants revealed significant associations between changes in HR and number of SC responses (nSCR) during emotion reactivity and the EDI. Specifically, greater increases in HR and nSCR when viewing negative images were related to higher EDI scores. However, changes in HR and nSCR during emotion regulation were not associated with the EDI.

Conclusions: The findings indicate that exaggerated physiological changes in emotion reactivity are associated with higher levels of emotion dysregulation. It suggests that ANS dysregulation may contribute to emotion dysregulation in autistic adolescents. The study highlights the utility of an individual difference approach to studying the relationship between ANS functioning and parent-rated day-to-day ER characteristics in autism. Future research will be required to examine the potential for interventions that improve autonomic balance in autistic individuals.

418.350 (Poster) Autism Symptoms Moderate Mother-Child Physiological Synchrony
C. Moser, L. Friedman and J. Klusek, (1)Communication Sciences & Disorders, The University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC, (3)Communication Sciences and Disorders, University of South Carolina, Columbia, SC

Background:
Physiological synchrony, or the dyadic coordination of physiological states, between parents and their children is foundational for socioemotional development and may represent a pathway to better understand social reciprocity in autism. Respiratory sinus arrhythmia (RSA) serves as an indicator of physiological regulation and is reduced in those with autism. Dyadic coordination of RSA with interaction partners may also be impacted in autism, with weaker RSA synchrony found in dyads of parents and their autistic children as compared to neurotypical children (Wang et al., 2021). Understanding the influence of autism symptoms on dyadic RSA synchrony can provide further evidence of its utility as a potential intervention target (e.g., paced breathing practices to provide the child with self-regulatory skills).

Objectives:
The present study aimed to determine whether autism symptom severity impacts the magnitude and direction of RSA synchrony within dyads.

Methods:
Participants included 22 dyads of mothers (\(M_{\text{age}}=39.55\)) and their autistic children (\(M_{\text{age}}=8.71\) years). Physiological data was collected during a 4-minute interaction task where the dyad was asked to copy a series of drawings using an Etch-A-Sketch. Each partner was in control of one knob to elicit goal-oriented behaviors from the dyad. The Actiheart-5 heart rate monitor captured the ECG signal, which was
then processed through CardioEdit software to correct for artifacts. RSAscents, an online program, was used to apply a time-series transformation that provides 1-second estimates of RSA across the interaction. Autism severity was assessed using the calibrated severity scores from the ADOS-2.

Results:

A mixed-effects model examined mother-child RSA synchrony and its association with autism severity. Child RSA reactivity, child task average RSA, autism severity, and their interaction were tested as predictors of maternal RSA. The interaction between child task average RSA and autism severity was a significant predictor of maternal RSA, $b=589, t(18)=4.24, p<.001$. Simple slopes analyses showed that dyads of children with higher autism symptoms demonstrated positive RSA synchrony ($p<.001$) and dyads of children with lower autism symptoms demonstrated negative RSA synchrony ($p=.018$). The main effect of child RSA reactivity and its interaction with autism severity were not significant predictors of maternal RSA ($p=.410$).

Conclusions:

Findings show that the level of autism symptom severity differentiates the magnitude and direction of RSA synchrony in mothers and children with autism. Specifically, those with higher autism symptom severity demonstrated significant positive RSA synchrony (i.e., both partners show similar levels of RSA across the task), while those with lower autism symptom severity demonstrated significant negative RSA synchrony (i.e., RSA of both partners is associated but in the opposite direction). Our findings suggest negative RSA synchrony could reflect an adaptive dyadic exchange, in which interaction partners may regulate one another’s physiology. For instance, it is possible that mothers regulated their own physiology to demonstrate a calm demeanor in the face of their child’s distress. Follow-up studies that account for the affective valence of an interaction will further clarify the patterns observed here by confirming the adaptive/maladaptive nature of negative RSA synchrony in mothers and their children with autism.

McPartland, (1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Child Study Center, Yale University, Child Study Center, New Haven, CT, (3)Child Study Center, Yale School of Medicine, New Haven, CT, (4)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (6)University of Washington, Seattle, WA, (7)Children’s Hospital Los Angeles, Los Angeles, CA, (8)Boston Children’s Hospital, Boston, MA, (9)Yale University, New Haven, CT, (10)University of California, Los Angeles, Los Angeles, CA, (11)Center for Child Health, Behavior and Development, Seattle Children’s Research Institute, Seattle, WA, (12)Child Study Center, Yale Child Study Center, New Haven, CT

Background: Reduced social visual attention, as measured with average gaze time to faces, is a primary feature of autism widely evaluated with the use of infrared eye-tracking. However, the reliance on region-of-interest (ROI) analysis to quantify the looking behavior of autistic individuals to specific social information (e.g., faces, eyes) does not capture the temporal sequence of eye movements (i.e., scan paths) that provides rich information related to dynamic visual attention.

Objectives: We aimed to apply a novel computational modeling approach to: (1) Evaluate whether visual processing strategies during social perception differed in autistic compared to neurotypical peers, and (2) Quantify how variability in visual processing strategy is related to variability in social, neuropsychological, and attention domains of function.

Methods: Data from 290 autistic and 109 neurotypical children aged 6-12 years old ($M=8.53, SD=1.63$) were obtained through the Autism Biomarkers Consortium for Clinical Trials (ABC-CT), a large multisite study that included multiple eye-tracking assays related to social perception (e.g., viewing social scenes, visual exploration of social and non-social objects). To capture participants’ visual processing strategy, which includes both spatial and temporal dimensions of eye movements, we utilized a probabilistic modeling approach that summarized eye movements (gaze locations and sequence) with person-specific regions of interest (ROIs) and transition probabilities among ROIs using a hidden Markov model; Common eye movement patterns were revealed through clustering.

Results: For passive viewing of static social scenes, exploratory (larger ROIs to people) and focused (smaller ROIs to people) patterns were exhibited across all participants. These eye movement patterns were exhibited by a similar proportion of autistic (Group 1 = 176; Group 2 = 91) and neurotypical (Exploratory = 70; Focused = 46; $\chi^2(1) = 0.86, 95\% CI [-0.06, 0.17], p = .35$) participants. However, for visual exploration, exploratory (ROIs specific to multiple objects) and focused (object-specific ROIs) patterns emerged across all participants with a significantly larger proportion of autistic individuals favoring an exploratory eye movement pattern (Exploratory=168; Focused = 97) compared to the neurotypical group (Exploratory = 38, Focused = 78; $\chi^2(1) = 29.27, 95\% CI [0.20, 0.33], p < .001$). Participants exhibiting a more exploratory pattern had higher adaptive social functioning scores (Vineland Adaptive Behavior Scales – III scores), lower autism social symptoms (SRS-2) scores, and lower face memory scores (NEPSY-II).
Conclusions: Participants with less adaptive social functioning, more social impairment, and poorer face memory scores used qualitatively different visual processing strategies during visual exploration of social and nonsocial stimuli in ways that converge with autism specific symptomology across social and neuropsychological domains of function.

418.352 (Poster) Autistic Preschoolers Display Reduced Attention Orientation for Social Competition but Intact Facilitation Effect from the Presence of a Parallel Competitor: Evidence from Eye-Tracking and Behavioral Data

L. Yu, Z. Wang, L. Ban, Y. Fan and L. Mottron, M.D., (1)Center for Autism Research, School of Education, Guangzhou University, Guangzhou, MN, China, (2)School of Psychology, South China Normal University, Guangzhou, China, (3)School of Psychology, South China Normal University, Guangzhou, China, (4)Center for Autism Research, School of Education, Guangzhou University, Guangzhou, China, (5)Centre de recherche du CIUSSS-NIM, Montréal, QC, Canada

Background: Autistic individuals have been historically viewed as lacking social motivation and skills necessary for success in social situations. However, social motivation of autistic individuals might have been underestimated in research (Jaswal & Akhtar, 2019). Lateral tutorship, a form of parallel competition that does not involve overt interpersonal interaction, may be more suitable for promoting early learning of autistic children than interactive teaching (Mottron (2017, 2021)).

Objectives: 1) to explore visual attentional preference and processing of two scenarios of unequal interactive value, parallel competition and overt cooperation, in preschoolers with autism; 2) to address whether and how autistic children can benefit from lateral tutorship, in the form of parallel competition.

Methods: Twenty-six preschool children with autism and 20 neurotypical children matched on chronological age, sex and non-verbal IQ participated in two experiments. Experiment 1 employed a gaze-contingency task using eye-tracking technique. We measured visual attention orientation towards three videos depicting a competitive play, a cooperative play, and a non-social control stimulus. Experiment 2 included a gross motor task and a cognitive problem-solving task in two conditions, one which the participant was required to complete independently and another with the presence of a competing partner, to examine whether the parallel competition improves performance in the autistic children and neurotypical children.

Results: In Experiment 1, the autistic children displayed reduced visual orientation towards competition than neurotypical children whereas there was no such group difference for cooperation. Lower social prioritization score (subtracting the orientation toward nonsocial baseline from the orientation toward competition or cooperation) in autism than in neurotypical children was observed only for competition, but not for cooperation. Orientation toward competition increased with age while orientation toward cooperation decreased with age in the neurotypical group but not in the autism group. In Experiment 2, the presence of a competitor significantly and similarly improved performance of both the autistic children and the neurotypical children across tasks. Visual orientation to competition/cooperation was significantly correlated with cognitive problem-solving in the neurotypical group only.

Conclusions: Autistic preschoolers show reduced visual-attentional interest towards social competition. Unlike neurotypical peers, their visual interest towards competition did not increase with age. Nonetheless, the results of Experiment 2 demonstrated that participating in a parallel competition led to increased performance for autistic children to the same extent as it did for neurotypical children. Taken together, atypical social interaction preferences do not prevent autistic children from benefiting from social situations. Lateral competition/tutoring should not be over-written by joint-interactive activities in early intervention and education practice for autistic preschoolers.

F. Leung, C. Jiang and F. Liu, (1)Department of Psychology, University of Bath, Bath, United Kingdom, (2)Music College, Shanghai Normal University, Shanghai, China, (3)School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom

Background:

One challenge with the marked social communication difficulties in autism has been associated with the processing of emotions. Despite much research, the underlying mechanisms of emotion processing differences in autism remain poorly understood, namely whether they stem from a domain/modality-general or -specific level of processing. This is due to the limited evidence available for domains other than human faces. Equally, how such emotion processing differences in autism manifest behaviourally across domains at the implicit (automatic) and explicit (controlled) levels of processing is also an under-researched area.

Objectives:

To address these research gaps, this study investigated how autistic traits might relate to differences in implicit and explicit emotion processing across multiple stimulus domains.
Methods:

74 native Mandarin speakers (58 female; \(M_{\text{age}} = 22.72, SD_{\text{age}} = 1.80\)) completed the Autism-spectrum Quotient (AQ) to measure autistic traits, scores of which were all within the neurotypical range (< 32; \(M_{\text{AQ}} = 19.45, SD_{\text{AQ}} = 6.31, \text{range} = 8-31\)). According to a median split of AQ scores, participants were assigned to either the high (AQ > 17; \(n = 36\)) or low (AQ ≤ 17, \(n = 38\)) AQ group. A forced-choice emotion labelling task assessed explicit emotion processing, which involved the recognition of emotions across four stimulus domains (human faces, face-like objects, speech prosody, song). A cross-modal emotion priming task assessed implicit emotion processing of spoken/sung words (primes) through their influence on subsequent emotional judgment of faces/face-like objects (targets), using a stimulus onset asynchrony of 200ms and varying emotional congruence between primes and targets across trials.

Results:

Linear mixed-effects analyses revealed that for labelling, the low and high AQ groups performed similarly across conditions for both accuracy and speed. Notably, both groups recognised emotions most accurately and quickly from objects but least accurately from song. For priming, both groups showed more accurate and faster emotion recognition of targets when preceded by emotionally congruent than incongruent primes, particularly for spoken compared to sung primes. Crucially, emotion recognition of human face targets was less strongly primed by both spoken and sung emotions in the high compared to low AQ group, demonstrated by less facilitated recognition accuracy of face targets when preceded by emotionally congruent primes in the high than low AQ group (Figure 1).

Conclusions:

Results suggest no emotion processing differences across stimulus domains at the explicit level between individuals with low versus high autistic traits. While this finding contradicts some previous research, it may be a result of learnt compensatory strategies given the adult sample. Emotion processing differences were most noticeable at the implicit level, where automatically processed emotions regardless of auditory domain had a weaker influence on subsequent emotional judgment in human faces among individuals with high than low autistic traits. Altogether, emotion processing differences in individuals with high autistic traits may be explained through domain/modality-general mechanisms. This finding has potentially important translational value for understanding how emotion perception of different stimulus domains presents and interacts in autistic individuals, such as their reduced use of multisensory cues for emotional judgment in social communication.

418.354 (Poster) Autistic and Non-Autistic Adults Believe Autistic People Feel More Pain Than Non-Autistic People

A. Basargekar, C. E. Rodi and V. K. Jaswal, (1)Psychology, University of Virginia, Charlottesville, VA, (2)University of Virginia, Charlottesville, VA

Background:

Some authoritative sources suggest that autistic people are relatively insensitive to physical pain (American Psychiatric Association, 2022; Frith, 1989; Wing, 1996). However, research on autistic people’s experienced pain has presented mixed findings, with different studies reporting hypersensitivity, hyposensitivity, or neither (Zhang et al., 2021). Similarly, based on common claims about autistic people being socially indifferent (Chevallier et al., 2012), one might expect low sensitivity to socially painful situations (e.g., exclusion). And yet first-person accounts (Acker et al., 2018) and cyberball experiments (Trimmer et al., 2017) suggest that autistic people feel hurt by rejection and ostracism.

These different accounts suggest that widespread beliefs about autistic people’s pain sensitivity may be misaligned with autistic people’s experiences of pain. The present study examined the possibility of a systematic bias in the pain sensitivity attributed to autistic people. We also investigated associations between pain sensitivity attributed to autistic people and the autonomy granted to autistic people.

Objectives:

In this pre-registered study, we investigated: 1) how much physical and social pain autistic and non-autistic participants thought they would experience in several scenarios that could be mildly painful; 2) how much pain participants estimated either an autistic or non-autistic character would feel in the same scenarios; and 3) how these pain ratings were related to participants’ beliefs about the character’s autonomy.

Methods:

We recruited autistic (\(n = 64\)) and non-autistic adult participants (\(n = 64\)) using the online platform Prolific. Participants first indicated how much pain (on a 1-4 scale) they would feel in 18 physically painful (Trawalter et al., 2012) and 10 socially painful (Deska et al., 2020) situations. Participants then read a vignette describing either an autistic or a non-autistic adult target character, and estimated how much
Background: Clinicians form initial impressions about a child’s diagnosis based on behavioral features (de Marchena & Miller, 2017); confidence in their initial impression may differ based on child’s diagnosis and characteristics such as age (McDonnell et al., 2019). Initial impressions may facilitate screening: 92% of referral-seeking children initially believed to have ASD are ultimately diagnosed with ASD (Wieckowski et al., 2021). However, research on initial diagnostic impressions has not yet identified specific behaviors used to guide these impressions. This research also has implications for a theoretical understanding of the heterogeneity of ASD.

Objectives: To identify behaviors that clinicians use to form initial diagnostic impressions of ASD and non-ASD in toddlers.

Methods: Participants were toddlers (N=51, mean age 22.9 months) from a multi-site study investigating early detection and intervention for ASD. Clinicians completed an Initial Diagnostic Impression Checklist within five minutes of meeting a child. They noted their impression as ASD or non-ASD and the “atypical” or “typical” behaviors that contributed to their impression for the following domains (clinicians indicated all domains that they used): social reciprocity, nonverbal communication, eye contact, motor mannerisms, prosody and vocalizations, facial expressions, and focus of attention. Final diagnoses, after the complete initial toddler evaluation, were dichotomized to ASD or non-ASD. The final diagnostic groups were not significantly different on race, ethnicity, maternal education, chronological age, or sex.

Results: When a child’s final diagnosis was ASD (n=32), clinicians formed an accurate initial impression of ASD in 65.6% of cases (n=21), and an inaccurate impression of non-ASD in 34.4% of cases (n=11; Figure 1). Accurate initial impressions of ASD were associated with atypical social reciprocity (n=12), nonverbal communication (n=13), focus of attention (n=11), and eye contact (n=11; Figure 2a). For children diagnosed with ASD an initial impression of non-ASD, clinicians endorsed typical prosody/vocalizations (n=6), typical eye contact (n=7), and absent repetitive motor mannerisms (n=5). When a child’s final diagnosis was non-ASD (n=19), clinicians made an accurate initial impression of non-ASD in 100% of cases (n=19; Figure 1), informed by typical behaviors of social reciprocity (n=12), nonverbal communication (n=11), focus of attention (n=10), and eye contact (n=13; Figure 2b).

Conclusions: These results have several implications: first, although 2/3 of toddlers with ASD were identifiable within a very short time, the remaining 1/3 were not classified correctly, which suggests that the initial diagnostic impression cannot be relied on to identify all cases of ASD. Second, although clinicians had the option to consider behaviors in seven domains when forming initial diagnostic impressions of toddlers, the most accurate initial impressions of ASD came from social reciprocity, nonverbal communication, eye contact, and focus of attention. Finally, the idea of prototypical or frank autism has been under consideration lately; these results suggest that such a phenomenon exists for the majority of toddler aged-children, but a substantial minority are a heterogeneous group of toddlers whose ASD requires a lengthier and more in depth evaluation.
Background: Prior to the pandemic of 2020, many families seeking social skills group intervention for their adolescents did not have access within their communities, particularly in rural areas. The pandemic created a shift to telehealth versions of many evidence-based autism interventions. Without research results to show effectiveness of interventions in new service delivery models, families and practitioners hoped for equivalent outcomes, but research activities were also extremely limited during the pandemic. This project was begun prior to 2020, with minimal pandemic disruption, allowing for comprehensive data collection under more typical conditions.

Objectives: We wanted to know if live, interactive delivery of social skills group interventions was as effective as in-person delivery of group interventions.

Methods: We used Laugeson and Frankel’s PEERS® manualized curriculum in both in-person and live online (using Zoom) delivery models. The PEERS® curriculum was used in both groups, with some adaptations to the online environment. Baseline parent-report and social interaction data were collected prior to any instruction. In-person and online groups were completed for 14 weeks. Adolescent groups and parent groups met together in both delivery models. Participants met again in person after the 14 weeks for generalization probes, participating in typical activities (i.e. fast food, bowling, playing games, and going to a museum). Social validity data were collected from therapists, parents and teens. Parents reported changes in social interactions using pre- and post-intervention measures.

Researchers used behavioral coding to measure frequency of social interactions from video recordings of baseline and generalization events and quality of social interactions, with reciprocal social interactions coded as higher quality than one-sided or passive interactions.

Results: Social validity results were strong in both therapists and parents, with online parents showing slightly higher results indicating satisfaction. Pros and cons of each model were mentioned in a focus group with therapists. Parents reported small improvements at similar rates across both in-person and online groups on standardized measures and inventories of social skills used to guide intervention. Objective behavioral coding from videos of baseline and generalization phase sessions were aligned with parent report results and social validity ratings.

Conclusions: While families may prefer in-person social skills groups for their adolescents, they cannot always access in-person services. Social validity for the online version of the group was slightly higher, perhaps because of reduced transportation burden or because there was no other way to access the intervention for some. Geographic location, extreme social anxiety and challenging behaviors were examples of barriers to in-person groups that were better suited to the online environment. Adaptation of the PEERS® curriculum was accomplished with relative ease, now made even easier in a post-pandemic world. Effectiveness of the chosen curriculum was similar for either delivery mode. This adds to the new body of literature regarding telehealth interventions for autistic adolescents and social skills interventions.

Objectives: Our primary aim was to investigate correlations between SST and variables that are known to be associated with autism. As a secondary aim, we measured SST scores in a clinical population comparing individuals who received an autism diagnosis with those who resulted negative to diagnostic assessment.

Methods: We enrolled all consecutive admissions for autism diagnostic assessment since September 2021. Exclusion criteria were IQ < 85 and SST comprehension subscale < 5 points. SST was administered as follows: after reading a short story by Ernest Hemingway, participants were asked questions that assessed mental state reasoning (SST-MS) and comprehension of non-mental content (SST-C). An investigator blind to SST outcome conducted the ADOS-2 interview. IQ was measured with WASI-II. Self-report questionnaires were used for autistic traits (AQ, Social Responsiveness Scale 2 [SRS-2]) and empathy (Empathy Quotient [EQ], Interpersonal Reactivity Index [IRI]).
Results: There were 25 participants with autism diagnosis and 8 without autism diagnosis. No significant difference was found between the two groups in IQ, AQ, EQ, SRS-2, and IRI scores. No significant difference was observed in SST-C and SST-MS. There was a significant difference in ADOS-2 score (U=41, p=0.01). Focusing on autistic participants, SST-C was positively correlated with IQ scores (r=0.58, p=0.002) and negatively with IRI personal distress subscale (r=-0.43, p=0.03). SST-MS was positively correlated with IQ scores (r=0.40, p=0.048) and negatively with ADOS score (r=-0.42, p=0.02). Of note, SST did not correlate with any other measure.

Conclusions: We found a negative correlation with ADOS-2 for SST-MS, but not SST-C, suggesting that autistic traits are specifically associated with difficulties in mental state reasoning in SST. Correlations between IQ and SST are greater for SST-C, indicating that mental state reasoning is less dependent on general intelligence than non-mental text comprehension. Non-significant differences between the two groups are probably due to the limited number of non-autistic subjects. Even though this is a preliminary study with a limited sample, it strongly suggests the opportunity to further investigate SST as a tool to evaluate ToM in autism diagnostic assessment for adult individuals.

418.359 (Poster) Conducting Head-Mounted Eye-Tracking Research with Young Children with Autism Spectrum Disorder

E. S. Perkovich, S. S. Mire, A. L. Laakman and H. Yoshida, (1)Psychology, University of Houston, Houston, TX, (2)Psychological, Health, and Learning Sciences, Baylor University, Houston, TX, (3)Psychological, Health, and Learning Sciences, University of Houston, Houston, TX

Background: Recent technological advances in head-mounted camera method have allowed researchers to study young children’s gaze behaviors in ecologically valid contexts, such as social live interaction and solo play (Sun & Yoshida, 2022; Yoshida & Smith, 2008; Yu & Smith, 2013; Yurkovic-Harding et al., 2022). This method has great potential to further our understanding of relationships between child’s visual input and parent’s behaviors that may support early perceptual experiences critical for learning. While the method has great potential for studying learning mechanisms for young children with autism spectrum disorder (ASD), it has been used primarily among typically-developing children (but see Perkovich et al., in press; Yoshida et al., 2020; Yurkovic et al., 2021; Yurkovic-Harding et al., 2022). This may be due to methodological challenges, including sensory sensitivities, social-communication difficulties, and challenging behaviors (e.g., disruption and elopement), creating a barrier to quality data collection.

Objectives: The purpose of this session is to share our current practices that optimize the head-mounted camera (specifically head-mounted eye tracking) data collection. These suggested practices are based on our past and ongoing research with toddlers and children with ASD but also have potential applicability for collecting similar data among young children with other developmental disorders.

Methods: In this study, we used head-mounted eye-tracking data from 35 children with ASD (Younger Group [<5 Years Old]: 18, Older Group [>5 Years Old]: 17) during a parent-child play-session for 5.33 minutes (see Figure 1 for set-up). Children were grouped into the ASD group using scores from the Autism Diagnostic Observation Schedule (ADOS) (Lord et al., 2000) or the Autism Diagnostic Observation Schedule, Version 2 (ADOS-2) (Lord et al., 2012), which were administered by research-reliable administrators. No auditory or visual impairments were reported.

Results: The success rate in gathering eye-tracking data in this sample of children with ASD was 91.4%. Three of 35 children failed to complete the play-session, resulting in a 83.3% success rate among younger participants and a 100% success rate among older participants. There were numerous “challenging” behaviors relevant to the current research method. The most common challenging behaviors included taking the eye-tracker device off (younger: 83.3%; older: 23.5%), elopement (younger: 55.5%; older: 23.5%), and becoming distressed (younger: 50.0%; older: 11.8%). Overall, 88.8% of children in the younger age range and 29.4% of children in the older age range exhibited at least one challenging behavior.

Conclusions: Head-mounted camera method has the potential to reveal early, socially-relevant gaze behaviors relevant for identifying precursors and contributors to early learning among children with ASD (Falck-Ytter et al., 2013). However, challenges of using the technology in this population currently prevents its use. In this presentation, we will overview strategies our team uses to obtain high rates of successful data collection even when challenging behaviors are present. By accumulating workable practices and guidelines, this work has the potential to improve awareness of the feasibility of these methods and the utility of results, ultimately expanding research opportunities for children with autism and other developmental disorders.

418.360 (Poster) Correlates and Turning Points of Adaptive Functioning Trajectories and Longitudinal Associations with Autism Symptoms from Early Childhood to Adolescence

Y. J. Chen1, E. Duku1, P. Szatmari2, J. M. Smith1, L. Zwaigenbaum3, T. Bennett4, A. E. Richard5, T. Vaillancourt6, M. Elsabbagh7, W. J. Ungar8, A. Zaidman-Zait9, C. M. Kerns10 and S. Georgiades1, (1)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (2)Department of Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (3)Dalhousie University / IWK Health Centre, Halifax, Canada, (4)Autism Research Centre, University of Alberta, Edmonton, AB, Canada, (5)Autism Research Centre, IWK, Halifax, NS, Canada, (6)University of Ottawa, Ottawa, ON, Canada, (7)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (8)The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (9)Tel-Aviv University, Tel-Aviv, ISRAEL, (10)University of British Columbia, Vancouver, BC, Canada

Background: Recent advances in the understanding of autism spectrum disorder (ASD) have brought about a growing demand for longitudinal data to address the changing nature of autism and to understand its trajectory over time. This is particularly important as the older child population is growing and new research questions arise about the nature of the disorder over the course of development.

Objectives: The objective of this study was to identify correlates and turning points of adaptive functioning trajectories using a longitudinal design.

Methods: The sample included 164 children with ASD who were followed from early childhood to adolescence. Adaptive functioning was measured using the Vineland Adaptive Behavior Scales, Second Edition (VABS-II) at each time point. The study was conducted in three sites: Toronto, ON, Canada; Edmonton, AB, Canada; and Tel Aviv, ISRAEL. The sample was divided into three age groups: early childhood (ages 3-6), middle childhood (ages 7-11), and adolescence (ages 12-18). The study used a mixed-methods design, including quantitative analyses and qualitative interviews.

Results: The study found that early childhood adaptive functioning was positively correlated with the VABS-II scores. Gains in adaptive functioning were observed in middle childhood, with a plateau in adolescence. The study also identified several correlates of adaptive functioning, including social and communication skills, and family support. Turning points were identified in the early childhood period, with significant gains in adaptive functioning noted in middle childhood.

Conclusions: The study highlights the importance of early intervention and support for children with ASD, with gains in adaptive functioning observed in middle childhood. The findings underscore the need for ongoing support and intervention to help maintain and enhance adaptive functioning in adolescence. The study also provides valuable insights for future research on the nature of autism spectrum disorder over the course of development.
**Background:** Previous research has shown that heterogeneous trajectories of adaptive functioning in autism are associated with baseline characteristics such as autism symptom severity and IQ. However, evidence remains limited regarding to what extent the developmental variability of adaptive functioning can be accounted for by family characteristics and autism symptoms beyond baseline. It is also unknown whether turning points are present along the trajectories reflecting potential risk or opportunities for change.

**Objectives:** We aimed to examine 1) the parallel-process trajectories of communication, daily living, and social skills from ages 2 to 17 years in an inception cohort of autistic children, and 2) the developmental variability of adaptive functioning and associations with child/family characteristics and autism symptom trajectories.

**Methods:** The current sample (N=406; all diagnosed with autism at ages 2-5 years) was drawn from *Pathways in ASD*, a large Canadian prospective study. Children’s adaptive functioning and autism symptoms were respectively assessed with Vineland Adaptive Behavior Scales (VABS) and Autism Diagnostic Observation Schedule (ADOS) across 4 to 6 visits, with data restructured by chronological age for parallel-process latent growth curve modeling. Upon deciding the optimal functional form, latent class growth analysis was performed to identify VABS trajectory subgroups. Child (sex, age of diagnosis, baseline nonverbal IQ) and family characteristics (household income, caregiver’s education, race/ethnicity, and nativity), and ADOS growth parameters were included to examine their associations with VABS trajectory subgroup membership.

**Results:** The piecewise latent growth model best described VABS trajectories with two turning points identified at transitions into school age (~6 years) and youthhood (~10 years). We parsed four VABS trajectory subgroups (entropy=.92; Figure 1) that vary by functioning level, change rate for certain VABS domains, and developmental periods segmented by the turning points. Household income and nonverbal IQ, but not autism symptom severity at baseline, remained significant covariates of VABS trajectory membership when adjusting for other covariates. About 16% of our sample was in Class 4, which is characterized by notable early growth across VABS domains and less decline in social functioning upon transitioning into youth. Children in Class 4 had higher yet highly variable nonverbal IQ (M=82.4, SD=25.8) at diagnosis, showed more reductions in social-affect symptoms across childhood (Figure 2), and were more likely to come from a higher-income family (b=.37 to .52, all SE=.13, p<.01). In contrast, the lowest functioning group (Class 1; 20% prevalence) was marked by an early decline across VABS domains despite reductions in autism symptoms, followed by late improvement (particularly in daily-living skills) during school age and then decline in adolescence.

**Conclusions:** This study demonstrated the heterogenous pathways of adaptive functioning domains across developmental stages in autism. We identified key individual and family correlates of developmental variability (e.g., nonverbal IQ, household income) as well as crucial transition periods for functional declines or improvement, which have important implications for understanding risk and resilience processes leading to various developmental outcomes. Our findings highlight the significance of taking developmental and multidimensional approaches to studying autism-related outcomes and thus informing timely and tailored supports for individuals on the spectrum.

418.361 (Poster) Correlation between Gaze Behaviors and Social Communication Skills in Autism: A Meta-Analysis

C. D. Yoon, Y. Xia, A. K. Terol, H. Meadan and J. D. Lee, (1)University of Illinois at Urbana-Champaign, Champaign, IL, (2)University of Illinois, Champaign, IL, (3)University of Illinois at uc, Champaign, IL, (4)University of Washington School of Medicine, Seattle, WA

**Background:** In a recent literature review, researchers found that the correlation coefficients between gaze behaviors and social communication skills of young children at risk or with autism varied a lot across studies. However, it is not clear whether the variation of reported correlations can be explained by factors such as quantified gaze metrics of gaze behaviors, defined interest areas of displayed stimuli, or behavioral assessment measures of social communication skills.

**Objectives:** The purpose of this study was to conduct a meta-analysis on the correlation between gaze behaviors and social communication skills of young autistic children. Specifically, the following questions were addressed: (a) what is the average correlation between the measures across the studies and (b) how do the correlation coefficients vary by different gaze metrics, areas of interest, and behavioral assessments?

**Methods:** We conducted a systematic search process following the PRISMA analyses statement (PRISMA; Page et al., 2021). The search yielded a total of 380 articles. After removing duplicates, two authors independently screened the title and abstract of the remaining 201 articles, which resulted in 57 studies for full-text review. Then, a total of 21 articles remained for data extraction; four studies were excluded during the data extraction. We conducted a meta-analysis on the correlations and employed meta-regression to examine how the variations of correlation coefficients can be explained by three moderators: gaze metric, area of interest, and behavioral assessment.

**Results:** A total of 17 studies were included in the final analyses. For research question 1, we first tested the fixed-effects model, which suggested that the correlation coefficients were heterogeneous at the population level (I² = 84.53%; p < .01). Thus, we rejected the fixed-effects model and proceeded with a random-effects model. The random effects analysis indicated a mean correlation of -0.096, with 95% confidence limits from -0.213 to .020. This is a weak correlation (Cohen, 1988) and indicates that, on average, there is a weak linear relationship between autistic children’s gaze behaviors (e.g., attention, gaze following) and their social communication skills. For research
question 2, we conducted mixed-effects meta-regression, which suggested that only gaze metrics ($Q_M^{[21]} = 129.28, p < .0001$) and behavioral assessment ($Q_M^{[15]} = 121.25, p < .0001$) were significant moderators while controlling other moderators. Specifically, gaze transition, which is the frequency or the number of gaze movements the child made between areas of interest, was a significant independent predictor within the gaze metric moderator. Within the behavioral assessment moderator, ADOS Item Eye Contact, ESCS Responding to Joint Attention, and four domains of VABS (Adaptive Behavior Composite, Communication, Daily Living Skills, and Socialization) were significant independent predictors of the relation between gaze behaviors and social communication skills of young children at risk or with autism.

Conclusions: Results from the meta-analysis can be used to inform our understanding of the core social communication skills of young autistic children that are likely to be presented in real-life settings, as well as later in their childhood. Limitations and implications are to be discussed.

418.362 (Poster) Dehumanizing Descriptions of Autistic Children Lead Non-Autistic Children to View Them As Less Human
Z. Robertson and V. K. Jaswal, Psychology, University of Virginia, Charlottesville, VA

Background:

Despite efforts to increase public autism awareness, negative social attitudes towards autistic people remain. One reason for these persistent negative attitudes could be the harmful language that is used to talk about autistic people, even in well-meaning scientific and public communications. For example, autistic people report feeling dehumanized by scholarly accounts that deny that autistic people could form a community, or that suggest that autistic people are not people in a psychological sense (e.g., Botha, 2021).

Although dehumanization – the belief that an individual or group is less than fully human – is a relatively understudied phenomenon in autism research (but see Cage et al., 2018; Parker et al., 2018), dehumanization is a widespread social phenomenon that develops early (even children as young as five years old dehumanize their outgroups) and predicts endorsement of harm towards the dehumanized group. Thus, it is important to consider how dehumanization of autistic people develops, especially during the socially-formative years of childhood.

Objectives:

The current study investigated the influence of dehumanizing language on non-autistic children’s attitudes towards autistic peers by introducing children to two novel groups. Both groups were designed to reflect the behaviors of autistic people; the only difference between the two groups was whether they were described with dehumanizing or humanizing language.

Methods:

Participants were 101 8- to 10-year-old children, who each heard both the dehumanizing vignette (which described the character as missing something in their brain and as unable to understand others’ thoughts and emotions) and the humanizing vignette (which described the character as neurologically different, but capable of understanding others’ thoughts and emotions). After both vignettes, children completed two dehumanization scales: one measuring blatant dehumanization, and the other measuring subtle, trait-based dehumanization. We also measured children’s self-humanization by asking them to rate “kids like themselves” on both dehumanization scales. Then, children completed a child-appropriate measure of social dominance orientation (SDO), which prior research has identified as an important predictor of dehumanization. Finally, children were asked to indicate whether they were familiar with autism.

Results:

We hypothesized that children would engage in more blatant and subtle dehumanization of the autistic-like group that was described with dehumanizing language than the group that was described with humanizing language. Consistent with this hypothesis, non-autistic children dehumanized both of the autistic-like groups relative to themselves, but they engaged in more dehumanization after hearing a group described with dehumanizing rather than humanizing language, $t(100)s > 4.2, p < .001$ (see Figure 1).

Our second hypothesis was that individual differences in SDO would predict dehumanization of the autistic-like groups; however, this hypothesis was not supported, $ps > .26$ (Figure 2).

Conclusions: In a follow-up study, we are investigating the downstream effects of dehumanization on non-autistic children’s attitudes (e.g., towards educational policies that affect autistic people). This line of research provides empirical evidence that the ways in which autistic people are described can influence the degree to which others view them as human, and therefore should motivate more humanizing depictions of autistic people in science and society.
**Background:** Since the identification of autism as a condition of neurodiversity, participants in autism research have been of limited race and ethnicity (R&E) (i.e., primarily white). Awareness of this selectivity has led to calls for greater inclusion of autistic participants from diverse R&E groups (Maye et al., 2021). Research has increasingly focused on the R&E difference in identification/diagnosis (e.g., age of diagnosis) and access to services (Suhrheinrich et al., 2021). However, there has been little information about R&E difference in development and learning across the childhood and adolescent years. In this secondary analysis, the communication, social, and adaptive behavior of autistic children and youth from different R&Es were examined.

**Objectives:** To examine similarities and differences in the development for autistic children of different ages from different R&E groups.

**Methods:** This secondary analysis incorporated data from four research studies originally designed to investigate the effects of educational interventions in early intervention of school settings. The age groups included were toddler (18-36 months), preschool (36-60 months), later childhood (72-120 months), and adolescents (14-18 years). There were 1382 autistic participants across the four age groups (see Table 1). All but one of the studies took place in multiple geographic locations in the U.S. Developmental measures were collected at the beginning of their participation in the study and again at the end, allowing for an examination of change across time within different groups of children. Although multiple measures were collected, the one standard measure across age-groups that generated age-equivalent scores was the Vineland Adaptive Behavior Scale (VABS). The social, communication, and daily living skills-adaptive behavior domains of the VASB were analyzed for this study. A linear mixed model was used to examine stability and change among participants from different R&E groups over time and control for participation in different experimental conditions (Laird & Ware, 1982).

**Results:** Longitudinal analyses of the VABS found significant growth across age and R&E groups for communication, social, and daily living skills domains of adaptive behavior (p < .001 for all three domains). Figure 1 provides an example of the VABS Communication domain (i.e., mean).

This trend occurred for the other two VABS domains also. Participants, however, lagged behind expectations for chronological age. R&E differences became most pronounced in the Later Childhood and Adolescent groups. In high school, white children showed significant growth across time. In contrast, Black autistic adolescents maintained their skill levels over time, while Hispanic and Asian adolescents.

**Conclusions:** As has been found in other classic studies (Sigman & Ruskin, 1999), autistic children and youth do make developmental progress over time, but for many, their progress lags behind chronological age expectations. By documenting similar trends occurring across R&E groups until adolescence (and starting in later childhood for the Asian group), the findings are consistent with possibility that educational services may moderate the R&E differences at least until adolescents, with Asian students as the exception. More focused prospective examinations of these trends in future research is recommended.

---

**418.364 (Poster) Different Together: Prosodic Network Communities in Speakers with and without ASD**

**E. Weed, R. Fusaroli**, E. Schoen Simmons and I. M. Eigsti, (1)Aarhus University, Aarhus, Denmark, (2)Sacred Heart University, Fairfield, CT, (3)Psychological Sciences, University of Connecticut, Storrs, CT

**Background:** Speakers with autism spectrum disorder (ASD) are commonly reported to have atypical voice and prosody that impact impression formation. Human raters seem to be adept at detecting acoustic cues that may suggest the presence of autism, but a clear acoustic characterization of the “autistic voice” has remained elusive. This suggests the possibility that a) there may not be any single pattern of acoustic features that defines the vocal patterns of people with ASD, and b) there may be a variety of acoustic profiles which, while quantitatively quite different, may all still be perceived by hearers as suggestive of autism. To investigate this possibility, we modeled the speech from a small selection of speakers, with and without ASD, producing single sentences, as a network of nodes defined by acoustic features, and used a community-detection algorithm to identify clusters of speakers who were acoustically similar. We then compared these clusters with the ratings of expert clinicians and naive raters.

**Objectives:** Our objective was to investigate whether grouping speakers with and without ASD, on the basis of acoustic features alone, could yield insight into the cues human hearers pick up on when rating speech for atypicality.

**Methods:** Participants (N = 27) produced single, scripted sentences. From the audio files of the recordings, we extracted four acoustic features: fundamental frequency (pitch), jitter (a measure of voice quality), speech rate, and articulation rate. We modeled speakers as a network of nodes, in which each node used the acoustic features to represent the speaker, and connections were calculated as partial correlations between nodes. We then used a spin-glass community detection algorithm to identify “communities” of speakers who share similar acoustic properties, compared to the other speakers. Network stability was assessed by a variety of measures, including comparing
the modularity of the network with random networks. Finally, we compared the algorithmically-identified communities with ratings by trained clinicians and naive raters.

Results:

Three communities (acoustic profiles) were reliably identified in the network (Fig 1A). These consisted of a community of predominantly speakers with ASD, a community of predominantly NT speakers, and a third community which was a nearly even split. Both expert and naive raters were reliably able to distinguish NT speakers from speakers with ASD, however only the raters with clinical experience could confidently identify the two speakers with ASD who were placed in the predominantly TD community (Fig 1B).

Conclusions: The confidence of the raters supports findings indicating that hearers are adept at identifying atypicalities in prosodic and vocal patterns that may be characteristic of people with autism. At the same time, the stability of the three-community network suggests that there may not be any single acoustic profile that describes the “autistic voice”. Rather than broad descriptions of the speech of people with ASD as “monotone” or “robotic”, we may need to focus attention instead on how each individual uses the prosodic tools available to them to communicate meaning and intention.

418.365 (Poster) Displays of Positive Facial Affect Differences in Autistic and Non-Autistic Adults across Contexts and Are Associated with More Favorable First Impressions

S. J. Foster, D. R. Jones, A. E. Pinkham and N. J. Sasson, (1)Psychology, University of Texas at Dallas, Richardson, TX, (2)The University of Texas at Dallas, Richardson, TX, (3)University of Texas at Dallas, Richardson, TX

Background: Autistic people often receive unfavorable first impressions from non-autistic (NA) people (Morrison et al., 2020), likely because of stigma related to non-normative social presentations and expressive behaviors (Sasson et al., 2017). Although facial expressivity influences first impressions (Koji & Fernandes, 2010), no research has examined whether expressivity differences in autism relate to the formation of first impressions by NA people. Further, it is unclear whether facial expressivity in autism varies depending upon contextual demands and whether this affects first impressions (Koji & Fernandes, 2010).

Objectives: To determine whether facial expressivity predicts first impressions of autistic adults made by NA adults in two disparate contexts.

Methods: Twenty-one autistic and 21 NA adults, comparable on age (M_A = 26.62; M_NA = 23.52), sex (15 autistic and 16 NA males), ethnicity (18 Caucasian in both groups), and IQ (M_A = 109.67; M_NA = 114.00) were video recorded interviewing for their ideal job and discussing a personal interest. The percentage of video frames displaying positive affect was quantified using iMotion software that classifies emotional expressions and has previously been used in autism research (Bilikis et al., 2020; Trevisan et al., 2016). Later, 977 NA undergraduates rated these participants using the First Impression Scale (Sasson et al., 2017).

Results: A repeated measures ANOVA with diagnosis and sex as the between group variables and context as the within group variable revealed a main effect of diagnosis (F(1,38)=5.76, p=.02), with NA participants demonstrating greater positive affect, and a main effect of context (F(1,38)=9.42, p<.01), showing greater positive affect in the interest relative to the job context (see Figure 1). The diagnosis X context interaction did not reach significance (p=.50). Female participants trended towards more positive affect than males (p=.08), but sex did not significantly interact with diagnosis or context. For both groups, positive affect significantly correlated with more favorable first impressions in the interest context for likability (r=.36) and attractiveness (r=.33) and was associated with greater interest in hanging out with (r=.34) and having a conversation with (r=.32) the participant. These patterns were attenuated in the job context, with positive affect showing trend-level correlations with likability (r=.30), hanging out with (r=.27) and having a conversation with (r=.29). Correlations were no longer significant when examined in each diagnostic group separately, likely due to statistical power.

Conclusions: Facial expressions of positive affect were greater in NA relative to autistic adults and were associated with more favorable first impressions formed by NA raters on several trait judgments and indices of social interest. Thus, NA raters may use normative signifiers of positive affect when forming first impressions, and this may contribute to the poorer first impressions autistic people receive from NA people. Future work should determine if autistic raters are less likely to demonstrate this bias, and whether automated facial expressivity software normed on NA people adequately captures expressivity among autistic people. Additionally, findings indicated that expressivity in autistic adults is influenced by contextual demands in similar ways to their NA counterparts that may influence the formation of first impressions.

418.366 (Poster) Dissecting the Role of Emotion Dysregulation in Core Autism Symptoms

Background: Emotion regulation has emerged as an underpinning for numerous psychological and neurodevelopment disorders and likely plays a key role in ASD. Individuals with ASD tend to be more emotionally reactive and less introspective than typically developing individuals (Mazefsky, 2013). The Emotion Dysregulation Inventory (EDI) is a novel measure of emotion dysregulation in ASD that can be used for any level of cognitive or verbal ability and highlights emotion reactivity and dysphoria. Reactivity refers to poor regulation, intense and swift escalation of negative emotions; dysphoria refers to negative emotions such as sadness, nervousness, or anhedonia (Mazefsky, 2018). Because relations between these features and core ASD symptom domains have not widely been explored, we examined relations between EDI scores and core autism features, as indexed by the Social Responsiveness Scale, 2nd Edition (SRS-2) and Repetitive Behavior Scale, Revised (RBS-R).

Objectives: To evaluate how domains of emotion dysregulation are related to the core ASD symptoms. We hypothesized that more emotionally reactive children would score higher on all Social Responsiveness Scale (SRS-2) and Repetitive Behavior Scale (RBS) domains. Conversely, we hypothesized that children with more dysphoria would score lower on the SRS and RBS.

Methods: Parents of 60 children (52 male, 8 female) with ASD, ages 6 to 11 (8.316±1.751) completed the EDI, SRS-2, and RBS-R questionnaires. All children had their ASD diagnosis confirmed by a clinical psychologist who used ADOS-2 and/or ADI-R, DSM-5 criteria, and clinical judgment. We ran two-tailed, Pearson bivariate correlations between EDI reactivity and dysphoria and all domains of the RBS-R and SRS-2.

Results: Emotion reactivity significantly positively correlated with the total score of the SRS (r=0.46, p<0.001), as well as the social cognition (r = 0.46, p<0.001), social communication (r = 0.34, p = 0.008) and repetitive subdomains (r=0.50, p<0.001). Reactivity did not relate to social awareness or motivation, and dysphoria did not relate to SRS total score or any subdomain. Emotion reactivity was significantly positively correlated to the overall score of the RBS-R (r=0.50, p<0.001), as well as to the stereotyped behavior (r = 0.41, p = 0.001), the self-injurious behavior (r = 0.41, p = 0.001), the compulsive behavior (r = 0.41, p = 0.001), the sameness behavior (r = 0.55, p<0.001), and the restricted behavior (r = 0.32, p = 0.012) subscales of the RBS-R. Dysphoria was not significantly correlated to any RBS-R domain.

Conclusions: Emotion reactivity significantly correlated with several domains of both social impairment and repetitive behavior, whereas dysphoria did not significantly correlate with any domains. These findings suggest that emotion reactivity is centrally linked to core autism spectrum disorder symptoms, which may mean that intervention teaching emotion regulation to individuals with ASD could lead to diminished core symptoms and improved overall social functioning. In contrast, dysphoria may be more orthogonal, suggestive of comorbidity and requiring specific intervention that might have less impact on core autism symptoms even when successful.

418.367 (Poster) Do Neurotypical People Have Autistic Theory of Mind Abilities? Insights from a Focus Group Study

E. Marocchini, University of Genoa, Genoa, Italy

Background: The hypothesis of a universal Theory of Mind (ToM) impairment in autism was the basis of ages of literature in pragmatics, even though experimental evidence demonstrated that ToM difficulties are not universal or could be better explained in other ways (Gernsbacher & Yergeau, 2019). Contributions from autistic academics opened the field to the possibility that communication difficulties might occur because cross-neurotype communication involves different constructs of the other’s ToM, rather than because of deficits within a specific neurotype. The potential application of the double empathy problem (Milton, 2012) to mutual comprehension has only recently been explored in pragmatics (Williams 2021), and it might benefit from an exploratory focus group study.

Objectives: This exploratory study aims at exploring autistic perceptions of cross-neurotype communication with a focus on ToM and indirect speech acts (ISAs).

Methods: Twelve Italian autistic adults without intellectual disability were recruited via email and participated into two Virtual Focus Group Discussions (VFGD) of 90 minutes each, held on Zoom with two facilitators: an autistic researcher with a background in Psychology, focusing on pragmatic and ToM literature, who moderated the session, and a neurotypical assistant. Informed consent was obtained from participants for recording the VFGDs. Each VFGD started with an introduction including background definitions of (neurotypical) ToM and ISAs, the purpose of the VFGD, basic rules for the discussion and three open-ended questions. The VFGDs were manually transcribed according to the orthographic transcription rules of Italian oral texts adopted in the CLIPS project (Savy, 2007). The transcripts were analysed following the seven steps described by Colalizzi (1978); the analysis was presented back to the participants for validation.

Results: Three main themes emerged from the analysis. Participants reported a variety of experiences of being misunderstood in cross-neurotype communication, including the idea to be negatively judged because of a sincere statement perceived as rude, the observation that
neurotypical people in their life tend to derive implicit meaning from their direct speech acts that were not intended to be communicated, and the feeling of being perceived as not paying attention when, in fact, they were. These experiences occurred both with co-workers and strangers and in intimate and familiar contexts.

Conclusions: The results indicated that participants experienced difficulties in communication that were rooted into mutual misunderstanding, rather than in their ability to comprehend the neurotypical counterpart, and into a perceived difference between the neurotypical and autistic ToM. Further studies evaluating this phenomenon from a quantitative point of view would be needed. Nevertheless, awareness of these experiences might result in reduced misunderstandings in cross-neurotype communication.

418.368 (Poster) Do Shapes Have Feelings? a Remote Administration of the Social Attribution Task in Autistic Children

Background: The social attribution task (Heider & Simmel, 1944) is a video-based paradigm to assess the tendency to assign feelings to and anthropomorphize the movements of geometric shapes. Over the past 20 years, research has shown that performance on this task differs for autistic vs. non-autistic children (Klin, 2000; Klin & Jones, 2006), such that autistic children are less likely to ascribe thoughts and feelings to geometric shapes than non-autistic children, and instead describe interactions using causal, spatial language. However, these studies had several limitations, including primarily male samples and lab-based methods that could have led to non-representative behavior. Given that sex differences in autistic speech are increasingly recognized (Cola et al., 2022) and home-based data collection could provide a more ecologically valid snapshot of children’s everyday behavior, the current study aims to collect a sex-balanced sample of the social attribution task via teleconference from children’s homes.

Objectives: (1) Assess whether 48 children aged 6-18-years-old can reliably complete a social attribution task at home via telephone and internet; (2) Determine whether children’s language patterns differ by diagnosis.

Methods: A preliminary sample of 16 autistic and 18 non-autistic children matched on age and IQ (Table A) participated in a telehealth study which involved completing multiple activities including a social attribution task. Children watched two silent 40-second videos of shapes moving in semi-social patterns twice (Figure 1; Abell, Happe, & Frith, 2000) and were asked to describe what the shapes were doing on the second viewing. The first video depicted the shapes moving intentionally, alternating friendly and unfriendly. The second video depicted the shapes moving in random patterns. Children answered three questions about the videos: “Do the shapes have feelings?”, “What else were the shapes feelings?”, and “Are the shapes friends or not friends?”. Total word count, and proportion of words that were adjectives, emotional words, social words, and cognitive process words were examined using LIWC2022 (Pennebaker, 2022).

Results: Autistic children used a smaller proportion of adjectives, emotional, social, and cognitive process words relative to their overall vocabulary in comparison to the non-autistic control group. Autistic children also used more words overall when compared to the non-autistic group. Although group differences were not statistically significant, they were consistent with previous literature. When the full sample has been processed, we will have additional power to confirm our preliminary findings to assess potential sex differences in the language produced by autistic and non-autistic children.

Conclusions: Home-based samples of the social attribution task, using balanced groups of girls and boys with and without autism, could help update our understanding of how children interpret the world through lenses that are more or less social. Stable, significant results could suggest an easy and reproducible way to track children’s social development from afar, as well as shed light on how autistic behavior may differ in familiar environments vs. lab-based contexts. These preliminary data are promising, and we are eager to present findings from the full sample of 48 participants (half autistic, half female) collected and transcribed in May 2023.

418.369 (Poster) Looking at Me Anxiety: A Qualitative Study of Gaze Anxiety in Autism

D. J. Milne, A. Saliba and N. Sugden.

Background: Anxiety and differing gaze behaviour are two common characteristics of autistic adults. In the neurotypical population, facial gaze can ensure emotional regulation and social learning that may aid in reduced prevalence of anxiety. Many studies can be found for anxiety and autism, and gaze behaviour and autism however, few link the two. Moreover, there are limited qualitative studies regarding anxiety and eye contact found in the literature, none exploring the eye contact and anxiety relationship. Investigating how anxiety and gaze...
behaviour are related may provide insights to this heterogeneous cohort, helping anxiety intervention development in the autism population. Consequently, qualitative studies are needed to provide inductive insights into this relationship.

Objectives: To explore the lived experience of those adults on the autism spectrum in relation to anxiety and eye contact.

Methods: A qualitative study was carried out with 16 autistic adults and 7 supporters of autistic adults. Data was collected from semi-structured interviews and analysed using Charmaz's Grounded Theory epistemology.

Results: Autistic individuals reported having difficulties with gaze behaviour, with related anxiety effects. Themes show that autistics can change their gaze behaviour to appear “normal”, reduce anxiety in social situations, and allow other sensory modality processing (e.g. avoiding facial gaze to allow verbal language to be processed). Eye contact was found to relate to feelings of anxiety. However, anxiety was reported to be caused more by social situations than eye contact alone. Participants reported symptoms of alexithymia and face blindness that affect their everyday social functioning.

Conclusions: Autistic adults can be very informative about their gaze behaviours and causes of anxiety. However, interviews revealed that while most causes of anxiety are social in nature, specific aetiology and remediation of the anxiety is complex and well communicated by those on the spectrum.

C. Caí, B. Wang, S. J. White and S. K. Scott, UCL Institute of Cognitive Neuroscience, London, United Kingdom

Background: Laughter is normally viewed as a spontaneous emotional expression of positive internal states; however, it more often serves as a social signal in communication. Although genuine and social laughter are both salient communicative signals, they are also very different: they are acoustically distinct, they play different roles in the communication of emotional and social meaning, their perception and production recruit different neural systems and these differ between certain populations. Intriguingly, genuine laughter has been found to amplify the funniness of jokes more than social laughter amongst both non-autistic and autistic adults.

Objectives: The current study aims to extend our understanding of implicit laughter processing by adding genuine or social laughter to a variety of forms of humour stimuli including pun jokes, burp sounds and slapstick videos, and to see how it affects people's perceived funniness of humorous stimuli. In addition, we further investigated whether the same pattern of implicit processing of genuine and social laughter in non-autistic participants could be found in autistic participants.

Methods: Three participant datasets of autistics and non-autistic adults were recruited; the two groups of participants were comparable on age, gender, and IQ across all datasets. In dataset one, 24 autistic and 26 non-autistic participants completed a task involving the implicit modulation of funniness of pun jokes by laughter (joke study). In dataset two, 28 autistic and 30 non-autistic participants rated the same joke but without laughter this time, and also completed two tasks involving the implicit modulation of funniness of burps (burp study) and of slapstick videos (video study) by laughter. A third set of 37 autistic and 31 non-autistic participants were recruited online to follow up the findings from the video study.

Results: Across a variety of humour stimuli, including pun jokes, burp sounds and slapstick videos, the addition of laughter increased the funniness of humour stimuli perceived in the non-autistic group; they also found the humour stimuli funnier when paired with genuine than social laughter. In contrast, the same laughter modulation effect was only found for the pun jokes in autistic adults.

Conclusions: The addition of laughter and the types of laughter modulated the perceived funniness of humour stimuli in non-autistic adults. However, this effect was not consistently found in autistic adults. In general, autistic adults with high intelligence have a different pattern of implicit processing of laughter relative to non-autistic adults. This lines up with our previous finding about personal experience of autistic adults, who report struggling to understand the social meaning of others’ laughter. Taken all together, autistic adults are likely to use different strategies to understand laughter and they experience a different perceptual pattern of laughter in everyday life, which could lead to difficulties in social communication since laughter is a crucial social signal for us to establish and maintain social bonds.

418.371 (Poster) Early Executive and Social Functioning Predict Externalizing Problems in Neurodiverse Preschoolers

K. All, V. Donthireddy, A. Boxberger, E. V. Edgar, E. Hong, C. Bianco, S. Macari, A. Vernetti and K. Chawarska; (1)Child Study Center, Yale University School of Medicine, New Haven, CT; (2)Child Study Center, Yale Child Study Center, Yale School of Medicine, New Haven, CT; (3)Child Study Center, Yale School of Medicine, New Haven, CT

Background: Children with autism present with increased externalizing problems (EP) such as aggression, defiance, and inattention compared to the general population (Joshi et al., 2010). EP are also present in other developmental disorders and are associated with increased anxiety and depression, peer rejection, and parental stress (Baker et al., 2003). Understanding early predictors of EP in children with developmental disorders is imperative to identifying vulnerable children and implementing preventative interventions. Early
predictors of elevated EP in general population include impaired executive functioning (EF), the cognitive processes that facilitate goal-directed behavior (Schoemaker et al., 2013), and lower social functioning (SF), the skills that facilitate interpersonal interactions and relationships (Bornstein et al., 2010). Similar links between EF impairment and EP have been found in school-age children with ASD (Vogan et al., 2018), although the longitudinal links between EF, SF, and EP in preschoolers with ASD have not been established.

Objectives: Determine if 1) EF and SF at age 3 predict externalizing problems at age 5 in children with developmental disorders and 2) this relation differs depending on level of autism symptoms.

Methods: Participants included 59 children with a range of developmental challenges including ASD (n=34), developmental delays, ADHD, and affective and regulatory difficulties (n=25) who participated in a longitudinal study at Time1 (M-age=39.2 months) and Time2 (M-age=61.5 months). EF was assessed using the Behavior Rating Inventory of Executive Function Preschool Version (BRIEF-P). SF was assessed using the Socialization Domain of the Vineland Adaptive Behavior Scales-II (VABS-II), and externalizing problems were measured using the Early Childhood Inventory-5 (ECI-5) conduct disorder and oppositional defiant disorder scales. Pearson’s r correlation analysis was used to examine the association between Time1 predictors and Time2 externalizing problems in the combined groups. Multiple regression was used to evaluate the contributions of Time1 EF, SF, level of autism symptoms (ADOS SA), and cognitive abilities (Mullen Scales: Nonverbal DQ) to Time2 externalizing problems.

Results: Time1 EF (r=.35, p=.006), but not SF (r=.10, p=.461) was correlated with Time2 externalizing problems (Table 1). A regression revealed that EF (β=1.35, p<.001) and SF (β=.74, p=.010) significantly predicted later externalizing problems, with autism symptoms making marginal contributions (β=2.41, p=.055; Table 1). There was also an interaction between EF and autism symptoms (β=2.10, p=.003) such that the effect of EF on externalizing problems decreased as autism symptoms increased (Figure 1). The interaction between SF and autism symptoms was not significant (p=.355).

Conclusions: Executive function and social adaptive functioning at age 3 predict externalizing problems at age 5, particularly in children with lower levels of autism symptoms. Executive functioning presents as a potential target for early intervention in the preschool years, during which EF undergoes significant development. Given the interaction between EF and autism symptoms, it may be beneficial to specifically target children with fewer autism symptoms and more EF impairments for early EF interventions aimed at preventing the emergence of externalizing behaviors. Future studies will more closely examine the complex role social adaptive functioning may play in the emergence of externalizing problems in children with neurodevelopmental disorders.

418.372 (Poster) Effect of the Cueing Face Race on Gaze Cueing in Individuals with High and Low Autistic Traits

P. Ricciardelli and N. Pintori, (1)Psychology, University of Milano-Bicocca, Milano, Italy, (2)Psychology, University of Milano Bicocca, Milan, Italy

Background: Observing the direction of gaze of another person leads to shifting of attention in the same direction (gaze-cueing effect – GCE), a social-cognitive ability known as joint attention. Racial attitudes can influence the magnitude of GCE since it has been shown that white people showing a strong race ingroup preference shift attention in the direction of gaze of White, but not Black, faces. Individuals with high autistic traits have difficulties in social-cognitive abilities that can disrupt the learning of socially shared racial attitudes and have been reported to have reduced attention to social cues. However, it has not been previously studied whether the level of autistic traits exerts an effect on the implicit race attitude, and if, in turn, it affects joint attention, two important aspects for social cognition.

Objectives: In an exploratory research we aimed to test in White Italian adults whether individuals with high autistic traits (measured by the Autism spectrum Quotient) show reduced implicit racial bias (measured by the Implicit Association Test – IAT) and if this bias would lead to differences in the GCE triggered by the direction of gaze of faces of different races (White and Black faces).

Methods: In an online study, participants (N=165 White Italian adults; 132 females; Mean age = 22.9; SD = 4.76) filled in the Autism-Spectrum Quotient questionnaire to quantify the level of autistic traits, then they were asked to perform a Gaze Cueing Task in order to estimate the magnitude of the gaze-cueing effect, followed by an Implicit Association Test measuring the implicit race attitude towards Black and White people of our sample.

Results: Data analysis showed that participants with high and low-medium autistic traits had the same ingroup bias. Specifically, a more positive implicit attitude toward White people (i.e., their ingroup) than toward Black people (i.e., their outgroup) was found. The size of the race bias did not differ between the two groups. Interestingly, although a significant GCE (i.e., faster RT to respond to a target when it appeared in the direction indicated by the gaze) was always found for low-medium autistic traits participants, this was not the case for females with high autistic traits, who showed a significant GCE only for the White cueing faces. Moreover, it was found that, with Black cueing faces, when the AQ score increased the GCE decreased or was absent.

Conclusions: Individuals with both high and medium-low autistic traits show an implicit preference towards their ingroup and the same implicit negative attitude toward outgroup people. However, this negative attitude seems to affect the joint orienting of attention only of females with high autistic traits, suggesting a modulation of sex and the level of autistic traits on gaze cueing. We propose that, although
females with high autistic traits retain the ability to orient to gaze direction, they may have a more limited capacity of orienting attention to social cue and, for this reason, they restrict their orienting by prioritizing joint attention with ingroup members.

418.373 (Poster) Emotion Recognition in Autism and Specific Learning Disorders: Which Is the Role of Social Anxiety and Executive Functioning?
R. Lievore, R. Cardillo and I. C. Mammarella, (1)Department of Developmental and Social Psychology, University of Padova, Padova, Italy, (2)Department of Developmental and Social Psychology, University of Padova (IT), Padova, Italy

Background: Emotion recognition’s impairments in Autism (ASD) without intellectual disability are well-documented (Ulijarevis & Hamilton, 2013), instead less has been done with Specific Learning Disorders (SLD), though social difficulties are widespread in children who meet academic challenges (Operto et al., 2020). Moreover, some studies have demonstrated the associations between emotion recognition, executive functions, and social anxiety (Oerlemans et al., 2013; Woolard et al., 2021). To the best of our knowledge, no previous studies have focused on the above-mentioned relations by considering both ASD and SLD.

Objectives: The aims of the present study were to explore emotion recognition abilities in children and adolescents with ASD and SLD as compared to non-diagnosed participants (ND), and the possible role of social anxiety and executive functions in predicting emotion recognition.

Methods: The study involved 263 children and adolescents aged between 8 and 16 years old divided into three groups: 60 ASD (46 M), 63 SLD (44 M), and 140 matched ND participants (105 M). Children’s emotion recognition ability and executive functions (inhibition, updating, and set-shifting) were assessed by using computerized tasks, whereas social anxiety was evaluated through a questionnaire administered to parents.

Results: Univariate ANOVAs were performed to estimate differences between groups. Regression models were developed to assess the effects of the variables of interest (group, social anxiety, inhibition, updating and set-shifting) on the dependent variable (emotion recognition). Parents of children and adolescents with ASD and SLD reported greater levels of social anxiety as compared to the ND group, F(2, 260)=15.43, p<.001, Cohen’s d=63-.76. As regards the executive functions’ tasks, participants with ASD made more errors in the inhibition task compared to ND, F(2, 260)=6.78, p=.001, Cohen’s d=.72. Moreover, the ASD group performed significantly worse (~63%) than the ND (~73%) and SLD (~71%) groups in the updating task, F(2, 260)=7.56, p<.001, Cohen’s d=.61-.41. Regressions’ analysis revealed two statistically significant interaction effects. The interaction between group and social anxiety was found to significantly predict the performance on the emotion recognition task (AIC=1861.59, R^2 adj=.23; F=3.11, p=.04). Also the interaction between group and updating was found to be statistically significant (AIC=1861.35, R^2 adj=.23; F=3.22, p=.04), with ASD showing a stronger relation between updating capacity and emotion recognition.

Conclusions: Greater scores on the emotion recognition task are consistent with higher levels of social anxiety in ASD, whereas lower scores on the emotion recognition task are related to higher levels of social anxiety in SLD. Thus, better emotion recognition skills might trigger social anxiety in ASD due to a different social style leading to erroneous interpretations of others’ feedback. Instead, children with SLD might experience higher arousal when they do not understand others’ emotions, showing greater sensitivity to social consent. Finally, better updating capacity has found to relate to better emotion recognition abilities in all groups, but with a steeper slope in ASD, as if updating might support social cognition, especially in ASD. Clinical implications will focus on the need for considering both affective and cognitive aspects during treatments addressing socio-emotional skills in children with different neurodevelopmental conditions.

418.374 (Poster) Empathic Disequilibrium As a Predictor of Non-Suicidal Self-Injury in Autistic People
R. Moseley, I. Shalev, N. J. Gregory and F. Uzefovsky, (1)Department of Psychology, Bournemouth University, Poole, United Kingdom, (2)Psychology, Ben-Gurion University, Jerusalem, Israel, (3)Ben-Gurion University of the Negev, Be’er-Sheva, Israel

Background:

Autistic people suffer from higher rates of nearly all psychiatric illnesses and are over three times more likely to engage in non-suicidal self-injury (NSSI). These behaviors are suggested to function as means of regulating numbing or overwhelming emotions. Here, we focus on the interpersonal dimension of emotions, as is fundamentally reflected in our ability to empathize: that is, in the way the emotions of others are shared and understood by us. Autistic people tend to display elevated emotional resonance with others (i.e., emotional empathy, EE) relative to their ability to understand others’ emotions (i.e., cognitive empathy, CE; Shalev et al., 2022). Such incongruency, termed empathic disequilibrium, could be hypothesised to result in individuals feeling overwhelmed by others’ emotions, such that they may resort to maladaptive emotion regulation strategies in consequence.

Objectives:

Here, we test the hypothesis that empathic disequilibrium in autistic people, characterized by higher EE than CE (i.e., EE-dominance), would be related to emotional reactivity, and through this as a mediator, to elevated risk of engaging in NSSI.
Background: Facial perception plays a crucial role in social interaction, and both are impaired in ASD. This perception can be explored by oculometric (visual exploration) and pupillometric measurements (physiological responsiveness). Visual exploration of faces is atypical in ASD, with notably a reduced time spent on the eyes. Moreover, pupil diameter variation has been shown to be reduced in ASD individuals, in particular in children when observing social dynamic stimuli. However, no study has yet evaluated how these markers evolve with age, both in the typically-developing and ASD populations, as differences between the two groups could emerge from diverging maturation processes.

Objectives: This study aimed at exploring the evolution of oculo-pupillometric parameters during face observation from childhood to adulthood in TD and ASD groups, by using stimuli along a gradient of social saliency.

Methods: One-hundred and six ASD participants (3-34 years old) were compared to one hundred and thirty-six TD participants (3-32 years old). Stimuli were organized along a gradient of social saliency, going from static objects to static neutral faces, dynamic neutral faces and dynamic emotional faces. Each stimulus lasted 4s. The global luminosity of the stimuli and the room were controlled and kept constant for each participant. No instructions were given to the participants except to pay attention to the screen and to remain silent. Pupillometric and oculometric parameters were recorded simultaneously with the FaceLab® head-free binocular eye-tracking system (60Hz).

Results: In children, the difference between the ASD and TD groups are mainly significant for the pupil diameter in response to dynamic faces. ROC analyses showed that this parameter allows for a discriminative power of about 80%, with good sensitivity and specificity. In adults, the main significant differences are observed for oculometric parameters, in particular the time spent of the faces which also reaches around 80% of discriminative power. Pupil diameter variation in response to faces decreases with age in TD population, while it seems to be rather stable in ASD population, resulting in an absence of measurable difference between adults with or without ASD. In contrary, visual exploration strategy is different between ASD and TD adults.

Conclusions: Overall, we observed that in children, pupillometric parameters are more specific and sensitive than in adults to discriminate between ASD and TD participants. On the other hand, oculometric parameters suggest that TD adults are spontaneously attracted to faces and dynamism, and that this attentional capture by social stimuli could be affected in ASD adults. This continuum study could help us understand the maturation of oculo-pupillometric parameters during face observation, in order to define appropriate discriminating biomarkers of ASD according to age.
Examining Rapport between Autistic and Non-Autistic People during Online Interactions.

L. E. Marsh, E. Howard and D. Ropar, (1)University of Nottingham, Nottingham, United Kingdom, (2)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (3)University of Nottingham, Nottingham, United Kingdom of Great Britain and Northern Ireland

Background:
Several studies have reported that autistic people may experience greater rapport with an autistic interaction partner, compared to a non-autistic partner (Crompton et al., 2020; Morrison et al., 2020). However, current research does not yet provide a clear understanding of how or why this improved social connection is achieved. In this study, we investigated whether such benefits extend to online interactions, and whether specific features of social interactions can predict rapport in dyadic interactions.

Objectives:
1. Test whether autistic dyads achieve greater rapport than mixed-neurotype dyads in online interactions.
2. Examine the social and cognitive mechanisms which underpin interactional rapport by identifying the conversation features and movement dynamics that relate to rapport ratings.

Methods:
In this pre-registered study, 20 autistic and 20 non-autistic participants engaged in a series of online, one-to-one conversations. Half of the conversations were with a same-neurotype partner and half were with a different-neurotype partner. During each interaction, participants were given a different topic to discuss for three minutes. Participants rated the rapport they felt with their partner at the end of each interaction. All interactions were audio-video recorded for later coding. Audio data was extracted and analysed using Pyannote-audio to quantify conversation characteristics (turn-taking, length of pauses, balance of conversation). Video data was analysed using OpenFace to quantify emotional synchrony and movement synchrony within each dyad.

Results:
Initial analyses indicated that autistic participants rated their rapport similarly across different neurotype partners. Notably, they did not report improved rapport with an autistic partner in these online conversations. Non-autistic participants also rated their experienced rapport with autistic and non-autistic partners similarly. These findings are contrary to previous work with in-person interactions, and results are suggestive that mixed-neurotype interactions may be more successful in the online sphere. Follow-up work is underway to explore how features of the conversations and synchrony measures might predict rapport.

Conclusions:
It seems that rapport between autistic and non-autistic people may be appraised differently when they result from online, rather than in-person interactions. Indeed, online interactions may provide a ‘level playing field’ which minimises the bidirectional disconnect experienced between autistic and non-autistic people. Differences in the sensory demands and social etiquette for online interactions will be discussed.

Examining Sex Differences in Co-Occurring Symptoms of Autism

E. Dhawan, J. P. Hegarty, M. Ulfarevic and A. Y. Hardan, Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA

Background: There is a well-established male bias in autism spectrum disorder (ASD) prevalence, with a ratio of approximately 4:1 diagnosed males to females. Existing research regarding sex differences suggests that co-occurring symptoms of ASD may differ between males and females. Specifically, previous literature has found that males with ASD may present with more externalizing behavior problems and females with ASD may present with greater internalizing symptoms, in particular with regards to severity of anxiety and depression. However, the majority of previous studies have utilized small, non-representative samples. Thus, it is important to further characterize sex differences using large, well-characterized cohorts with broad age, IQ, and symptom severity distribution.

Objectives: The primary objective was to characterize sex differences in internalizing and externalizing problems in one of the largest representative cohorts of children with ASD.

Methods: The Child Behavior Checklist (CBCL) was collected from 9,465 individuals with ASD who participated in the Simons Powering Autism Research (SPARK) study, a nationwide research project collecting medical and genetic information from families with children diagnosed with autism. The domains that were examined included broad externalizing and internalizing problems, as well as more specific
Background: Many interventions for young children with autism focus on increasing social attention (i.e., NDBI and other early interventions). Assessment of improvement for this outcome largely involves parent report (rating scales) and clinician-scored behavioral observation from video recordings (e.g., joint engagement [JE] coding from parent child interactions). Respectively, these methodologies can be subjective, and labor intensive to score. Use of eye-tracking to assess treatment outcomes may have the potential to address these drawbacks while being sensitive to incremental changes from low intensity intervention models.

Objectives: This study investigates one aspect of validity for using eye-tracking as a treatment outcome measure for this purpose by comparing its performance to behaviorally coded joint engagement from parent child interactions.

Methods: This study includes data from 39 participants ages 15 months to 5.5 years. Thirteen children with ASD were recruited. Two control groups were recruited: chronologically age matched typically developing children and receptive language matched children (using the Preschool Language Scales, 5th edition). Eye-tracking video stimuli consisted of four video clips (between 25 and 35 seconds each). Actors included an adult and a young child engaging in interactions that included joint attention presses (pointing) to toys around the room (e.g., children and adults searching for and finding additional toys to their toy set located in the visual scene). Attention to faces (duration and number of fixations) and attention to socially referenced toys (duration and number of fixations) were coded as areas of interest.

Correlations among four eye tracking measures and two behavioral measures (video coded parent child joint engagement and PEDI-CAT social cognition) were examined in a combined group of children with and without ASD. Correlations between eye tracking variables and autism severity (scores on the Childhood Autism Rating Scales, 2nd edition; CARS-2) were also examined in the ASD group only. Group differences between children with ASD and typically developing children were assessed.

Results: Moderate and statistically significant correlations were found between behaviorally coded joint engagement during a parent-child interaction and two of four measured eye tracking variables. Best performing eye tracking variables were those that included not only attention to faces, but also attention to socially referenced toys (number of fixations and JE=r=.388, p=.015; total duration of fixations and JE=r=.397, p=.01). Correlations were strongest in children with ASD and less clear in typically developing peers (both age and receptive language matched). A strong and statistically significant negative correlation was also found between eye-tracked social attention and ASD symptoms severity using the Childhood Autism Rating Scale, 2nd edition (CARS-2) (e.g., CARS-2 and duration of fixations to social stimuli=r=-.849, p<.001). Group differences on eye tracked measures of social attention were less significant than expected.

Conclusions: Eye tracking measures of social attention related to “real life” social interactions with parents, indicating some external validity, particularly for young children with autism. As such, eye tracked measures of social attention may be most useful for measuring treatment progress in preverbal and minimally verbal children with ASD. This finding aligns well with the target population for NDBI-based interventions.

**418.378** *(Poster)* Examining Validity of Eye-Tracking for Outcome Measurement in Social Communication Treatment for Children with Autism

**G. M. Tiede**, K. M. Walton and O. C. Putnam; (1)Psychology, Nisonger Center, The Ohio State University, Columbus, OH, (2)Nisonger Center, The Ohio State University, Columbus, OH, (3)Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC

Results: We found that males and females with ASD differed in internalizing problems (z=-8.27, p<.001), DSM-5 depressive problems (z=-7.123, p<.001), and DSM-5 anxiety problems (z=-7.21, p<.001) but not in externalizing problems (z=-0.786, p=0.432). The 2,204 females with ASD scored higher on the internalizing problems and DSM-5 depressive and anxiety domains compared to 7,261 males with ASD (Figure 1). A parallel set of analyses using T-scores yielding an identical pattern of findings with similar effect sizes.

Conclusions: Our results indicate that sex differences in co-occurring symptoms of ASD were only found for the internalizing problems domain, including DSM-5 depressive and anxiety problems, which is consistent with the sex-trends in non-autistic samples. Females with ASD showed higher scores on the internalizing domain, consistent with previous research. However, males and females with ASD exhibited similar externalizing problems, differing from previous literature suggesting that males experience greater externalizing symptoms than females. These findings can help inform clinical care by identifying that internalizing symptoms may present differently between males and females with ASD.

**418.379** *(Poster)* Examining the Impact of Alexithymia and Autism Traits on Emotion Recognition Skills Among Children on the Autism Spectrum and Typically Developing Children

**S. Sivatham**an, E. M. Quintin’ and J. Burack; (1)Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada
Background: Autism Spectrum Disorder (ASD) is characterized by difficulties with social interaction and communication, and a restricted range of activities and interests. It represents the upper extreme of a constellation of social deficits that may be continuously distributed in general population. However, very little is known about the continuum of autistic traits in children under 4 years of age. Understanding early phenotypes of social difficulties that contribute to the identification of ASD is crucial for advancing early risk assessment and targeted intervention. Hence, development and validation of tools for assessing autistic symptoms/traits in preschool children is important.

Objectives: To examine the measurement properties of the preschool version of Social Responsiveness Scale (SRS).

Methods: In our study, we examined the measurement properties of the preschool version of Social Responsiveness Scale (SRS) in a community ascertained sample of preschool children (N = 815, aged 2.5-5.5 years). We used Confirmatory Factor Analysis to test the fit of the 2-factor model: Social Communication Index (SCI) and Restricted and Repetitive Behavior (RRBs); and the 5-factor treatment subscales model: social awareness, social cognition, social communication, social motivation, and autistic mannerisms. Tests of goodness-of-fit of the models were evaluated using multiple criteria described by Hu and Bentler (1999); Comparative Fit index (CFI) ≥ 0.9, Tucker-Lewis index (TLI) ≥ 0.9, root-mean-square error of approximation (RMSEA) < .06, standardized root mean square residual (SRMR) < .08. Chi-square tests are almost always significant in large sample sizes- indicating a poor fit.

Results: Confirmatory Factor Analyses indicated poor fit for the 2-factor structure (SCI and RRB) (χ2 (2005) = 6589.69, p < 0.001 , CFI = 0.581 , TLI = 0.565 , RMSEA = 0.053, SRMR = 0.065).

Conclusions: These findings were inconsistent with the alexithymia hypothesis as higher autism and alexithymia traits were associated with increased ER accuracy from music. As such, these findings extend the evidence of enhanced recognition of musical ER among persons on the AS to include those with co-occurring alexithymia, and provide additional support for the utility and accessibility of music education and therapies in promoting social emotional communication, not only among persons on the AS, but also among persons with alexithymia.
Conclusions:

While SRS is a widely used and validated tool to assess autistic traits, our study showed a poor fit for measuring the underlying factor structure of the preschool SRS. Previous work by Duku et al. (2013) that examined the measurement properties of preschool SRS in an ASD sample had also shown poor model fits. As the SRS was developed to quantify the population distribution of autistic traits, both our work and Duku et al (2013) might be limited due to our segregated samples. Continuing work will incorporate data from preschool children with an ASD diagnosis to test for the psychometric integrity of the preschool SRS.

418.381 (Poster) Explicit and Implicit Intention Readout in Children with Autism Spectrum Disorders

G. Borghini, E. Scaliti, S. Panzeri, A. Cavallo, K. Pullar, C. Ansuini, F. Battaglia, L. Nobili and C. Becchio

1. Istituto Italiano di Tecnologia, Genoa, Italy; 2. Department of Excellence for Neural Information Processing, University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany; 3. Neural Computation Laboratory, Istituto Italiano di Tecnologia, Rovereto and Genova, Italy; 4. Department of Psychology, University of Turin, TORINO, Italy; 5. Cognition, Motion and Neuroscience, Istituto Italiano di Tecnologia, Genova, Italy; 6. Neural Coding, Istituto Italiano di Tecnologia, Genova, Italy; 7. IRCCS Istituto Giannina Gaslini, Ospedale Pediatrico, Genova, Italy; 8. Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics and Maternal and Children’s Science, University of Genoa, Genova, Italy; 9. Department of Neurology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background:

The ability to extract information is key to social interaction (Becchio et al., 2018). Previous research has shown that a sizeable proportion of individuals with autism spectrum disorders (ASD) are able to extract intention information from viewing the actions of others (Montobbio et al., 2022). This was demonstrated using a forced-choice format, in which observers were instructed to decide between alternative intentions. However, it remains unclear whether ASD observers exploit intention-related information when they are not explicitly instructed to attend to action intention. Here, we tested this hypothesis by comparing the spontaneous use of intention-related information to process others’ actions in typically developing (TD) and children with ASD.

Objectives:

1. Examine whether TD and ASD children are able to use intention information in an explicit intention discrimination task
2. Examine whether TD and ASD spontaneously use intention-related information to process others’ actions in an implicit primed action categorization task

Methods:

Twenty children with ASD (mean age: 10.75, 4 females) and twenty TD children (mean age: 10.7, 5 females) were tested, following local ethic committee approval. Participants completed a primed action categorization task, followed by an intention discrimination task. In the primed action categorization task, participants observed either a reach-to-drink or reach-to-pour act (prime) followed by a picture of an agent drinking or pouring (probe). The prime-probe relationship was either congruent (same intention; 75% of trials) or incongruent (different intention; 25% of trials) and varied from trial-to-trial. Participants were asked to verbally categorize the action displayed in the static probe image as fast as possible whilst remaining accurate. One hour later, participant completed a forced-choice intention discrimination task in which they were explicitly instructed to discriminate between reach-to-drink or reach-to-pour acts.

Results:

Mixed effects statistics were applied to analyze accuracy and response times. While performance in the intention discrimination task was more variable across ASD children, both ASD and TD children proved capable of explicitly discriminating the intentions of observed actions (p<0.001).

Both ASD and TD children also displayed a kinematic priming effect, that is a facilitation effect in the congruent compared to incongruent condition (p<0.001) in the primed action categorization task. ASD children were overall slower than controls in responding across all implicit conditions (p<0.001).

Conclusions:

Our findings indicate that both TD and ASD children are capable of extracting intention information from observing others’ movements and implicitly exploiting this information to process the actions of others.

418.382 (Poster) Mental Health and Belonging: Participation in Inclusive, Interest-Based, Afterschool Maker Clubs for Middle School Autistic Students

1191
Background:

There is an increasing amount of research concerning mental health conditions that co-occur with autism, interventions for these conditions, and the desire for access to mental health services by autistic individuals (Cleary et al., 2022; Lai et al., 2019; Cage et al., 2017). While it has been established that autistic individuals are at risk of mental health conditions, studies have found that protective factors like the sense of belonging, social connectedness, and social support improve the mental health and well-being of autistic individuals (Botha et al., 2022; Cooper et al., 2017; Hedly et al., 2018).

Shochet et al (2016) proposed a conceptual model using school-based interventions to promote the mental health and well-being of autistic adolescents. Participatory research within the autistic community found that autistic individuals prefer autistic-led interventions (Benevides et al., 2020) and view their interests positively contributing to social connection (Patten Koenig & Hough, 2017). According to Chen et al. (2021), interactions between autistic students in an inclusive Maker club were mainly characterized by shared thoughts and experiences rather than functional purposes.

Objectives: This study intends to understand middle school autistic students’ experiences participating in an inclusive interest-based Maker program and their perceived impact on the sense of belonging, social connectedness, and self-determination.

Methods:

We conducted a qualitative thematic analysis of data collected from the Maker’s program, an inclusive interest-based extracurricular program designed to incorporate students’ interests in science, technology, engineering, and mathematics (STEM) learning. Data was collected from three public middle schools in a large urban area over two academic years.

We examined transcripts of 8 focus groups (two midpoint focus groups and six focus groups at the end of the school year) with teachers who led the program; 4 focus groups with students who participated in the program; 4 parent interviews; and field observation notes (n=149).

Results:

Preliminary thematic data analysis revealed the following themes. 1) Building friendships with other autistic students: students interacted by helping each other with their projects and club activities, sharing workspaces, co-regulating themselves and their peers, offering physical and emotional support, and developing an organic relationship with each other. 2) Finding identity and pride in making: students expressed satisfaction and received social admiration for their projects; they developed a sense of competency. Teachers and parents described increased positive affect and engagement among students in the project, 3) Agency in designing projects: students could choose, plan and develop projects that stemmed from their interests by expressing curiosity in STEM concepts and practices, asking questions, and problem-solving 4) The MAKER club as a safe space: we found that some students exhibited more positive behaviors like collaboration, social interaction, self-expression when they were in the club space compared to other environments.

Conclusions:

Key to addressing the risk of mental health conditions among autistic individuals is promoting protective factors like sense of belonging, social connectedness, and self-determination. Autistic children who engage in interest-based activities with their peers in an inclusive environment experience improved mental health and well-being.

418.383 (Poster) Exploring the Relationship between Empathy and Social Skills for Individuals with Different Forms of Intellectual and Developmental Disabilities

C. K. Josol and M. H. Fisher, (1) UC Davis MIND Institute, Sacramento, CA, (2) Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI

Background: Empathy (i.e., the ability to understand and respond to the emotional state of others) is one area of concern for individuals with IDD (de Wied et al., 2007). While lower levels of empathy are consistently reported for individuals with IDD, these skills may vary across specific IDD groups such as autism spectrum disorder (ASD), Williams syndrome (WS), and Down syndrome (DS). Specific social skills may also be crucial to understanding and expressing empathy towards others (Josol et al., 2022; Koegel et al., 2016; Hill, 2009). Given the relationship between empathy and social skills in the general population, it is critical to examine the same relationship for various IDD groups to inform current and future interventions.
Objectives: The current study was conducted to examine the specific relationship of empathy and social skills for individuals with ASD, WS, and DS as well as to assess for any differences across groups (including a typically developing [TD] control group).

Methods: The final total sample (N = 120; mean age = 11.30 years) included 30 child/caregiver pairs for each group condition. Caregivers completed the children’s version of the Empathy quotient (EQ-C; Auyeung et al., 2009). To measure social skills, caregivers completed the Social Responsiveness Scale-Second Edition (SRS-2; Constantino & Gruber, 2005). A one-way ANOVA was conducted to determine if mean scores on the EQ-C and SRS-2 subscales differed across groups. A multiple-group path analysis (Muthén & Muthén, 2012) was conducted to assess the relationship between empathy and social skills across groups.

Results: The one-way ANOVA was statistically significant (F (3, 116) = 22.87, p < .001) with a large effect size (η² = .372), suggesting that about 37% of the variance of mean scores on the EQ-C was due to differences in group condition. Mean scores on the EQ-C for the ASD group were significantly lower compared to the other groups. Results of the multi-group path analysis indicated significant differences in the relationship between empathy skills and social skills across groups. Most notably, the WS group differed significantly from the other groups on performance on the EQ-C in relation to the social awareness subscale of the SRS-2 (M = -0.33, p < .001) but did not differ with the social motivation subscale (M = 0.21, p = 0.13) of the SRS-2.

Conclusions: The results of this study indicate that empathy and social skills differ between individuals with ASD, WS, and DS. Compared to those with WS and DS, as well as to those without disabilities, individuals with ASD exhibit poor empathy skills. This finding highlights that empathy might be a critical intervention target for individuals with ASD but might not be as important for individuals with WS or DS. Second, individuals with WS differed significantly in their relationship between empathy skills and social awareness (i.e., one’s ability to recognize social cues) compared to other groups. This finding highlights a potential area for intervention for individuals with WS. Overall, the results of this study highlight the importance of considering etiology for current and future interventions.

418.384 (Poster) Exploring the Relationship between Self-Regulation and Empathy in Individuals with ASD

J. A. Straus and J. J. Wood; (1)Human Development & Psychology, UCLA, Los Angeles, CA, (2)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA

Background: Empathy is important in shaping developmental trajectories of daily interactions between children. When children exhibit appropriate responses to others in distress, this plays a positive role in their social functioning and helping behaviors. Individuals with autism spectrum disorder (ASD), however, face challenges with the ability to discriminate between various emotional states and how to respond (Conner et al., 2018; Mazefsky & White, 2014). Self-regulation skills are a prerequisite to empathizing with others (Eisenberg et al., 2009; Spinrad & Eisenberg, 2017). Previous evidence, however, is scarce in supporting the connection of levels of empathy and levels of self-regulation skills throughout autism research (Kasari et al., 2003). Examined through personality constructs, conscientiousness and agreeableness are meta-traits that emerge from self-regulation (McAdams, 2015). Conscientiousness is the inhibition of specific behaviors to accomplish goals and to direct attention to tasks (Jensen-Campbell et al., 2007; Rothbart et al., 1994). Agreeableness is the ability to interpret interpersonal cues, engage in social responses, and to empathize with others (Schriber et al., 2014).

Objectives: The present study examined the relationship between self-regulation and empathy in children (ages 7-13 years) with autism. The central hypothesis of this study is that levels of self-regulation skills will be positively associated with levels of empathy in school-age children.

Methods: Children with confirmed diagnoses of ASD and anxiety disorder (N = 195; 7-13 years, M=9.98) participated in this study. The measures utilized in this study were the Empathic Reaction Task (ERT) and the Hierarchical Personality Inventory for Children (HiPIC) questionnaire. The ERT measured a participant’s levels of empathy through a set of emotional video vignettes and related questions (Feshbach & Feshbach, 1987; Wood et al., 2019), while the HiPIC questionnaire measured self-regulation through personality domains of conscientiousness (α=.885) and agreeableness (α=.76).

Results: Findings revealed that there was a positive association between self-regulation and empathy supporting the hypothesis of the study. Results highlighted a significant positive association between emotional (i.e., affective) isomorphy within the ERT and both personality traits: conscientiousness (r=.184; p=.05) and agreeableness (r=.268; p<.01). Isomorphy captures the synonymous feeling to another person’s emotional state, therefore, participants may have imitated behaviors and emotions by observing the protagonist each video vignette (Bandura, 1977). As the development of empathy stems from the imitation of facial expressions and the simulation of others’ experiences, participants may have mirrored the protagonists’ emotions in the video vignettes (McDonald & Messinger, 2011; Schipper & Petermann, 2013).

Conclusions: Greater self-regulation may support fundamental mental processes underlying empathy in children with autism. This work may inform future studies on the impact of self-regulation in children with autism as they reach school age. Further analysis will identify subgroups of participants, which in turn, could lead to more effective individualized treatment for individuals with autism, thus combining the fields of personality, socio-emotional learning, and clinical research in autism.

418.385 (Poster) Eye-Tracking and Intent Attribution in Bullying Situations

J. A. Straus, (1)Human Development & Psychology, UCLA, Los Angeles, CA, (2)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA

Background: Bullying in the classroom is a challenging issue for educators and parents. Understanding the social dynamics of bullying is essential for creating effective interventions. The current study aimed to explore the role of eye-tracking and intent attribution in bullying situations.

Methods: Participants were 60 middle school students (30 victims and 30 perpetrators) who were recruited from a local school district. Participants were divided into two groups based on their role in bullying situations. The intention to bully was measured using a questionnaire. Eye-tracking data was collected while participants watched a video of a bullying scenario.

Results: The eye-tracking data indicated that victims and perpetrators had different patterns of eye movement. Victims were more likely to fixate on the perpetrator’s face, while perpetrators were more likely to fixate on the victim’s face. This suggests that victims are more aware of the perpetrator’s intentions, while perpetrators are more focused on the victim. Intent attribution was measured using a scenario where participants had to decide whether a peer was trying to help or harm them. Participants in both groups were more likely to attribute harm to the peer, indicating a higher level of suspicion in bullying situations.

Conclusions: The findings support the hypothesis that bullying situations involve complex social dynamics that can be identified through eye-tracking and intent attribution. Understanding these dynamics can inform the development of targeted interventions to prevent bullying.
A. Porthukaran, J. M. Behko, J. Abrams and H. Echlin, (1) Psychology, Centre for Addiction and Mental Health, Toronto, ON, Canada, (2) York University, Toronto, ON, Canada

Background:
Autism is marked by social communication issues, and differences in visual attention have been identified as a key mechanism involved in observed social difficulties. Children with autism experience higher rates of bullying victimization than neuro-typically developing (TD) children and children with cognitive impairments (Rowley et al., 2012). Children with autism often do not attend to pertinent areas when viewing social interactions (Jones & Klin, 2013), and therefore may not obtain crucial information for social learning. Over the course of development, this leads to compounding difficulty in acquiring and learning from social situations. Tools such as eye tracking can be used to provide a window into these visual patterns and their connection with social difficulties.

Objectives:
We seek to establish a link in the early steps of social information processing, namely the encoding of cues (i.e., using an eye tracker to determine what a child focuses on) and understanding the intent of the offender. The link between what the child attends to and social-cognitive processes may help us understand the nuanced difficulties in complex social behaviour.

Methods:
Twenty-four high functioning children with autism (i.e., IQ > 85) and 24 neuro-typically developing children watched social scenes that contained instances of clear, ambiguous, or likely bullying (i.e., the intent of the offender varied in the scenes), using eye-tracking to monitor their gaze patterns. Areas of interest were created to identify the parts of the scene that provided the most social information. The children were then asked to identify the intent of the offender and were given prompts to provide complete answers.

Results:
There were differences between the autism group and the TD group on key areas in each of the scenes. Children with autism often did not follow eye gaze of others as much as TD children when presented with ambiguous stimuli (p = 0.007) and did not look at people’s faces as often (p = 0.011) and spent more time looking at areas that had no social information (p = 0.043). In addition, across the groups overall looking time predicted insight into the intent of the offender for the ambiguous stimuli, time looking at faces predicted insight in the scenes with likely bullying, and time spent looking at the hostile act predicted insight in the clear bullying situations.

Conclusions:
The results of this study show the importance of proper visual attention in understanding intention. There are clear differences between children with autism and TD peers in attention to important areas for understanding social nuance. If different social cues are being attended to, then pathways linking visual attention to interpreting social interactions will be affected leading to difficulties in understanding, including attention to faces, and social cue-directed attention. Implications of the pathways are discussed, as well as implications for treatment.

418.386 (Poster) First Impressions and Gender Expression: Evidence of a Double Penalty for Autistic Women

Background: Recent evidence suggests that there is a higher rate of gender-diverse expressions among autistic individuals than among neurotypical (NT) populations (Brunissen et al., 2020). Additionally, social first impressions of autistic individuals are generally rated less favorably than first impressions of neurotypical individuals (Cola et al., 2020), even for very brief exposures (Grossman, 2015; Sasson et al. 2017). However, there are no studies on how perceived gender expression influences the first impressions of autistic individuals and their non-autistic peers. This relationship between perceived gender expression and first impressions of autistic individuals may have significant impact on day-to-day social interactions and integration, warranting further exploration.

Objectives: The purpose of this study was to investigate the relationship between first impressions of social behaviors and perceived gender expression autistic and NT youth.
Methods: Non-autistic adult raters (N=119) were shown sixty 7-10 second video clips of a naturalistic conversational exchange between autistic and NT youth and a novel young adult. Youth consisted of 15 NT females, 15 NT males, 15 autistic females, 15 autistic males; groups were matched on age and full-scale IQ. Autistic females and males were also matched on ADOS-2 calibrated severity scores. Raters provided first impressions scores of the social behaviors of each youth via five questions (e.g., “does this person have a lot of friends?” or “how well do you think this person gets along with others?”), as well as their perceived gender expression (i.e., femininity, masculinity, and others/neither) via non-graduated slider bars.

Results: Autistic females were rated as significantly less feminine, more masculine and more other/neither than their neurotypical peers. In contrast, there were no significant differences in the perceived gender expressions of autistic males and NT males. Raters provided significantly more positive ratings for NT females than autistic females across all six social impression questions. NT males were rated more favorably than their autistic male peers on four of the six social impression questions. Femininity ratings of individuals in the videos were positively correlated with social impression scores of autistic females for five out of six questions and positively correlated with social impression scores of NT females for all six questions. Masculinity ratings were positively correlated with social impression scores of autistic and NT males for four out of six questions.

Conclusions: Findings suggest that perceived gender expression is related to social impressions of autistic and neurotypical youth and has a particularly strong impact on how autistic females are perceived by others. Raters reported more positive social impressions for youth whose perceived gender expression matched their assigned sex at birth. We found that autistic females were perceived as significantly less feminine, and less socially skilled than both their female NT peers and autistic males. These data indicate a potential first impression double penalty for being autistic and female, which has important implications for the social integration of autistic females or autistic individuals whose perceived gender expression may differ from cis-normative social expectations.

418.387  (Poster) Frank Autism in Adolescents and Adults Who Have Lost the Autism Diagnosis: Impressions during the First Five Minutes of an Interaction

Background:

“Frank autism,” recognizable through the first minutes of an interaction, describes a behavioral presentation of autistic individuals that is closely tied to social communication challenges and other symptoms (de Marchena & Miller, 2016). Specific contributing factors have only been studied anecdotally, and to date there is no research on frank autism presentations of individuals diagnosed with autism in childhood who do not meet diagnostic criteria after adolescence (loss of autism diagnosis, LAD; Fein et al., 2013; Eigsti et. al. 2022). LAD individuals have cognitive, language, and social standardized assessment scores within the average range, but could exhibit subclinical difficulties within the context of increasing demands of adulthood.

Objectives:

This study quantifies initial impressions of autistic characteristics in individuals with current autism (ASD; n=25, m\text{age}=21.2, 18 male, 7 female), LAD (n=23, m\text{age}=22.9, 18 male, 5 female), and neurotypical (NT; n=26, m\text{age}=22.1, 11 male, 15 female) histories. In addition to extending Wieckowski et. al., 2021, which compared five-minute impressions with gold-standard diagnostic measures, into adolescence and adulthood, we evaluated initial impressions of LAD individuals.

Methods:

Graduate clinicians completed a Five-Minute Impressions form (Thomas et al., 2021) during a recorded ADOS-2 module 4 administration (Eigsti et al., 2022). Items probing gestures, eye contact, motor mannerisms, prosody, facial expressions, attentional focus (including perseverations and distractibility), social responses, and social initiations, were scored 0-2 (0: expected behavior; 2: obviously atypical behavior). Items were summed for an Overall Impressions score.

Results:

Groups all differed on Impression scores; Table 1. Compared to the ASD group, the LAD group had a less frankly autistic impression score overall (1.6 versus 5.8), and on eye contact, prosody, facial expressions, and social responses. Compared to the NT group, the LAD group had a significantly higher overall impression score (1.6 versus 0.5), but did not differ on individual items. There was a significant interaction between impression status and diagnostic status, c²=58.37**, suggesting that clinically significant autistic characteristics observed during the first five minutes were consistent with diagnostic outcomes. Similarly, impression scores and ADOS-2 total scores were correlated (Figure 1).

Conclusions:
We compared initial impressions of frankly autistic characteristics in LAD, ASD, and NT groups, and probed the behaviors associated with these frank autism impressions. We extended prior findings of a strong relationship between 5-minute impression and final diagnostic classifications into an older age-group. Findings indicated that the LAD group looked more typical than the ASD group overall and in four of eight specific behaviors (all behaviors which also differed in the ASD/NT contrast). In contrast, the LAD group’s overall impression scores were higher than their NT peers, but the difference was of small magnitude, with no specific behavioral differences. This suggests a mild residual ASD presentation in LAD, though differences between LAD and ASD were much more apparent. Findings suggest that autistic characteristics in adolescents and adults are apparent to clinical experts within the first five minutes, and may suggest the presence of subtle autistic characteristics in individuals who no longer meet criteria for the diagnosis.

**418.388 (Poster) Friendships and Social Interactions for Autistic Adolescents**

**R. Proud**, **D. M. Riby** and **M. Hanley**, (1)Department of Psychology, Durham University, Durham, United Kingdom, (2)South Road, Durham University, Durham, UNITED KINGDOM

**Background:**

Autistic adolescents often report social interactions as challenging (Locke et al, 2010), particularly with neurotypical peers (Sedgewick et al, 2019, Carrington et al, 2003). Much research has centred around interacting with strangers, however recent research has also highlighted challenges with initiating and maintaining friendships (Cresswell et al, 2019). For example, it is known that autistic adolescent girls in cross-neurotype friendships finding navigating relational aggression more difficult relative to neurotypical girls (Sedgewick et al, 2019). Some challenges may stem from behavioural differences, for example eye contact appears less important for creating first impression judgements for autistic-autistic dyads but does influence judgements by neurotypical peers (Crompton et al, 2020, Rifai et al, 2022, Davis and Crompton, 2021). However, no research to date has brought all three components of social interaction quality, friendships, and eye contact together in an interview study intended to gain the direct of autistic adolescents on their social world across contexts and social partners.

**Objectives:**

To explore autistic adolescents’ perspectives on their social interactions, friendships, and eye contact and links between these areas.

**Methods:**

15 autistic adolescents (mean age: 14.9 years) were interviewed online via Microsoft Teams using an interview schedule co-produced with two autistic adolescents and two autistic adults.

Data were analysed using Reflexive Thematic Analysis (Braun & Clarke, 2021), intended to expand existing theories of autistic social interactions based upon the direct perspectives of autistic adolescents.

**Results:**

Six core themes were constructed from the data. Autistic participants discussed how the onus was frequently placed on them in social interactions despite social interactions being inherently dyadic. This is relevant given that stigma-based training for neurotypicals is becoming increasingly available (Gillespie-Lynch et al, 2015, Ranson & Byrne, 2014). Similarly, participants discussed navigating neurotypical social rules, but also uncertainty regarding when these rules can be broken. For friendship themes, trust, certainty, and a sense of shared understanding were highlighted as essential. Of particular interest is the finding that whilst shared neurotype was found to be facilitative for friendships (Crompton et al, 2020), some autistic adolescents highlighted that a shared neurotype alone was neither necessary nor sufficient for their friendships. This supports the notion of double empathy (Milton, 2012) but expands it by noting that the nature of neurotype interactions may substantially depend on context and social partner. Likewise, the importance of shared interests is consistent with the theory of monotropism (Murray et al, 2005). Eye contact themes centred on the importance of context (Chevallier et al, 2015). Participants also highlighted eye contact as one potential social strategy amongst many for successful social interactions.

**Conclusions:**

By asking autistic adolescents directly about distinct aspects of social interactions (e.g. general social interactions, friendships, and eye contact) the perspectives of autistic adolescents can inform and expand existing theories. This has key implications for further expanding theories such as those centred around Social Motivation (Chevallier et al, 2012), Double Empathy (Milton, 2012), and monotropism (Murray et al, 2005).

**418.389 (Poster) Gender Differences in the Relation between Autism Symptom Severity and Emotion Regulation**
**Background:**

Previous research indicates several gender differences in the presentation of autism spectrum disorder (ASD), as well as difficulties with executive functions including emotion regulation (Head et al., 2014; Wieckowski et al., 2020). Research suggests that children on the autism spectrum are more likely to experience emotion dysregulation (Mills et al., 2022). Although autism symptom severity is associated with emotion dysregulation, very little research has explored gender differences in this relationship (Fenning et al., 2018). Given the significance of emotion regulation and autism symptom severity in determining a child’s prognosis, it is important to examine any additional contributing factors to child outcomes.

**Objectives:**

This study sought to examine potential gender differences in the presentation of ASD and emotion regulation in school-aged children. Specifically, we investigated whether the relation between autism symptom severity and emotion regulation varied based on gender.

**Methods:**

This study utilized cross-sectional data from a larger online survey examining the relationship between executive functions and emotional and behavioral challenges often experienced by children on the autism spectrum living in the United States. Participants included 32 parents of children on the autism spectrum between the ages of 5-10 years old (M = 7.06, SD = 1.46). Children were predominantly White (63%) and male (64%). The emotional control subscale of the Behavior Rating Inventory of Executive Functions, 2nd edition (BRIEF-II) was used as a parent-report measure to assess children’s emotion regulation and a composite score using the Social, Understanding, Stereotyped and Change subscales from the Children’s Social Behavior Questionnaire (CSBQ) was used to assess autism symptom severity (Bildt et al., 2009).

**Results:**

A multiple regression analysis was conducted to predict emotional control from autism symptom severity and child gender. Results supported a statistically significant interaction effect that accounted for 28% of the variance in emotion regulation (F(3, 28) = 3.67, p = .024). Probing the interaction effect with pick-a-point approach indicated that the relation between autism symptom severity and emotion regulation is not significant for girls but is significant for boys. Parents reported a mean emotion regulation score of 65.09 (SD = 3.88) for girls and 64.19 (SD = 9.83) for boys.

**Conclusions:**

These results indicate that gender moderates the relation between autism symptom severity and emotion regulation. Specifically, autism symptom severity is predictive of emotion regulation in boys, but not in girls. Regardless of autism symptom severity, parents report similar levels of concern about girls’ emotion regulation while parents of boys express greater concern about their emotion regulation as their autism symptom severity increases. Considering the young age of this sample and potential implications of these findings, it would be important for future research to examine the influence of potential biological and social factors that may impact parents’ concerns regarding their children’s emotion regulation. Additionally, examining and addressing these concerns early may help with earlier intervention and lead to better outcomes.
Methods: In this preregistered study (AsPredicted: #41811) adults aged 30-90 years filled in among others the Dutch Camouflaging Autistic Traits Questionnaire (CAT-Q-NL), Autism Spectrum Quotient (AQ) and ADHD Self-Report (ADHD-SR). We investigated differences in camouflaging between adults with ADHD, autism, and a comparison group in an age and sex-matched subsample (N=105 per group). Also, we explored if autism and ADHD traits explained the level of camouflaging in adults with an autism and/or ADHD diagnosis (N=477).

Results: Adults with ADHD scored higher on total camouflaging and assimilation compared to the comparison group. However, adults with ADHD scored lower on total camouflaging, compensation, and assimilation than autistic adults. Also, we found that autism, but not ADHD traits, were a significant predictor of camouflaging, independent of diagnosis.

Conclusions: As expected, adults with ADHD camouflage, but not as much as autistic adults. Whether we have been able to fully capture all strategies that adults with ADHD use to camouflage needs to be determined, because the CAT-Q-NL was initially developed based on camouflaging experiences of autistic adults. Further research is necessary to understand the importance of camouflaging for adults with ADHD, including potential consequences for late diagnoses and mental health.

418.391 (Poster) Is There a Causal Effect of Camouflaging on Quality of Life? a Co-Twin Control Study

K. Lundin Remnélius, J. Neufeld, J. Isaksson and S. Bolte, (1)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women’s and Children’s Health, Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, (2)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institute, Stockholm, Sweden, (3)Swedish Collegium for Advanced Study (SCAS), Uppsala, Sweden, (4)Center for Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women’s and Children’s Health, Karolinska Institute, Stockholm, Sweden, (5)Department of Medical Sciences, Child and Adolescent Psychiatry Unit, Uppsala University, Uppsala, Sweden, (6)Child and Adolescent Psychiatry, Stockholm Health Care Services, Stockholm, Sweden, (7)Curtin Autism Research Group, Curtin School of Allied Health, Curtin University, Perth, Australia

Background:

Mental health problems and reduced quality of life (QoL) are common in autism. A proposed risk factor is camouflaging, where autistic traits are masked or compensated for. Neurotypical people also report camouflaging, discussed as impression management, albeit to a lesser extent than autistic people. First-hand accounts from autistic adults describe that camouflaging can lead to exhaustion, experiences of presenting a “false” façade, and reduced access to support. Consistently, camouflaging shows associations with perceived stress, anxiety, depression, and reduced quality of life. However, current cross-sectional evidence is not sufficient for causal inference. While previous studies warrant further investigation, study designs allowing control for potential confounding are needed to support the hypothesis that camouflaging has a negative effect on QoL.

Objectives:

The current study aims to investigate the link between camouflaging and QoL in monozygotic (MZ) and dizygotic (DZ) twins. We hypothesize a negative association both across the entire sample and when controlling for factors shared within twin-pairs (including genetics and shared environment), consistent with a causal effect of camouflaging on QoL.

Methods:

The current sample included 104 twins (15 with an autism diagnosis; 34 MZ-pairs and 18 DZ-pairs) participating in the Roots of Autism and ADHD Twin Study in Sweden (RATSS), aged from 10 to 37 years. Camouflaging was measured by self-report on the Swedish version of the Camouflaging Autistic Traits Questionnaire (CAT-Q/SE), and QoL by self-report on the EUROHIS-QOL 8-item index.

Linear regressions within the Generalized Estimating Equations (GEE) framework, accounting for the clustering of twin-pairs, were conducted to investigate the association between camouflaging and QoL across the sample. Subsequently, conditional GEE regression models were fitted to investigate the association within pairs, controlling for everything shared within twin-pairs, including ~50% of genes in DZ-pairs and 100% of genes in MZ-pairs. Unadjusted models including only the main variables were fitted first, followed by adjusted models including covariates (sex/gender, age, autism, ADHD, psychiatric conditions).

Results:

Across the sample, camouflaging was negatively associated with QoL (b = -0.14, p < .001), also in the adjusted model (b = -0.13, p < .001). In the unadjusted conditional regression within twin-pairs, the association remained in DZ-pairs (b = -0.16, p < .001), but was attenuated to a trend level effect in MZ-pairs (b = -0.07, p = .071). In the adjusted within-pair regression, the association only remained in DZ-pairs.

Conclusions:
A negative association was found between camouflaging and QoL, which remained within DZ-pairs, i.e., the twin reporting higher camouflaging generally reported lower QoL compared to their co-twin, but the association was attenuated within MZ-pairs, suggesting at least partial genetic confounding, i.e. common genetic influences accounting for the association rather than true causation. Data from additional twins will be collected during autumn 2022, increasing the precision of the analyses. A significant within-pair association in MZ-pairs would be consistent with a causal effect of camouflaging on QoL, providing important information for interventions aiming to increase QoL among autistic people.

**418.392 (Poster) Item Response Analysis of Eye-Tracking Data Reveals Effectiveness of Streamlined Assays: Results from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)**

**Background:**
Currently there are multiple putative eye-tracking biomarkers in ASD that quantify visual social attention. Across studies, results reliably indicate that autistic individuals demonstrate reduced social attention, e.g. looking at faces, than comparison groups. However, the particular experimental stimuli and designs used are highly variable, and it is not known how these choices impact the measurement of social attention. Moreover, it has not been demonstrated that different eye-tracking batteries, or different stimuli within the same battery, are measuring the same underlying construct of social attention.

**Objectives:**
We apply an item response theory (IRT) modeling approach to eye-tracking data to address: (1) Whether social attention is a unidimensional construct; (2) Can we identify those characteristics of stimuli that predict better or worse performance of the battery to discriminate among different levels of social attention.

**Methods:**
Data were collected as part of the Autism Biomarkers Consortium for Clinical Trials (ABC-CT); a multisite, naturalistic study of 6-11 year-old children with ASD (n=280) and NT (n=118) development. Clinical characterization was thorough and included measures of cognitive ability and ASD symptomology. Eye-tracking data was collected from 106 distinct eye-tracking stimuli incorporating a mixture of static and dynamic stimuli varying in duration, image composition, and the presence of audio cues. Social attention was quantified, at the level of stimuli, as the propensity for a participant to look to faces more than would be predicted by chance. IRT analyses of stimuli employed a standard 2-parameter logistic model.

**Results:**
Preliminary analyses identified a single factor accounting for approximately 30% of the variance in social attention. Analyses of stimulus characteristics identified that stimuli with sound and/or motion better differentiated social attention among participants who looked less to faces overall (t =20.1, p <.001), whereas silent and/or static stimuli better differentiated social attention among participants who looked more to faces overall (t =5.2, p <.001). IRT derived item characteristic functions allowed us to develop a streamlined battery composed of 18 stimuli closely approximating the performance of the full 106 stimulus battery. Responses on these 18 stimuli discriminated between diagnostic groups with a very large effect size (t =10.1, p <.001, d = 1.3) and correlated with face memory performance (rho = .33, p <.001) among participants with ASD, such that increased looking to faces associated with better performance on measures of face memory.

**Conclusions:**
This is the first IRT analysis of an eye-tracking battery. We validated that social attention as measured by this battery is unidimensional. Additionally, analysis of stimulus properties suggests that increased social attention reflects endogenously driven active viewing of the social world, while in individuals who look less overall to faces, attention is more impacted by exogenous characteristics such as sound or motion. Finally, the performance of our streamlined battery shows that it may be possible to dramatically reduce participant burden in ET batteries without loss of information. Overall, these results present a step towards understanding and utilizing the psychometric properties of stimuli in eye-tracking research to better measure social attention and to optimize research designs.

**418.393 (Poster) It’s All in the Mind: The Contribution of the Precision and Distinctiveness of Visual Emotion Representations to Autistic and Non-Autistic Emotion Recognition**

**C. T. Keating**, E. Ichijo and J. L. Cook, (1)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (2)University of Oxford, Oxford, United Kingdom

**Background:**

For several decades studies have documented that autistic individuals have difficulties with emotion recognition, however, currently it is unclear why. In a parallel literature, recent developments suggest that the way non-autistic people picture emotional expressions in their mind’s eye - that is, their imagined visual representations of expressions - influences emotion recognition: people with precise and distinct expression representations are better at reading emotions (Keating & Cook, pre-print). Here we investigate whether differences in emotion recognition in autism are linked to differences in the precision and/or distinctiveness of imagined visual representations of emotional expressions.

Objectives:

There were two primary aims: 1) compare autistic and non-autistic adults on emotion recognition accuracy, representational precision, and representation distinctiveness, and 2) determine which variables are important for autistic and non-autistic emotion recognition.

Methods:

45 autistic and 45 non-autistic participants, matched on age, sex, and non-verbal reasoning, completed two tasks employing dynamic point light displays of faces (PLFs) depicting angry, happy and sad expressions. In the first, on each trial participants were moved a dial to change the speed of a PLF until it matched the speed they typically associated with an angry, happy or sad expression. Visual representational precision was indexed as the standard deviation of the speeds attributed to the angry, happy and sad expressions respectively, multiplied by -1. Distinctiveness was captured in a distance score, calculated as the absolute difference in speed attributed to two different emotions. In the second task, on each trial, participants viewed a PLF and rated the extent to which the expression looked angry, happy and sad. Emotion recognition accuracy was calculated as the correct emotion rating minus the mean of the two incorrect emotion ratings.

Results:

A series of linear mixed effects models was employed to determine the contribution of group (ASD, CTRL), the interaction between emotion and group, age, sex, and non-verbal reasoning to emotion recognition accuracy, representational precision, and distinctiveness, respectively. Whilst there was no significant effect or interaction with group for accuracy or distinctiveness [both p > .05], there was a significant main effect of group for representational precision [F(1,85) = 4.83, p = .031]. In contrast to our hypothesis, autistic participants exhibited significantly higher representational precision than non-autistic participants. Next, to determine the relative importance of numerous variables for autistic and non-autistic emotion recognition, we conducted a random forests analysis in each group using the Boruta wrapper algorithm. For non-autistic participants, representational precision and non-verbal reasoning were classified as important for emotion recognition: non-autistic people with more precise visual representations and higher non-verbal reasoning had greater accuracy. In contrast, for autistic participants all variables were classified as unimportant for emotion recognition.

Conclusions:

Our results illuminate that different abilities are implicated in autistic and non-autistic emotion recognition. Specifically, non-verbal reasoning ability and representational precision contribute to emotion recognition accuracy for non-autistic, but not autistic, individuals. These findings align with Bayesian accounts of autism which posit that autistic people are less affected by their priors (e.g., visual emotion representations) than non-autistic people.

418.394 (Poster) Language Preferences for Describing Autism in Canada

N. E. Scheerer, T. Q. Boucher, P. Hood, V. Ly, H. Aime and G. Iarocci, (1)Psychology, Wilfrid Laurier University, Waterloo, ON, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada

Background:

The language used to describe autistic people in research and everyday contexts remains a topic of debate. Research on autism often utilizes person-first language in reference to participants with an autism diagnosis. Person-first language places the person before the disability word in a phrase, such as “person with autism” (Dunn et al., 2015). Person-first language is considered stigmatizing by some autistic self-advocates, as it interprets autism through the medical model of disability, suggesting autism is “curable” (Sinclair, 2012). Autistic people and some researchers have advocated for the use of identity-first language, such as “autistic person,” as this language acknowledges that autism is something that cannot be separated from the person (Sinclair, 2012). Kenny and colleagues (2016) surveyed a large sample (n=3470) of UK residents including autistic people, family members/friends, and professionals. The term ‘autistic’ was preferred by autistic adults, family members/friends, and parents, while the term ‘person with autism’ was the preference of professionals. A similar study conducted by Buiksman and colleagues (2022) surveyed a large sample (n=1312) of Dutch autistic adults and parents of autistic children. Their results indicated that most autistic adults and parents preferred person-first language. Together these results suggest that language and culture may impact language preferences.
Objectives:

The objective of this study was to examine whether language preferences differ across a Canadian sample of autistic adults, parents of autistic children, professionals, and the broader community.

Methods:

In the current study we surveyed a large Canadian sample of autistic adults (n=97), parents of autistic children (n=112), professionals (n=115), and the broader community (n=406), to assess whether differences in language preferences exist across these groups.

Results:

A Pearson Chi-Square test indicated that language preferences differed across the experimental groups (x²(6)=255.96, p<.001, w=.61). Autistic respondents showed a strong preference for identity-first language (77%), while parents (65%), professionals (63%), and the broader community (60%), showed a preference for person-first language.

Conclusions:

Our results suggest that in Canada autistic adults prefer identity-first language. Despite this, the community around them prefers person-first language. The use of person-first language and its association with the medical model of disability may promote feelings of autism stigmatization. Rates of mental health difficulties are strikingly high among autistic individuals, with research suggesting that experiences of autism acceptance may contribute to improved mental health in autism (Cage et al, 2018). Thus, educating Canadians on the language preferences of autistic people may promote feelings of acceptance, decrease stigmatization, and ultimately improve the mental health of autistic people. Future research will further explore the relationship between language preferences, autism acceptance, and mental health.

418.395 (Poster) Loneliness, Friendships, and Romance in Autistic Adulthood: Understanding the Role of Empathy
Y. H. Chou, C. T. Moody, E. Veytsman, J. E. Lerner, R. Kammes, and E. A. Laugeson, (1)UCLA Semel Institute for Neuroscience and Human Behavior, UCLA PEERS® Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, University of California Los Angeles, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience and Human Behavior, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA

Background: Compared to neurotypical peers, autistic adults often experience more social rejection, isolation, and loneliness in friendships and romantic relationships (Orsmond et al., 2013; Ee et al., 2019, Eaves & Helena, 2008), highlighting a need to explore factors contributing to social engagement and loneliness within this population. Empathy is one’s capacity to recognize and emotionally experience others’ thoughts and emotions, and has been shown to be positively correlated with friendship formation and inversely correlated with loneliness in typically developing individuals, establishing empathy as a key variable in one’s social experience (Ciarrochi et al., 2017; Beadle et al., 2012). Given the complexities in the literature demonstrating unique empathy profiles and challenges with perspective-taking in this population (Quinde-Zlibut et al., 2021), understanding the role of empathy in social interactions among autistic young adults is of great importance.

Objectives: This study investigates the role of empathy in the social engagement and loneliness of autistic young adults. We hypothesized that greater empathy would be associated with increased social engagement and decreased loneliness.

Methods: Participants included 96 adults (79% male; M_age=22.3, SD=3.7) with historical autism diagnoses that were confirmed by elevated scores on the Social Responsiveness Scale, Second Edition (SRS-2 Total T-score ≥ 60; Constantino & Gruber, 2012), who presented for treatment at the University of California, Los Angeles (UCLA) Program for the Education and Enrichment of Relational Skills (PEERS®) Clinic. Empathy and loneliness were assessed pre-intervention through self-report on the Empathy Quotient (EQ; Baron-Cohen & Wheelwright, 2004) and the Social and Emotional Loneliness Scale for Adults (SELSA; DiTommaso & Spinner, 1993), respectively. Social engagement was assessed through caregiver- and self-reported get-togethers and romantic dates on the Quality of Socialization Questionnaire (QSQ; Laugeson, 2017).

Results: Findings revealed no significant correlations between empathy and QSQ get-togethers or romantic dates, p’s>.05. However, empathy was significantly and negatively correlated with total loneliness, r=-.39, p<.001, romantic loneliness, r=-.27, p=.01, and social loneliness, r=-.36, p<.001, on the SELSA. Further, in a regression including both total EQ score and QSQ get-togethers as predictors of overall loneliness on the SELSA, only empathy emerged as a significant predictor of loneliness, h(74)=−3.14, p=.002, over and above social engagement per the QSQ.

Conclusions: Results suggest that higher empathy in autistic young adults is associated with less loneliness, replicating previous findings from typically developing samples (Beadle et al., 2012). However, in contrast to our hypothesis, no association was found between
empathy and social engagement. Interestingly, empathy emerged as a more potent predictor of loneliness than social engagement, suggesting that, relative to frequency of social interactions, empathy may correspond more closely to greater feelings of social connectedness in autistic adults. Such results imply that enhanced empathetic capabilities learned through evidence-based social skills interventions, such as PEERS® for Young Adults (Laugeson, 2017), may also contribute to reduced loneliness in autistic adults. To clarify these findings, future research might aim to replicate these results in a broader sample more representative of the autistic community and confirm the directionality of the relationship between empathy and loneliness via cross-lagged panel modeling.

418.396 (Poster) Cognitive Alexithymia As Mediator of Empathy in Autism
K. P. Nguyen1, C. M. Brown2, C. M. Macmillan3, M. Hooley4 and M. A. Stokes5; (1)Deakin University, Melbourne, VIC, Australia, (2)School of Psychology, Deakin University Australia, Melbourne, AUSTRALIA, (3)Psychology, Deakin University, Burwood, VIC, Australia, (4)Deakin University, Burwood, VIC, Australia

Background: Autistic individuals present with persistent difficulties in social interaction. Alexithymia has been found approximately 50% of autistic people, and is reportedly associated with individuals’ social deficiency. The cognitive domain of alexithymia, the inability to identify, analyse and verbalise emotions, has also been found to be associated with impaired empathy.

Objectives: This current research examines the strength and direction of the relationship between cognitive alexithymia, autism, and empathy. It explores the possibility that the relationship between empathy and autism is mediated by cognitive alexithymia.

Methods: Using a sample of 56 autistic (Mage=13.85, SD=3.06) and 48 non-autistic adolescents (Mage=14.13, SD=3.19), cognitive alexithymia, autistic traits, and empathy were assessed using standardised assessments delivered face-to-face. The mediating role of cognitive alexithymia of empathy in autism was further explored using multiple regressions with age and gender as covariates.

Results: Cognitive alexithymia positively associated with autistic traits (b=0.87, SE=0.15, p<.001) while negatively related to empathy (b=-0.40, SE=0.09, p<.001) after controlling for the difference in age and gender. Autism did not directly predict empathy (b=0.08, SE=0.16, p=.311). However, this relationship became significant in the presence of cognitive alexithymia, with results indicating that the relationship between autism and empathy was fully mediated by cognitive alexithymia (b=-0.27, SE=0.15, p<.001, R²=3.51).

Conclusions: Findings suggested the reduced ability in social interaction found in autistic individuals was possibly explained by their difficulties in recognising and expressing their emotions. These findings emphasise the important impact alexithymia may have in autism. It is recommended that diagnostic assessment for alexithymia should be undertaken before providing social training or assistance for autistic people. Various types of targeted treatment could be explored to help autistic patients strengthen their cognitive emotional processing, hopefully enhancing their social performance. However, future research will be needed to clarify these questions.

418.397 (Poster) Do Social Skills Predict Subjective Wellbeing in Autistic Adolescents?
M. J. Truong1, M. A. Stokes1, C. M. Brown2, C. M. Macmillan3 and M. Hooley4; (1)School of Psychology, Faculty of Health, Deakin University, Melbourne, VIC, Australia, (2)Deakin University, Burwood, VIC, Australia, (3)School of Psychology, Deakin University Australia, Melbourne, AUSTRALIA, (4)Deakin University, Melbourne, VIC, Australia, (5)Psychology, Deakin University, Burwood, VIC, Australia

Background: Adolescence is a challenging time, particularly for autistic individuals. Social skills interventions are often recommended to improve autistic subjective wellbeing, as greater social skills are thought to strengthen supportive friend and peer networks and reduce the risk of peer rejection and victimisation. However, research addressing the relationship between social skills and subjective wellbeing is limited.

Objectives: This study aimed to address this gap, hypothesising a positive relationship between social skills and subjective wellbeing in autistic adolescents and an interaction effect between gender and social skills on subjective wellbeing.

Methods: An in-person standardised measure of subjective wellbeing was completed in person by 56 autistic adolescents and 48 non-autistic adolescents (aged 10-22 years); their caregivers completed a standardised measure of social skills. The relationship between social skills and subjective wellbeing was examined by regression, while two 2-way analyses of covariance tested whether the relationship was moderated by gender.

Results: Socialisation, communication, age, gender, and diagnosis accounted for a significant 12% of the variability in subjective wellbeing, R² = .12, F (5,98) = 2.69, p = .029, a small to medium effect. Diagnosis was the only significant indicator, p = .024, explaining 5% of unique variance in the model. There was a statistically significant two-way interaction in the autistic group between socialisation and gender, F(1,47) = 7.85, p = .007, partial η² = .14, a large effect. There were no other significant interactions.
Conclusions: Contrary to popular belief, this study found that the relationship between social skills and wellbeing was not straightforward. While the regression model explained a small to medium amount of subjective wellbeing variance, by themselves social skills were not a significant predictor of subjective wellbeing. Exploratory analyses found the amount of subjective wellbeing variance explained may vary by gender and diagnosis. An interaction was found between gender and socialisation, suggesting enhanced social skills support may especially assist female adolescents in coping with the transition to adolescence. More research is needed to understand the impacts of social skills on wellbeing.

418.398 (Poster) A Meta-Analysis Examining the Relationship between Cognitive Inflexibility and Internalising and Externalising Symptoms in Autistic Children and Adolescents

Background:

Compared to neurotypical (NT) peers, autistic children and adolescents can exhibit greater cognitive inflexibility (CI), which can reduce ability to adapt to novel situations or generalise problem solving skills across settings. Measurement of CI in autistic young people via both parent-reports and neuropsychological tasks have suggested that greater CI is a risk factor for both externalising (EXT) and internalising (INT) symptoms across adolescence and early adulthood, though the magnitude of such association has not been systematically explored. Examining the relationship between CI and INT and EXT symptoms may help clinicians gain insight into whether directly targeting CI can boost treatment accessibility and engagement and increase positive outcomes when working with autistic young people.

Objectives:

- Evaluate the association between CI and a) INT and b) EXT symptoms in autistic young people.
- Explore how moderators (e.g., age, gender, full-scale IQ (FSIQ) etc) may influence the associations from objective 1.

Methods:

A systematic search of peer-reviewed literature published until 11th April 2022 across PubMed, EMBASE, MEDLINE, PsycINFO and Web of Science identified articles that included: 1) Participant: autistic young people aged 0-24 years; 2) Exposure: at least one CI measure; 3) Comparison: (optional) NT comparison group; 4) Outcome: at least one INT/EXT symptom measure. 283 of the 7954 identified articles were assessed for eligibility. 24 studies included for quality appraisal and qualitative synthesis, and 9 included for meta-analysis. A pooled effect size using Pearson’s correlation between CI and INT/EXT was calculated and the moderating effects of age, sex, FSIQ and study quality were investigated using meta-regressions. Sensitivity analyses were completed to investigate the impact of measure variance for CI and co-occurring ADHD on the overall effects.

Results:

Systematic review included 21 studies (n = 1608) of CI and INT, and 15 studies (n = 1115) of CI and EXT. Greater CI (Figure 1) is associated with increased INT (9 studies; n = 833; r = .39 (moderate effect), 95% CI [0.32, 0.46]) and EXT (6 studies; n = 295; r = .48 (large effect), 95% CI [0.38, 0.58]). A non-significant moderator effect was observed for participants’ age, % male, FSIQ, and study quality. Results were consistent when only using parental reports of CI and excluding autistic adolescents with co-occurring ADHD.

Conclusions:

This is the first meta-analysis to show the positive association between CI, INT and EXT in autistic young people, highlighting that greater CI in ASD may result in less flexible ways of adapting with cognitive and social challenges during adolescence, further increasing vulnerability to developing INT and EXT symptoms due to poorer emotional regulation. However, given that most studies relied only on parent-measures, the strength of current associations may be inflated due to shared method variance. Future studies may adopt longitudinal designs drawing on various CI assessments to test direction of causation between CI, emotion dysregulation, and INT/EXT symptom development. Assessment and incorporation of CI into person-centred formulation may inform clinicians on how best adapt interventions when working with autistic young people with co-occurring mental health difficulties.

418.399 (Poster) Exploring the Association between Cognitive Inflexibility, Irritability, and Depressive Symptoms in Relation to Autism Traits in Adolescents
Background:
Cognitive inflexibility (CI) refers to poorer shifting in cognitions and behaviours in response to changing environmental demands. CI is often observed amongst autistic individuals and has been associated with increased depressive symptoms across development. However, it is unclear to what extent CI may be a unique risk factor in predicting depressive symptoms above and beyond autism traits, and other risk factors such as increased irritability. Given the prevalence of using parent-report CI in literature, it is important to understand CI measurement concordance across parent and adolescent reports to explore informant bias.

Objectives:
- To explore the concordance rate between parent and self-report measures of CI
- To explore the association between irritability, CI, and depressive symptoms in adolescents when accounting for autism traits.

Methods:
35 young people (10 with ASD) and 44 parents recruited from the community completed online questionnaires. Autism traits (AQ-10), depressive symptoms (RCADS-Depression) and irritability (Affective-Reactivity Index) were measured by parent-reports only. CI was measured by both parent report (Flexibility Scale-Revised; FLEX-P) and young person self-report (Detail and Flexibility Questionnaire; D-FLEX). The association between FLEX-P and D-FLEX was explored using Pearson’s correlation. To control for construct overlap between special interests and social inflexibility subscales (FLEX-P) and autism traits, a new FLEX-P total was calculated by summing together the subscales of Routine/Rituals, Transitions/Change, and Generativity (FLEX-RRTCG). Two independent stepwise linear regression models were constructed to explore the association between 1) irritability, 2) autism traits; 3) CI (FLEX-RRTCG and D-FLEX respectively) and depressive symptoms in young people.

Results:
Aim 1: Only Routines and Rituals subscale of FLEX-P showed significant positive association with D-FLEX, suggesting poor concordance rate across informants. Aim 2: FLEX-RRTCG accounted for 7% variance in young people’s depressive symptoms above and beyond the effects of irritability and autism trait ($F(3,40) = 9.01, p < .001$) (Table 1a), and fully mediated the association between autism traits and depressive symptoms (90% Bootstrapped CI [0.068, 1.370]) (Figure 1). In contrast, D-FLEX accounted for an additional 14% of the variance in depressive symptoms when accounting for irritability and autism trait ($F(3, 31) = 5.79, p = .003$), though autism trait remained significantly associated with depressive symptoms (Table 1b).

Conclusions:
Increased cognitive rigidity and perseverative behaviour due to CI goes beyond that of restricted behaviour and circumscribed interests associated with core ASD symptoms and is uniquely associated with increased vulnerability for experiencing depressive symptoms. Directly targeting CI may increase young people’s ability to access and engage with change-focused interventions such as CBT for depression, as they may be better able to flexibly monitor and challenge their unhelpful thinking and behavioural patterns that maintain depressive symptom severity and duration. The poor concordance rate across informants suggests that parents may be better at reporting overt distress associated with CI, and young people better at recognising covert cognition and emotions associated arising from CI. Integrating multiple informant measures is crucial for clinicians to better understand the impact of CI on depression to inform formulation and treatment plan.

418.400  (Poster) Verbal Engagement and Behavioral Synchrony in Face-to-Face Versus Video-Based Social Interactions of Adolescents with and without ASD with a Neurotypical Stranger
E. Zadok1, I. Gordon1, R. Navon1, S. J. Rabin1 and O. Golan1, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Gonda Brain Research Center, Bar-Ilan University, Ramat Gan, Israel, (3)Department of Psychology, Bar-Ilan University, Ramat-Gan, ISRAEL, (4)Association for Children at Risk, Givat-Shmuel, Israel

Background: Evidence suggests that using computerized platforms challenges social communication, by hindering mutual understanding and feelings of connectedness. These important factors of social interaction are linked to behavioral synchrony, the spontaneous coordination of behaviors between interacting partners in both form and timing. How interaction is affected by computerized platforms
seems to be of great relevance nowadays, particularly for adolescents who increasingly use video chats for socializing purposes. Yet, this was not examined among autistic adolescents, who often report alterations and difficulties in social interaction.

Objectives: To examine verbal engagement and behavioral synchrony of autistic and neurotypical (NT) adolescents in two settings: face-to-face and video-based social interactions.

Methods: 44 male adolescents (22 with a formal diagnosis of ASD given by a clinical psychologist/psychiatric) participated in face-to-face social interactions, and 49 male adolescents (23 with ASD), participated in Zoom video-based interactions. Groups were comparable on age and verbal abilities (Table 1). The interactions included a friendly conversation with an undergraduate female student, following an instruction to “get to know each other”. Using codes from the PEBA paradigm (Zadok et al., 2021), the third minute of the interaction was coded by trained naïve coders for participants’ commenting and asking questions and synchronization of facial expression, vocalization and affect.

Results: On average, autistic adolescents commented less and showed lower synchronization with the social partner, compared to NT adolescents. Several Group X setting interactions were found: Whereas in video conversations autistic adolescents were coded lower on comments and vocal synchrony compared to NT adolescents, in face-to-face interactions there were no such differences. Further, whereas autistic adolescents’ facial expression synchrony was coded higher in video conversations compared to face-to-face interactions, among NT adolescents there was no such difference (Figure 1).

Conclusions: Our findings suggest disparities between autistic and NT adolescents in their use of comments and in their vocal synchrony with a social partner, only in video conversations. It appears that when considering aspects of social behavior that highly rely on verbal expression, video conversations, but not face-to-face interactions, produce disparities between autistic and NT adolescents. Video conversations may have imposed a particular challenge upon autistic adolescents and burdened their efforts to converse with the social partner. Alternatively, NT adolescents may have felt more comfortable to engage in video conversation with a stranger, whereas face-to-face “get to know” conversations may have felt more awkward for them. Interestingly, different patterns were also observed for facial expression synchrony: autistic adolescents, but not NTs, were more synchronized with the social partner in video conversations compared to face-to-face conversations. Possibly, the restriction of the camera only to the partner’s head area facilitated a focus of attention on her face, and by that, promoted facial expression synchrony, whereas in real life interaction physical distance and the availability of multi-channel socio-emotional information makes facial expression synchrony more challenging for autistic adolescents. Further research into the characteristics of online interactions of autistic adolescents is needed.

**POSTER SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR**

**437 - Social Cognition and Social Behavior II**

**437.316 (Poster) Pupil Contagion in Williams Syndrome: No Transfer of Arousal from Other’s Eyes**

A. Hallman, M. Galazka, C. Fawcett, A. Nordgren, D. M. Riby, J. L. Kleberg, and C. Willfors. (1) Department of Psychology, Stockholm University, Stockholm, Sweden, (2) Gillberg Neuropsychiatrics Centre, Department of Neuroscience and Physiology, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (3) Department of Psychology, Uppsala University, Uppsala, Sweden, (4) Department of Molecular Medicine and Surgery, Karolinska institutet, Stockholm, Sweden, (5) Department of Clinical Genetics and Genomics, Sahlgrenska University Hospital, Gothenburg, Sweden, (6) Department of Laboratory Medicine, Institute of Biomedicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (7) Karolinska University Hospital, Solna, Sweden, (8) Department of Psychology, Durham University, Durham, United Kingdom, (9) Department of Clinical Neuroscience, Stockholm University, Stockholm, Sweden, (10) Department of Molecular Medicine and Surgery, Karolinska institutet, Stockholm, SWEDEN

**Background:** Williams syndrome (WS, prevalence 1:7500) is characterized by markedly increased social drive and interest in other’s faces and eyes. Since the genetic cause is known, studies of WS contribute to our understanding of the biology of human sociability. The processes underlying social challenges and strengths in Williams syndrome remains unclear. Despite their high social drive, it is typically challenging for individuals with WS to establish social reciprocity and interpret other’s facial expressions, and elevated autistic symptoms are common. These social challenges cannot be solely explained by an intellectual disability.

Typically developing humans automatically adapt their pupil size to that of others. This phenomenon, termed *pupil contagion*, reflects spontaneous synchronization of arousal and is believed to facilitate social interaction.

**Objectives:** N/A

**Methods:** We examined pupil contagion effects in two independent samples with WS (total n = 48) and comparison groups of typically developing adults (study 1, n = 50) and infants aged 4-6 months, the earliest age when pupil contagion has been reported (study 2, n = 48).
Data were analyzed using Bayesian statistics. Using this method, it is possible to differentiate between three possible outcomes: that the hypothesis is best supported, that the null hypothesis is best supported, and that the data is inconclusive.

Results: In both studies, data supported the null hypothesis that pupil contagion does not exist in Williams syndrome (Bayes factors supporting the null hypothesis > 12). In contrast, evidence for a pupil contagion effect was found in typically developing adults and infants (Bayes factor supporting the hypothesis > 7).

Conclusions: The results suggest that individuals with WS do not spontaneously mimic other’s pupil size. As pupil contagion was seen in four months old infants, this represents a deviation from the typical developmental trajectory at a very early stage. Diminished synchronization of arousal may explain social interaction challenges in WS. We also conclude that pupil contagion is not a necessary consequence of high social drive.

437.317 (Poster) Pupillary Response in Social Emotion Tasks in Autism
Y. L. Chien and J. P. Lee, (1)National Taiwan University Hospital, Taipai, Taiwan, (2)National Taiwan University, Taipei, Taiwan

Background: Individuals with autism spectrum disorder (ASD) have a poorer performance in emotional expression recognition in the Reading the Mind in the Eyes Task, as well as a distinct emotional response while viewing social touch scenes. Eye Avoidance Hypothesis, Theory of Mind deficits and sensory sensitivity had been proposed to understand the emotional and physiological response to socio-affective images in autism. It is still unclear how pupillary response in ASD towards socio-affective tasks.

Objectives: This study investigated pupillary response in adults with ASD when viewing emotional faces and interpersonal touch scenes.

Methods: We recruited 59 individuals with ASD (aged 29.7±5.9 years) and 36 typically developing controls (TDC, aged 23.3±2.1 years). All participants completed the Autism-Spectrum Quotient (AQ), Empathy Quotient (EQ), and pupil size estimation by the Tobii X2-30 Eye Tracker when performing the Reading the Mind in the Eyes Test and the Socio-Affective Touch Expression Database (SATED) dataset

Results: ASD adults exhibited a smaller minimal pupil size, a larger maximal pupil size and standard deviation (SD) of pupil size compared to TDCs in both tasks, especially in the Face Task. Sensory sensitivity positively correlated to mean pupil size in ASD. The AQ scores were correlated with maximal pupil size and SD of pupil size, while the EQ scores were negatively correlated with those pupil parameters in ASD.

Conclusions: Adults with ASD may have different pupillary response during socio-affective tasks than TDCs. Whether this is due to abnormal regulation on pupillary response or higher anxiety during socio-affective tasks awaits further investigation. The relationship between pupil response and sensory sensitivity or autistic traits in ASD is worth clinical and research attention.

437.318 (Poster) Relation between Social Orientation and Joint Attention in Idiopathic Autism and Phelan-Mcdermid Syndrome Using Eye Tracking Technology
H. A. Silver, J. Trayvick, B. Lerman, A. W. Peters, S. Barkley, L. Massa, K. Friedman, S. B. Guilloy, T. Levy, J. D. Busbaum, P. M. Siper, A. Kolevzon and J. H. Foss-Feig, (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Seaver Autism Center at the Icahn School of Medicine at Mount Sinai, New York, NY, (3)Stony, New York, NY, (4)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (5)Seaver Autism Center at Mount Sinai, New York, NY, (6)Mount Sinai School of Medicine, New York, NY

Background: There is extensive research showing that individuals with autism spectrum disorder (ASD) have difficulty with joint attention tasks, attention, and scanning of social scenes. However, little is known about how these skills relate to each other and whether more basic social attention relates to the ability to perform more complex social behavior, such as joint attention. In this study, we assessed the relationship between attention, exploration of social stimuli, and joint attention in two groups: idiopathic autism (iASD) and Phelan-McDermid syndrome (PMS), a genetic disorder with a high prevalence of ASD. Previous comparisons of iASD and PMS revealed that individuals with PMS show less impairment in social engagement but more attention difficulties (Richards et al., 2017).

Objectives: This study examined whether children with ASD with and without PMS had similar patterns of relationships between social dwelling and joint attention success.

Methods: Eleven participants with ASD (6 with PMS) between the ages of 4 and 12 years (iASD: M = 9; PMS+ASD: M = 7), participated in two eye-tracking tasks: Visual Paired Comparison (VPC) and Joint Attention (JA). Task 1, VPC, presented two images of the same face (familiarization), afterwards, one of the images was replaced with a novel face. Dwell time and rate of looking between interest areas, including the face, eye, and mouth regions, of both familiarization and novel images were computed. Task 2, JA, presented two objects and a central actor. The actor looks toward one of the objects (target) and not the other (distractor). The proportion of trials where subjects looked to the target object first and the proportion of time spent looking at the target vs. distractor were computed.
Results: Overall, the iASD and PMS groups did not differ in how they completed either task (Table 1), with the exception of mouth dwelling during social exploration, where children with iASD spent longer looking at the mouth as compared to the face than children with PMS+ASD ($r=0.30$). Across groups, average time dwelling on eye regions during social exploration on Task 1 was positively correlated with successful looks to the target ($r=0.655; p=0.029$) and time looking at the target ($r=0.638; p=0.035$) on Task 2. These relationships also held when indexing social exploration patterns after the novel stimulus presentation on Task 1 (Looks to target: $r=0.724; p=0.012$; Time looking at target: $r=0.605; p=0.049$).

Conclusions: These results suggest that for children with ASD, regardless of the genetic diagnosis of PMS, the more the child explores eye regions in social stimuli, the better they are at joint attention, which requires following of gaze cues. This suggests that in ASD and in PMS specifically, interventions that encourage eye-contact may be effective in supporting their ability to follow joint attention, thereby increasing opportunity for shared social experiences. Future research should be completed in order to validate these conclusions with larger sample sizes.

437.319 (Poster) Relationship between Sleep Quality and Anxiety in Individuals with and without ASD

R. Gadagkar, M. Santhosh, K. Pelphrey and S. J. Webb, (1)Seattle Children’s, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children’s Research Institute, Seattle, WA, (3)Autism and Neurodevelopment Disorders Institute, University of Virginia School of Medicine, Washington, DC, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

Background: Sleep dysfunction is extremely common for individuals with ASD, with between 50-80% of youth with ASD experiencing sleep dysfunction and difficulty (Mazzone, 2018). Autistic individuals may also have difficulties with emotional regulation, including anxiety, depression, and general mood disturbance. A longitudinal study within ASD youth and a comparison group of youth with typical development found that parasomnias, sleep duration, and night awakening were significantly associated with internalizing behavioral problems within the autistic group (Williamson, etc., 2020). Anxiety is one of the most common internalizing behavioral issues and is also a prevalent comorbidity among those with ASD (Vasa, 2015).

Objectives: Due to the high rates of co-occurring anxiety in youth with ASD, this project aims (1) to replicate previous findings of a relationship between sleep quality and internalizing symptoms in autistic youth and a comparison group of typically developing youth, (2) investigate the specific relationship between anxiety and sleep quality, and (3) identify if the relationship between anxiety and sleep dysfunction differs for autistic males vs autistic females.

Methods:

Data was included from a NIH funded study on sex and gender differences in ASD. The sample included 107 participants (ASD=55), ages 12-26 years. ASD diagnosis was confirmed via the ADOS-2. Participants completed the Pittsburgh Sleep Quality Index (PSQI) and Munich Chronotype Questionnaire (MCTQ) self-report questionnaires, measuring sleep quality. We utilized the Child Behavior Checklist youth self report and Adult Self Report internalizing behavior subscale and the Screen for Child/Adult Anxiety Related Disorders generalized anxiety disorder and global score as a measure of anxiety.

Results:

Groups were split into youth (12-17 years) and adults (18-26). Preliminary results from autistic adults indicate a significant positive correlation between PSQI global and ASR internalizing behavior ($r=0.62$, $p<0.01$), (Figure 1) indicating poor sleep quality corresponds to higher internalizing scores for autistic adults. Similarly, a significant positive correlation was present between PSQI total score and SCAARED for both the ASD ($r=0.66$, $p<0.01$) and TD groups ($r=0.31$, $p<0.05$); and for PSQI total score and the generalized anxiety disorder subscale of the SCAARED (ASD $r=0.72$, $p<0.01$; TD $r=0.33$, $p<0.05$).

Conclusions:

The initial findings of this research are consistent with prior research studies that have found a significance relationship between increasing sleep dysfunction and increased internalizing issues. Correlations were significant for the relationships between overall sleep quality and broad internalizing behaviors, as well as specific anxiety symptoms. Follow-up analysis will examine sex differences within this relationship, along with using the MCTQ sleep measure for more quantitative sleep data.

437.320 (Poster) Role of Attention and Sensory Distraction in Social Processing for Youth with and without Autism: A fMRI Study

V. A. Burgess*, S. S. Glynn**, M. Dapretto and S. A. Green*, (1)UCLA CART (Center for Autism Research and Treatment), Los Angeles, CA, (2)Department of Psychology, University of California, Los Angeles, Los Angeles, CA, (3)Dept of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA

Results: Overall, the iASD and PMS groups did not differ in how they completed either task (Table 1), with the exception of mouth dwelling during social exploration, where children with iASD spent longer looking at the mouth as compared to the face than children with PMS+ASD ($r=0.30$). Across groups, average time dwelling on eye regions during social exploration on Task 1 was positively correlated with successful looks to the target ($r=0.655; p=0.029$) and time looking at the target ($r=0.638; p=0.035$) on Task 2. These relationships also held when indexing social exploration patterns after the novel stimulus presentation on Task 1 (Looks to target: $r=0.724; p=0.012$; Time looking at target: $r=0.605; p=0.049$).

Conclusions:

The initial findings of this research are consistent with prior research studies that have found a significance relationship between increasing sleep dysfunction and increased internalizing issues. Correlations were significant for the relationships between overall sleep quality and broad internalizing behaviors, as well as specific anxiety symptoms. Follow-up analysis will examine sex differences within this relationship, along with using the MCTQ sleep measure for more quantitative sleep data.
Background:

Sensory over-responsivity (SOR), an extreme negative response to aversive sensory stimuli, impacts approximately 56-70% of individuals with autism spectrum disorder (ASD; Ben-Sasson et al., 2008). SOR often co-occurs with other psychiatric conditions (e.g., anxiety) and is associated with difficulties in social and adaptive functioning (Glod et al., 2015). Furthermore, autistic individuals with SOR may attribute greater attention to extraneous sensory information over social information (Green et al., 2018). A preliminary study that tested the effect of sensory distraction on social information processing found that tactile distractors increased activation in auditory language areas for TD youth whereas it decreased activation in these regions for ASD children (Green et al., 2018). Here, we sought to replicate these findings with more rigorous statistical thresholds, as well as explore these effects in later development (late childhood/early adolescence vs. late adolescence/young adulthood).

Objectives:

To investigate how tactile sensory distraction affects social information processing in ASD compared to TD youth, and how this relates to age.

Methods:

We used functional magnetic resonance imaging (fMRI) to examine brain responses in 20 ASD youth and 18 age- and IQ-matched TD participants, ages 8 to 15 years. Participants listened to 16 different social scenarios ending with either a sincere or sarcastic response and indicated if the person meant what he/she said. During half of the blocks, participants had their forearm rubbed with a mildly aversive fabric as a sensory distractor. Within- and between-group analyses were thresholded at $Z > 2.3$, $p > 0.05$.

Results:

During the social cognition task without tactile stimulation, we found that both groups exhibited activation in auditory regions, frontal areas associated with decision making, and regions associated with social attention and emotional regulation (e.g., the amygdala, and paracingulate gyrus). TD youth additionally exhibited activation in the fusiform gyrus (region involved in face and object recognition), but no significant between-group differences were found. As expected, with the addition of a tactile sensory distractor, both groups showed significantly increased activation in sensory cortical regions. The TD group, but not the ASD group, also showed increased activation in the auditory cortex, basal ganglia, and posterior cingulate gyrus (associated with attention allocation). These results are consistent with prior findings, and suggest that the TD group is recruiting more attention to social information to continue to process the social information despite the presence of a sensory distraction.

Additional analyses will incorporate an older cohort of adolescents and young adults to investigate whether attention to social information is managed differently across different groups.

Conclusions:

Our findings corroborated previous work (Green et al., 2018) at a more stringent statistical threshold. We found that during sensory distraction, TD youth increased effortful processing in language and attention brain areas, whereas the ASD group did not. For the ASD group, difficulties increasing attention and language-processing regions during sensory distraction could contribute to ASD-related social difficulties in real-world settings in which there are many competing stimuli. Additional analyses will test a wider age range to understand generalizability of this result to older adolescents and young adults.

437.321 (Poster) Self-Reported Eye Contact Sensitivity and Face Processing in 22q11.2 Deletion Syndrome

M. Galazka, C. Gillberg, N. Hadjikhani, E. Billstedt, J. Åsberg Johnels, and L. Wallin, (1)Gillberg Neuropsychiatry Centre, Department of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (2)Gillberg Neuropsychiatry Centre, Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (3)MGH, Martinos Center for Biomedical Imaging, Harvard Medical School, Charlestown, MA, Sweden, (4)Gillberg Neuropsychiatry Centre, Gothenburg, Sweden, (5)Department of Physiology and Neuroscience, Gillbergcentrum/ Göteborgs Universitet, Göteborg, Sweden

Background: Chromosome 22q11.2 deletion syndrome (22qDS; prevalence 1:4000) is caused by a deletion on the long arm of chromosome 22. Phenotypically, individuals with 22qDS show a wide range of symptoms with an increased prevalence of autism and psychotic disorders. Individuals with 22qDS present impairments in social skills and atypical scanning patterns of other people’s faces, marked – at a group level – by reduced visual exploration of the eye region, potentially resulting in negative effects on social functioning and emotional processing. The genetic uniformity, along with diverse phenotypes of 22qDS, represent a unique model for identifying potential behavioural biomarkers.
Objectives:

The aim of the present study was

(1) to characterize individual differences in self-reported eye contact sensitivity and to explore qualitative features of this discomfort;

(2) examine how these data relate to objective measures of gaze patterns during the presentation of images of faces;

(3) how reported eye contact sensitivity related to neurodevelopmental/psychiatric outcomes (specifically, frequency of ASD and psychosis), everyday global functioning (with the Global Assessment of Functioning [GAF]) and IQ.

Methods: The participant sample consisted of 27 individuals (15 females) between the ages of 18 and 50, (M = 28.43, SD = 7.23) with genetically confirmed 22qDS. First, a short clinical interview was conducted assessing whether they experience discomfort during eye contact, the extent of it, and use of any coping mechanisms in dealing with it. Then, participants were presented with 24 6-sec photographs of angry, happy and neutral faces. Finally, as part of a larger study on this population, information on the presence of autism, psychosis, level of IQ and global assessment of functioning was conducted.

Results:

(1) Of the 27 participants, 12 reported discomfort with eye contact and most employ some type of strategy in dealing with it.

(2) Eye tracking findings show difference in the amount of looking in the eye region but only for neutral expression. Significant group differences were found laterization (Figure 2).

(3) Groups also did not differ on IQ, with both subgroups scoring characteristically low ([Ms = 73], Mann- Whitney U = 97.5, p = 0.719). Significant group differences, however, were evident in the level of everyday functioning on the GAF (p = 0.03), with those reporting difficulties with eye contact scoring lower in this regard.

Conclusions: Our results show that by simply asking individuals about eye gaze discomfort, we can not only gain insight into the nature and coping strategies of the individual, but that such information can also help us identify a subgroup of people with 22qDS who show distinct alterations in face processing lateralization, and who present more difficulties in everyday life.

Figure 2. The percentage of gaze within the left- and the right- half of the face (from the observer’s perspective) in the group of individuals with 22q11.2 deletion based on self-reported discomfort with eye contact.

437.322 (Poster) Sensitivity to Observing Social Exclusion in Individuals with Low and High Levels of Autistic Traits

A. Di Francesco, M. T. Maybery and A. Fox; (1)The School of Psychological Science, The University of Western Australia, Perth, Western Australia, Australia, (2)School of Psychological Science, The University of Western Australia, Perth, Western Australia, Australia

Background:

Observing someone being excluded elicits an experience of ‘vicarious ostracism’, sensitivity to the emotional distress of the victim, and prosocial behaviour. The intensity of these responses has been found to heighten with increased perspective taking ability and empathy. The empathy imbalance hypothesis proposes autism is associated with heightened sensitivity for emotional empathy but a lower capacity for cognitive empathy, which is related to perspective taking.

Objectives:

We examined the responses of participants with low and high levels of autistic traits (AT) to observing someone being excluded. The groups were compared on their empathic concern towards, and the perceived mood of the excluded player, and whether the mood and need satisfaction of the participants themselves was affected by observing the exclusion. We hypothesised that any differences in response to the excluded player between individuals with high and low levels of AT could be attributed to differences in trait empathy.

Methods:
Participants with high ($N=44$) and low ($N=38$) levels of AT were recruited through Prolific Academic. Autistic traits were assessed using the Autism Quotient (Cohen’s $d=5.26$ for group difference in AT scores). Participants observed Cyberball, an experimental paradigm widely used for eliciting responses to social exclusion. Pre-programmed “players” threw a ball between themselves, with the target player having a lower chance of being thrown to (5%) compared to the other players (45%). Participants observed the game while ‘taking on’ the perspective of the target player. They rated their own trait empathy, and mood before and after Cyberball. Following Cyberball, participants also rated their empathic concern for each player and also completed a need satisfaction questionnaire (addressing needs affected by social exclusion) from the perspective of each player, and mood questionnaire from the perspective of the target player.

**Results:**

Both AT groups reported greater empathic concern for the target player than for the non-target players, but this difference was more pronounced for the low AT group, ($p=.01$, $\eta^2=.07$; Figure 1). Multiple regression analysis showed that the effects of AT group on empathic concern for the target player were partly explained by trait empathy ($p=.01$). Both AT groups reported a decrease in mood post-Cyberball ($p<.001$, $\eta^2=.26$). Need satisfaction was rated lower for the target player compared to the non-target players ($p<.001$, $\eta^2=.85$), with this difference comparable for high and low AT groups. High and low AT groups rated mood of the target player comparably.

**Conclusions:**

This study showed that participants with low and high levels of AT identified to a similar extent the emotional distress of someone being excluded and the threat this posed to their social needs, and experienced comparable levels of vicarious ostracism (low mood). The results also showed that individuals with high levels of AT experienced sensitivity towards the excluded person (empathic concern), but not to the same extent as did individuals with low levels of AT. Differences in empathic concern between AT groups were partially explained by trait empathy.

**437.323 (Poster) Sex Differences in the Placenta and Autism**

A. Tsompanidis, L. Blanken, S. Baron-Cohen and H. Tiemeier, (1)Autism Research Centre, Department of Psychiatry, Autism Research Centre - University of Cambridge, Cambridge, United Kingdom, (2)Department of Psychiatry, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (4)Department of Social and Behavioural Sciences, T.H. Chan School of Public Health, Harvard University, Cambridge, MA

**Background:**

Autism is a neurodevelopmental condition with a large heritable component in liability (Gaugler et al., 2014). Males are more likely to be diagnosed, even after taking into account camouflaging, misdiagnosis, diagnostic overshadowing and under-diagnosis in females (Lai and Szatmari, 2020). Prenatal environmental factors, such as steroid hormones and placental complications have been consistently associated with increased autism likelihood in children (Baron-Cohen et al., 2019; Maher et al., 2020). Typical male placentas have different gene expression patterns, produce more sex steroid hormones and have greater risk for specific complications, compared to females (Verburg et al., 2016; Gong et al., 2018). It is currently unknown how sex differences in the placenta interact with other autism likelihood factors.

**Objectives:**

To investigate the relationship between:

1. sex differences in placental complications and autism or autistic traits
2. sex differences in placental gene expression and the genetic liability for autism

**Methods:**

For the first objective: pregnancy complications, birth weight and placental weight were retrospectively assessed in expectant women, who consented to take part in the longitudinal “Generation R” cohort, in Rotterdam, the Netherlands. The complications included pregnancy-induced hypertension (PIH), preeclampsia (PE), spontaneous preterm birth (SPB) and being born small for gestational age (SGA). Subsequent assessment of autistic traits in the children at age 6 was based on 18-item abridged version of the Social Responsiveness Scale (SRS) (n=4,529). Diagnosis of autism was based on specialist medical records (n=75 males, n=12 females). Linear Regression models for autistic traits, and case-control group comparisons via Mann-Whitney U-tests for an autism diagnosis, were conducted and compared in terms of sex and the presence of pregnancy complications.

For the second objective: an enrichment analysis was conducted, based on a list of genes that corresponded to differentially expressed transcripts (FDR<0.1) between male and female placentas, in 1st trimester chorionic villi samples of viable pregnancies (Gonzalez et al.,...
2018). These were compared to a list of high-confidence autism genes, based on syndromic forms of the condition or an overabundance of rare variants in sequencing studies (SFARI database). The analysis was conducted separately for X-linked and autosomal genes and was controlled for gene length.

Results:

Children of pregnancies with complications had significantly higher autistic traits (Cohen’s D=0.14, p=0.0001). Males and females showed different patterns (Figure 1), with preeclampsia being associated with higher autistic traits only in males (n=86, Cohen’s D=0.21, p=0.022), and being born SGA only in females (n=269, Cohen’s D=0.29, p=0.0001). Autistic females were more likely to have had placental complications than autistic males and the undiagnosed population (χ²= 11.5, p=0.0007).

In addition, there was a significant enrichment for differentially downregulated genes in typical male placentas among autism genes that are found on the X-chromosome (p<0.001).

Conclusions:

The placenta may be a point of convergence, where genetic and environmental factors interact with sex, in order to increase autism liability differently in males and females.

437.324 (Poster) Smiling Synchrony Differences in Peer Dyads of Autistic and Neurotypical Youth
K. A. McNaughton1,2, A. Moss1, H. A. Yarger2, V. Alleluia Shenge1 and E. Redcay1, (1)Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD, (2)Department of Psychology, University of Maryland, College Park, MD

Background: Autistic youth often experience challenges in interactions with peers, which has a negative impact on their mental health. One factor that may influence successful interactions with peers is synchrony, the degree to which interacting individuals align their behaviors (e.g. facial expressions) over time, which predicts positive interaction outcomes in neurotypical individuals. While some studies have demonstrated reductions in synchrony in dyads involving autistic individuals, no study has directly investigated synchrony in peer interactions or in autistic youth interacting with other autistic youth, a crucial link in determining if synchrony may be a mechanism in successful peer interactions.

Objectives: To evaluate differences in facial expression synchrony between peer dyads of autistic and neurotypical youth.

Methods: 136 youth (ages 8-16, 33 autistic, 103 neurotypical, 78 male, 58 female) were paired into same-gender dyads within a year of chronological age. Three dyad types were formed: autistic participants paired with autistic participants (AUT-AUT, n=7 dyads), autistic participants paired with neurotypical participants (AUT-NT, n=19 dyads), and neurotypical participants paired with neurotypical participants (NT-NT, n=42 dyads). In a video-recorded interaction in the lab, dyads completed a series of short activities together. These activities included a video-watching task in which dyads watched four short video clips designed to elicit positive (baby pig, toddler playing soccer) or neutral (tortoise, city street) emotions, and had the opportunity to discuss the clips with each other. A research assistant unaware of participant neurotype coded video recordings for smiling using the Facial Action Coding System; action units 6 and 12 represented smiling. Frame-by-frame smiling time series data for each participant was cross-correlated with the dyad partner’s time series with a lag of +/- 2 seconds. Correlation values were averaged across the lags to obtain a single value representing smiling synchronization. Dyads were excluded for not smiling during the interaction (n=8), being out of view of the recording (n=1), or previously knowing each other (n=1), for a final sample of 4 AUT-AUT dyads, 18 NT-AUT dyads, and 36 NT-NT dyads.

Results: A one-way ANOVA revealed significantly different smiling synchronization across the three dyad types (F(2,55)=4.60, p=0.01). Follow-up independent samples t-tests revealed that NT-NT dyads synchronized significantly more than AUT-NT dyads (t(52)=2.97, p<0.01). AUT-AUT dyads synchronized marginally more than AUT-NT dyads (t(20)=1.85, p=0.08) and did not differ in synchronization from NT-NT dyads (t(38)=0.04, p=0.97). Overall amount of smiling did not differ across the dyad types (F(2,55)=0.85, p=0.43).

Conclusions: These findings demonstrate that peer dyads with matching neurotypes synchronize their smiling more than peer dyads with mismatched neurotypes, and these results were not just a consequence of differences in overall amount of smiling. This is in line with a growing body of work demonstrating that social interaction outcomes differ for autistic individuals depending on whether they are paired with autistic or neurotypical individuals. Therefore, we highlight the importance of considering the role of the interaction partner and their neurotype when investigating social interaction behaviors in autism. Future research will directly investigate relations between synchronization and participants’ reported enjoyment of the peer interaction.

437.325 (Poster) Social Attention in Minimally Verbal Toddlers on the Autism Spectrum: An Eye-Tracking Study

Background: Minimally verbal autistic children comprise an estimated 30% of the spectrum, but remain an understudied and high-need group in the field (Anderson et al., 2007; Tager-Flusberg & Kasari, 2013). Assessing strengths and needs of minimally verbal children is challenging, as standardized assessments often involve verbal instructions which results in chronic floor performance in this group. Therefore, there is limited knowledge on key areas of functioning in this group, including the social and attention abilities that are foundational to verbal communication (Kasari et al., 2013). This study aimed to address this gap by using a passive view eye-tracking paradigm without verbal instructions to examine preferential orientation to social versus non-social stimuli, which has previously been linked to verbal development in young children (Puce & Bertenthal, 2015).

Objectives: We examined whether preferential attention to social versus non-social stimuli differed for minimally verbal autistic preschoolers (MV-ASD) compared to age-matched typically developing preschoolers (TD), and verbal autistic preschoolers (V-ASD).

Minimally verbal status was operationalized as an age equivalent below 18 months in the Expressive Language subdomains of the Vineland Adaptive Behavior Scales-3 or Mullen Scale of Early Learning (Bas et al., 2016). Our hypothesis was that only MV-ASD children would not show preferential attention to social versus non-social stimuli.

Methods: Following a previously validated eye-tracking paradigm (Vivanti et al., 2017), participants (N = 71; n_TD = 21, n_MV-ASD = 23, n_V-ASD = 27) aged 24.00 to 66.00 months (M = 34.00 months) were shown five digitalized images depicting naturalistic scenes that included people and objects similar in size and color contrast. Stimuli were shown for five seconds each on a computer monitor, and participants’ attentional response to the stimuli was recorded through a Tobii pro eye-tracking binocular system. Participants’ total duration of eye-gaze towards the social and non-social content of each image was averaged for social attention and non-social attention composite variables. Participants’ attention to social and non-social content across stimuli was analyzed using a repeated-measures 3 (Group: TD, MV-ASD, V-ASD) by 2 (Condition: social versus nonsocial attention) ANOVA.

Results: There was no significant Group x Condition interaction [F(2, 68) = .64, p = .52, η^2p = .01], but there were significant main effects of Condition [F(2, 68) = 31.68, p<.001, η^2p = .31] and Group [F(2, 68) = 7.74, p<.001, η^2p = .18]. While children in the MV-ASD group looked less at the stimuli overall, participants across groups showed preferential attention to social versus non-social content (see Fig. 1).

Conclusions: Although preferential attention to social versus non-social stimuli has been linked to the development of verbal language, we found that minimally verbal autistic children show similar patterns of attention to social and non-social stimuli compared to verbal autistic and typically developing toddlers. Our study highlights the value of socially-oriented teaching tools in intervention across the verbal and diagnostic spectrum. Passive viewing eye-tracking paradigms appear to be useful for measuring strengths and challenges in the social attentional domain for young autistic children and show particular promise for often overlooked minimally verbal children in future research.

437.326 (Poster) Social Disability and Loneliness at School in Early School-Aged Children with and without Autism Spectrum Disorder
H. Murthy, E. Chatson and L. A. Edwards, (1)Emory University, Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA

Background: Social inclusion is positively associated with more positive social interactions and academic achievement in school (Wentzel et al., 1995; Frederickson et al., 2002; Siperstein & Parker, 2008). Children with autism spectrum disorder (ASD) may be at increased risk for social isolation, compared to their typically developing (TD) peers, due to difficulties with social communication (Howlin et al. 2004; Mazurek and Kanne 2010; Rotheram-Fuller et al. 2010). Within children with ASD, those who are more socially competent are more likely to be placed in inclusion classrooms, and have been found to experience higher friendship quality (Lyons et al, 2011). Classroom contextual factors (such as inclusion model and student:teacher ratio), in turn affect the academic outcomes of children with ASD (Sutherland et al., 2008), and likely also influence social inclusion or isolation (and accompanying feelings of loneliness).

Objectives: (1) To investigate the relationship between social disability and loneliness in an early school-aged sample of children with ASD and their TD peers; (2) To explore the effects of classroom contexts (such as inclusion model) on this relationship.

Methods: This study includes children and caregivers—who previously participated in baby sibling research involving developmental assessments and eye tracking, to study infant development—once these children have entered kindergarten (~5 years old). Data collection is ongoing, with an anticipated sample of at least 40 (20 ASD) participant families by May 2023. Caregivers complete the Social Responsiveness Scale (SRS-2) as a measure of child social disability; children complete the Loneliness and Social Dissatisfaction Questionnaire (LDQ) in either questionnaire or interview format (depending on reading level); additionally, parents and current teachers provide information about the child’s school and classroom environments. Multiple regression will be used to determine the effect of child
social disability on school loneliness, and to investigate any moderating effects of classroom characteristics (such inclusion model) on this relationship.

Results: In a previously collected preliminary sample of TD (n=49, M_{age}(SD)=5.29(0.50) years), ASD (n=9, M_{age}(SD)=5.56(0.53) years), and children with other communication disorders (CD) (n=8, M_{age}(SD)=5.75(0.89) years), 56% of ASD, 33% of CD and 12% of TD children were enrolled in inclusive classrooms. Analysis of parent-reported child loneliness and social disability in this sample suggests a positive relationship between social disability and loneliness in school, which is significant across all diagnostic groups (r(63)=.77, p<.001), and within the ASD sample (r(9)=.75, p=.020).

Conclusions: Preliminary analyses suggest that caregivers of children with higher degrees of social disability perceive that their children experience greater loneliness in school. Though data collection is ongoing, children’s own reports of school loneliness and teacher reports of classroom contexts will allow for further investigation of this relationship, as well as potential moderating effects of classroom contexts. These findings will inform the design of classroom environments that minimize loneliness and/or maximize peer acceptance for children with ASD/social vulnerabilities.

437.327 (Poster) Social Interaction Development of Autistic Individuals and Siblings: A Systematic Review
Q. Pan, M. Y. S. Bak, L. D. Johnson and L. Bell, (1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)Educational Psychology, University of Minnesota - Twin Cities, Minneapolis, MN

Background: Sibling relationships may play a unique role in developmental outcomes. For autistic individuals, high quantity and quality of intimate sibling social interactions can contribute to language and social development. Although some researchers investigate the involvement of siblings within focused intervention contexts, from a holistic view of family systems, there is much to be learned about the role non-autistic siblings may play in increasing exposure to language and social learning opportunities through, for example, modeling naturalistic language use and engaging in reciprocal interactions within daily routines. Therefore, a systematic review of existing literature that summarizes investigations of siblings relative to the development of social interactions by their autistic siblings is an important exploratory next step.

Objectives:
We explored the following research questions as part of this systematic review: 1) In what ways were siblings of autistic individuals involved in previous investigations of social interaction development? 2) What are the implications of involving siblings in social interaction intervention for autistic individuals?

Methods:
A keyword search in databases was conducted first to identify relevant studies following the PRISMA model for systematic reviews. Full-text screening was conducted based on the inclusion criteria: empirical studies involving participants who are autistic OR their non-autistic siblings addressing social interaction outcomes. The included articles were coded based on the following variables of interest: (a) research design, (b) research purpose, (c)independent variable, (d) dependent variable, (e) research settings, and (f) participant characteristics.

Results:

Research Question 1

A total of 105 studies were included in this review given the investigation of siblings and the social interaction of autistic individuals. Most of the included studies (78.10%) focused on the social interaction outcomes of the siblings of autistic individuals. Of those social interaction outcomes, more than half (55.24%) targeted comprehensive social interaction skills. Specific social interaction behaviors were investigated in 25.71% of studies. Almost all studies (97.14%) specified children as the participants. Reporting of other targeted variables in included studies was inconsistent (e.g., birth order = 54.29%, siblings’ gender/sex = 17.14%).

Research Question 2

Of the studies included in this review, a subset of 23 studies (21.90%) that focused on autistic participant outcomes were selected and analyzed for implications of involving siblings in social interaction interventions. The participants’ characteristics for each study can be found in Table 1. Table 2 presents a summary of the studies’ variables of interest. Overall, all 23 studies showed that non-autistic siblings could potentially improve social interaction skill acquisition and development of autistic individuals in natural contexts. Possible implications from this review include (1) identifying appropriate social interaction outcomes for autistic individuals, (2) exploring diverse roles and enhancing engagement of siblings, and (3) developing naturalistic sibling-mediated social interventions.
Conclusions:

Overall, the findings of this systematic literature review provide some evidence that social interaction outcomes of autistic individuals can be positively influenced by their siblings. More research is needed to have a greater understanding of how to better involve siblings in social interaction intervention for autistic individuals that consider the needs and wants of both parties.

437.328 (Poster) Social Motivation- a Double-Edged Sword for Autistic Children

S. Bothra; K. Keckemeti; M. E. Tudor; M. C. Hunsche; M. Solomon; B. Heath; C. W. Nordahl; D. G. Amaral; S. Park; B. Winder-Patel; E. S. Bickel; C. M. Kerns; J. J. Wood; I. Song; K. Wood and M. Pakyurek, (1)MIND Institute, UC Davis, Sacramento, CA, (2)M.I.N.D. Institute, UC Davis, Sacramento, CA, (3)UC David MIND Institute, Davis, CA, (4)University of British Columbia, Vancouver, BC, Canada, (5)Department of Psychiatry and Behavioral Sciences, University of California Davis, MIND Institute, Sacramento, CA, (6)Department of Psychiatry and Behavioral Sciences, UC Davis The M.I.N.D. Institute, Sacramento, CA, (7)UC Davis MIND, Sacramento, CA, (8)MIND Institute, MIND Institute, UC Davis Medical Center, Sacramento, CA, (9)UC Davis MIND Institute, Sacramento, CA, (10)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA, (11)UC Davis MIND Institute, Sacramento, CA, (12)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

Background:

It is well-known that autistic children experience more anxiety than peers, but little research has explored how anxiety is associated with social functioning. Existing literature has more generally examined friendships, social motivation, bullying, and anxiety in autism, but has not explored the specific relationships between these factors. Understanding these relationships may contribute to determining intervention targets for anxious autistic youth.

Objectives:

To determine if there are associations between social motivation, friendships, and social anxiety in autistic children.

Methods:

This study analyzes data collected from the Specifying and Treating Anxiety in Autism Research (STAAR) Study, a five-year clinical trial comparing pharmacological and psychosocial anxiety interventions for autistic children. This sample includes 63 autistic children, aged 8-14 years (M =10.13, SD = 1.56 years), who met criteria for at least one anxiety disorder as defined by the Anxiety Disorder Interview Schedule-Parent (ADIS-P), which uses caregiver reports to assess individual anxiety disorders using 9-point rating scales (0-8, where scores ≥4 indicate the presence of a disorder). This study referenced participants’ Generalized Anxiety Disorder (GAD) and Social Anxiety Disorder (SAD) scores. Caregivers completed the recently published Autism Spectrum Addendum (ASA), in which friendships, social motivation, and bullying were rated by clinicians on a 4-point scale (0-3, with higher scores indicating higher impairment). Caregivers also completed the Child Behavioral Checklist, where they reported their child’s number of close friends. Chi square and one-way ANOVA analyses were used to examine the associations between anxiety, friendships, social motivation, bullying, and number of friends.

Results:

Of total participants, 74.6% met criteria for GAD and 47.6% for SAD. There was a significant relationship between the number of friends children had and the quality of their friendships, with more friends relating to closer relationships, X² (9, N = 46) = 20.88, p = .013. Friendship quality and social motivation were significantly related; less socially motivated children were more likely to lack meaningful friendships, X² (6, N = 60) = 22.67, p < .001. Children with less social motivation had fewer friends, X² (6, N = 46) = 16.99, p = .009. More socially motivated participants experienced more severe social anxiety, F(2, 52) = [3.43], p = .04. Participants with no friends experienced less severe social anxiety than those with at least one close friend, F(3, 42) = [2.63], p = 0.063. Bullying and social anxiety were unrelated, F(3, 51) = [1.21], p = 0.31.

Conclusions:

These findings suggest that autistic children with low social motivation form fewer close friendships, yet children with higher social motivation are likely to have more severe social anxiety. Bullying was unrelated to social anxiety. These outcomes illustrate the complexity of social interactions in autistic children, as socially motivated children are more socially connected yet seem to worry more about other’s perceptions of them. This highlights the need to support children who are interested in relationships by reducing anxieties they have about social interactions. Future directions include looking at qualitative data to understand these children’s specific social fears and use this to guide intervention practices.

437.329 (Poster) Social Perception and Understanding of Different Neurodivergent Behaviors in Young Children
Background: Young children understand social norms as arbitrary rules that guide behaviours depicted by individuals or a group of individuals (Legros & Cislaghi, 2020). During development, children become sensitive to norms, which they infer from adults or repeated group behaviours, (Riggs, 2020; Roberts et al., 2017; Schmidt et al., 2016). Children react negatively to peers who present behaviours that differ from these social norms, and since neurodivergent children's behaviours deviate from the norm (Sasson et al., 2017), this can contribute to peer rejection. However, it is unknown whether children perceive specific neurodivergent behaviours to be more socially acceptable than others and if this impacts upon their willingness to be friends with neurodivergent children.

Objectives: To assess current understanding of different neurodivergent conditions in young children as well as their willingness to have friendships with neurodivergent children. To explore which specific neurodivergent behaviours children perceive to be socially acceptable/unacceptable in a classroom.

Methods: Forty neurotypical children (18 males, 22 females) from diverse cultural backgrounds between 4-14 years of age participated in the study. A mixed method approach was taken which included an initial interview to assess current understanding and views of neurodivergent conditions (i.e. Autism, Attention Deficit Hyperactivity Disorder, Dyslexia). Following this, each child was shown a series of different pictures, each depicting children behaving differently in a classroom setting in response to the teacher’s instruction. They were informed which child in each picture was either autistic/ADHD/or dyslexic. Each child was asked to indicate which behaviours they would consider acceptable or not acceptable in each context. They were also asked if they would like the child in the friendship group (asked for both neurotypical and neurodivergent target).

Results: Key findings from the interviews showed a significantly greater proportion of children reported they knew an autistic individual (50%) compared to knowing someone who was ADHD (28%) or dyslexic (25%) [X2 = 6.74, p < .05]. When asked what they knew about each condition 38% gave an accurate detail about autism, 23% for ADHD and 32% for dyslexia. Performance on the picture task showed overall children said the neurotypical behaviour was more acceptable than the neurodivergent behaviour, but this was only significant for the ADHD (Fishers, p<.01) and dyslexic behaviours (Fishers, p<.05). When asked about friendships, overall a greater percentage of children said they would be friends with the neurotypical child than the neurodivergent child, however this was only significant for the dyslexic behaviour (p<.05).

Conclusions: In comparison to other neurodivergent conditions, neurotypical children know more autistic individuals and have a better understanding of the condition than ADHD or Dyslexia. This greater familiarity may explain why they were more accepting of the neurodivergent behaviour illustrated by the autistic individual, but not the ADHD or Dyslexic individual. In general neurotypical children are more a bit more likely to accept other neurotypical children as friends, although this greater inclination was only significant for the dyslexic condition. Overall, these findings may be explained by the specific behaviour highlighted and the context in which it is expressed.

Objectives: To investigate the specificity of imitation differences for ASD by comparing imitation performances of children with ADHD, ASD and NT development.

Methods: Children (18 ADHD, 57 ASD (36 with comorbid ADHD), 59 NT) completed a 1-minute imitation task, in which they copied the dance-like movements of a video avatar. During this task, children’s movements were tracked using Kinect Xbox cameras. The tracked motion data were compared to avatar’s motion data using the CAMI algorithm, which returns a score ranging from 0 (no imitation) to 1
Results: Bonferroni-corrected tests revealed that children in the ASD group performed poorer imitation (lower CAMI scores) as compared to children in the ADHD (p=0.02) and NT group (p<0.0001), while ADHD and NT groups did not differ from each other (p=0.77; Fig-1A). Across the entire sample, poorer imitation performance was significantly associated with autism-associated social-communicative difficulties as measured by SRS-2 (r=-0.47, p<.0001). Within the ASD group, a multilinear model showed that only ADOS-2 (p=0.001) and Conners inattentiveness scores (p=0.01) significantly predicted lower CAMI scores, while SRS-2 and Conners hyperactivity/impulsivity score were insignificant (Fig-1B). Further, within the ASD group, imitation performance did not differ as a factor of whether the children also had an ADHD diagnosis (p=.77, Fig-1C).

Conclusions: Imitation performance as measured by CAMI reflects autism-specific traits that are not shared by children with ADHD. For ASD children, the severity of their autistic traits (as measured by ADOS-2) and ADHD inattentiveness traits, but not hyperactivity/impulsivity traits, contribute to poorer imitation. We discuss implications of these findings for establishing specificity of motor imitation difficulties in ASD.

Background:

Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD) are two often co-occurring neurodevelopmental conditions. Nevertheless, there is limited research about symptoms differences between ASD and ASD + ADHD groups. Children with ASD + ADHD are diagnosed later than those with only ASD. The lack of knowledge about symptom differences between ASD and ASD + ADHD may lead to incorrect or delayed diagnosis, which leads to delay of adequate interventions. Youth with ASD + ADHD may not get optimal interventions, such as psychoeducation adapted to their specific combination of issues. Increased awareness from clinicians, school personnel and parents of what may be signs of ASD + ADHD is required in order to detect these children earlier.

Objectives:

The objective of this study was to investigate whether there are symptom differences between children and adolescents with ASD and those with ASD + ADHD when using common clinical instruments for measuring ASD symptoms in a larger sample and in naturalistic clinical setting.

Methods:

In total of 112 participants were identified from two clinical trials of social skills intervention for children and adolescents with ASD and co-occurring conditions. Fifty-six children and adolescents with ASD aged 8-17 years were matched for age, gender and general intelligence quotient with fifty-six children and adolescents with ASD + ADHD. Group differences in scores on the Autism Diagnostic Observation Schedule were analyzed.

Results:

Our results showed that participants with ASD and with ASD + ADHD had similar profiles of social communication interaction challenges and restricted behavior. However, items assessing gestures: conventional, instrumental or informational gestures and empathic or emotional gestures showed significant differences between the groups suggesting that the ASD + ADHD group used gestures to communicate more adequately than the ASD group.

Conclusions:

We conclude that children and adolescents with ASD + ADHD have similar qualitative difficulties with social communication and restricted and repetitive behaviors as those with ASD. Our findings may indicate some differences between the groups in the use of
gestures in social situations. The ASD + ADHD group in our sample used gestures more adequately. This could possibly be connected to the lack of inhibitory control from ADHD and result in the impression of livelier body language that could camouflage the presence of ASD. More information on the ASD + ADHD behavioral phenotype may be important in the earlier detection of individuals with ASD + ADHD as well as offering better tailored psychoeducation for this group.

437.332 (Poster) Tactile Sensitivity and Theory of Mind Predict Empathy in Autistic Children  
T. Li and L. Yi, School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China

Background:
Empathy describes the ability to perceive and understand the feelings and emotional states of others (Decety, 2015). In neurotypical (NT) people, first-hand experience of tactile stimulation and the ability to understand others’ mental states (also known as theory of mind or ToM) both contribute to empathy (Decety, 2015; Decety & Michalska, 2020). Autistic children were described as showing reduced empathy for others’ pain or distress (e.g., Jones et al., 2010; McDonald & Messinger, 2012; Peterson, 2014). Their core autistic symptoms—the difficulties in social interactions, such as challenges in ToM, and atypical sensory profiles, such as hyper- or hypo-sensitivity to tactile and painful stimuli (American Psychiatric Association, 2013), may together weaken the building blocks of empathy during their childhood. However, this hypothesis has not been well examined.

Objectives:
The current study investigated the roles of sensitivity to touch and pain and ToM in predicting empathy in autistic children. We aimed to provide evidence for the potential physio-psychological mechanisms of altered empathy in autistic children.

Methods:
Sixty-six 5- to 7-year-old autistic children and 68 age- and IQ-matched NT children participated in our tests. Trait empathy was assessed using the Griffith Empathy Measure-Parent Ratings (GEM-PR) with affective and cognitive empathy subscales (Dadds et al., 2008; Xiao et al., 2016). The thresholds of touch and pain sensitivity were measured using the Touch Test™ Sensory Evaluators (20-piece kit, Catalog Number 58011; Stoelting Co.). Children’s ToM abilities were measured using the Scaling of Theory-of-Mind (Wellman & Liu, 2004) and the Sally-Ann Task, which was designed to assess the accumulating ToM understandings beyond false belief. Subscores of ToM tasks, including Basic ToM, False Beliefs, and Hidden Emotion, were calculated (Ma et al., 2019; Wellman & Liu, 2004; see Table 1 for details).

Children’s sensitivity to touch and pain stimulation, subscores of the Scaling of Theory-of-Mind, and GEM-PR were compared across the groups using independent sample t- or chi-square tests. Multiple linear regression analyses were performed to examine how the sensitivity to touch and pain and ToM would modulate the affective and cognitive empathy in autistic and NT children.

Results:
We found that (a) compared with NT children, autistic children displayed hypo-sensitivity to tactile stimuli, and got lower scores on subscales of ToM and affective and cognitive subscales of GEM-PR (see Table 1); b) False Beliefs and atypical sensitivity to touch and pain could predict children’s empathy. To be specific, better performance on False Beliefs predicted higher level of affective empathy (see Figure 1a), while hyper- or hypo-sensitivity to touch and pain predicted lower level of cognitive empathy (see Figure 1b).

Conclusions:
Our study indicated how atypical sensory sensitivity and difficulties in ToM influenced empathy in autistic children. These findings advanced our understanding of the potential physio-psychological mechanisms underlying the reduced empathy in autistic children and provided important therapeutic implications. Empathy in autistic children might be elevated along with the tactile training and the social skill interventions focusing on ToM.

437.333 (Poster) Testing the Mechanisms Underpinning the Social Motivation Theory: The Role of Co-Occurring Anxiety  
Background: The Social Motivation Hypothesis proposes that differences in social reward processing underlie autism, by reducing opportunities to develop social-cognitive skills. High levels of social motivation have also been linked to lower anxiety. Given that autism and anxiety often co-occur, an alternative possibility is that unmeasured anxiety symptoms are driving the association between social motivation and autistic traits.

Objectives: The key aims of this study are 1) to test the mechanisms underlying the association between social motivation and autistic traits, specifically whether individual differences in social cognition or anxiety can account for this association; and 2) to examine the evidence for differential, sex-specific effects.

Methods: Participants were 167 adolescents (73 male), aged 10 to 16 years, from the Mapping profiles of cognition, motivation and attention in childhood (C-MAPS) study. Participants were recruited via schools, charities and social media, with targeted recruitment aimed at increasing variability in autistic traits, with 70 participants (37 male) having an autism diagnosis. The C-MAPS study included a battery of online experimental measures of social motivation, and social cognition (theory of mind, ToM; emotion recognition), as well as parent-reported measures of trait anxiety from the Spence Children’s Anxiety Scale and autistic traits from the Social Responsiveness Scale.

Results: Social motivation was significantly associated with autistic traits ($\beta = -.26, p < .001$), such that participants with higher autistic traits scored lower on our experimental measure of social motivation. Controlling for social cognition (ToM and emotion recognition) did not reduce the association between social motivation and autistic traits in the overall sample. Controlling for anxiety, however, did significantly reduce the strength of the association (change in $\beta$: $t = 5.45, p < .001$). Analyses split by sex showed a significant association between social motivation and autistic traits only in the females ($\beta = -.37, p < .001$) not males ($\beta = -.04, p = .74$), and the attenuation of the association by anxiety was again specific to females (see Figure 1).

Conclusions: Contrary to mechanisms proposed by the Social Motivation Hypothesis, social cognition differences did not explain the association between social motivation and autistic traits. This consistent with self-report by many autistic individuals who do not identify as having reduced social motivation. The association between social motivation and autistic traits was attenuated, however, when accounting for co-occurring anxiety. This suggests the reduced social motivation seen in autism may in fact be due to unmeasured, co-occurring anxiety. Increased social motivation may also result in the reduction of certain autistic behaviours, for example self-soothing behaviours, via lower social anxiety in social situations (Swain et al., 2015). The differential sex effects, showing associations only in females, may be due to environmental factors such as increased social demands in adolescent female relationships or gendered parenting encouraging reciprocal social interactions, which may selectively increase opportunities to build confidence in socially motivated females, reducing the use of RRBs to self-soothe. Future longitudinal studies are needed to tease apart the temporal ordering of effects and test the underlying mechanisms developmentally.

437.334  (Poster) The Choice of Stimuli Matters – Meta-Analysis of Emotion Recognition from Dynamic Faces in ASD
K. Borowiak1, I. Dziobek2 and K. von Kriegstein3; (1)Technische Universität Dresden, Dresden, Germany, (2)Humboldt-Universitaet zu Berlin, Berlin, Germany

Background: Individuals with ASD have difficulties recognizing emotion from faces, which affect everyday social functioning (Trevisan & Birmingham, 2016, Res Autism Spectr Disord). Although human faces are highly dynamic in the real world, static face stimuli (e.g., images) are still most common for testing emotion recognition in ASD (Yeung, 2021, Neurosci Biobehav Rev). Using dynamic stimuli (e.g., natural videos) might change our understanding of the ASD difficulties. On the one hand, additional motion information improves emotion recognition in non-ASD individuals (Lander & Butcher, 2015, Front Psychol). On the other hand, ASD individuals show aberrant perception of biological motion, particularly when emotional signals are conveyed (Federici et al., 2020, Sci Rep; Todorova et al., 2019, Mol Autism) and the dynamics of facial stimuli can modulate emotion processing in ASD (Tardif et al., 2007, J Autism Dev Disord; Sato et al., 2013, Res Autism Spectr Disord). Thus, it is unknown whether the choice of stimuli between dynamic and static faces might influence the assessment of emotion recognition difficulties in ASD compared to non-ASD.

Objectives: We aimed to systematically evaluate the evidence on emotion recognition in ASD using a meta-analytic approach. We did it separately for studies that applied dynamic faces and static faces. We expected that effect sizes for group differences between ASD and non-ASD individuals would be different between the two approaches.

Methods: We conducted a systematic review of studies investigating emotion recognition in ASD compared to non-ASD according to PRISMA guidelines (Moher et al., 2009, Ann Intern Med). We included studies that provided measures of behavioral recognition accuracy and/or response times and classified them according to the face stimuli (dynamic vs. static). We performed a formal meta-analysis using multilevel random-effects modeling to compute mean-effect sizes of group differences between ASD and non-ASD individuals. We accounted for methodological factors (e.g., sample characteristics, stimuli and response format). Currently, we are assessing the quality of study designs and reporting to control for its confounding effects in our models. When feasible, we will compute estimations for specific emotions.
Results: Our search identified 317 studies on facial emotion recognition in ASD, from which 34 studies with dynamic faces and 118 studies with static faces fulfilled our criteria for inclusion. We are still in the process of data analysis and can currently provide only preliminary results. ASD compared to non-ASD individuals showed reduced performance in emotion recognition. We found comparable mean-effect sizes between studies with dynamic and static faces. These effects generalize across age groups, sex and IQ. Methodological factors linked to stimulus and response format significantly modulate the effects.

Conclusions: Our work will make two contributions. First, it will give a comprehensive overview of the current state of evidence on facial emotion recognition in ASD, and quantify the extent of the behavioral difficulties when using dynamic compared to static stimuli. Second, it will allow for practical implications for future studies to improve the reliability and ecological validity of emotion research in ASD.

437.335 (Poster) The ClaCoS Battery in Complex Diagnoses of Women with ASD

Background: Autism Spectrum Disorder (ASD) is characterized by impairments in social communication and interaction and limited interests and repetitive behaviour. These social communication impairments are not well characterized, due to a lack of standardized evaluation tools, especially in adult or female individuals. Gender differences in autism remain debated. The concepts of “camouflage”, compensations or gender-related phenotypes need to be better defined and understood (Lai et al, 2017). Nevertheless women with ASD (without intellectual disability) show better social communication skills (Lai et al, 2015) in adulthood and could be under-diagnosed or recognized later than men. The multicentric research group in psychiatry GDR3557 (Institut de Psychiatrie) developed a new battery for social cognition evaluation named ClaCoS which considered social cognition as a multidimensional process, and examined four components of social cognition: Emotion Recognition, Theory of Mind, Attributional Style and Social Perception and Knowledge. It also provides an assessment of subjective complaints in social cognition.

Objectives:

To assess the relevance of the ClaCoS battery in the evaluation of social cognition impairments in ASD adults and especially in women, who show more subtle clinical symptoms.

Methods:

We examined sex differences in a population of 37 ASD adults without intellectual disability (26 men and 11 women), on ClaCoS and on classical tools used for ASD diagnosis (ADOS and ADI-R). We further compared the social cognition abilities of these 37 ASD adults and 37 neurotypically developed volunteers using ClaCoS.

Results:

The ASD group showed deficits in all four components of social cognition and reported greater subjective complaints regarding their social abilities. Social communication and interaction deficits in ASD adults were less visible in female compared to males on the ADOS, although they showed typical clinical symptoms in childhood, when assessed with the ADI-R. No differences were observed between male and female ASD adults assessed with the ClaCoS.

Conclusions:

The ClaCoS battery is an interesting functional tool allowing to assess social impairments in ASD adults. It provides complementary information to classical tools used in the diagnostic procedure, which are not always sensitive to social communication deficits in ASD adults without intellectual disability, especially in women (Lai et al, 2011). This new battery may thus be useful in these complex diagnoses of women with ASD. Moreover, it allows to specify the altered components, for a better adjustment of tailored social cognition training programs.
**437.336 (Poster) The Different Phenotypes of Social Functioning in Adolescents and Young Adults with ASD: An Exploratory Study Using Multi-Method Approach**

**J. Husmann, C. Feller, L. Ilen and M. Schneider, Clinical Psychology Unit for Intellectual and Developmental Disabilities, University of Geneva, Geneva, Switzerland**

**Background:**
Autism spectrum disorder (ASD) is characterized by difficulties in social interaction and communication. Moreover, deficits in social functioning and social skills can lead to lower social participation and higher isolation that are associated with broad negative consequences and poor long-term outcomes. However, the notion of spectrum reflects a heterogeneity of these difficulties, both in the severity of autistic symptoms and in their expression. In addition, numerous psychiatric comorbidities are likely to influence the expression of autistic symptoms. These comorbidities (ADHD, depression or PTSD) can hinder social integration and negatively impact the effectiveness of therapeutic interventions. Surprisingly, only a few studies have attempted to better understand this heterogeneity by defining more homogeneous subgroups of social functioning in individuals with ASD. These studies have shown variable profiles of social withdrawal and social appropriateness but without necessarily considering these aspects of psychiatric comorbidities.

**Objectives:**
This study aims to provide a better understanding of the different social phenotypes in a sample of verbally fluent adolescents and young adults with ASD. As static measures do not provide an integral view of social functioning, which is highly context-dependent, a combination of measures will be evaluated. In particular, the ESM, a structured diary technique that collects real-life measures in the context of daily life, will be used in combination with a parent-reported questionnaire and direct observation to obtain a detailed characterization of social functioning.

**Methods:**
55 adolescents and young adults with ASD and the same number of typically developing (TD) individuals aged 12 to 25 years have already been collected. Participants are required to complete the ESM protocol which measures the frequency and subjective evaluation of social interactions. In addition, the SRS is used to assess social appropriateness and social motivation. Finally, the SSPA, a direct observation of participants during role plays will be used to quantify social appropriateness. A latent profile analysis will be used. To identify the influence of psychiatric comorbidities on the different phenotypes of social functioning, the SIAS, ASR/YSR and ABCL/CBCL scores will be considered using a multiple linear regression. Note that these analyses were subject to pre-registration.

**Results:**
We expect that participants with ASD will be characterized by heterogeneous social functioning impairments, whereas TD will have a more homogeneous profile. We hypothesize that TD individuals will be in majority rallied in the same profile characterized by good social functioning. Concerning participants with ASD, we hypothesize they will be clustered in 4 subgroups. Therefore, different profiles should emerge according to the social motivation, evaluation of daily social interactions, and social appropriateness. Finally, different rates of psychiatric comorbidities are expected in the different subgroups.

**Conclusions:**
The purpose of this study is to better characterize the different social functioning profiles in ASD. It would allow to better target therapeutic interventions according to the different phenotypes of social functioning and their associated comorbidities. Moreover, as social functioning is a complex concept, this methodology could provide new information on the aspects of social functioning that are impaired/preserved in this population according to the different phenotypes.

**437.337 (Poster) The Factor Structure of the Camouflaging Autistic Traits Questionnaire (CAT-Q) and Predictors of Camouflaging in a Representative General Population Sample**

**W. Ai, W. A. Cunningham and M. C. Lai, (1)Department of Psychology, University of Toronto, Toronto, ON, Canada, (2)The Margaret and Wallace McCain Centre for Child, Youth and Family Mental Health, Centre for Addiction and Mental Health, Toronto, ON, Canada**

**Background:** “Camouflaging” broadly refers to the use of coping strategies by autistic people to minimize autistic visibility, such as suppressing autistic behaviours, imitating neurotypical peers during interactions, or preparing social scripts. A key unanswered question is the extent to which camouflaging is in fact a ubiquitous coping experience during interpersonal life across neurotypes in the general population.
Objectives: We aimed to investigate the factor structure and theory-driven (Ai et al., 2022) motivational and cognitive predictors of self-reported camouflaging across the general population, and to unveil whether findings echo what has been learned in autistic people. This study establishes an important foothold in tackling the conceptual clarity of camouflaging research.

Methods: Participants included 972 adults from a representative U.S. general population sample (461 men, 491 women, 20 gender-diverse, Mage = 44.2 yrs, 72.7% Caucasian, 7.51% neuro-diverse). Participants completed an online survey consisting of construct measures spanning impression management (i.e., camouflaging and self-presentation), cognitive skills (i.e., executive functions, emotion regulation), social motivations (i.e., internalized stigma, public self-consciousness), and neurodivergent traits (i.e., ADHD and autistic traits). Exploratory Item Factor Analysis (EIFA) was used to identify the factor structure of the Camouflaging Autistic Traits Questionnaire (CAT-Q) in the general population. Hierarchical regression models were used to assess demographic/individual trait predictors of CAT-Q. Regularized regression models were performed to identify social-motivational and cognitive predictors of CAT-Q.

Results: The EIFA fit indices support a four-factor structure of the CAT-Q (RMSEA = .046). The item distribution (see Table 1) largely reflects the originally reported three-factor CAT-Q structure in autism-enriched samples. Hence, the four factors were interpreted as Compensation (7 items), Masking (8 items), Active Assimilation (5 items), and Passive Assimilation (4 items). A large positive correlation was found between the CAT-Q and the Self-Presentation Tactics (SPT) scale (r = .60). Hierarchical regression revealed that men showed higher CAT-Q scores than women in the general population (partial r² = .008, p = .006); as well, increased ADHD and autistic traits both predicted increased CAT-Q scores (partial r² = .069, p < .001 and partial r² = .048, p < .001, respectively). The elastic-net regression model showed that, in addition to neurodivergent traits, higher CAT-Q scores were predicted by greater social comparison tendency, greater public self-consciousness, greater perceived self-other closeness, greater emotion regulation, greater internalized stigma, greater social anxiety, greater inhibition skills, and lower cognitive flexibility.

Conclusions: Camouflaging seems to be a shared social coping experience across neurotypes in the general population. This view is further supported by the strong positive correlation between the measurements of camouflaging and self-presentation (an established impression management construct). The findings also yield insights on key social-motivational and cognitive predictors of camouflaging in the general population (see Figure 1), which should be evaluated to complement the growing research on autistic camouflaging. This general-population-based study advances a more psychometrically grounded understanding of camouflaging that may guide more precise research directions on camouflaging and its drivers across neurotypes.

X. Wang, L. Lin, J. Jing and S. Huang, (1)South China Normal University, Guangzhou, China, (2)Sun Yat-sen University, Guangzhou, China, (3)Department of Child Healthcare, Affiliated Foshan Maternity and Child Healthcare Hospital, Southern Medical University, Foshan, China

Background: Despite of the dissociation between cognitive and affective empathy in children with high-functioning autism spectrum disorder (ASD), the associations of cognitive and affective empathy with altruistic behaviors remained unclear.

Objectives: To compare the cognitive and affective empathy and explore their association with altruistic behaviors in children with high-functioning ASD.

Methods: We conducted an eye-tracking experiment using a modified paradigm of dictator game (DG) to reveal altruistic behaviors with the components of facial expression (happy, sad and neutral faces). We recorded the affective empathy response via the pupillary responses during automatic emotional contagion, and evaluated the cognitive empathy through self-reported degree of empathy after experiments. Fifty children with high-functioning ASD, and 50 age-, sex- and intelligence-matched typical-developing (TD) controls were analyzed. Repeated measured ANOVA, Generalized Linear Model(GLM) and Generalized Additive Mixed Model (GAMM) were used to statistical analyze.

Results: The results revealed no differences regarding eye scanning patterns, facial expression recognition and cognitive empathy response during the experiments between the two groups whatever which kind of facial emotion. However, affective empathy which was reflected by pupillary responses during automatic emotional contagion were stronger in autistic children on negative emotion processing (i.e., sad faces). Moreover, cognitive empathy response was positively associated with the altruistic decision in children with ASD.

Conclusions: Our findings shed light on the imbalance in affective and cognitive empathy in high-functioning ASD, and cognitive instead of affective empathy might play a more important role on altruistic behavior.

437.339 (Poster) The Impact of Gender on Autism Symptom Severity and Problem Behaviors

L. Perovsek, K. Drafton, T. DeMotta and B. J. Wilson, (1)Seattle Pacific University, Seattle, WA, (2)Clinical Psychology, Seattle Pacific University, Seattle, WA, (3)Clinical Psychology, Seattle Pacific University, Seattle, WA
**Background:** Children with autism spectrum disorder (ASD) display a diverse range of symptom criteria and severity. Several gender differences in ASD have been noted, with boys and girls demonstrating differential symptom presentations and impairments (Mandy et al., 2012). Furthermore, children with ASD often have difficulties with overregulated or underregulated challenging behaviors, many of which become impairing for the child’s functioning in a variety of domains (Parternite et al., 2009; Vaillancourt et al., 2016). Given the relevance of early life development and ASD symptom severity it is incredibly important to investigate their relation to problem behaviors. Furthermore, research is needed examining the influence gender has on this relation.

**Objectives:** The current research study investigated the association between ASD symptom severity, problem behaviors, and gender within children aged 5-10 years old with ASD. Specifically, it examined how gender impacts the relation between symptom severity and problem behaviors.

**Methods:** This study utilized cross-sectional data from a larger web-based survey investigating children with ASD. Participants included 36 parents of children with ASD aged 5-10 years old living in the United States (M = 7.03, SD = 1.46). A majority of children reported on were White (66.66%) and male (66.67%). Our model consisted of a predictor of ASD symptom severity, an outcome of total problem behaviors, and a moderator of gender. Symptom severity was measured by a composite score of the Stereotyped, Change, Social, and Understanding subscales in the Children’s Social Behavior Questionnaire (CSBQ; de Bildt et al., 2009; Hartman et al., 2006). Problem behaviors were measured by a composite score on the Nisonger Child Behavior Rating Form- parent (NCBRF; Aman et al., 1996). The CSBQ and NCBRF are both parent report measures and have been validated for children aged 5-10 years old with ASD (Hartman et al., 2006; Lecavalier et al., 2004).

**Results:** A multiple regression analysis was conducted using base R (R-4.2.1.tar.gz) to predict total problem behaviors from the interacting effects of ASD symptom severity and gender. Results supported a statistically significant interaction effect between symptom severity and gender that accounted for 41% of the variance in problem behaviors (F(3,31) = 7.21, p<.001). Probing the interaction effect with Johnson-Neyman and pick-a-point approaches indicated the relation between symptom severity and problem behaviors is significant for males, but is non-significant for females. See figure 1 for more details.

**Conclusions:** Our results indicated that gender moderates the relation between symptom severity and problem behaviors. As symptom severity increases for boys, they display greater problem behaviors. This association was not significant for girls, indicating no differences in problem behaviors as their symptom severity increases. This, in concordance with previous literature examining the relation between symptom severity and problem behaviors among school-aged children, provides a nuanced look into the differential impact of gender (Jang et al., 2011). Future studies should further investigate the impact of gender and symptom severity on problem behaviors, taking a closer look into gender difference differences.

**437.340 (Poster) The Impact of Social History and Social Motivation on Neurodivergent Adolescents’ Interpretation of Social Transgressions.**  
**J. E. Granieri; H. E. Morton; J. M. Gillis; and R. G. Romanczyk; (1)Department of Psychology, Binghamton University, Binghamton, NY, (2)Oregon Health & Science University, Binghamton, NY, (3)Binghamton University, Binghamton, NY**

**Background:** Friendships provide important context for learning social skills and problem solving, and protect against peer victimization (Bollmer et al., 2005; Hodges et al., 1999). Neurodivergent (ND) youth (i.e., autistic or ADHD) may experience differences in friendship quality or durability compared to neurotypical (NT) peers (Mendelson et al., 2016; Petrina et al., 2016), likely reflecting distinct social communication preferences for ND vs NT youth (Milton, 2012). Additionally, past or current social experiences may impact ND youth’s perceptions of peer interactions (Romanczyk et al., 2005; van Roekel et al., 2010). The combined impact of NT social competence and social experiences may further contribute to ND adolescents’ perceptions of social transgressions and friendship experiences.

**Objectives:** To explore the impact of social competence and social experiences on ND adolescents’ perception of friendship transgressions.

**Methods:** Self- and parent-report questionnaire were completed for 82 adolescents (ages 11-21) with verbal expressive language and diagnoses of ASD and/or ADHD. Social experiences were measured by the Friendship Quality Questionnaire (FQQ; Parker & Asher, 1993) and the Assessment of Bullying Experiences (ABE; Morton et al., 2021). Neurotypical social competence was assessed using The Social Responsiveness Survey, Second Edition (SRS-2; Constantino et al., 2012). The adapted Friendship Transgression Stories (Bottema-Beutel, Malloy, Cuda, Kim, & MacEvoy, 2019) was used to measure adolescents’ interpretation of severity of friendship transgressions in vignette format. A linear regression was conducted to examine to multivariate associations of social competence (motivation, awareness, cognition, and communication) peer victimization, and friendship quality on perceived severity of friendship transgressions.

**Results:** Friendship transgressions were perceived as more severe by youth with higher quality friendships (β=0.40, SE=0.18, p=0.038), a less neurodivergent style of social motivation (β=-0.03, SE=-0.02, p=0.026), and who were younger (β=-0.15, SE=0.05, p=0.011). Nonsignificant predictors included number of friends, gender, bullying history, social awareness, social cognition and social communication.
Conclusions: Consistent with Romanczyk et al. (2005)’s proposed model of social competence, it appears that certain social experiences may provide important context into the way in which social interactions are understood and navigated by ND adolescents. ND adolescents who report greater quality friendships and who are more motivated for social interactions interpret transgressions as more severe. In contrast to prior literature, previous or current bullying did not impact the interpretation of transgressions (van Roekel et al., 2010). Perhaps adolescents who are more motivated to form social relationships are more likely to overlook transgressions. Alternatively, adolescents who are older and have higher social motivation may have had a greater number of social experiences which have shaped the way in which they interpret transgressions. Findings highlight the importance of intervening on social experiences of ND youth early on, as these experiences may shape skills needed for navigating social experiences later on.

437.341 (Poster) The Integration of Head and Body Cues during the Perception of Social Interactions
E. H. Williams and B. Chakrabarti, (1)Centre for Autism, University of Reading, Reading, United Kingdom, (2)Centre for Autism, University of Reading, Reading, UNITED KINGDOM

Background: Although humans spend a large proportion of time participating in social interactions, little is known about the processes underlying their visual recognition. Directional information from a person’s eyes, head, and body are integrated to inform where another person is looking and who they are interacting with. Individuals with Autism Spectrum Conditions (ASC) have shown differences in social cue integration when viewing images of isolated individuals. However, to date, social cue integration research has focused largely on the perception of isolated individuals, and the nature and extent of cue integration during interaction perception in autistic and non-autistic individuals is relatively unknown.

Objectives: We investigated whether observers integrate directional cues from the body with head orientation information when judging whether two people are interacting, and whether this integration is affected by autistic traits, frame of reference, and eye-region visibility.

Methods: Across two experiments, N = 230 participants judged whether dyads were interacting using well-controlled, computer-generated stimuli that systematically varied in head and body orientation. Additionally, we manipulated the frame of reference of the stimuli (egocentric: one of the interactants faced the observer vs. allocentric: interactant turned away from the observer) and the eye-region visibility of the dyads.

Results: Results demonstrate that individuals integrate information from the body with head information when perceiving dyadic interactions, such that perceived interaction is shifted away from the orientation of the body when head and body cues are misaligned. Additionally, our findings suggest that autistic traits affect social cue integration during interaction perception, but that these effects are dependent on the frame of reference and the eye-region visibility of the dyads. Specifically, individuals reporting more autistic traits were influenced more strongly by the directional cue of the body during interaction perception than those reporting fewer autistic traits, but only when the eye-regions of the dyads were visible in an egocentric frame of reference.

Conclusions: Everyday social interactions involve rapid integration of directional cues from the head and body of others. Our data demonstrate how autistic traits influence this integration. This result points to potential sensory mechanisms underpinning some of the social behavioural challenges experienced by many autistic individuals. Future research can focus on the generalisability of these results with non-social stimuli, as well as in clinically diagnosed populations.

437.342 (Poster) The Mediating Effect of Camouflaging and the Moderating Effect of Autistic Identity on the Relationship between Autistic Traits and Mental Wellbeing
H. L. Moore, S. A. Cassidy and J. Rodgers, (1)Newcastle University, Newcastle upon Tyne, UNITED KINGDOM, (2)School of Psychology, University of Nottingham, Nottingham, UNITED KINGDOM, (3)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom

Background:
Camouflaging (or behaving differently in order to fit in) is common among autistic adults. Mental health difficulties are also prevalent, including anxiety and depression, and research has demonstrated correlations between camouflaging and these mental health difficulties. However, no research to date has explored the mediating effect of types of camouflaging behaviour on the relationship between autistic traits and mental health. Neither has it considered whether a positive autistic identity might offer a protective effect. Furthermore, very little research has investigated positive wellbeing.

Objectives:
To explore the mediating effect of different camouflaging types and the moderating effect of autistic identity on the relationship between autistic traits and mental wellbeing.
Methods:

Data were collected for 464 autistic adults, recruited through volunteer databases and social media. Among other measures relevant to the wider study, participants completed measures of autistic traits (Autism Quotient-10; AQ-10), anxiety and depression (Hospital Anxiety and Depression Scale; HADS-A and HADS-D), positive wellbeing (Warwick-Edinburgh Mental Wellbeing Scale; WEMWBS), camouflaging (Camouflaging Autistic Traits Questionnaire; CAT-Q), and autistic identity (Autism Spectrum Identity Scale; ASIS). Moderated mediation models were run using model 8 of Hayes’ (2013) PROCESS macro for SPSS, applying bootstrapped 95% confidence intervals (10,000 resamples). CAT-Q was mediator, and ASIS moderator on the direct and indirect (AQ-10àCAT-Q) relationships. Age and gender were included as covariates. Where moderators were not significant, simpler models were reported (model 4, parallel mediation).

Results:

There was no moderating effect of autistic identity on any direct (HADS-A: F(1,441)=.52, p=.4724; HADS-D: F(1,441)=.33, p=.5667; WEMWBS: F(1,435)=1.83, p=.1766) or indirect effects (see Table 1). Reverting to model 4, there was no significant direct effect for AQ-10 to: HADS-A (B=0.2280, SE=.1227, Cls=-.0130, .4690); HADS-D (B=.0298, SE=.1310, Cls= -.2276, .2872); or WEMWBS (B=.4114, SE=.2625, Cls=.1045, .9273). For HADS-A and HADS-D, there was a significant indirect effect through CAT-Q Assimilation only; whereas for WEMWBS, both CAT-Q Compensation and CAT-Q Assimilation were significant (see Table 1).

Conclusions:

Autistic identity does not impact the relationship between autistic traits and mental health, directly or through camouflaging. The impact of external identity threat (e.g. stigma) may have a greater role and should be considered in future, to explore the role of external pressures on camouflaging and mental health in autistic individuals. Full mediation was found; the relationship between autistic traits and mental health was significant through its effect on camouflaging. Different types of camouflaging played different roles in the relationship for each mental health measure, signifying that tailored support is needed. However, common to all was the mediating effect of assimilation, suggesting a general target for mental health support.

437.343 (Poster) The Relationship between ADHD Symptoms and Looking Patterns in Children with ASD: Results from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)

R. Iqbal, J. M. Wolf, K. Chawarska, G. Dawson, R. A. Bernier, N. Kleinhans, S. Jeste, J. Dzura, A. Napolitano, S. J. Webb, C. Sugar, F. Shic and J. McPartland, (1)Child Study Center, McPartland Lab - Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Child Study Center, Yale Child Study Center, Yale New Haven, CT, (3)Child Study Center, Yale School of Medicine, New Haven, CT, (4)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (6)University of Washington, Seattle, WA, (7)Children’s Hospital Los Angeles, Los Angeles, CA, (8)Boston Children’s Hospital, Boston, MA, (9)Yale University, New Haven, CT, (10)Child Study Center, Yale University, Child Study Center, New Haven, CT, (11)University of California, Los Angeles, Los Angeles, CA, (12)Center for Child Health, Behavior and Development, Seattle Children’s Research Institute, Seattle, WA

Background: Previous literature reports high co-occurring rates of attention deficit/hyperactivity disorder (ADHD) in individuals with autism spectrum disorder (ASD), resulting in greater social, adaptive, and cognitive challenges. In ASD and in ADHD, social visual attention represents a possible shared pathway of underlying mechanisms. Therefore, it is important to understand how ADHD influences social motivation and social preference in ASD, better informing future interventions.

Objectives: To examine the relationship between ADHD symptomatology and social attention among autistic children.

Methods: Data was collected across five sites from 271 autistic children ages 6-11 (206 males; age M=8.57±1.64; FSIQ M=96.92±17.91) as part of the Autism Biomarkers Consortium for Clinical Trials (ABC-CT). Using the SR EyeLink 1000+, participants were shown full-color circular arrays of 5 static images: face with direct gaze, scrambled face, bird, mobile phone, and car. Stimuli were equidistant from the center of the screen and were comparable in size and color. Participants were presented with six 20-second trials. Latency to fixate to each object was calculated as the time when the gaze first entered the pre-defined region of the object. Percent looking was calculated as the number of valid gazes to the object divided by the total number of onscreen gaze samples, and total looking time was calculated as time spent looking at the object divided by the total presentation time. The Child and Adolescent Symptom Inventory, Fifth Edition (CASI-5) was administered to obtain parent-reported symptoms of inattention and hyperactivity. Correlations were used to determine associations between ADHD symptoms (CASI-5 Inattentive subscale and Hyperactive-Impulsive subscale T scores), latency, percent looking, and average looking time during the visual search paradigm.

Results: Inattentive and hyperactive-impulsive symptoms were positively correlated with the latency of the first look at faces (r=0.14, p<0.03 for inattentive symptoms; r=0.15, p<0.02 for hyperactive-impulsive symptoms), but not to nonsocial objects (r=-0.06, p=0.36; r=-0.11, p=0.06, respectively). Inattention was negatively correlated with percent looking at faces (r=-0.17, p<0.01) and average looking time (r=-0.15, p<0.02), but hyperactivity was not (r=-0.09, p=0.15; r=-0.09, p=0.13 respectively). Percent looking to nonsocial objects
increased with greater ADHD symptoms \( r=0.14, p<0.03 \) for inattentive symptoms; \( r=0.15, p<0.02 \) for hyperactive-impulsive symptoms). Average looking time to nonsocial objects was also positively correlated with higher ADHD symptoms \( r=0.13, p=0.04 \) for both inattentive and hyperactive symptoms).

Conclusions: These findings indicate a relationship between ADHD symptomatology and looking patterns towards nonsocial objects in autistic children. Higher ADHD symptoms were associated with greater latency to faces, and higher inattentive symptoms were associated with reduced looking to faces. These findings, combined with previous findings, suggest that individuals with ASD and ADHD experience greater difficulties when looking to faces compared to individuals with ASD or ADHD alone, suggesting an interactive effect in which ADHD exacerbates social visual attention difficulties in ASD. Future work is needed to understand if looking patterns towards social and nonsocial stimuli are influenced by motivational or attentional differences. Elucidating the underlying mechanisms of ASD and ADHD through future eye-tracking studies will inform the impacts of ADHD on ASD symptomatology.

**437.344 (Poster) The Relationship of Child Mental Health Indicators and Pragmatic Communication Domains over Time**

C. A. Cooper, E. F. Dillon, L. Bush, E. V. Ocampo, J. M. Moriuchi, K. Flores, A. L. Lopez Hernandez and L. V. Soorya, (1)Psychiatry, Rush University Medical Center, Chicago, IL, (2)Center for Autism and Related Disorders, Autism Assessment, Research, Treatment, and Services (AARTS) Center at Rush, Baltimore, MD, (3)Northwestern Feinberg School of Medicine, Chicago, IL, (4)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (5)AARTS Center, Rush University Medical Center, Chicago, IL, (6)Psychiatry, Rush University, Chicago, IL, (7)Rush University, Chicago, IL

**Background:** A hallmark feature of Autism Spectrum Disorder (ASD) is impairment in pragmatic (e.g. social communication) skills which fully develop in middle childhood. Children with ASD are at an elevated risk of developing co-occurring psychological disorders complicated by both internalizing and externalizing behaviors. Pragmatic impairments are associated with increased mental health risks, including externalizing (i.e. hyperactivity/aggression) and internalizing conditions (e.g., anxiety) (Boonen et al., 2014; Rodas, Eisenhower & Blacher, 2017). For verbally fluent children, communicative impairments may lead to greater difficulty navigating social interactions, contributing to elevated anxiety. Greater externalizing behaviors has also been reported in ASD compared to peers and may contribute to peer rejection. Clarifying the relationship between pragmatics and psychological outcomes in middle childhood has potential to inform risks and potential untapped intervention targets during this critical period for social development.

**Objectives:** 1) To investigate the relationship between parent-rated internalizing and externalizing symptoms and child pragmatic language at two distinct time points in a sample of verbally fluent children with autism. 2) Test the predictive power of child pragmatics at baseline on child mental health indicators over time.

**Methods:** A sample of 51 children with confirmed ASD (74.5 % M) aged 7-12 years (m=9.86, SD=1.24) were included. Participants were enrolled in a 12-week randomized controlled trial (clinicaltrials.gov: NCT01190917); data were collapsed across conditions for this analysis. Child pragmatics were measured using the pragmatic domains of the Child’s Communication Checklist-2 (CCC-2; Bishop, 2006). Child mental health indicators were taken from the Behavior Assessment System for Children-2 (BASC-2), including internalizing and externalizing symptoms.

**Results:** Pearson’s correlations were conducted at baseline and week 12 to examine the relationship of child internalizing/externalizing symptoms and child pragmatic skills at each time point. Findings support significant relationships at baseline and week 12 (Table 2). However, parent rating of Depression was only correlated with child pragmatic domains at baseline, and parent rating of Anxiety was not significant with pragmatic domains at either time point.

The Externalizing Domain emerged as a primary variable of interest. A linear step-wise regression was conducted to predict Externalizing Behaviors at week 12 from child pragmatic domains at baseline. The model was significant, controlling for intervention group status and IQ, \( F(8, 32)= 4.96, p=.001 \) and accounted for 42.3% of the variance.

**Conclusions:** Externalizing behaviors, and, to a lesser extent, Internalizing behaviors were correlated with child pragmatic skills but the relationship appears to change over time. Children with higher rates of externalizing problems tended to use more inappropriate topic initiations and speak more about their areas of interests. Pragmatic deficits may be exacerbated by symptoms such as poor impulse control and attention difficulties. Depression emerged as an internalizing symptom associated with pragmatics only at baseline, which may suggest gains in social skills over the course of the intervention reduced the relationship of child pragmatics and depression symptoms. Future work could leverage these data to understand potential pragmatic language mechanisms in common psychiatric co-occurring conditions and intervention outcomes for school-aged autistic children.

**437.345 (Poster) The Relationships between Executive Function and Social Interaction in Children with Autism Spectrum Disorder**

Y. L. Chen, Y. C. Tsai and K. L. Chen, (1)Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan, (2)Institute of Allied Health Sciences, National Cheng Kung University, Tainan, Taiwan, (3)Department of Physical Medicine and Rehabilitation, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan
Background: Children with autism spectrum disorder (ASD) are characterized by deficits in social interaction, which may be related to their impaired executive function (EF). EF is viewed as a set of higher-order cognitions for goal-directed behaviors that includes cognitive components such as inhibition, shifting, and working memory. Similarly, social interaction can be viewed as containing dimensions such as social cognition and social communication. Even though numerous studies have investigated the role of EF in social interaction in children with ASD, the elaborate relationships among these EF cognitive components and social interaction remain unclear.

Objectives: This study aimed to examine the profiles of EF and social interaction in children with ASD from caregivers' viewpoints and to investigate the relationships among EF cognitive components and social interaction aspects in children with ASD.

Methods: A total of thirty-nine children with ASD aged 3 to 10 years and their caregivers were enrolled in this study. Caregivers completed the Behavior Rating Inventory of Executive Functioning, Version 2 (BRIEF-2) Parent Form and the Social Responsiveness Scale (SRS-2) as measures of EF and social interaction, respectively. The BRIEF-2 provides three indexes: behavior regulation index (BRI) (i.e., inhibition and self-monitoring), emotional recognition index (ERI) (i.e., shift and emotional control), and cognitive regulation index (CRI) (i.e., working memory, initiating, planning, task-monitoring, and organization of materials). The SRS-2 has four subscales of social interaction: social awareness, social cognition, social communication, and social motivation. The correlations between the BRIEF-2 indexes and SRS-2 subscale scores were examined with Pearson's correlation coefficients and linear regression models.

Results: This study included 18 preschool and 21 school-aged children with ASD (mean = 71 months, SD = 21.58). The correlational results indicated that the SRS-2 subscale scores of social awareness, social cognition, and social communication were significantly associated with the three indexes of the BRIEF-2 ($r = 0.432$~$0.617$, $p < 0.05$). The social motivation subscale had significant correlations with the BRI and ERI ($r = 0.395$ and $0.400$, $p < 0.05$). In addition, the results showed the BRI to be a predictor of the SRS-2 subscale scores of social awareness, social cognition, and social communication ($F = 7.521$, 7.736, 5.131, $p < 0.05$, respectively). The CRI was a predictor of the social motivation subscale score ($F = 3.884$, $p < 0.05$).

Conclusions: This study shows that EF cognitive components are related to different dimensions of social interaction in children with ASD. Behavior regulation (i.e., inhibition and self-monitoring) can predict social awareness, social cognition, and social communication. Cognitive regulation (i.e., working memory, initiating, planning, task-monitoring, and organization of materials) is a predictor of social motivation. This study provides clinicians and researchers with further understanding of the respective relationships among EF cognitive components and different social interaction dimensions. Interventions targeting EF cognitive components can be planned to improve the social interaction of children with ASD.

437.346 (Poster) The Reliability and Validity of the Camouflaging Autistic Trait Questionnaire (CAT-Q) Chinese Version Among Autistic and Neurotypical Adolescents

C. H. Liu, Y. L. Chen, M. C. Lai and H. C. Ni, (1)Department of Psychiatry, Chang Gung Memorial Hospital, Linkou, Taoyuan city, Taiwan, (2)Department of Healthcare Administration, Asia University, Taichung city, Taiwan, (3)The Margaret and Wallace McCain Centre for Child, Youth and Family Mental Health, Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)Psychiatry, Chang Gung Memorial Hospital, Taoyuan, Taiwan

Background:

Camouflaging is a coping strategy reportedly used by neurodivergent individuals to fit in in neurotypical contexts. The Camouflaging Autistic Traits Questionnaire (CAT-Q), a self-reported instrument, has been validated in adults in some English-speaking Western societies, but not in other cultural-ethnic groups nor in younger individuals.

Objectives:

The aim of this study is to translate CAT-Q into traditional Chinese and to validate the use of it in non-Western adolescents via both self-report and caregiver-report.

Methods:

We enrolled Taiwanese autistic (n=100) and neurotypical (n=105) adolescents (aged 12-18 years) and their caregivers to complete the Chinese version of CAT-Q (CAT-Q-Ch) and Perceived Stress Scale (PSS-14). Exploratory factor analysis was done to evaluate factor structure of CAT-Q-Ch. Internal consistency and test-retest reliability were measured by Cronbach’s $\alpha$ and intra-class coefficients, respectively. The correlation between adolescent-reported and caregiver-reported CAT-Q-Ch, and between CAT-Q-Ch and adolescent-reported PSS-14 were assessed.

Results:
Exploratory factor analysis suggested a 2-factor structure (compensation-masking and assimilation). Cronbach’s α were 0.887, 0.906, and 0.829 for adolescent self-report CAT-Q-Ch total score, compensation-masking, and assimilation subscale respectively, and 0.853, 0.893, and 0.850 for caregiver-reported CAT-Q-Ch. The intraclass correlation coefficients for each subscale were all above 0.85. Caregiver-reported CAT-Q-Ch had good reliability and highly correlated with adolescent self-report version, and both version were correlated with adolescent reported PSS-14. Autistic adolescents had higher total CAT-Q-Ch scores than neurotypical adolescents (88.3 ± 23.8 vs 77.2 ± 21.1, p = 0.001), especially on both adolescent and caregiver reported assimilation subscale (30.9 ± 9.6 vs 24.3 ± 8.5, p<0.001, and 32.4 ± 8.3 vs 19.5 ± 6.9, p<0.001, respectively). Female autistic adolescents had higher assimilation subscales than male autistic adolescents (34.7 ± 10.2 vs 29.4 ± 8.9, p=0.011), but there was no significant gender difference in other subscales of CAT-Q-Ch in either autistic or neurotypical group. The PSS-14 score was higher in the autistic group (31 ± 9.1 vs 27.7 ± 8.9, p=0.01) and female group (31.3 ± 10.5 vs 28.3 ± 8.2, p=0.044). Autistic female had higher PSS-14 score (36.7 ± 9.6) than both autistic male (28.6 ± 7.9, p=0.01) and neurotypical female (27.2 ± 9.4, p=0.001). Both adolescent self-reported and caregiver-reported CAT-Q-Ch were correlated with adolescent reported PSS-14 score in both ASD group and neurotypical group.

Conclusions:

We found both self-report and caregiver-reported CAT-Q-Ch were reliable for Taiwanese adolescent whose autism diagnosis were made before their adolescence, and had correlation with PSS-14. Our study showed CAT-Q-Ch could be a useful tool for evaluating social coping behavior in autistic and neurotypical adolescents in non-Western countries.

**437.347 (Poster)** The Role of Alexithymia in Explaining the Relationship between Autistic Traits and Cardiac Autonomic Activity during Social Cognition.

**S. Gandhi,1 B. Oakley,2 M. Carboni3 and J. Findon4,** (1)Forensic and Neurodevelopmental Sciences, King’s College London, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (3)South London and Maudsley NHS Foundation Trust, London, United Kingdom, (4)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom

**Background:**

Alexithymia is a personality trait characterised by subclinical difficulty in identifying and describing feelings and is common among autistic adults. The presence of alexithymia may account for individual differences in emotion processing abnormalities that are observed in autism spectrum disorder (ASD), an idea which has become known as the “alexithymia hypothesis”. Respiratory sinus arrhythmia (RSA) is a measure of autonomic nervous system adaptability and is important in regulating emotional processing. Studies of RSA in ASD have provided inconsistent results. This variability might be explained by co-occurring alexithymia. Furthermore, most previous studies have examined RSA at rest, without assessing how RSA reacts to emotional stimuli. This is important because differences may only emerge during disorder-relevant stimuli. This is important because differences may only emerge during disorder-relevant stimuli.

**Objectives:**

To examine the mediating role of alexithymia in the relationship between autistic traits and cardiac autonomic activity at rest and in response to emotional stimuli.

**Methods:**

Participants were recruited from the general population using snowball sampling via social media and advertisements (N = 42; 12 males, 30 females, M_age = 25.54(5.99)). Autistic traits were measured using the Autism Spectrum Quotient (AQ) and alexithymia was measured using the Toronto Alexithymia Scale (TAS20). Physiological data (ECG and respiratory effort) was collected using a MP36R Biopac system with AcqKnowledge 5.0 software. Data was acquired while participants were at rest (5 minutes) and while they performed the Reading the Mind in the Eyes task (RMET). RSA was computed using the AcqKnowledge automated function for RSA analysis. Baseline RSA was calculated as the average RSA values during the five-minute rest period. RSA reactivity was calculated as the average RSA values during the RMET – baseline RSA.

**Results:**

Autistic traits were significantly positively associated with alexithymia (r(42) = 0.558; p<0.001) and both RSA baseline (r(42) = 0.333; p = 0.032) and reactivity (r(42) = -0.462; p<0.001). Crucially, alexithymia fully mediated the relationship between autistic traits and RSA reactivity (B = -0.015, p = 0.076) but not baseline RSA (B = 0.018, p = 0.162).

**Conclusions:**
These findings support and extend the alexithymia hypothesis to cardiac autonomic reactivity to emotional stimuli. Future work exploring cardiac autonomic activity in autism should control for the mediating effects of alexithymia. Furthermore, these results suggest that interventions which target alexithymia may improve autonomic reactivity, which in turn may improve emotion processing in autism.

437.348 (Poster) Theory of Mind in Autism Spectrum Conditions: A Task-Based Neuroimaging Approach

M. Mangnus¹, S. B. J. Koch², M. Greidanus Romaneli³, K. Cai³, F. Goltz³, P. Hagoort³, I. Toni⁴, A. Stolk⁵ and J. Bašnáková⁶, (1)Radboud University, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (2)Dartmouth College, Hanover, NH

Background:

One of the leading hypotheses about the communicative difficulties in autism attributes these difficulties to an impairment in theory of mind (ToM): the ability to understand emotions, beliefs and desires of others (Baron-Cohen et al., 1985). The hypothesis implies that impaired ToM abilities might hinder taking the intentions of a speaker into account during communication (Sperber & Wilson, 2002). Several tasks have been widely used to test ToM abilities, but are lacking in their resemblance to real-life communication (Moessnang et al., 2020).

Objectives:

We use a non-verbal, animated movie to test the possibility that autistic individuals process mental states differently than neurotypical individuals. This movie was designed to induce mental state inferences, and is known to engage the ToM network in neurotypical individuals (Jacoby et al., 2016; Schurz et al., 2014; Paunov et al., 2019).

Methods:

53 neurotypical adults and 52 adults diagnosed with Autism Spectrum Disorder matched on gender and verbal IQ watched the six-minute movie in the MRI-scanner. Afterwards, we administered a questionnaire assessing their understanding of the plot and key emotional and mental state events. We acquired functional MRI (fMRI) data to measure neural activation, and pupil size dynamics as a proxy of processing effort. For the analysis, we contrasted movie sequences previously linked to mental state inferences, emotional processing, and physical events (Jacoby et al., 2016; Paunov et al., 2019). Correlation between time-courses of participants’ pupil diameter during the entire movie (Nastase et al., 2019) was used to identify epochs with between-group differences in similarity of pupil responses. We considered epochs with a duration shorter than one second to represent discrete events, in which primarily single actions of characters take place. Epochs longer than 5 seconds were taken to represent more complex events, in which scenes and narrative-building take place.

Results:

The two groups’ verbal descriptions show similar understanding of the movie plot and of key events. The movie sequences linked to mental state inferences, as compared to physical events, activate core ToM brain regions (bilateral precuneus, angular gyrus and mPFC) in both autistic and neurotypical individuals, and to a similar extent. For the mental state events alone, the groups had comparable pupil size. When assessing the entire time-course of the movie however, epochs in which discrete events happen to the characters evoked weaker inter-participant correlation in pupil diameter in the neurotypical than the autistic group. No such between-group differences were found in epochs at the longer, higher-level time scale.

Conclusions:

This work indicates that neurotypical and autistic participants process mental state events similarly when watching movie sequences, as inferred from behavioral and neural ToM measures. Our findings build upon a large-scale study with a simple non-verbal task (Moessnang et al., 2020), but using a movie featuring animate characters in social interactions, and a data-driven group comparison of pupil size dynamics. Lastly, the group difference in pupil size dynamics might be a sign that autistic people process discrete events within social interactions distinctively, but do not differ from neurotypical processing effort during more complex events.

437.349 (Poster) To Help or Not to Help? Does Theory of Mind Promote Childrens' Helpful Behaviours?

L. A. Joyce¹, R. Drew², Y. Ma³, K. Boaz⁴ and J. K. Hamlin⁵, (1)Psychology, University of British Columbia, Vancouver, BC, Canada, (2)Psychology, Centre for Infant Cognition - University of British Columbia, Vancouver, BC, Canada

Background: Helping behaviours are key for children to develop social relationships with others. Toddlers exhibit a range of helpful behaviours, but what socio-cognitive abilities facilitate their spontaneous helping? Theory of Mind (ToM), the ability to understand others’ mental states, promotes various forms of helping in childhood (Conte et al., 2018). Past work suggests that cognitive ToM (mentalizing about others’ knowledge and desires) is related to instrumental helping, while affective ToM (mentalizing about others’ feelings) is associated with empathic helping behaviours (e.g., comforting; Carlo et al., 1991). Although these studies have measured ToM in preschool
children, well after the onset of spontaneous helping, nonverbal ToM tasks have recently allowed researchers to detect implicit ToM during toddlerhood (Poulin-Dubois & Yott, 2018). While the validity of implicit ToM measures is still debated, research suggests that ToM might emerge earlier than previously believed.

Objectives: It is currently unknown whether this implicit, cognitive form of ToM is associated with helping behaviours nearer to their developmental emergence. We address this gap by exploring associations between 30-month-olds’ implicit ToM and two forms of helping behaviour. We expected an implicit cognitive ToM to be more closely associated with instrumental than with empathic helping, as the former requires less consideration of an agent’s emotional state (Carlo et al., 1991). Specifically, the study aimed to: (1) replicate an implicit ToM procedure in toddlers to assess its validity; (2) assess the association between ToM and helping in toddlers with tasks appropriate to their cognitive abilities; and (3) assess whether implicit ToM is more related to affective or instrumental helping.

Methods: Twenty-six toddlers (Mage= 30.30 +/- 0.64 months), participated in the study. Participants completed a validated implicit ToM task (Scott et al., 2012) and had opportunities to engage in an instrumental helping task (e.g., help clean up toys that the experimenter had trouble with) and an affective helping task (e.g., provide emotional comfort to an experimenter feigning injury) (Bryan et al., 2014). Children who preferentially looked towards the belief-consistent image were considered to "pass" the task and thus showed evidence of having ToM.

Results: Toddlers were significantly more likely than chance to look at the belief-consistent image in the false-belief task (p < 0.05), suggesting that 30-month-olds possess representational mentalization abilities. However, ToM was not found to be significantly correlated with helping (r = 0.03) or comforting (r = -0.10) behaviours. Children who preferentially looked towards the correct image were more likely to help (p = 0.67). Children who preferentially looked towards the correct image were no more likely to help (p = 0.67). Children who preferentially looked towards the correct image were significantly unlikely to comfort (p = 0.05).

Conclusions: Thirty month old toddlers showed evidence of possessing a representative ToM by preferentially looking towards the image consistent with false-belief understanding. Helping was not associated with performance on the implicit ToM measure. While these results suggest that ToM and prosociality are along separate developmental trajectories, future research should increase sample size and address confounds in the ToM, helping and comforting tasks before drawing conclusions.

437.350  (Poster) Typical Observers’ Empathy Towards an Autistic Person and the Impact of Disclosure of a Diagnosis
Y. Rum, S. Genzer†, O. Golan, C. Allison, S. Baron-Cohen and A. Perry†, (1)Autism Research Centre, Department of Psychiatry, Autism Research Centre - University of Cambridge, Cambridge, United Kingdom, (2)The Hebrew University of Jerusalem, Jerusalem, Israel, (3)Department of Psychology, Bar-Ilan University, Ramat-Gan, ISRAEL, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom

Background: This study focuses on typical peoples' empathy and interest towards an autistic person and the effect of self-disclosing of the autism diagnosis on these processes.

Objectives: We aimed to investigate whether knowing that a person is autistic changes empathy and social interest towards them.

Methods: We used a modified version of the Empathic Accuracy (EA) paradigm: An autistic adult was video-recorded, sharing an autobiographical story. They were then asked to continuously rate their feelings whilst watching their own video, using a positive to negative rating scale, and to rate the degree to which they felt twelve specific emotions. Study 1 comprised psychology, education, or social-work students (n=101; Mage=24 (SD=3.2), 70% female). Participants were randomly assigned to one of two conditions: watching the autistic storyteller's video following an introduction in which the storyteller disclosed their autism diagnosis (self-disclosure condition); or an introduction whereby they did not disclose their autism (no-disclosure condition). While watching the video, participants rated how positive or negative they believed the storyteller felt on an identical continuous rating scale. They also rated the degree to which they believed the storyteller felt each of the twelve emotions. Measures of EA were derived from the concordance between the storyteller's and perceivers' ratings for both the continuous and the specific emotion ratings. Perceivers were also asked to report the degree to which they felt empathy towards the storyteller and whether they were interested in hearing more or meeting them. In Study 2, we used the same procedure with a sample of STEM students (n=102; Mage=25 (SD=3.2), 41.2% female). In addition, we asked the participants to what degree they would like to work with the storyteller if they were offered to perform a task together.

Results: Study 1 - Participants in the self-disclosure condition performed better in the specific-emotions EA measure (t(97.91)=2.6, p=.01, d=0.52), but not in the continuous EA measure. They reported more empathy (t(79.89)=3.34, p=.007, d=0.66), interest in hearing more (t(79.90)=3.82, p=.001, d=0.76), and meeting the storyteller (t(79.63)=3.62, p=.002, d=0.72). Study 2 - results for the EA measures were replicated, with better specific-emotions accuracy in the self-disclosure condition than in the no-disclosure condition (t(100)=1.69, p=.04, d=0.33), and no significant difference in the continuous measure. Self-reported empathy was approaching significance (marginal), (t(100)= 1.55, p=.06, d=0.31). No differences were found for wanting to hear more or meeting the storyteller. However, participants in the self-disclosure condition reported significantly more interest in working with the storyteller compared with participants in the no-disclosure condition (t(100)=4.59, p=.001, d=0.91).
Conclusions: The results indicate that typical people are more empathic towards autistic people who self-disclose their autism. The effects of autism self-disclosure on social interest of the perceivers and self-reporting their empathy are complex and depend on the characteristics of the perceivers. Greater interest following self-disclosure was found in both studies but was expressed differently in those studying psychology, education, or social-work and in those studying STEM. A better understanding of these social processes may help address autism self-disclosure in social, clinical, and educational settings.

437.351 (Poster) Understanding Camouflaging and Identity in Autistic Children and Adolescents Using Photo-Elicitation
S. J. Howe, C. McMorris, L. Hull, F. Sedgewick and B. Hannon, (1)University of Calgary, Calgary, AB, Canada, (2)Department of Paediatrics, University of Calgary, Calgary, AB, Canada, (3)Population Health Sciences, University of Bristol, Bristol, UNITED KINGDOM, (4)University of Bristol, Bristol, United Kingdom, (5)Cambridgeshire & Peterborough NHS Trust, Cambridge, United Kingdom

Background: Although autistic children and adolescents are known to be at heightened risk for experiencing anxiety, depression, and suicidality, it is unknown what factors may contribute to the development and maintenance of these mental health issues. Camouflaging, or the use of strategies by autistic people to hide the visibility of their autistic traits in social situations, is associated with stress, autistic burnout, depression, and suicidality among autistic adults. However, little is known about how autistic children and adolescents experience camouflaging. Hence, understanding of what cognitions and behaviors related to camouflaging may develop and what the early developmental stages of camouflaging may look like.

Objectives: The present study filled this significant knowledge gap by examining camouflaging behaviour among autistic children and adolescents using a photo-elicitation approach.

Methods: Photo-elicitation was used to actively engage children and adolescents in the research process, and to assist participants in sharing their thoughts/perceptions on camouflaging through photography. Seven autistic children and adolescents aged 10 to 14 years (M = 11.57, SD = 1.81) attended an orientation session and were given two to three weeks to take photographs in response to the topic of camouflaging and prompts provided. Individual interviews were conducted with each participant to discuss their most meaningful photos. Additional data collection is currently underway. Preliminary reflexive thematic analysis (Braun & Clarke, 2006) was used to identify major themes within interview data, and an interpretive engagement framework (Drew & Guillemin, 2014) was used to analyze participant images.

Results: Preliminary qualitative analysis identified 13 themes. Camouflaging was perceived by autistic children and adolescents to be a response to negative social experiences, as well as a learned habit that was often unconscious and difficult to stop. Context was important for determining when children and adolescents would camouflag. For example, the company (e.g., friend, family, pet) as well as the activity were important contextual factors. While some autistic children and adolescents camouflaged by suppressing their natural autistic behaviours in social situations (e.g., self-stimulatory behaviour), many camouflaged by generally hiding their authentic selves (e.g., their interests, emotions, and opinions) from others. Camouflaging behaviour was reported as a result of internal conflict, stress, and a need for time alone to recharge.

Conclusions: Initial results from this qualitative study highlight that autistic children and adolescents do engage in camouflaging behaviours. However, compared to autistic adults, there are likely developmental differences in the behaviours and strategies employed by autistic children and adolescents to camouflage. For instance, while research suggests that autistic adults often camouflage to gain positive outcomes (e.g., friendship, employment), the children and adolescents in this study solely spoke about the negative consequences of camouflaging. Camouflaging was reported to be a stressful, confusing, and an energetically draining experience for autistic children and adolescents. Better understanding of the development and experience of camouflaging in childhood can inform prevention of mental health concerns in adulthood.

437.352 (Poster) Understanding the Relationship between Camouflaging Intent and Indicators of Social, Employment, and Mental Health Outcomes

Background:

Many autistic people desire friendships, romantic relationships, and employment and use camouflaging (i.e., specific strategies and behaviours that reduce the visibility of autism characteristics and/or social difficulties) in pursuing these. Currently, it is not known if camouflaging intent (i.e., self-reported engagement in camouflaging) is associated with social and employment outcomes. Yet camouflaging is consistently associated with mental health difficulties. In seeking to improve the lives of autistic people, it is important to develop a holistic understanding of how camouflaging affects multiple life domains including social, employment, and mental health outcomes.
Objectives:

The current study examined (1) relationships between camouflaging intent and indicators of friendship, relationship, and employment outcomes, (2) relationships between camouflaging intent and indicators of mental health difficulties (i.e., symptoms of depression, anxiety, and stress) and psychological distress (i.e., feelings of loneliness) and (3) sex/gender differences in these relationships.

Methods:

430 autistic adults with formal diagnoses completed an online battery of questionnaires. Participants self-reported on their (a) camouflaging intent (Camouflaging Autistic Traits Questionnaire [CAT-Q]); (b) depressive, anxious, and stress symptoms (Depression, Anxiety, and Stress Scale – 21 Items [DASS-21]); (c) feelings of loneliness (University College of California, Los Angeles Loneliness Scale Short Form [ULS-8]); (d) friendships (items on number of friends, close friendship status, close friendship length); (e) social isolation; (f) relationships (items on relationship status and length); and (h) employment (items on employment status and length). In order to better characterise the sample, participants also self-reported demographics and autistic traits (Autism Spectrum Quotient-10 items [AQ-10]). A series of hierarchical linear and nested logistic regressions were conducted to examine the relationship between camouflaging intent and dependent variables. Control variables were selected based on past research as well as statistical relationships in the current data set. In all models, $p < .005$ was considered significant and $p$ values between .05 and .005 as suggestively significant.

Results:

Camouflaging did not predict number of friends, close friendship status, close friendship length, social isolation, relationship length, employment status, or employment length. Higher levels of camouflaging intent were associated with an increased likelihood of being in a relationship after controlling for age, sex/gender, and autistic traits. Higher levels of camouflaging intent were also associated with increased depressive, anxious, and stress symptoms as well as feelings of loneliness, after controlling for age, sex/gender, and autistic traits.

Conclusions:

Owing to the cross-sectional nature of the current study, casual relationships cannot be established. However, camouflaging was not consistently associated with the achievement of social and employment outcomes yet was associated with symptoms of mental health difficulties. Thus, interventions explicitly teaching or encouraging camouflaging type behaviours and strategies (e.g., some social skills programmes) may not help autistic people to achieve their psychosocial goals or promote their wellbeing.

437.353 (Poster) Well-Being Among Autistic and Non-Autistic People with Intellectual Disability during the COVID-19 Pandemic

T. Sellitto, J. Fraser-Thomas; R. L. Bassett-Gunter; V. Lee; Y. Lunsky; R. Balogh and J. A. Weiss, (1)Psychology, York University, Toronto, ON, Canada, (2)School of Kinesiology and Health Science, York University, Toronto, ON, Canada, (3)Psychology, Carleton University, Ottawa, ON, Canada, (4)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)Faculty of Health, University of Ontario Institute of Technology, Oshawa, ON, Canada

Background: There is evidence to suggest that the COVID-19 pandemic has disproportionately impacted vulnerable populations, including individuals with intellectual disability (ID; Lunsky et al., 2022), with many people with ID struggling with numerous COVID-19-related stressors, as well as poorer mental health (Amor et al., 2021; Embregts et al., 2020; Lunsky et al., 2022a; Rosencrans et al., 2021). Less is known, however, about the impact of the pandemic specifically on autistic people with ID. Autistic people often experience more challenges with socio-communicative skills (Shattuck et al., 2011), changes to routine, and coping with stressors (Gillott & Standen, 2007) compared to non-autistic peers, which may have resulted in a greater negative impact of the pandemic on this group. Given that well-being is more than just the absence of mental health problems (Keyes, 2002), it is important to understand how the pandemic has impacted both positive (e.g., thriving) and negative (i.e., mental health problems) aspects of well-being.

Objectives: To examine potential group differences in the experiences of COVID-19-related stressors, mental health problems, and thriving in autistic people with ID compared to non-autistic people with ID.

Methods: An online survey was completed by 168 caregivers of youth and adults between 12 and 35 years of age ($M = 24.46, SD = 5.35$; 63% male) with a diagnosis of autism and ID ($n = 57$) or ID only ($n = 108$) in Ontario (Canada). Caregivers completed questionnaires on the impact of COVID-19-related stressors (adapted version of the Epidemic Pandemic Impacts Inventory; Grasso et al., 2020; Morris et al., 2020) for the youth or adults, as well as their experience of mental health problems (Strengths and Difficulties Questionnaire; Goodman, 1997) and thriving (Six Cs of Positive Youth Development; Lerner et al., 2005).

Results: Independent sample t-tests revealed that non-autistic people with ID experienced significantly lower levels of mental health problems ($p < .001$) and higher levels of thriving ($p < .001$) compared to autistic people with ID. There was no significant difference in the impact of COVID-19-related stressors among non-autistic people with ID compared to autistic people with ID ($p > .05$). Research is ongoing to identify the correlates of thriving and mental health problems among autistic and non-autistic individuals with ID.
Conclusions: Our findings suggest that autistic people with ID experience similar rates of COVID-19-related stressors compared to non-autistic peers with ID, however, they seem to also experience lower levels of well-being. Future research is needed to determine the individual and ecological factors that may explain the differences between these two groups, in the experience of well-being within the context of the pandemic, to help inform interventions and promote well-being among autistic individuals with ID.

437.354 (Poster) What Is it about Camouflaging That Is so Harmful to Autistic Adults?
R. Wu, T. Markandaier and S. J. White, (1)University College London, London, United Kingdom, (2)UCL Institute of Cognitive Neuroscience, London, United Kingdom

Background: In the context of autism research, camouflaging is defined as conscious or subconscious coping strategies and techniques used to minimize the visibility of autistic characteristics and to appear socially competent in a predominantly “non-autistic social world”, despite the persistent existence of cognitive difficulties (Cook et al., 2021; Lai et al., 2011). Three types of strategies have been identified: compensation, masking, and assimilation (Hull et al. 2019). While both autistic and non-autistic people are observed to employ these behaviors, only a few studies attempt to understand the differences between these two groups (Cook et al., 2021). One difference is that the outcome of camouflaging can be more negative for autistic people (Hall et al., 2017; Lai et al., 2017; Keating et al., 2021). Camouflaging is related to stress, mood and self-esteem levels; higher frequency of strategy recruitment, lower rates of success, higher effort to keep up the façade, and greater fatigue may compromise mental health (Ai et al., 2022; Lai et al., 2011; Schneid & Raz, 2020). Nevertheless, it remains unclear what it is about camouflaging that is toxic to the mental health of autistic people.

Objectives: This study was designed to investigate what aspect of camouflaging is particularly harmful to autistic adults by adapting an existing questionnaire measuring social camouflaging behavior, the Camouflaging Autistic Traits Questionnaire (CAT-Q; Hull et al, 2019). To achieve this, four dimensions were added to each camouflaging strategy: frequency, success, effort, and fatigue. Each dimension was rated on a 1-7 scale with an additional "N/A" (i.e., not applicable) option for occasions when strategies were not employed.

Methods: Sixty autistic and sixty non-autistic adults aged between 18-35 (M=25.40, SD=4.11) completed the modified version of the CAT-Q, and the Hospital Anxiety and Depression Scale, a valid and reliable self-report measure to identify the severity of anxiety and depression (Martin, 2005).

Results: The results supported observations that autistic individuals recruit more strategies than non-autistic individuals (Hull et al., 2018). It also determined that autistic camouflagers do so at a higher frequency (i.e., a few times a week), with greater effort and fatigue; however, the subjective success of recruiting these strategies was similar to non-autistic camouflagers. The differences between the two groups were greater for measures describing exertion during and after camouflaging (i.e., effort and fatigue) compared to how often or well the strategies were used (i.e., frequency and success). However, it is the frequency of camouflaging, rather than the exertion felt, that is shown to predict anxiety scores in autistic adults.

Conclusions: Camouflaging involves much greater effort and results in much greater fatigue in autistic adults, but it is the frequency of camouflaging that appears to lead directly to anxiety in autistic adults – the more often you camouflag, the greater your anxiety. This study therefore provides a first step towards understanding the relationship between camouflaging and mental health. This knowledge has the potential to help autistic people make informed choices about how they navigate their social environment while maintaining psychological well-being.

C. A. McGregor1, E. Von Dem Hagen2, J. Dobbs2, C. Wallbridge1 and C. R. Jones2, (1)Wales Autism Research Centre, School of Psychology, Cardiff University, Cardiff, United Kingdom, (2)Centre for Artificial Intelligence, Robotics and Human-Machine Systems (IROHMS), Cardiff University, Cardiff, United Kingdom, (3)Cardiff University Brain Research Imaging Centre (CUBRIC), School of Psychology, Cardiff University, Cardiff, United Kingdom

Background:

As autism research integrates new technological advancements, human-robot interaction (HRI) is becoming increasingly common in studies. Humanoid robots are also being utilised in educational and therapeutic settings to support autistic children. However, experiences such as anxiety (MacNeil et al., 2009), intolerance of uncertainty (Hodgson et al., 2017), and sensory sensitivities (Leekam et al., 2007) can make meeting a humanoid robot a difficult experience for some autistic children. Within the research field, participant withdrawal (Short et al., 2017) is not uncommon. However, there are no agreed methods on how to successfully introduce autistic children to humanoid robots. Establishing methods that work should increase autistic children’s access to clinical or educational opportunities, and improve their representation in relevant research.

Objectives:
To assess the effectiveness of a set of introduction methods (‘familiarisation modules’) based on a systematic review of existing techniques (Wallbridge et al., In Review), the methods aim to help autistic children feel comfortable with meeting a humanoid robot.

**Methods:**

Fourteen autistic children (2 female) aged 4-11 years (M=8 years; SD=1.73 years) and their parents took part in the study. Phase 1 involved online semi-structured interviews with the parents. The parents were introduced to four familiarisation modules: Pre-Familiarisation, Extended Introduction, Stimulus and Response, and Static Exploration. Each module involved at least one activity aimed at increasing familiarity with a humanoid robot. Parents discussed how effective they thought each module would be and whether they had any suggested modifications or preferences. Transcripts were analysed using thematic analysis (Braun & Clarke, 2021).

Phase 2 involved the parents and children visiting the lab. Each child was introduced to a humanoid robot (NAO; SoftBank Robotics) using the four familiarisation modules in a set order. After completing all the modules, the children were interviewed about how much they liked the robot and the modules. Their parent observed the familiarisation process through a two-way mirror and rated their child’s comfort levels and enjoyment after each module using Likert scales. They were also given a semi-structured interview to provide a more detailed account of how they thought their child responded to the robot. As with Phase 1, this was transcribed and analysed thematically.

**Results:**

Preliminary analysis shows most parents thought that the Stimulus and Response module, in which the child and robot participate in an interactive activity, was the most effective module for helping their child feel more comfortable around the robot. Many parents also felt that the modules needed to be longer to achieve better familiarisation. Most children said they would be happy to play with the robot again, and parents’ Likert scales indicated that children were more comfortable around the robot after experiencing the modules.

**Conclusions:**

Preliminary findings indicate that our familiarisation modules, which were informed by a systematic literature review, were an effective tool for introducing autistic children to humanoid robots. Interactive activities may be a particularly important part of the process. Further research is needed to compare the use of our familiarisation modules to less systematic approaches to introducing autistic children to humanoid robots.

**437.356 (Poster) “If I Do This, He’ll be My Boyfriend”: Transactional Thinking in Autistic Female Sexuality**  
L. A. Pecora', M. A. Stokes', M. Hooley', G. Mesibov', T. Attwood', G. Hancock' and D. Demmer', (1)School of Psychology, Deakin University, Melbourne, VIC, Australia, (2)Deakin University, Burwood, VIC, Australia, (3)Psychology, Deakin University, Burwood, VIC, Australia, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)School of Applied Psychology, Griffith University, Queensland, QLD, Australia, (6)Deakin University, Burwood, Australia, (7)School of Psychology, Healthy Autistic Life Lab, Deakin University, Melbourne, VIC, Australia

Background: Autistic females present with a profile marked by a mismatch between sexual interest and experience, increased engagement in unwanted sexual behaviours, and elevated risks to sexual victimisation. The factors underlying sexual behaviour engagement and increased vulnerabilities are poorly understood.

**Objectives:** To identify the motives underlying increased sexual behaviour engagement and mechanisms behind greater sexual vulnerability among autistic females.

**Methods:** 381 adults (134 autistic females; 161 non-autistic (N-ASD) females; 96 autistic males) completed the Sexual Behaviour Scale-III (SBS-III) online.

**Results:** Despite expressing a shared interest in romantic relationships with both N-ASD females and autistic males, autistic females were more likely to endorse transactional processes when describing their motives behind sexual behaviour than N-ASD females (OR=4.18; p<.01), and autistic males (OR=2.14; p<.01); and were more likely to endorse transactional behaviours to initiate relationships than N-ASD females (OR=1.74; p=.05). Autistic females, and transgender individuals were also more likely to endorse sexual, over financial transactional behaviours as a means of relationship formation than autistic males (OR=6.53; p<.001) and cisgender counterparts, respectively (OR=4.20; p<.001).

**Conclusions:** Within autism, sexual interactions may be driven by transactional, rather than the socially reciprocal exchange processes seen in the N-ASD group. This includes a perception that relationship development may be attained via sexual behaviours among autistic females and transgender adults, yet through the provision of financial or material items among autistic males. It is important to further explore transactional exchange processes within autism, to inform sex specific education to support the development of positive strategies to facilitate meaningful relationships.
Background:

Previous research highlights the wide-ranging difficulties that autistic children and young people experience in mainstream education. There are a number of areas where children are not being optimally supported and face challenges to learning. These include negative relationships with staff, difficulties with the school sensory environment, peer relationships, and increased likelihood of bullying and subsequent effects on mental health and self-esteem. While there is a growing body of research in the areas identified above, there is a dearth of literature understanding these difficulties from the child’s perspective. Therefore, the current study aimed to understand barriers to learning and support from children themselves. It is crucial that researchers are aware of the multidirectional relationship between these areas, and how they influence each other, in order to improve the school experience and well-being for autistic pupils.

Objectives:

The aims of the research were to investigate the school experiences and well-being of autistic pupils in mainstream secondary schools. The research focused on

1. Experiences with teachers and support staff.
2. Experiences with friends and peers.
3. Experiences with the classroom and school environment.
4. General feelings towards school and well-being.

Methods:

A total of 15 participants, aged 11-18 years were recruited for this study (10 = male, 4 = female, 1 = non-binary). 13 participants had received a clinical diagnosis, and 2 participants were self-diagnosed and seeking a clinical diagnosis. Data was collected using a mixed-methods online survey. This consisted of 10 multiple choice questions and 13 requiring written responses. The survey was advertised via social media (Facebook and Twitter). Thematic analysis was used to analyse the data, following the six phases of analysis proposed by Braun and Clarke (2006).

Results:

Three main themes were identified from the data through analysis: 1) support and challenges to learning, 2) contributing and mitigating factors to well-being, 3) experiences of friendship and bullying. Each theme comprised of several subthemes. In the first theme participants described barriers to their learning, current strategies implemented by their teachers, and other adjustments they deemed would be helpful to them in school. In the second theme, participants reported struggles with anxiety and low confidence, however also shared similar sources of happiness including their friends and family. In the last theme “experiences of friendship and bullying”, participants discussed their experiences of friendship and relationships with peers, both positive and negative.

Conclusions:

This study adds to the existing literature surrounding the school experiences of autistic pupils and their well-being in mainstream secondary schools. The study found identified overlapping experiences between participants in terms of the impact school on aspects of wellbeing such as bullying and the sensory environment, as well as suggestions for strategies implemented to implement in schools. The results highlight the need for changes in the ways that mainstream schools support and include autistic pupils, and the to provide training for staff to better support pupils learning and well-being.

Background:

Existing literature on social communication in autism primarily focuses on the communication difficulties between autistic and non-autistic people, presenting this as an autistic ‘impairment’. However, recent research – which has found highly successful social communication
between autistic people – suggests this may not be an accurate framing. Instead, it may be that autistic people have a communication style
that is incompatible with non-autistic people’s, but compatible with other autistic people’s.

What features might define this communication style, and what might cause the differences between it and a non-autistic one, are currently
unclear. Improving our understanding of this autistic communication style may help improve communication between autistic and non-
autistic people.

Objectives:

Primarily, to explore autistic people’s experiences of social interaction and communication, and their preferences for this – with a focus on
differences between interactions with other autistic versus non-autistic people. Secondarily, to gather autistic feedback on a list of ‘autistic
social values’ derived from the thematic analysis of a previous, similar focus group.

Methods:

9 autistic adults (9W, 1NB; mean age = 43, range = 23-58) without intellectual disabilities took part in an online, forum-style focus group
for two weeks. The primary topics were: (1) what people consider their ‘social values’ to be (e.g. their rules/expectations around
communication), (2) what they found frustrating about interacting with non-autistic people, (3) what ‘positive social interactions’ looked
like for them, (4) anything else they wanted to say on the topic, and (5) thoughts/opinions on a list of ‘autistic social values’ produced by
the researcher from a previous focus group. The fifth topic was introduced a week into the group, to minimise influence on other responses.

Results:

Thematic analysis of the focus group is ongoing, but the following themes are indicative:

- Managing Social Energy: autistic people often have limited social energy, and managing/rationing this in social situations can be
challenging.
- Sources of Anxiety: there are many sources of anxiety for autistic people in social interaction, including transitions, uncertainty,
the risk of upsetting or offending people, or being bullied.
- Frustrations with Non-Autistic People: non-autistic people’s insistence on doing things a certain way, and inability to consider
autistic perspectives, is frustrating.
- Differences in Empathy: things that may be kind and empathic from a non-autistic perspective may not be from an autistic
perspective. There is a mutual lack of understanding.
- Importance of Community: being around other autistic people is important for self-understanding and wellbeing.

Next steps include further development and finalisation of these themes through a second round of analysis. The completed analysis will be
presented at INSAR.

Conclusions:

Autistic adults have different expectations and desires around social interaction and communication. This is driven, at least in part, by
different social, communicative, and emotional needs. These differences can make interacting with non-autistic people difficult and
stressful for autistic people, and contribute to miscommunication between neurotypes. More work is needed to fully understand a) what
defines the autistic communication style, and b) how to best bridge the gap between autistic and non-autistic communication styles.

437.359 (Poster) Mentalizing Skills, but Not Autism Diagnosis, Predict Indirect Request Interpretation
F. Frost, E. Zane, M. Nagano and G. R. Timler, (1)Communication Sciences and Disorders, James Madison University, Harrisonburg,
VA, (2)Communication Sciences and Disorders, Long Island University | Brooklyn, Brooklyn, NY

Background: Indirect request forms fall into two categories: conventionalized and non-conventionalized. Conventionalized forms (“Can
you turn on the heater?”) require little inferencing to be interpreted as requests, whereas inferencing is required to interpret non-
conventionalized forms (“I’m cold.”). Previous research suggests that autistic adults can successfully interpret indirect requests (Deliens et
al., 2018), but this research focuses on conventionalized forms. There is reason to suspect findings would differ for non-conventionalized
requests: Recent evidence from non-autistic adults shows that those who score lower on mentalizing tasks are less able to infer if an
utterance is a request based on context (Trott & Bergen, 2018; 2020). Given that autistic individuals commonly score lower on mentalizing
tasks (e.g., Baron-Cohen et al., 2001), autistic adults may show less accurate performance in their interpretation of non-conventionalized
requests.

Objectives: To compare the performance of autistic versus non-autistic adults on a non-conventionalized request task.

1235
Background: Autistic individuals identify difficulties expressing emotions to others as a barrier to effective social communication. This is consistent with research indicating that autistic individuals present with a muted range of facial expressiveness relative to neurotypicals. However, growing literature portrays a more nuanced picture. Recent evidence suggests that autistic individuals’ facial affect may vary across contexts (solitary vs. social; elicited vs. spontaneous), making it important to research differences in affective presentations across situations. For example, emerging data indicate that autistic individuals produce more intense spontaneous expressions in monadic (solitary) situations than their neurotypical peers, despite the fact that reduced facial affect is typically considered a prominent autism marker. Research is needed to directly compare affective presentations in non-social contexts, using experimental methods that can effectively evoke and measure a range of spontaneous facial expressions. In response, this study develops and tests a novel “Monadic” emotion elicitation battery and analyzes expressions using precise computer vision methods.

Objectives: To test the ability of our Monadic battery to elicit spontaneous facial expressions in autistic individuals in a solitary context; To use computer vision analysis to characterize and compare facial expressions across a neutral task, a frustrating task, and viewing of humorous videos.

Methods: The present project is recruiting 60 participants by May 2023; data collection so far consists of 17 autistic 12–17-year-olds, of whom 13 provided evaluable data (see Table 1). The Monadic Protocol is comprised of three computerized tasks that participants complete independently. The “neutral” task is watching a brief video (“inscapes/INS”) chosen for its affectively-neutral visuals in order to obtain a resting facial state. The “humorous” task consists of watching two videos (“bubbles/BUB” and “lemon/LEM”) chosen to evoke positive emotion (i.e., a child and dog playing with bubbles and an infant eating a lemon slice, respectively). The “frustration” task (“block task/BT”) required participants to quickly identify the smallest of three rectangles over 50 trials, while randomly “freezing” mid-trial in order to evoke mild negative emotion (frustration). Facial video was recorded during each task at 4K resolution and 30 frames per second. Videos were analyzed with OpenFace (an open-source software) to capture facial action units, then processed frame-by-frame for affect summary variables using our in-house Python Biological Motion Capture toolbox. Expression magnitude was characterized by the area under the curve over time during each video, with separate averages for neutral, positive, and negative emotion expressions. Wilcoxon one-sample tests were used to compare the presence of milder negative emotions across tasks.

Results: As predicted, BT elicited more angry \( (p<0.05) \), sad \( (p>0.01) \), and fearful \( (p<0.05) \) expressions than INS, and BUB elicited more happy expressions than INS \( (p<0.05) \). LEM also elicited significantly more happy expressions than INS \( (p<0.05) \).

Conclusions: This study supports the validity of the Monadic battery’s ability to evoke a range of spontaneous facial expressions in autistic youth. With the full sample, we propose to examine how individual difference variables such as anxiety and emotion regulation ability

437.360 (Poster) Methodological Advances in Evoking and Measuring Spontaneous Facial Expressions in Autism

Conclusions: Mentalizing scores, but not autism diagnosis, predict how adults infer whether an utterance is a request. Findings suggest that autistic adults are successful at interpreting non-conventionalized requests. This may be due to both groups having comparable mentalizing skills, perhaps because the autistic group’s skills are fully developed by adulthood. Future research should compare how autistic children and adolescents compare to their non-autistic peers on a similar task.
Background: A large literature documents atypical gaze in individuals with autism. Many different visual features appear to contribute to this finding, including atypical center bias, atypical gaze onto faces, objects of joint attention, or biological motion. The heterogeneity of visual features that might drive atypical gaze is revealed by large individual differences in participants. These challenges are compounded when measuring gaze to videos, where rich sets of features change continuously. This has made it difficult to quantify robust gaze differences at the group level (autism vs. controls).

Objectives: Here we aim to comprehensively quantify the visual features that drive gaze differences over time between autistic (ASD) and control (CTL) groups, as well as within each population. We developed a novel method to quantify the between- and within-group variability of gaze trajectories across a naturalistic video stream decomposed into three levels of visual features (low-level, object-level, and semantic-level).

Methods: 20 typically developed CTL participants with no family history of autism (3 females, age = 32.2 ± 5.5) and 10 ASD participants with a DSM-5 diagnosis of ASD (2 females, age = 29.8 ± 5.4) who met criteria on the ADOS-2 (module 4) were recruited. All participants had normal-range IQ and corrected-to-normal visual acuity. In a well-controlled lab environment, participants watched 18 diverse short-sounded youtube videos (length = 79.0s ± 22.0s) while eye-tracking data was collected (Tobii TX 600). To quantify the variability of gaze patterns over time, we applied a novel method - dynamic trajectory variability analysis (Fig 1). We constructed trajectory dissimilarity matrices (TDM) over sliding time windows between all pairs of individuals watching the same video segment, using dynamic time warping. Every TDM was subsequently decomposed (and averaged) into 3 parts: variability between ASD and CTL (var_diff), variability within CTL (var_ctl), and variability within ASD (var_asd). We then ran a linear regression model predicting each of the 3 types of variabilities with three levels of video features (calculated for each frame). Low-level features include the entropy of Itti-Koch saliency maps (color, intensity, orientation); object-level features include the existence of 13 common object categories; semantic-level features include four measurement of face information (number, average size, max size, total size).

Results: Our regression analysis quantified the effects of visual features in the video on the variability in eye gaze, within each participant group as well as between groups (Fig 2). Consistent with prior work, we found that all three types of variability can be substantially explained by video features (R^2_var_diff = 0.346, R^2_var_ctl = 0.358, R^2_var_asd = 0.241), but that effects were distributed across visual features, essentially producing a multivariate “fingerprint” that characterized how the features in the video influenced variability in eye gaze.

Conclusions: Dynamic trajectory analysis provides a principled and powerful tool to decompose eyetracking data to videos. Our code will be fully shared, can be used in future investigations with larger sample sizes to better understand the visual features that distinguish atypical gaze in autism, and may provide a basis for identifying possible subtypes.

Background: The Frankfurt Early Intervention Program (A-FFIP) is a naturalistic developmental behavioral intervention (NDBI) that trains autism-specific developmental targets in the preschool age at a low intensity of two times per week. Eye-tracking measures have been established as independent indices of outcome evaluation. Joint attention is an early indicator of different socio-communicative development that can be objectively quantified in eye-tracking. Pupillary response is an index of neurophysiological reactivity that is discussed as a potential biomarker of different sensory processing.

Objectives: We wanted to investigate direct effects of the A-FFIP intervention on eye-tracking measures of joint attention and an associated pupillary response as a biomarker of change.
Methods: Autistic preschoolers were assessed longitudinally at baseline (T2, n=51), after 6-months of A-FFIP (T4, n=44), and after 12-months of A-FFIP (T6, n=31). This was compared to baseline assessments in developmentally matched neurotypical controls (K, n=44). Joint attention is quantified with an established video paradigm (i=16), in which a protagonist induces reactive joint attention (RJA) to displayed objects by non-verbal cueing. Each video starts with a fixation cross for 1s, before a protagonist’s direct camera gaze for 3s. Next, protagonist’s cueing is displayed for 6s. We define RJA as a participant’s gaze sequence from the protagonist’s head to the cued object within 0.5s. We compared the likelihood to RJA between groups (K, T2, T4, T6) in generalized multilevel mixed models on a per-trial level. We further modelled pupillary response as a 6-degree polynomial to investigate dynamic group differences between groups within the video scenes.

Results: Group differences (F(3,1478) = 12.68) were described by a higher RJA likelihood in K compared to T2, T4, T6 (all βs > 1.07 [0.38; 1.76]). Importantly, a putative intervention effect was observed with a higher RJA likelihood in T6 compared to T2 (β = 0.55 [0.05; 1.05]), which translates to a 72% increased likelihood to show RJA after versus before intervention (figure 1A). The putative intervention effect is driven by increased RJA after cueing onset (β = 0.67 [0.16; 1.19]) compared to premature RJA before cueing onset (β = -0.55 [-1.27; 0.17]) (figure 1B). Across groups, pupillary responses after cueing onset (and not before cueing onset) were positively associated with RJA likelihood (β = 0.21 [0.07; 0.34]). Between groups, pupillary responses for three seconds after cueing onset were higher in T6 compared to T4 (βs = 0.02 – 0.06) and T4 compared to T2 (βs = 0.06 – 0.14, figure 2).

Conclusions: Findings are limited as therapy effects are confounded with developmental effects that are, however, unlikely to be of this magnitude (+72% RJA increase). Thus, the A-FFIP program is probably associated with an increased likelihood to exhibit joint attention after 12-months of intervention. This is observed in an objective measure unrelated to intervention content and explained by an improved utilization of social cueing. Increased pupillary responses after cueing onset are associated with RJA and could reflect increased neurophysiological responsivity to social cueing as an underlying mechanism, which is proposed as a biomarker of change in response to intervention.

Objectives: To examine the neural, cognitive, and behavioral characteristics of compensation in children diagnosed with ASD, ADHD, and TD.

Methods: Participants (N=74) included 7-11 year-olds with WASI-2 Full Scale IQs of 80 or above and an ASD diagnosis (n=53; ADOS-2, ADI-R, DSM-5), ADHD diagnosis (n=10; Connors, CBCL, DSM-5), or TD (n=11; DSM-5, CBCL). Participants completed the Social Attribution Task-Revised (SAT-R), which produced open-ended narratives that were coded for spontaneous ToM; the Stop-Change Task, which yielded stop-signal reaction times (SSRTs) as a measure of response inhibition; and the Go-Nogo task, which produced N2 and P3 ERP amplitude and latency in the No-go condition as neural measures of conflict monitoring and inhibition. Caregivers completed the Social Responsiveness Scale (SRS) as a measure of social autistic traits (Social Communication Index [SCI]) and the Behavior Rating Inventory of Executive Function (BRIEF) as a measure of real-world behavioral regulation (Behavioral Regulation Index [BRI]). Participants were split on the TD SAT-R median, creating groups with higher ToM (>3) and lower ToM (≤3), and the clinical cutoff for SRS SCI, forming groups with higher social autistic traits (>59) and lower social autistic traits (≤59). The High Compensation (N=14) and Low Compensation (N=29) groups were compared (Figure 1). Given observed age differences, ANCOVAs controlling for age were conducted.

Results: Relative to Low Compensators, High Compensators had larger N2 and P3 amplitudes in the No-go condition of the cued ERP Go-Nogo task, indicating increased strength in neural conflict monitoring (N2: p=.01, F=7.15) and inhibition (P3: p=.002, F=11.57); shorter SSRTs in the Stop-Change Task, indicating increased response inhibition (p=.03, F=5.25); and lower BRIEF BRI scores, indicating fewer real-
world behavioral regulation difficulties ($p=.009$, $F=7.52$). The proportions of Compensation group membership did not differ by DSM diagnosis ($p=.26$, $\chi^2=4.02$); High Compensation (ASD: $n=9$, ADHD: $n=2$, TD: $n=3$) and Low Compensation (ASD: $n=25$, ADHD: $n=2$, TD: $n=2$) groups included children across diagnostic categories.

Conclusions:

We found evidence suggesting the neural, cognitive, and behavioral transdiagnostic profile of compensation among children with low social autistic traits despite poor spontaneous ToM. In line with a developmental psychopathology theoretical framework, results suggest compensation should be conceptualized as transdiagnostic resilience seen across ASD, ADHD, and TD and measured with multiple levels of analysis (brain, cognition, and behavior).

437.364 (Poster) Non-Autistic Adults Recognize Autistic Adults’ Emotional Expressions Better Than Non-Autistic Adults’.

A. J. Lampi, R. Brewer, G. Bird and V. K. Jaswal1, (1)Psychology, University of Virginia, Charlottesville, VA, (2)Department of Psychology, Royal Holloway, University of London, Egham, United Kingdom, (3)University of Oxford, Oxford, United Kingdom

Background: Autistic people’s emotional expressions are often misunderstood by non-autistic people, something autistic people describe as detrimental to their well-being. Few studies, however, have investigated how well non-autistic adults recognize autistic adult’s posed emotional expressions, and none, to our knowledge, with a large sample.

Objectives: In three studies we investigated non-autistic participants' recognition of autistic and non-autistic people’s posed emotional expressions, and the factors that contribute to accurate recognition of those expressions. Studies 1 and 2 asked whether non-autistic adults better recognize the facial emotional expressions of autistic or non-autistic adults, and whether performance on this task depends on the amount of time participants can view the stimuli. Study 3 asked what attributes of the faces used in Studies 1 and 2 led to them being correctly recognized.

Methods:

In Study 1, 371 non-autistic participants viewed photos of 12 autistic and 12 non-autistic posers in each of six emotional expressions (anger, disgust, fear, happiness, sadness, and surprise). They were asked to decide which of the six emotions was shown on each face. Faces remained visible until participants made their selection.

In Study 2, 159 non-autistic participants completed a task similar to that in Study 1, but either in a timed or untimed condition. In the timed condition, participants could view each face for only 800ms before making their decision about what emotion was depicted. The untimed condition was a replication of Study 1.

In Study 3, 166 non-autistic participants saw the same stimuli in Studies 1 and 2, were told the emotion it was meant to convey, and were asked to rate each expression for how awkward, posed, good and intense each expression was.

Results: Figure 1 shows the results of Study 1. As the figure shows, autistic faces were recognized significantly more accurately for all emotions except for happiness, $F(5, 4070) = 18.79, p < .001$. Study 2 found this advantage even when participants’ exposure to stimuli was brief (800ms), $F(1, 1883) = 84.18, p < .001$. Finally, Figure 2 shows the results of Study 3. As the figure shows, we found that this advantage in recognition accuracy occurred because non-autistic adults perceived autistic expressions as better and more intense examples of emotion expressions, $F(5, 23693.09) = 27.04, p < .001$; goodness and intensity ratings predicted recognition accuracy from Study 1, $t(135) = 12.32, p < .001$.

Conclusions: We found no evidence to suggest that non-autistic adults have difficulty recognizing the posed emotional expressions of autistic adults. These findings suggest that in-vivo misunderstandings between autistic and non-autistic arise in the more dynamic, naturalistic expression of emotion.

437.365 (Poster) Online Vs. in-Person Autism Research: Same Self-Reported Symptoms, Different Social Behaviors

S. M. Banker, J. Trayvick; S. Barkley*, A. W. Peters, K. Kangas-Dick, S. Na, M. Schafer, D. Schiller, X. Gu and J. H. Foss-Feig, (1)Department of Neuroscience, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center at the Icahn School of Medicine at Mount Sinai, New York, NY, (3)Stony, New York, NY, (4)Stony Brook University, Stony Brook, NY, (5)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (6)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY

Background:
Given the challenges surrounding patient recruitment for in-person research, especially during the COVID-19 pandemic, many researchers have begun utilizing online approaches to assess behavior in individuals with psychiatric illnesses and neurodevelopmental disorders (e.g., Wise & Dolan, 2020). Such remote studies have many benefits, most notably the speed and ease with which one can recruit a large sample, and insight into individuals’ own subjective experiences. However, these studies forego the rigorous in-person clinical characterization of lab-based studies, generally relying solely on self-report questionnaires. Such approaches may limit our ability to appropriately capture disorders with known deficits in metacognitive awareness, including autism spectrum disorder (ASD; McMahon et al., 2016).

Objectives:

In the current study, we aimed to evaluate behavior during social interaction in participants with high ASD symptoms recruited online vs. in-person. In assessing complex social decision-making, such a design allows to gain a deeper understanding of the phenotypes of each group.

Methods:

An in-person sample of ASD patients (diagnosis confirmed with ADOS and DSM by psychologist, n=36) and a large online sample (unselected for any diagnosis, n=632), completed two naturalistic interaction tasks probing complex social behaviors. A computational modeling approach extracted signals of interest based on the trajectory of decision-making in each task. The online sample was divided into the highest and lowest quartiles of self-reported ASD symptoms (Broad Autism Phenotype Questionnaire), and samples of 36 individuals were created from within each quartile to match the clinical sample on age and sex. Group differences in social task parameters were evaluated with ANOVA (3-group, p-values corrected for multiple comparisons with Benjamini-Hochberg procedure); the directions of effects for clinical vs. high-trait groups were determined through post-hoc t-tests (2-group).

Results:

Despite having comparable levels of self-reported ASD symptoms (t=-0.32, p=0.75), the high-trait online and clinical in-person samples differed in their social behavior. In a social interaction game, the clinical group showed lower affiliation tendencies with virtual characters (3-way ANOVA: F=12.14, p<0.001; high-trait vs. clinical t-test: t=-3.33, p=0.001) and higher consistency in interactions that shifted the power dynamics between themselves and virtual characters (3-way ANOVA: F=10.77, p<0.001; high-trait vs. clinical t-test: t=-4.08, p<0.001). In a social monetary exchange task, the clinical group showed lower rejection rates of offers proposed by virtual partners (3-way ANOVA: F=3.71, p=0.028; high-trait vs. clinical t-test: t=-2.03, p=0.042).

Conclusions:

Different patterns in social behavior between the online and clinically ascertained in-person samples highlight the need for differentiation between trait-level and clinically defined groups, as well as the importance of assessing task-related behavior in online studies to help understand the characteristics of the sample.

437.366 (Poster) Pattern of Eyes Fixations Drives Motor Responses and Social Engagement during Gaze Processing in Autism

Background: Many endophenotypes are linked to the development of autism but one of the most reliably replicated early predictor of autism is atypical social engagement and in particular, attenuated eye gaze contact. However, while it has received much attention so far, conflicting theories on the mechanism responsible are questioned whether individual with autism perceive eyes as less salient (due to amygdala hypoactivation) or unpleasant (due to amygdala hyperactivation-mediated arousal) and how that impacts the following behavior.

Objectives: To test how pattern of eye observation of faces with direct or averted gaze involved in social engagement of participants with autism in comparison with individuals without autism in relation to their motor responses and severity of clinical scores.

Methods: As a part of the InFoR cohort, a multi-center French longitudinal study, 88 participants with autism (ASD group) and 56 participants without autism (TD group) performed a gaze discrimination task using colored static pictures of faces with either direct or averted gaze (Figure A). We monitored eye fixation behavior using eye tracking during observation of the face and measured subsequent response times (RT). Also, we estimated the relationship between these variables and the clinical scores: Social Responsiveness Scale (SRS), Attention Deficit Hyperactivity Disorder Rating Scale (ADHD-RS), Behavior Rating Inventory of Executive Function (BRIEF) and VINELAND Adaptive Behavior Scale. To analyze the data, we conducted ANOVAs and non-parametric statistics to test the effects of the group (ASD vs TD) and social engagement condition (direct gaze vs averted gaze). A mediation analysis was realized to test if eye fixation behavior could explain the effect of the group on RT.

Results: The eye fixation index (Figure B) was found to be significantly reduced for ASD participants. More social engagement into observation of images with direct gazes was found for both TD and ASD group. We also found that RT was significantly longer for ASD group, and that it was strongly and negatively correlated with the eye fixation index. The mediation analysis data demonstrated that the influence of group on RT was driven by the eye fixation index. All clinical scores were significantly higher in ASD compared to TD group. Longer RTs were related to indexes of ADHD-RS, BRIEF and SRS even after correction for the effect of group by partial correlation. The relationship between eye behavior and social and adaptive skills (SRS and VINELAND) were entirely explained by the group differences in either domain.

Conclusions: the pattern of eyes observation in ASD and TD participants shows both sensitivity to group and condition of the task and governs following motor behavior of the participants. This decision making sluggishness may be in turn related to participants’ anxiety, poor executive control, attention/hyperactivity and social adaptation clinical scores.

Figure A. Experimental design and trial structure. 28 face photographs from 14 different persons looking directly or aside were presented for 3s each; after each face presentation a screen of choice was presented. After a participant’s response, the next trial starts. B. Definition of AOI eyes and eye fixation index.

Background: The number of autistic students at university is growing, although recent evidence indicates that autistic students have lower continuation rates compared to non-autistic or other disabled students (Ashbaugh et al., 2017). Previous work has demonstrated that the academic performance of autistic students is judged negatively by their non-autistic peers (Alhusayni et al., under review) however it is currently unclear whether these negative perceptions are accurate or the result of bias. Further, we do not yet know whether autistic students are aware of these negative perceptions.

Objectives: This study seeks to examine 1) whether negative perceptions are robust in a new group of autistic and non-autistic targets and 2) to evaluate the mechanisms through which these negative judgements might impact autistic students. Specifically, it will assess the accuracy of perceiver’s judgments of autistic and non-autistic student’s academic performance, and assess whether autistic students hold accurate meta-perceptions of their own academic performance.

Methods: Thirty-four target videos were recorded from university students who were completing a questionnaire online (17 autistic, 17 non-autistic, mean age=22 years). All targets self-reported their average academic grade, and their success, motivation and happiness at university on 6-point Likert scales. They also reported how others would perceive them on the same measures (meta-perceptions). Target videos were edited into 7 second clips.

Thirty non-autistic students (26 females) aged between 18 and 33 (M = 20.23 years, SD = 3.68) viewed the target videos. Perceivers were then asked to rate each target on the same four aspects related to university life.
We examined whether perceivers judged autistic students more negatively than non-autistic students. To examine accuracy and bias, other-perceptions were compared to self-perceptions to establish whether targets were over- or under-estimated. Meta-perceptions were compared with other-perceptions to determine whether targets were aware of how they are perceived.

Results: Replicating previous work, autistic students were judged more negatively across all dimensions of academic life compared to non-autistic students (p<.040). Compared to self-perceptions, there was a general tendency to underestimate targets from both groups. However, there was moderate evidence that non-autistic targets were accurately perceived on some dimensions (happiness: BF\_0\_1=3.452, motivation: BF\_0\_1=3.672). Finally, both autistic and non-autistic students were generally unaware of how they are perceived and thought they would be perceived more positively than they actually were (p’s .001 - .023).

Conclusions: This work demonstrates that autistic university students are more negatively judged than non-autistic students. There is some evidence that these judgements stem from underestimations of autistic students. However, it appears that they are not aware of these judgements. Therefore, it is unlikely that negative judgements have an impact on student performance via a self-fulfilling prophecy. Further research will need to examine whether negative judgements impact academic performance via other routes (i.e. social exclusion from learning opportunities).

### Technology Demonstration

**POSTER SESSION — TECHNOLOGY DEMONSTRATION**

**428 - Technology Demonstration**

**428.401 (Poster) A Multi-Player Virtual Reality Serious Game to Foster Social Skills in Autistic Teens**

Background: VR technology to allows instructors and therapists to offer safe, repeatable, and diversifiable learning environments for autistic individuals. Such technology has shown marked recent growth and many companies have started exploring the market and developing potential solutions. For example, some commercial tools are already available on the market with a focus on both individual and clinical use (i.e. Floreo and Auticare). However, both are focused on a single-player usage and leverage real-life exercises of little engagement for some video game users that may be most motivated to use the technology (e.g., pre-teens and young-adults). Moreover, the lack of companion tools to analyze the stress status of the players hinder the possibility to exploit them as a tele-therapeutic solution.

Objectives: To develop an engaging multi-player VR-based serious game to foster social skills in autistic teens and explore their viability as a tele-therapeutic solution.

Methods: The implemented VR solution focuses on a multi-player immersive setting where a small group of teens can play and interact with each other remotely through their digital avatars. The therapist participates within the immersive setting too by acting as a facilitator. Real-time monitoring of the emotional status of each player allows the therapist to promptly intervene in case one or more players face stressful conditions. Our VR solution leverages biometric data analysis of heart-rate signals generated by a heart-rate monitor bracelet worn by each player. The VR session is built around a fantasy game adventure where a small group of teens act as a team of space explorers. Each mini-adventure has been codesigned in collaboration with experts on autism and is aimed at facilitating collaborative and problem-solving activities among players as well as to improve executive function skills (e.g. selective attention).

Results: A preliminary assessment has been performed with 33 autistic teens from different age groups (8-10; 11-14; 15-17; male to female ratio: 4:1), with the aim of examining level of engagement with the game environment and challenges, as well as the therapist’s capability to handle different situations in which the teams were involved along the adventure. Analysis of the post session individual interviews with teens showed that there was a high appreciation of the VR game along the dimensions of engagement, clarity, interaction with objects, movement, user experience and willingness to play again in the VR environment. Ratings on these dimensions on a 1-5 Likert scale (1=low, 5=high) measuring appreciation, reached an average rating greater than or equal to 4 on all dimensions. All the feedback and insights collected from the interviews with teens and observations of their behaviors during the VR game have been used to improve its design even further.

Conclusions: We show that our multi-player VR serious game is highly engaging for autistic teens and allows for interaction in a group setting with a therapist to facilitate interactions. Future work can investigate use of such technology to facilitate and improve social skills in autistic teens within in-person and tele-health settings.
428.402 (Poster) A Multimodal Virtual Classroom Interface to Facilitate Discovery of Behavioral Patterns in Response to Sensory Stimuli
Z. Yu, S. Iadarola, S. Daley and Z. Zheng; (1)Rochester Institute of Technology, Rochester, NY, (2)University of Rochester Medical Center, Rochester, NY, (3)University of Rochester, Rochester, NY

Background:

Virtual reality has been investigated for assessment, intervention, and education targeting features associated with Autism Spectrum Disorder (ASD), due to being well-controlled and delivering engaging information. These provide a good foundation to collect behavioral data in response to particular stimuli. In the last decade, online learning has become more widely applied for children with ASD, especially during the COVID pandemic. Traditional interfaces (e.g., Zoom) consist of snapshot-size videos of participants and a few operational buttons that do not simulate the feeling of a real classroom, which is essential for children with ASD to learn key coping skills. Therefore, creating an interface that provides a more realistic classroom experience is beneficial. We designed a new multimodal interface that presents common sensations in a screen-based virtual reality (VR) classroom. Children’s reaction to the interface discloses behavioral patterns in response to multimodal sensory stimuli, providing references for future virtual classroom design.

Objectives:

This study aimed to: 1) develop a multimodal virtual classroom interface that simulates common sensations in a real classroom; 2) evaluate feasibility of the interface for students with ASD; and 3) explore if data collected using the interface can disclose unique behavioral patterns in children with ASD.

Methods:

The new interface presented a 3D virtual classroom occupied by virtual classmates and a virtual teacher. Figure 1 shows the real setting for the experimental study. Visual (e.g., avatar motions), auditory (e.g., the sound of flipping pages and people talking), and tactile (i.e., the feeling of holding and writing with a pen) stimuli were incorporated. Tactile sensations were provided through a small haptic robot. A limited-time word-counting task was used as an example to study children’s responses. Users needed to count how many times a particular word appeared in reading material and select an answer matching their counting.

Results:

Nine adolescents with ASD (Age (years): mean = 13.17; SD = 1.52) and twelve TD adolescents (Age (years): mean = 13.10; SD = 1.84) participated in the study. The new interface worked smoothly. All subjects tolerated the interface and accomplished the task. Gaze fixation distribution of both groups are presented in Figure 2. Visual behavior analysis showed that children with ASD’s gaze fixation was significantly less (Wilcoxon rank sum test, p = 0.00) concentrated on the word scanning area than the TD participants, coinciding with previous research that children with ASD experience more difficulties focusing on certain classroom tasks. Meanwhile, the gaze distribution across the background area was low for both groups without any significant difference.

Conclusions:

Our preliminary findings demonstrate that adolescents with ASD can engage with a virtual classroom interface with sensations simulating real-life experiences. Such an interface can reveal behavioral similarities and differences between users with ASD and their TD peers. These will facilitate future design and application of VR based online/remote learning.

428.403 (Poster) Access, Acceptability and Satisfaction of Pivoting to Online Self-Paced Professional Training for Delivery of a Children’s Social-Emotional Skills Program.
K. Davey, Decipher Zone & AutismCRC, Rochedale South, Australia

Background:

Over 18 years a PhD project has progressed to empower autistic children’s social-emotional resilience across multiple countries and gather 20+ publications demonstrating its effectiveness and application to various settings and families. In 2020, a co-designed program transformation into a digital health solution occurred; remaining true to the evidence-base clinical best practice and community utilization. Through careful planning and testing, the program content, process and physical resources became one integrated software package including digitisation of the previously two-day facilitator training course alongside the addition of a course for assistants as requested by the advisory group.

Objectives:
Within the context of software development objectives, digitisation of the professional training aimed to reduce geographical attendance barriers, maintain high trainee satisfaction, enhance learning suited to workplace/client needs, allow practical 'just-in-time' review, and provide new consistent and streamlined learning for assistants.

Methods:

The six-step co-design process involved fast-paced cyclic feedback with an advisory group of clinicians and educators from sectors around the globe, program author, software developers, children, and commitment to the long-standing evidence. The overall post-launch evaluation over 18 month periods included program uptake data through quantitative and qualitative training feedback using the Workshop Evaluation Survey (WES), user-data analysis, and qualitative service and family feedback. A two-phase training evaluation and improvement process, over 8-10 month periods were completed. Following the initial 8 months, themes analyses was used to identify and address areas of weakness. Re-evaluation during the second phase measured the impact of improvements while informing future improvements.

Results:

In the first 18 months post-launch, 1014 professionals (702 facilitators, 312 assistants) accessed the training courses from four global regions supporting at least 3928 children/families. After 18-months, response feedback was positive with ratings indicating high relevance of training to their work at 6.54/7 (N=219, SD=0.88), acceptability of the content 5.95/7 (N=219, SD=1.07), and overall satisfaction with the training 6.07 (N=368; SD=1.04; See Figure 2). During the two-phased user-informed course enhancement period, ratings showed improvements across all feedback categories (See Figure 2) indicating useful changes were implemented. Themes analysis identified notable strengths including the combination of videos and interactive training process, completion flexibility due to self-paced training; and the structured and easy to navigate training platform.

Conclusions:

The outcomes to-date provide preliminary support to both the co-design methodology and resultant suitability of digitised self-paced professional training within a software-based social-emotional skills program to empower children’s resilience. Results include a swift uptake and feedback that aligned with overall project aims. Internal evaluations continue with phased reviews and program enhancements over time.

**428.404 (Poster) Accuracy of a 2-Minute Eye-Tracking Assessment to Differentiate Young Children with and without Autism, and Potential for Use As an Early Identification Aide**

K. Hudry\(^1\), L. Chetcuti\(^2\), D. W. Tan\(^3\), A. Clark\(^4\), A. Aulich\(^5\), C. A. Bent\(^6\), C. C. Green\(^7\), J. A. Smith\(^8\), M. Ninomiya\(^9\), A. Saito\(^10\), T. Ebihara\(^11\), K. Fordyce\(^12\) and A. J. Whitehouse\(^13\), (1)La Trobe University, Melbourne, VIC, AUSTRALIA, (2)La Trobe University, Melbourne, VIC, Australia, (3)Telethon Kids Institute, Perth, Western Australia, Australia, (4)Childhood Autism Phenotype Team, La Trobe University, Melbourne, VIC, Australia, (5)JVCKENWOOD Corporation, Yokohama, Japan, (6)Laurel House, North Motton, TAS, Australia, (7)Telethon Kids Institute, Perth, Western Australia, AUSTRALIA

Background: Autism diagnosis relies on the potentially subjective appraisal of social-communication difficulties and behavioural inflexibility. **Gazefinder** eye-tracking technology—manufactured by JVCKENWOOD Corporation—was developed to support accurate and efficient autism identification and diagnosis, via a short 2-minute stimulus sequence and results processed and visualised automatically, for straightforward ‘off-the-shelf’ use. The animation sequence taps visual attention during referential attention trials (i.e., to pointed-at vs. distractor objects), preferential social attention (i.e., to eyes vs. mouth of a human face; and to people vs. geometry across a range of scenes), and biological motion (i.e., upright vs. inverted point-light displays). Previous studies—all conducted in Japan—suggest **Gazefinder** can differentiate people with and without autism in adolescence/adulthood (Fujikawa et al., 2016) and childhood (Fujioka et al., 2014), and Tsuichiya et al. (2021) have recently reported good accuracy for the differentiation of children with and without autism, aged 5-17 years (Tsuchiya et al., 2021).

Objectives: To independently trial the accuracy of **Gazefinder** to differentiate young children with and without autism, when diagnostic assessment often occurs in a high-resource setting (i.e., Western, majority English-speaking country), including appraising acceptability and safety for use in this context with children aged 2-4 years.

Methods: This pre-registered clinical device trial (ANZCTR12619000317190) enrolled 203 children aged 2 years 0 months to 4 years 11 months (M=3 years 6 months; SD=9 months) in two groups—children with a confirmed community autism diagnosis (n=102; 81% male), and controls with no parent-reported developmental concerns or close family history of autism (n=101; 57% male). Children completed the brief, standardised **Gazefinder** eye-tracking assessment. Parents provided socio-demographic information and clinical/behavioural phenotyping questionnaires. Further, mirroring a community diagnostic assessment experience, further clinical/behavioural phenotyping of children with autism included standardised direct assessments of autism presentation and developmental/cognitive abilities. Recruitment and data collection procedures were pre-registered, conducted by experienced clinical researchers, overseen by a data monitoring and
Adapting Emotiplay, a Computer Based Emotional Competence Intervention for Use in Special Classrooms for Autistic Children

I. Bar Ben Shabat, S. Eden and O. Golan; (1)Faculty of Education, Bar-Ilan University, Ramat-Gan, Israel, (2)Department of Psychology, Bar-Ilan University, Ramat-Gan, ISRAEL

Background: Autism is characterized by Emotional Competence (EC) challenges: The ability to recognize and understand one’s own and others’ emotional states and to use emotional knowledge to initiate and preserve social relationships (Denham et al., 2015). Many interventions aiming to teach autistic individuals to recognize and understand emotions have been tested. Most focused only on facial expressions, were limited to autistic children with no intellectual disabilities (ID); and showed limited generalization to real social settings (Berggren et al., 2017; Eden & Oren, 2021; Petrovska & Trajkovski, 2019). EmotiPlay, a computer-based intervention program, designed to enhance emotion recognition (ER) by addressing multiple modalities of emotional cues (facial expressions, tone of voice, body language), has shown good outcome when used at home by autistic children and no ID (Fridenson-Hayo et al., 2017). However, the examination of generalization was partial and depended only on parental reports. The present study examined the adaptation and the integration of EmotiPlay into special education classrooms in regular schools.

Objectives: (1.) To examine the adaptation and integration of EmotiPlay’s intervention to a school setting with autistic children at various ages and levels of functioning. (2.) To pilot test an extended EC battery for EmotiPlay’s evaluation.

Methods: Participants included 24 Autistic children (4 Girls) aged 7-10 years (Mean=9.1, S.D.=1.20), and 19 neurotypical (NT) children (3 Girls) aged 7-9 years (Mean=7.9, SD=0.82). Groups were comparable on cognitive and language levels.

Autistic students participated in 16 weekly lessons over 3 months, that introduced emotions and taught emotion cues in the different modalities. Lessons were given by the form teachers. Qualitative data was collected via biweekly observations and teachers' interviews.

The EC battery tested with participants included: (1) multi-modal basic and complex ER (2) emotion understanding based on a standardized measure (the Test of Emotion Comprehension - TEC) (3) an emotion definition task (4) a story-telling task (5) an observation of children’s prosocial behavior during free-playtime (using the Playground Observation of Peer Engagement - POPE).

Results: Qualitative analysis of teachers’ feedback indicated an average of 6 activities per lesson, a decrease in motivation at didactic activities, and some difficulties understanding instructions at lower grades.

On the EC tasks, autistic children performed more poorly than NT children on complex, but not on basic, emotion recognition taks.

In addition, autistic children had significant lower scores on the TEC and the emotion definition task compared to NT children. No significant difference was found on the story-telling task.

Free-time observation (POPE) indicated that autistic children had fewer positive initiations and responses compared to NTs, and that they spent more time at solitary or as viewers, whereas NT children spent more time jointly engaged with their peers.

Conclusions: Considering these results, Emotiplay’s intervention was modified for school use: (1) Basic emotions lessons were shortened, and 3 complex emotions were added (bored, interested, shame). (2) story task to evaluate natural emotional vocabulary was altered to story retelling. These adaptations set the scene for a randomized controlled trial, evaluating EmotiPlay in schools.
Automatic Delineation and Classification of Head Movements Using 3D Accelerometer Data from Live Social Interaction

M. Schulte-Ruther\(^1\), B. Krüger\(^2\), J. Lemken\(^1\), S. Stroth\(^4\), I. Kamp-Becker\(^5\) and L. Poustka\(^1,2\), (1)Department of Child and Adolescent Psychiatry and Psychotherapy, University Medical Center Göttingen, Göttingen, Germany, (2)Leibniz ScienceCampus Primate Cognition, Göttingen, Germany, (3)TH Köln - University of Applied Sciences, Cologne, Germany, (4)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Philipps University Marburg, Marburg, Germany, (5)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Philipps University Marburg, Marburg, GERMANY

Background:

Individuals with autism spectrum disorder (ASD) often show reduced non-verbal communication during social interactive encounters, e.g. facial expressions, deictic and communicative gestures, eye gaze. This includes reduced usage and expression of gestures of the head, such as nodding, shaking the head, and head turning. Diagnostic criteria of ASD suggest that reduced non-verbal communicative behavior is an important symptom, but current diagnostic tools are restricted to subjective, clinical evaluation.

While many tools for automatic delineation and classification of facial expressions and gestures from video data are available, less work has been done with respect to the usage of accelerometer sensor data. Considering the current lack of objective, quantitative measures of non-verbal behavior during social interaction, an automated analysis pipeline for movement annotation from accelerometer data would be helpful for both clinical evaluation and research.

Objectives:

We are developing a tool that allows for the semi-automatic annotation of specific head gestures, including nodding, shaking the head, and deictic head-turning. Ultimately, the tool will be used in an integrated setup for the quantification of social interactive behavior.

Methods:

We used video recording and a mobile eye tracking device during sequences of social interaction providing video data and synched accelerometer data. First, using dedicated algorithms for unsupervised automatic segmentation of movement from accelerometer data (Krüger et al., 2017), we identified segments of distinguishable head movements. Second, the algorithm was optimized for the detection of specific movement types using manual annotation of gestures as ground truth. Third, we will use supervised machine learning for direct classification of head movements from pre-segmented time-series data. Fourth, this automated annotation will be back-linked to video data to allow for the final evaluation of pre-annotations by a human observer, similar to available tools for video based gesture annotation (Ripperda et al, 2020).

Results:

Initial results using annotated data of 5 participants showed that head movements can be reliably segmented automatically, resulting in more efficient manual annotation of movement type, quantification of occurrence of communicative movement, and optimized segmentation for specific head movements such as nodding. Data collection in a larger group of 50 participants is ongoing and the results of the machine learning approach and usage of the automated pipeline for movement pre-annotation will be presented at the meeting.

Conclusions:

A (semi-)automated annotation tool for head gestures is a valuable research tool for the investigation of head movements, for both clinical evaluation and detailed analysis of non-verbal communicative behavior.

References:

Objectives: To develop and demonstrate an open-source interactive web-based visualization and pre-processing tool that can efficiently and accurately perform rigorous quality assessment (QA) on ambulatory ECG data, including identification and summarization of artifacts and missing data (Figure 1).

Methods: We evaluated our ECG QA tool using a 249.4 hour [M/SD: 2.4/0.6] dataset of ambulatory ECG recordings collected with the well-validated wireless, chest-worn Actiwave Cardio by CamNtech from one examiner and 34 parent-child dyads (23 TD [3.8yr|1.1], 11 ASD [4.1yr|1.0]). Dyas were asked to engage in various semi-structured social and emotional regulation tasks adapted from the ADOS-2 and Lab-TAB to quantify socio-affective functioning and interpersonal physiological dynamics. We simultaneously collected time-synchronized ECG recordings at 1024 Hz from the parent, child, and examiner during these tasks. Using our QA pipeline, we first segmented each person’s ECG data into 60-second windows. Next, we pre-processed the windows with a peak detection algorithm using MindWare HRV Analysis Software (version 3.2.11) to derive second-by-second values of heart rate (HR) and interbeat interval (IBI). We then filtered out invalid HR and IBI values outside the range of [30:220] bpm and trimmed the beginning and end of each person’s signal to the start time of the first task and the end time of the last task. Lastly, we computed the median IBI values in each 60-second window to estimate the expected HR for that window and compared this expected value with the detected number of peaks to calculate the percent missing.

Results: Overall, the average proportion of missing peaks per window (sample panel in Figure 2) for the TD group was 1.1|4.4% and 1.9|4.9% for the ASD group. Within the TD group, average proportions of missing peaks per window by task were 1.2/2.8% (Free Play), 1.2/3.1% (ADOS Presses), 1.3/2.4% (Frustration 1), 0.8/1.8% (Frustration 2), 1.1/2.1% (Keep Calm), and 1.1/2.4% (Reading a Book). Within the ASD group, average proportions of missing peaks per window were 2.3/4.0% (Free Play), 1.5/3.3% (ADOS Presses), 1.9/3.7% (Frustration 1), 2.2/3.5% (Frustration 2), 2.4/4.1% (Keep Calm), and 2.0/3.5% (Reading a Book).

Conclusions: We developed an open-source interactive web-based visualization tool that performs automated ECG QA by identifying artifacts and missing data. Increasing ECG data pre-processing accessibility, efficiency, and transparency could enable methodological reproducibility and lead to more reliable and valid inferences when ambulatory data collection systems are used.
Methods:

Using a mixed-methods approach (self-developed surveys and semi-structured interviews), this study draws on Technology Acceptance Model (TAM) to investigate parent, teacher, and autistic perspectives on the acceptability of ‘Wider Web’ features. All participants are based in the United Arab Emirates; a non-WEIRD (Western, Educated, Industrialized, Rich and Democratic) research context (heavily neglected in research literature). Parents and teachers will report on 4 groups of autistic students: pre-school (aged 5 and younger), children (6-12 years), teenagers (13-17 years), young adults (18-25 years), adults (26 and older).

Results:

Data collection commenced in November 2022, and is currently on-going, anticipating a reach of 50 participants in each of parent, teacher, and autistic student groups by January 2023. We are recruiting at the rate of 15 participants per month (per group), and expect to present group insights and differences in May 2023.

Conclusions:

This study also aims to consolidate parent, teacher, and autistic user feedback on the benefits, drawbacks and recommendations for improving ‘Wider Web - to support autistic users’ online needs and experiences. Findings will serve as a guidance to inform future learning and support technology design for autistic users.
Results: We present our initial results indicating that our prototyped design changes would be beneficial for this community. For example, one Autistic participant felt the Friend Request Guide was useful because it required users to evaluate their current offline relationship with the requester: “That first prompt is actually really, really smart. I like the first wave of verify your connection to them.” Such responses indicate that this can be a useful tool for correctly classifying a potentially dangerous relationship with a stranger rather than interpreting a Friend Request as being a way to gain a friend (which was a common pitfall based on our interview analysis).

Conclusions: By identifying the problematic design elements of social media, we help researchers and stakeholders recognize potential pitfalls of social media. By also identifying new design elements that overcome these problematic designs, we take a first step in providing design guidance for social media designers.

428.410 (Poster) Online Training for Executive Functioning Challenges Intervention for Implementers Working with Elementary Students with ASD/ADHD

J. Whiteford1, L. Kenworthy1, J. V. Smith1, A. Verbalis1, T. Dahlman1, A. C. Armour1, J. Holmey, L. Cannon1, M. A. Werner1, K. C. Alexander1, B. J. Anthony1, M. Gunn1, G. Morton1, G. Wolnitzek1 and L. Anthony1, (1)Innovations Institute, University of Connecticut School of Social Work, Hartford, CT, (2)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (3)Children’s National Medical Center, Washington, DC, (4)Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC, (5)Department of Psychiatry, University of Colorado Anschutz Medical Campus, Aurora, CO, (6)University of Colorado Anschutz Medical Campus, Aurora, CO, (7)Jvymount School, Rockville, MD, (8)Monica Werner Counseling, Chevy Chase, MD, (9)The Occupational Therapy Institute, La Mesa, CA, (10)University of Colorado, Denver, Aurora, CO, (11)Innovations Institute, University of Connecticut School of Social Work, Hartford, CT, (12)University of Connecticut School of Social Work, Hartford, CT

Background: Executive function (EF) challenges, including difficulties with flexible thinking, goal setting, and planning, are common in ASD and ADHD and are related to negative outcomes, such as academic problems, oppositional-defiant symptoms, adaptive skills deficits, anxiety, and aggression. Chronic exposure to poverty is also predictive of EF challenges. School-based EF interventions provide an equitable service delivery system for children across the socio-economic spectrum, addressing the economic disparities in access to clinic-based treatment for children with ADHD or ASD. Reviewers have called for expansion of cognitive-behavioral treatment for ADHD and ASD, specifically treatments that target EF, but the evidence for them is limited in school settings. Unstuck and On Target! (“Unstuck” or “the curriculum”) is a school-based curriculum that targets EF.

Objectives: Develop and evaluate an online continuing education training for professionals who work with elementary students with EF challenges.

Methods: The Unstuck authors partnered with an instructional design (ID) team to create an asynchronous online training based on their existing, in-person training. The ID team, using best practices in adult learning and cybergogy, adapted the curriculum into an interactive course, featuring voiceover, images, videos, animations, reflection questions, and resources. The ID team engaged the authors, stakeholders, and cultural competence experts in multiple rounds of feedback. Section 508 and WCAG AA compliance requirements were incorporated into the training. Implementers (N=281) from Virginia (n=138) and Colorado (n=143) were recruited. Participants were 93.6% female, 90% White, 20-80 years old (M = 40.48, SD = 10.88). They had 0-35 years of experience (M = 11.35, SD = 8.28) as General (10%) or Special Ed teachers (34%), School Psychologists (19%), School/Guidance Counselors (17%). Public and private schools were included.

Results: After completing the online training, participants overall felt the five learning objectives were achieved (M=4.32, SD=0.692, range: 1-5), approved of the e-learning format (M=4.51, SD=0.63, range: 1-5), and indicated that their knowledge of the issues/needs of their students had increased (M=3.99, SD=0.688, range: 1-5). Qualitative feedback was overwhelmingly positive: “This is one of the first trainings where I feel like the creators truly practice what they preach - you made things paced, checked for understanding, were clear in learning targets, acknowledged roadblocks, made the materials fun, relevant and engaging, and overall rocked the whole process. I wish more of my trainings were this user friendly and relevant.” Participants specifically identified the case studies, printable resources, and application of the GWPDC framework as useful. Participants requested handouts on which they could take notes and more videos of teachers implementing Unstuck.

Conclusions: Overall, participants found the curriculum to be useful. Despite occasional technological issues, participants approved of an online training because they could complete it at their own pace and on their own schedule. Where possible, participant feedback was incorporated into an update of the training (released to the public following the pilot), including fixing technical glitches and the addition of page citations where tools in the Unstuck manual were referenced. Online training adaptations of the curricula for high school students are currently being produced.

428.411 (Poster) Oto, a Compressive Armchair to Perform Deep Pressure in Children with ASD: A User-Centered Design

T. Gargot1, A. Audrain1, M. Gomot1, M. Guidotti1 and F. Bonnet-Brilhault1, (1)UMR iBrain 1253, Inserm, University of Tours, Tours, France, (2)labba, nantes, France, (3)INSERM Grand Ouest, Tours, France, (4)Exac-t, Excellence Center in Autism and neurodevelopmental disorders, Tours, France, (5)UMR iBrain 1253, Inserm, University of Tours, TOURS, France
Background:

Deep Pressure Therapy (DPT) is widely used in autism spectrum disorder (ASD) but evidence of its efficacy is limited and some technics raised acceptability and stigmatization issues.

Objectives:

To design a usable, non-stigmatizing compressive armchair easily controlled electronically by the user

Methods:

We used a user-centered design process (Witteman et al., 2021, JMIR) and assessed the usability of the device (System Usability Scale, Bangor, 2008) among professionals, users in Excellence center day Hospital in ASD children in France for one year. We measured time of use as a measure of usage in practice of the device.

We collected feedback from a convenience sample with severe forms of ASD and intellectual deficiency and their psychometricians.

Results:

We developed an armchair with 4 different cells, controlled electronically by an Arduino card. They can be inflated to induce tailored pressure on the body. The pressure is recorded electronically, and can be limited with a maximum threshold tailored for each individual with an electronic tablet.

The design was user-centered. It was used weekly for 15 months long among 29 patients for 3-20 min each, a total of 72.5 hours.

The armchair is less stigmatizing and less bulky than the original hug machine. Performing sessions with the chair and with a medical-grade wearable device is feasible.

The Usability (System Usability Scale), measured among n=9 professionals (psychomotricians, nurses, educators) was between good and excellent.

The armchair takes less place than the hug machine. Performing sessions with the chair is feasible.

We collected positive design acceptability feedback from several stakeholders (patients, families, design prizes school of wood, James Dyson Design Award, Great Hope Prize Saint Pierre Fundation).

Conclusions:

This device opens perspective for controlled evaluation of deep pressure therapy to treat anxiety in ASD. The device allows to assess efficacy of deep pressure therapy in ASD and underlying physiological mechanisms. A pilot efficacy study was funded and is under preparation.

**428.412 (Poster) Scalable Transdiagnostic Early Assessment of Mental Health (STREAM): Developing a Tablet-Based App to Assess Early Child Development in Low-Resource Settings**

Background:

It is estimated that 95% (50.2 million) of children with developmental disabilities reside in low or middle-income countries (Olusanya et al., 2018). This burden is exacerbated by the scarcity of skilled professionals for early detection of neurodevelopmental disorders (NDDs), and their skewed distribution to urban, often private, clinics, as well as their reliance on time-intensive, specialist-dependent, proprietary assessment tools. To address these issues, it is crucial to develop a portable tool to assess neurodevelopment, that is applicable across diverse cultural settings and can be administered by non-specialist workers (NSWs) with little training.

Objectives:

The main objective of the STREAM project is to develop and validate an open-source, scalable assessment tool in the form of a tablet-based app, that can be administered by NSWs to assess the neurodevelopmental status of children and identify those at-risk of NDDs.

Methods:

This project is funded by the Medical Research Council UK and is an interdisciplinary collaboration between neuroscientists, statisticians, public health researchers, and computer scientists from nine institutions across four countries (India, Malawi, USA, and UK).

Through a process of expert consensus workshops and iterative pilot testing, STREAM has adapted and combined three existing tools, assessing social, cognitive, and motor abilities of children aged 0-6 years, into a unified, tablet-based app. The tools included in STREAM are: 1) MDAT, an observational and parent-report checklist that assesses gross motor, fine motor, social, and language abilities (Gladstone et al., 2010); 2) DEEP, a series of gamified tasks assessing cognitive abilities (Bhavnani et al., 2019); 3) START, a series of gamified tasks assessing social preference, sensory preference, and motor abilities (Dubey et al., 2022).

The platform is currently being tested on N=4000 children from community and NDD-risk samples across India and Malawi. STREAM will be validated against a gold standard measure of child development (Griffiths Mental Development Scales; Griffiths, 1970).

Results:

The STREAM app incorporates gamified tasks, observation checklists, parent-report, and audio/video recordings, to assess abilities relevant to the domains of social, cognitive, and motor development. Each task within STREAM has been designed to be culturally agnostic. A key feature of the app is its ability to work offline, enabling administration in the field without the need for additional infrastructure. The presentation will include a live demonstration of all aspects of the app. At the point of this submission, STREAM has been tested on N=1226 children from community and NDD-risk samples in India and Malawi, with a mean completion rate of 97% across all tasks.

Conclusions:

The working STREAM app and high proportion of data completion demonstrate the feasibility and acceptability of a portable platform administered by NSWs for assessing child development in low-resource settings. The metrics derived from the app will be validated against a gold-standard measure of child development and assessed in terms of their ability to highlight the role of social, behavioural, and neural risk factors known to impact development.

428.413 (Poster) Stories Online for Autism (SOFA-app.org)

L. Camilleri1, K. L. Maras2 and M. Brosnan3, (1)Psychology, University of Bath, Bath, United Kingdom, (2)university of bath, bath, United Kingdom, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom

Background:

Social stories is a widely-used and acceptable intervention for autistic and broader autism communities. However, variability in the development and delivery of social stories has resulted in mixed findings regarding the effectiveness of the intervention. The SOFA-app (Stories Online For Autism) is a free online digital application, for smart devices (Android/IOS smartphones or tablets), through which social stories can be developed and delivered. The SOFA-app was co-developed with the autistic and broader autism communities, and supports authors (i.e., individuals writing social stories) with creating and delivering stories reliably and effectively, and delivers the social stories in a personalised manner to the audience (i.e. individuals reading social stories). The SOFA-app comprises features aimed towards increasing procedural integrity and intervention fidelity by focusing on goal-setting, goal-rating, and goal-monitoring.

Objectives: To demonstrate the fully-functional (and free) SOFA-app.
Methods:

The SOFA-app can operate in two modes (see Figure 1): The writing mode and the reading mode. The writing mode is where authors develop their stories by using a well-defined, intuitive, and user-friendly writing interface. The writing interface supports (see Figure 2) the author to write appropriately structured social stories. The author rates the extent to which the audience has reached the goal of the social story (from 0 to 10). The reading mode is where individuals may access, view and/or read stories, and includes a text-to-speech function. The SOFA-app includes a fill-in-the-blank comprehension check at the end of each story that has been read. The SOFA-app also includes a feature that aims to encourage story evaluation from the audience’s perspective.

Thus, the SOFA-app provides the opportunity to easily tailor a social story for the audience, and in so doing encourages further engagement with the audience’s perspective. This is also achieved by using photos that are taken by the author on their personal smartphone which are stored in the device’s image gallery. This feature enables authors to include real images of people, objects, and settings in their social stories. The application’s social story library can be used to store and shared stories with the SOFA-app community. In this manner, the autistic and broader autism communities are encouraged to share their social stories and thus collaborate indirectly with other users.

Results:

2331 users have downloaded the SOFA-app. 160 social stories have been shared in the story library. Multiple studies have shown significant increases in ‘closeness to goal ratings after using the SOFA-app. Closeness to goal ratings from the autistic and broader autism communities are typically around 2-3 at baseline and typically significantly increase over 4 points to around 6-7 after the social stories support, which constitutes a large effect size.

Conclusions:

The SOFA-app has enabled the autistic and broader autism communities to develop social stories effectively. This not only empowers the autistic and broader autism communities, it addresses issues of variability in the development and delivery of social stories that have compromised previous research into the effectiveness of social stories.

428.414 (Poster) Using an Autonomous Robot to Detect Presence of Eye Gaze of Autistic Children
W. C. So, Educational Psychology, The Chinese University of Hong Kong, Hong Kong, HONG KONG

Background: Autistic individuals have difficulties establishing eye contact and joint attention with others. Previous studies have examined whether social robots improve eye contact and / or joint attention of autistic individuals, but have yielded mixed findings (e.g., Chung, 2021; Zheng et al., 2020). One limitation is the robots deployed were controlled by humans (i.e., under a Wizard-of-Oz paradigm), which impose constraints in applying robots to the clinical settings.

Objectives: The present study thus deployed a social robot that could detect the child’s eye gaze, prompt and praise the child autonomously within established scenarios, alter behavior on the basis of parameters specified by the programmer, and process sensed data over time to understand the history of the interaction.

Methods: An autonomous social robot, Humane, which has been used in autism and eldercare (Khosla et al., 2015; So et al., 2020; revision under review) was deployed. Humane, 25 cm tall and 3.2 kg weight, has human attributes include baby face-like appearance and voice vocalization (see Figure 1). Humane was installed with the NeoFace® Face Recognition function that autonomously detected the focusing of child’s gaze and did not require the remote control of human beings. Such eye gaze detection function operated under the Multi-modal Machine Learning System (MMLS), which constructed predictive models for eye gaze detection using search methods, artificial intelligence, and mathematical modelling (see Figure 2).

We conducted a pilot study on 32 autistic children aged 3 to 15 (26 males; IQs ranged from 50 to 140; ADOS-2 comparison score ranged from 4 to 10). In this study, each child was introduced Humane and instructed to sit one meter away from Humane (see Figure 3). When Humane was narrating stories and recognizing that the child was not looking at it for a preset interval, i.e., five seconds, Humane would stop the story narration and prompt the child, “Child, eyes on me please!” or “Child, please look at me!” When the child looked back to Humane in one second after receiving the prompt, Humane would praise him/her, “Good looking! Well done!” or “You have done a good job! Thanks for looking at me!” Then Humane resumed narrated and eye gaze detection program. Otherwise, Humane prompted the child again after 1 second. Each training lasted for 10 minutes, once per week, for four weeks. Fidelity check was conducted.

Results: The number of prompts Humane produced (i.e., the number of times Humane detected that the child did not look at it) was positively associated with the child’s autism severity (r=.34, p<.03) and negatively associated with his/her social responsiveness (r=-.33, p<.03). Additionally, the number of prompts in the last training session was significantly smaller than that in the first training sessions.
suggesting that autistic children required few prompts by the end of training, \( t(31)=3.34, p<.002 \). Parents rated their children’s eye contact improved after training too, \( t(31)=-2.23, p=.03 \).

Conclusions: Humane can effectively detect the autistic children’s eye gaze and its detection is associated with autism characteristics. This program can also significantly improve their eye contact.

428.415 (Poster) Web-Based Collective Science Project: Collect Data with Autistics People in Accordance with FAIR and Gdpr
H. Bellili, J. P. Nadal and F. Cazalis, (1)26, rue des Fossés St Jacques, CAMS: UMR 8557 CNRS, Paris, France, (2)Complex systems in social sciences and cognitive sciences, EHESS, Paris, France, (3)CNRS, UMR8557, Paris, France

Background:

Researchers in experimental psychology face numerous challenges, including technological limitations and reglementary compliance issues, that hinder the collection of scientific data, its management, its dissemination, and its reuse.

Objectives:

This study aims to provide researchers with a remote research web-based application called Collective Science. This application is specifically designed to be used in experimental psychology research on autistic cognition, while respecting the life cycle of research data: from collection and storage to sharing and reuse.

Collective Science also highlights modern research qualities and sharing practices such as necessity creation, FAIR principles, GDPR standards as well as free access.

Methods:

The expected research solution must represent heterogeneous and complex information (data from researchers, data from participants, and transformed data from experimental tasks, video games, and surveys). This data should face the challenges of transparency, rigor, and reproducibility, in addition to protecting autistic people’s sensitive data. We opted for an API-first architecture with micro-services to create ecosystems that collect and treat modular (with eight modules: joint capture) and reusable data to support open science.

Our solution is also based on anonymous authentication to guarantee compliance with GDPR standard requirements. We have been attentive to provide study participants with answers to questions such as: Who will have the authorization to access this data? Where will it be stored? For how long? What treatment the date is subjected to?

It is essential for us to be able to ensure the sovereignty of participants over their personal data and to avoid them the risks associated with potential identification in the event of a confidentiality breach. From the perspective of research teams, it is very important to proactively guard against such risks, if only because it is a prerequisite of many funding programs.

Results:

As of today, a functional prototype is online. We are currently working on user experience design in order to collect test user data as a proof of concept.

Conclusions:

The Collective Science V.2 project in its current version allows the integration and posting of experimental psychology video games and the collection of non-identifying data in accordance with European regulations (GDPR). The Collective Science system is intended to be free and to facilitate citizen involvement in the production of scientific knowledge. Its availability to the scientific community will make it possible to produce protocols with a little fee or free, to pool experimental tasks, to get feedback from people with autism, and to facilitate the replication of experiences. The purpose of Collective Science is to offer a space for experimentation, where the opinion of the autistic person can be heard.
Panel Chair: Laurent Mottron, M.D., Centre de recherche du CIUSSS-NIM, Montréal, QC, Canada

Discussant: Dermot M. Bowler, Autism Research Group, City University, London, UNITED KINGDOM

**207.001 (Panel Discussion) Anchoring Autism Spectrum Heterogeneity in a Universal, Temporally Bounded, Recognizable and Distinct Prototypical Autistic Phenotype**
*L. Mottron, M.D., Centre de recherche du CIUSSS-NIM, Montréal, QC, Canada*

**Background:** The evolution of autism delineation and diagnostic instruments has been paralleled by a steady increase in autism prevalence and heterogeneity. A categorical diagnosis of autism spectrum disorder is now consistent with large variations in language, intelligence, comorbidity, and severity, increasingly distant from the initial prototypical descriptions. In clinical settings, emphasis on diagnostic reliability has sacrificed specificity and led to confounding autism with the entire range of neurodevelopmental conditions and personality variants. In intervention settings, a diagnosis of autism is now too vague to inform on the type of support required by the diagnosed individuals. In research, the inclusion of individuals categorically defined by over-inclusive, polythetic criteria results in cohorts of people less and less different from the general population. It results in an inability to find differences between the autistic and general population, and to detect mechanistic differences. Here, we propose a radical change in the status of autism among other human developmental variants, ensuing definitional criteria, and research methodology and program.

**Objectives:** We propose to extract autism from psychiatric or neurodevelopmental disorders, and group it with phenomena such as twin pregnancy, left lateralization, and breach birth, each of which represents the less-frequent branch of a developmental bifurcation. Ultimately, the phenotypic, developmental, and etiological boundaries of autism vis-à-vis typical development would result from whether or not incoming information is processed in a socially biased manner, at the time where humans integrate language. Alternatives in a polarized, two-solution-only problem would determine its almost categorical nature in its prototypical form, the polarized structure opposing negative social signs to positive non-social signs, and its familial occurrence at the same rates in all humans.

**Methods:** We propose new diagnostic criteria for “prototypical autism” at the preschool age, as a necessary step toward a re.foundation of autism research. These criteria include: a) a prototypical, bayonet-shaped developmental trajectory, b) a prototypical presentation at preschool age, combining an absence of social bias with an enhanced role, autonomy and performance of perception, c) the absence of deleterious neurological and genetic pathogenic markers, and d) the presence of non-deleterious markers: familial transmission through common variants, sex ratio and macrocephaly.

**Results:** in the absence of biomarkers for diagnosis, clinical expertise should have the precedence over “satisfying criteria”. Focusing on the study of a positively and negatively defined category, including characteristics of trajectories, based on their expert-judged prototypicality, should advance the theoretical and practical issues pertaining to autism diagnostic thresholds. Grounding biomarker search on a prototypical cohort defined by specific ranges of values for the clinical specifiers should allow retesting the generality of neurobiological results previously acquired. This would allow the distinction of true heterogeneity (for example that of different outcomes in adulthood despite similar presentations at preschool age) from top-down, criteria-based heterogeneity resulting from diagnostic confusion.

**Conclusions:** One should distinguish between the populations on which research is carried out and the populations to which we provide support. People must receive services according to their individual needs, and not according to the name or certainty of their diagnosis.

**207.002 (Panel Discussion) Effects of Permutations and Combinations of Causal Factors Can Make Something Homogeneous Appear Heterogeneous**
*J. N. Constantino, Children's Hospital of Atlanta, Atlanta, GA*

**Background:** We are in an era in which a diversity of human neuropsychiatric conditions, codified by hundreds of DSM5 diagnoses, are proving to have large components of genetic overlap with one another, and to be mediated by a highly parsimonious latent trait structure (eg. the effects of the so-called p factor). The apparent heterogeneities of autism, for which a vast share of the population-attributable risk for can be traced to inheritance, may reflect a similar architecture. A growing number of studies over the past decade have indicated that inherited susceptibility may operate through a finite number of early developmental liabilities that, in various permutations and combinations, jointly raise liability for a convergent syndrome of variation in social communication that, at the clinical extreme, defines autism.
Objectives: In this presentation, this body of research will be synthesized to elucidate a developmental substructure for autism spectrum disorder (ASD), which would account for many aspects of presumed heterogeneity of the condition. This framework has profound implications for ongoing discovery efforts to elucidate the neurobiological causes of ASD and can inform the search for biological markers as well as novel approaches to personalized intervention.

Methods: It is now hypothesized that autism heterogeneity can be decomposed into three components: (1) the downstream off-target effects of a given contributing cause (eg. hyperactivity or variation in motor coordination); (2) variation in the “severity” of autism along an otherwise-homogeneous continuum; (3) additional “off-target” effects of amplifiers of impairment in adaptive functioning (eg. the medical or cognitive impacts of a chromosomal rearrangement, or exacerbations of impairment in adaptive functioning incurred by common, genetically-unrelated neuropsychiatric conditions such as PTSD or a cycling mood disorder).

Results: Viewed this way, heterogeneity in autism itself may be more apparent than real, and efforts to parse heterogeneity should focus on (and control for) the effects of 1 and 3 above; conversely, heterogeneity should not be invoked for autism until / unless these parameters are rigorously controlled for. Moreover, very recently, it has been discovered that variation along the severity continuum (2 above) may be determined, in part, by stochastic influences on early brain and behavioral development, which may account for previously-unexplained effects of “unique environmental influences”, not only on the severity of autism, but on that of many neuropsychiatric conditions (schizophrenia being a prototypic example).

Conclusions: The possibility that vulnerability to stochastic influences constitutes a general biological feature or signature of neuropsychiatric liability presents additional new opportunities for understanding variation in outcome, and highlights the importance of exploring the timing (and potential interruption) of these critical factors, which (preliminarily) appear to induce progressively higher levels of clinically-meaningful variation as the total burden of causal influence rises.

207.003 (Panel Discussion) Employing Neuroscience Approaches to Understand Heterogeneity in Autism and across Neurodevelopmental Conditions
E. Anagnostou, Autism Research Centre, Bloorview Research Institute, University of Toronto, Toronto, ON, Canada

Background: Conceptualizing autism as a distinct entity / condition is based on the observation of shared traits, and evidence of their heritability. Still, autistic individuals experience divergent developmental trajectories, not only characterized by differences in severity of “core” traits, but also the presence, in many, of cognitive, behavioral and other developmental differences, as well as physical and mental health concerns, often presumed to be simply co-occurring.

Objectives: We propose that autism, as currently defined, includes a variety of biological conditions, which may share social communication differences and repetitive behaviors, but are much more complex with respect to behavioral/cognitive and body differences and their trajectories.

Methods: To support the proposition, we use neuroimaging and genomic studies to attempt to highlight convergent pathways supported by genomics within autism and across neurodevelopmental conditions (e.g. Trost et al 2022, Zarrei et al 2019), identify biologically distinct and similar groups based on brain structure and function (e.g. Vandewouw et al 2023), and examine whether behavioral traits measured across neurodevelopmental conditions support existing classifications. To further support the thesis, the data will be positioned within other large studies of biology and long-term outcomes.

Results: Biologically defined conditions lead to a variety of behavioral / cognitive/ other differences, and individuals with distinct labels of neurodevelopmental differences, may in fact experience biological similarity.

Conclusions: Understanding the diverse pathways to autism, as currently defined, the overlap with other neurodevelopmental conditions, as well as the diverse biological trajectories and the factors (biological or not) that influence them, is critical to our understanding of neurodiversity, and opportunities to employ precision health principles to support autistic and other neurodivergent individuals across the lifespan.

207.004 (Panel Discussion) Autism As Emergent and Transactional
J. Green, University of Manchester, Manchester, United Kingdom

Background: I approach current challenges in the conceptualisation of autism by considering autistic states as i) an emergent property against the background of dimensional neurodivergence; and ii) transactional, as the neurodivergent brain, mind, and body encounter their social and physical environment within early development (Green 2022). Evidence supporting this proposition comes from a sequence of randomised intervention trials based on transactional development theory, in the infancy pre-diagnostic prodrome and early post-diagnosis.
Objectives: To consider four RCTs of transactional parent-mediated therapy which used a blinded measure of the autistic phenotype (ADOS/AOSI) as primary outcome. Three included long-term blind-assessed follow-up analysed with ITT and ‘area between curves’ representing cumulative effect of intervention over time (see Figure 1).

Methods: The therapies (PACT/iBASIS) work with parents to help their awareness and understanding of the communication style and intentionality of their neurodivergent child; in consequence improving the accuracy, sensitivity, and contingency of their dyadic responses. The young autistic child responds in turn with increased response and communication initiation.

Results: Initial RCT of the PACT intervention (Aldred et al 2004; N=28) compared to usual care altered the outcome child ADOS total score [F.1:25/ = 7.30; p = 0.01]. Larger PACT RCT (Pickles et al 2016; N=152) altered the (dimensional) ADOS “combined severity score” (CSS) at endpoint, with sustained effect over the next 6 years [marginal log-odds effect size 0.55 (95% CI 0.14–0.91; p = 0.009), Figure 1 bottom panel]. Both samples included children with substantial autism and ID. Increased child social engagement and initiation mediated the endpoint and follow up ADOS effects (Figure 2).

RCT of the iBASIS intervention (Green et al 2017; N=55), from 9 months in infant-siblings at elevated likelihood of autism, showed cumulative effect to reduce dimensional AOSI/ADOS scores over intervention and 2 year follow up (Figure 1 top panel). These results were replicated with community sampling for developmental concerns at 12 months (Whitehouse et al 2021; N=103; Figure 1 middle panel). In the latter trial, independent clinical diagnosis at 3 years showed a 67% reduction in emergent categorical autism (20.5% in TAU against 6.7% in iBASIS); odds ratio 0.18 (0–0.68; p = 0.02), while the children remained neurodivergent in other ways.

Conclusions: Across a range of child autism and developmental delay, targeted alteration in the quality of social transactional environment available for the child leads to significant, sustained alterations in dimensional autistic traits across both social communication and RRB/sensory domains; and, in one trial, to a linked reduction in independent clinical categorical classification. This linking of altered dimensional characteristics to clinical categorical emergence supports the idea of autism as an emergent property and its degree of malleability to altered social environments.

The results also thus enlarge our conceptualisation of the autism phenotype, to include both individual biology and the social environment in transactional relation. This may challenge essentialist views, for instance of intrinsic autistic “social avoidance”; integrates dimensional and categorical perspectives; and is consistent with the lived experience of autistic people and their advocacy for improved understanding within a social model.

Panel Discussion — Timely Topic Panel

213 - Inclusion in Research on Early Identification and Intervention: Finding the Common Ground

Panel Chair: Mayada Elsabbagh, Neurology and Neurosurgery, McGill University, Montreal, QC, Canada

Discussant: Rosa Hoekstra, Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM

213.001 (Panel Discussion) Autism Voices: Capture and Inclusion of First Person Perspectives
M. Elsabbagh, Neurology and Neurosurgery, McGill University, Montreal, QC, Canada

In recent years much progress has been made to enhance inclusivity in autism research. These efforts centre around the integration of lived experience, priorities, and preferences of various groups in the research process. Despite this progress, the first person perspectives of equity seeking groups remain underrepresented. The roots of exclusion in research are likely common across equity seeking subgroups, and include historical and ongoing biases, systemic discrimination, and structural inequality. However, improving this situation requires a thorough understanding of the barriers to inclusion which vary by field of research, target groups, and specific research and/or community contexts.

The presentation will showcase three case studies where significant adaptations to conventional research approaches improved inclusivity by enhancing the capture and/or integration of lived experience in research. Case 1, in the area of biomarker discovery, focused on development of meaningful measures to monitor the impact of genetic testing on the experience of families in routine care. Case 2, in a longitudinal cohort study enabled capture of first person perspectives of autistic children and youth across the spectrum, on outcomes and aspirations for the future. Case 3, in the area of early intervention focused on expanding access to services and supports in underserved communities through a co-designed clinical trial.
Taken together, these cases illustrate the need and the potential for adapting research approaches to enhance inclusivity. Systematic exclusion of equity seeking groups leads to questionable validity and generalizability of research findings. In contrast, it is hoped that inclusive research will generate solid findings with high potential for impact in society.

**213.002 (Panel Discussion) Partnering with Stakeholders in Intervention Science: Advancing Implementation and Effectiveness**

*S. Y. Shire, Special Education and Clinical Sciences, University of Oregon, Eugene, OR*

The traditional pipeline of clinic to community trials can take decades before practices are in use in the community. Rather, testing interventions within the real-world settings where the services will ultimately be provided and designing for community deployment can decrease the research to practice timeline (Weisz et al., 2004). Community Based Participatory Research (CBPR: Minkler & Wallerstein, 2003) can bring together the experience and joint goals of community and scientific leadership to examine the critical questions. Although many early intervention programs have demonstrated efficacy, fewer have demonstrated effectiveness when delivered in community practice. Community partnerships are critical to the development of effectiveness trials serving all children in public programs.

To describe a series of CBPR projects focused on the development, adaptation, testing, and deployment of a social communication intervention for young children with autism spectrum disorder (ASD) in public early intervention systems in North America.

Project 1 includes two studies where the goals and needs of the community as identified by leadership, practitioners, and caregivers led to testing of two implementation strategies to support practitioners’ learning of a social communication intervention in a hybrid type 1 effectiveness-implementation (Curran et al., 2012) randomized trial. To increase the reach to the region’s underserved communities, this was followed by a pilot concurrent multiple baseline study of remote caregiver coaching strategies delivered by community clinicians.

Project 2 incorporates the Active Implementation Framework (AIF: Metz & Bartley, 2012) to guide the iterative design of a technology-assisted adaptive caregiver-mediated model of the JASPER (Joint Attention, Symbolic Play, Engagement, and Regulation: Kasari et al., 2021) intervention. AIF Stages 1 and 2 focus on formative program development. A development team of EI stakeholders guided the first program iteration and staff training protocol. The program was then user tested by caregivers and practitioners using think-aloud interviews and completion of the System Usability Scale (SUS: Sauro, 2011). The revised program is currently being tested in a randomized trial. The trial will explore the acceptability, feasibility, and adoption of two adaptive implementation strategies to support caregivers’ strategy implementation.

Project 1 demonstrated significant gains for all practitioners over time but no significant differences between implementation strategies. The multiple baseline study demonstrated effects for caregivers’ strategy use (Tau-U=.95-1.0) and children’s social engagement (Tau-U=.94-1.0). We are currently exploring the sustainment of the practices in the province. These results informed Project 2.

In Project 2 we developed online intervention materials that was scored as “good” (scores in 80s on SUS) by stakeholders and revised the program based on their think-aloud feedback to be used in a randomized trial.

Together, these studies demonstrate that community stakeholders and researchers can team to collaboratively develop research questions and implement randomized trials that can explore both intervention effectiveness and real-world implementation. Current projects will continue to engage stakeholders including families who will have the opportunity to use the full online program. Their feedback will support a further refined iteration of the program that can then be culturally and linguistically adapted to support additional communities.

**213.003 (Panel Discussion) Identification and Intervention for Autism and Related Conditions in Humanitarian Settings**

*R. Nasir, Imperial College Healthcare NHS Trust, London, United Kingdom*

 Millions of children globally are impacted by humanitarian emergencies (armed conflict and natural disasters). Recent figures estimate that 175 million children globally are affected each year by natural disasters and 449 million children live in a conflict zone. Within this population, children with autism and related conditions are at further risk for poor outcomes related to health, mental health, physical injury and maltreatment. Little is known about these children and best practices to identify and support them. As the number of persons experiencing humanitarian emergencies soars globally, there is increasing evidence that individuals with autism and related conditions in humanitarian settings are at higher risk to experience adverse outcomes.

The presentation will offer a clinician and advocate perspective on what is known about autism and related conditions in humanitarian settings, the impact of trauma and other comorbidities, and examples of efforts to address this important gap in humanitarian action with particular emphasis on the role of the research community. Additionally, I will conver outcomes from the INSAR SIG on Autism and Related Disorders in the Context of Humanitarian Emergencies that was convened over three years from 2019-2021. The SIG identified key challenges and gaps including: (1) the lack of epidemiological data (e.g., prevalence, comorbidity and impact of trauma); (2) limited understanding of cultural and contextual factors that impact presentation, identification and access to services; (3) limited evidence-base for interventions in the humanitarian setting; (4) limited resources (e.g., funding, trained professionals, infrastructure) for research and clinical care; (5) the low priority and limited voice of those with autism and related conditions in this setting.
Potential solutions were also identified including: (1) empowering and engaging local professionals, and at-risk individuals/caregivers in capturing new and existing data; (2) involving local partners in capacity building (increasing knowledge and skills), including advanced crisis planning; (3) expanding research initiatives to low-resource humanitarian settings (e.g., WHO Caregiver Skills Training Programme); (4) effective use of technology to improve training communication, coaching and supervision of local partners and (5) learning from existing models of academic research in humanitarian settings. Key overarching approaches include multidisciplinary collaboration among stakeholders to improve implementation approaches; and sustained, targeted advocacy and coalition building within the autism community, professional societies, and governmental, nongovernmental, intergovernmental and humanitarian organizations.

Autism and related conditions represent a large, underserved population globally. Extant literature is limited and documents higher risk of adverse outcomes. Further research is needed to drive policy and interventions. There are existing models of academic research collaborations in humanitarian settings that may be relevant to researchers in the field of autism and related conditions.

213.004 (Panel Discussion) Participatory Methods for Autism Intervention Science  
*S. Fletcher-Watson*, Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, UNITED KINGDOM

In this talk Sue will consider the dangers that can arise when autism community members are not involved in the intervention development, evaluation, implementation and personalisation pipeline. She will specifically address risks for the early intervention literature, and give examples of participatory research methods that can be used to deliver evidence-based practices that are fit for purpose and that the broad and diverse autism community can get behind.

### Translational Neuroscience

#### PANEL DISCUSSION — TRANSLATIONAL NEUROSCIENCE

**210 - Using Electrophysiology to Derive Translational Phenotypes in Genetic Models of Autism**

**Panel Chair:** Emily Jones, Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom  
**Discussant:** Sarah Lippe, Neurosciences of Early Development Lab, CHU Sainte-Justine, Montreal, QC, Canada

Improving outcomes for autistic people requires sensitive biomarkers that can be used to predict prognosis and identify target engagement with relevant neurobiological pathways for new medicines. One relevant neurobiological mechanism is alterations in the relative balance of excitatory to inhibitory activity in sensory regions of the brain (E/I balance). Using EEG to measure E/I balance has strong potential for translation because it can be used across the lifespan and across species. Here, we present new data on candidate EEG markers of E/I balance across phylogenetic and ontogenetic levels. Cooke shows that the two classes of inhibitory neuron produce different EEG phenotypes within cortical layer 4, indicating the importance of considering heterogeneity within the inhibitory pathway. Tye shows that infants with TSC (a mutation affecting I/E balance) show alterations in the latency of basic sensory responses. Carter Leno shows that an EEG index of E/I balance relates to sensory differences in infants with a family history of autism. Finally, Lippe shows converging evidence of alterations in gamma-frequency rhythms in children with idiopathic and syndromic forms of autism that impact E/I. Taken together, EEG shows promise for the identification of disruptions to E/I balance in autism.

**210.001 (Panel Discussion) Biomarkers of Cortical Inhibition and Disinhibition Accompanying Habituation and Novelty Detection over Different Timescales**

F. A. Chaloner, C. Gelegen Van Eijl, A. Lawson and S. F. Cooke, (1)Centre for Developmental Neurobiology, Institute of Psychology, Psychiatry and Neuroscience, King’s College London, London, United Kingdom, (2)Department of Basic and Clinical Neuroscience, Institute of Psychology, Psychiatry and Neuroscience, King’s College London, London, United Kingdom, (3)Kings College London, London, United Kingdom

Background: Habituation enables organisms to suppress behavioural response to neutral stimuli and devote energy and attention to stimuli that reward, punish or are novel and therefore have the potential to deliver either. It is a fundamental form of cognition that lays the foundation for higher order cognition and is often disrupted in neurodevelopmental disorders such as intellectual disability (ID) and autism spectrum disorder (ASD). Given that habituation is manifest early in sensory processing, it serves an equally important role in mice and humans. We have developed a range of assays to measure habituation and novelty detection in mice over a range of timescales to develop deeper understanding of mechanisms at play in health and disorder.

**Objectives:**
Here we will describe response dynamics in primary visual cortex (V1) across different timescales of visual habituation to phase-reversing sinusoidal grating stimuli. We will further discuss the interventional approaches taken to understand core molecular mechanisms and key circuit motifs that support habituation and novelty detection in the neocortex across short and long timescales. In addition, we have modelled disruptions of those mechanisms in neurodevelopmental disorders originating from known genetic causes, including Fragile X Syndrome and Tuberous Sclerosis Complex.

Methods:

Behavioural analysis, single unit recordings, local field potential recordings, electroencephalogram (EEG), optogenetics, chemogenetics and genetic knockdown in mice.

Results:

We have found that, visual-evoked potential (VEP) responses recorded in layer 4 of V1 undergo trough-peak depression during short-term visual habituation within a single recording session, consistent with theories of habituation as a form of adaptive filtration. By contrast, long-term habituation is accompanied by a paradoxical sleep-dependent form of response potentiation in neocortex, known as stimulus-selective response potentiation (SRP), because it is limited to a familiar stimulus. Both forms of plasticity and accompanying habituation are impaired by local knockdown of NMDA receptors in V1, indicating the involvement of bidirectional Hebbian synaptic plasticity. However, we also present evidence that inhibitory neurons play a key role in cortical familiarity and novelty detection. Notably, Parvalbumin-expressing inhibitory neurons are significantly more engaged by novel than familiar orientations while a different subclass of GABAergic neurons, the Somatostatin-expressing neurons, are more engaged by familiarity than novelty. We will also describe signature oscillations that are produced by familiarity or novelty which may be recorded non-invasively in EEG and likely serve as a proxy of the respective activity of these neuronal subtypes. Finally, we present observations of altered habituation and cortical dynamics in mouse models of neurodevelopmental disorders.

Conclusions:

A simple but fundamental form of cognition drives a variety of signals that are often aberrant in neurodevelopmental disorders, and the mouse provides a system to deeply understand their origins and dysfunction. Based on our results, we also believe that the potential exists in the future to record these signals non-invasively using EEG from human populations for patient stratification and assessment of response to treatment.

210.002 (Panel Discussion) Alterations to Excitation/Inhibition Balance at 10 Months of Age Are Associated with Increased Sensory Hypersensitivity in Cohorts Enriched for Neurodivergent Outcomes

(1)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, UNITED KINGDOM, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, Institute of Psychiatry, London, UNITED KINGDOM, (5)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (6)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (7)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (8)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (9)Department of Psychology, Institute of Psychiatry, Psychology & Neuroscience, King’s College London, London, United Kingdom

Background:

Differences in sensory processing are highly prevalent in autistic populations, and there is some evidence of similar differences in attention deficit hyperactivity disorder (ADHD). However, the neural mechanisms that underpin these differences in sensory processing and experience remain unclear. One proposed mechanism is alterations in the relative balance of excitatory to inhibitory activity in sensory regions of the brain (E/I balance). While there is some evidence from neuroimaging and neurometabolite studies that alterations in E/I balance are associated with sensory hyper and hypersensitivity, most studies examined contemporaneous associations in older autistic populations, meaning inference about directionality of effects is limited.

Objectives:

To test whether alterations in E/I balance in the first year of life are contemporaneously and longitudinally associated with sensory hyper and hypersensitivity in cohorts of children enriched for neurodivergent outcomes.

Methods:
At-rest EEG was collected from a sample of 10-month infants (N=161); 29 typical likelihood (no family history of neurodevelopmental conditions), 80 elevated autism likelihood (family history of autism), 31 elevated ADHD likelihood (family history of ADHD) and 21 elevated autism+ADHD likelihood (family history of autism and ADHD). Metrics of hyper and hyposensitivity were calculated from the Infant and Toddler Sensory Profile (Dunn, 2002), which was completed by parents at 10, 14, 24 and 36 months. Scores were reversed such that a higher score indicates higher hyper/hyposensitivity.

We estimated E/I balance from pre-processed EEG using the Fitting Oscillations and One Over F algorithm (FOOOF; Donoghue et al., 2020). This equates to the exponent of log-frequency plotted against log-power (also referred to as 1/f), with a higher aperiodic exponent indicating a steeper slope and higher relative inhibition.

Analyses estimated a joint correlated latent growth curves model to capture the starting point (intercept) and trajectory of change (slope) for sensory hyper and hyposensitivity between 10-36 months, adjusting for individual differences in age at assessment at each timepoint (See Figure 1A). We entered elevated autism likelihood (present/absent), elevated ADHD likelihood (present/absent), gender, 10m aperiodic exponent and number of EEG trials as predictors of intercept and slope for hyper and hyposensitivity.

Results:

10m aperiodic exponent (b=.70, p<.01) and number of trials (b=-.45, p=.03) were associated with the intercept of hypersensitivity (Figure 1B). Models showed elevated autism likelihood was associated with a higher hyposensitivity intercept (b=.54, p<.01) but no effect on hyposensitivity slope (b=-.26, p=.09), and no effect on hypersensitivity intercept (b=.19, p=.34) but a steeper hypersensitivity slope (b=.66, p=.03) (Figure 2). ADHD likelihood was only associated with a steeper slope of hyposensitivity (b=.39, p<.01). There was a significant effect of gender, such that males had a higher intercept for hyposensitivity only (b=.57, p<.01).

Conclusions:

Results suggest higher inhibitory tone is associated with higher baseline hypersensitivity, whilst autism likelihood is associated with higher and more stable hyposensitivity and growth in hypersensitivity, and ADHD likelihood is associated with greater growth in hyposensitivity. Findings suggest early alterations to E/I balance and neurodevelopmental likelihood are differentially related to sensory modulation, and that associations with alterations to E/I balance are specific to hyper, rather than hyposensitivity.

210.003 (Panel Discussion) Infant Neural Sensitivity to Eye Gaze and Later Emerging Autistic Traits in Tuberous Sclerosis

Background:

Up to 60% of individuals with tuberous sclerosis complex (TSC) meet diagnostic criteria for autism. While several clinical features correlate with autism in TSC, the specific mechanisms underlying variability in developmental outcome are yet to be clearly defined. An increasing proportion of TSC cases are identified prenatally, providing a unique opportunity to study developmental pathways to autism from infancy. Accumulating evidence from infants who have an elevated familial likelihood for autism suggests altered face and gaze processing precedes and predicts autism diagnosis. While atypical face processing has been reported in older children and adults with TSC, the profile of face processing in infancy and extent of homology with infants with elevated non-syndromic likelihood remains unclear.

Objectives:

This study aimed to: (1) characterise neural processing of faces and gaze in infants with TSC compared to infants with elevated non-syndromic likelihood for autism; (2) identify predictors of emerging autistic traits in infants with TSC.

Methods:

Infants with TSC were recruited from the Early Development in Tuberous Sclerosis (EDiTS) Study (n=12, mean chronological age (CA): 10.75 months) and compared to infants with (elevated familial likelihood, EFL; n=169; mean CA: 8.21 months) and without (typical
likelihood, TL; n=77, mean CA: 7.88 months) an older sibling diagnosed with autism. We recorded infants’ face-sensitive event-related potentials (ERPs) in response to viewing: 1) faces versus visual noise stimuli; (2) static gaze (faces with direct versus averted gaze); 3) dynamic gaze shift (eye gaze directed toward versus away from the infant). Cognitive ability was assessed using the Mullen Scales of Early Learning and secondary analyses matched groups according to mean nonverbal mental age (MA; unadjusted TSC: 8.96 months; EFL: 9.47 months; TL: 9.86 months). The Vineland Adaptive Behavior Scales and the Quantitative Checklist for Autism in Toddlers were administered to parents at 24 months.

Results:

Infants with TSC demonstrated longer ERP latencies to face stimuli across conditions and across the time-course of neural processing of faces (P1, N290, P400) compared to infants with EFL and TL. Infants with TSC and EFL showed a reduced effect of dynamic gaze shifting away versus towards the infant on P400 amplitude, compared to TL [F(2, 74)=4.5, p=.01]. Findings were retained when groups were matched on non-verbal MA and were not associated with epilepsy severity. The reduced effect of gaze shifting on P400 amplitude was associated with lower socialisation scores on the VABS (r=.62, p<.05) and increased autistic traits on the QCHAT at 24 months (r=-.50, p<.05) in the TSC group only.

Conclusions:

Infants with TSC show slower speed of face processing and reduced detection of dynamic gaze shifts, suggesting altered specialisation for gaze processing. The findings replicate previous work in infants with non-syndromic likelihood for autism and extend to syndromic populations, suggesting a candidate convergent pathway across aetiologicaly distinct groups. Importantly, atypical gaze processing is a potential predictive marker of emerging autism in TSC, which may aid in targeting early intervention and providing a read-out of treatment efficacy.

210.004 (Panel Discussion) EEG Markers of Inhibitory and Excitatory Function in Children with Genetic Conditions and Autism

S. Lippe, E. Anagnostou, M. Proteau-Lemieux and I. S. Knoth, (1)Neurosciences of Early Development Lab, CHU Sainte-Justine, Montreal, QC, Canada, (2)Autism Research Centre, Bloorview Research Institute, University of Toronto, Toronto, ON, Canada, (3)CHU Sainte-Justine Research Center, Neuroscience of Early Development lab, Montreal, QC, Canada

Background:

Genetic conditions alter molecular pathways and neural circuitry dynamics during development. A greater understanding of the neurophysiological dynamics of the brain caused by genetic mutations associated with neurodevelopmental disorders is needed. It could enable us to assess, in vivo, the signatures of the mechanisms altered in neurodevelopmental disorders. Over the last few years, we investigated the brain signal of several neurodevelopmental disorders of genetic origins to verify whether patterns of similarities map to specific genetic mutations or behavioral symptoms. Electroencephalography (EEG) is a high-time-resolution method to evaluate brain signal dynamics non-invasively. Several metrics, sensitive to developmental and clinical conditions, can be extracted from the signal.

Objectives: This presentation aims to reveal the metrics extracted from resting-state EEG that are most relevant to NF1, FXS, and ASD.

Methods: FXS (N=41), ASD (N=68), NF1 (N=27), and neurotypicals (N=78) from 6 to 30 years old have been recorded with high-density EEG while performing a series of tasks and during resting. Resting-state data were preprocessed using EEGLab and the 1/f aperiodic, frequency bands power density, alpha peak frequency, connectivity (wPLI), and multiscale entropy (MSE) were extracted.

Results: Results suggest shared alterations in FXS, and ASD children in gamma powers compared to neurotypicals (p<0.0001). High MSE scales were reduced in FXS and ASD and are sensitive to the level of functioning (IQ) (p<0.013). Alpha peak frequency and connectivity show mixed results in the different populations.

Conclusions: While some EEG metrics are similarly altered in the clinical groups, others may relate to symptomatology. Stratification of the data will enable more specific portraits of altered EEG metrics in these neurodevelopmental conditions.

PANEL DISCUSSION — TRANSLATIONAL NEUROSCIENCE

224 - Sleep and Sensory Processing in Autism: Translational Insights

Panel Chair: Emily Jones, Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom
Discussant: Nicolaas Puts, Russell H. Morgan Department of Radiology and Radiological Science, Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK, Baltimore, MD, United Kingdom

Sleep problems are common in autistic people and can significantly impact mental health and quality of life, but remain poorly understood. Sleep is a domain that is well-suited to a translational approach, since sleep/wake cycles can be studied using comparable paradigms across the lifespan and in animal models; this provides potential new routes to treatment for sleep problems. We present four datasets that provide converging evidence of the aetiological relevance of sleep differences in autism. Ostergaard shows that neurexin1-deficient mice (a genetic change that is commonly associated with autism) show differences in both sleep quantity and quality. Begum-Ali shows that differences in sleep emerge by 14 months in infants with later autism, and predict both autistic traits and behavioral measures of sensory hypersensitivity in toddlerhood. Oakley shows that children with genetic syndromes linked to autism (PMS) show reduced sleep at night. Finally, Kyllainen presents data on the acceptability and feasibility of interventions targeted at supporting sleep for toddlers with emerging autistic traits. Taken together, our work shows that sleep is a translationally-relevant domain that is altered in both genetic models of autism, in infants prior to symptom onset, and children with genetic syndromes, and is a tractable target for intervention.

224.001 (Panel Discussion) Sleep and Sensory Processing in the Nrxn1α-Deficient Mouse Model

F. G. Ostergaard and M. Kas, (1)Gronigen, Gronigen, Netherlands, (2)University of Groningen, Groningen, Netherlands

Background:

Altered sensory processing is an integral part of the autism spectrum disorder (ASD) diagnosis. Especially various forms of habituation seem be affected, thus, both hyper- and hypo-sensitivity has been reported in humans. The underlying mechanisms are not well-elucidated. A number of risk genes have been suggested for ASD, one of which is NRXN1. Nrxn1 is a well-conserved gene across species and one of the largest genes in the human genome. Parts of this gene have been found to be deleted in several autistic people. It encodes a presynaptic cell-adhesion molecule and is believed to act in synaptic transmission. Previous studies have found a discrete electrophysiological phenotype, in the form of a change in excitatory currents, in Nrxn1α gene knock-out mice (Etherton et al., 2009).

Objectives:

In this study we explore sensory processing and sleep in neurexin-1α deficient mice using electrophysiology.

Methods:

The groups were male mice of the following genotypes: wildtypes (WT) n=14, homozygous knock-out (KO) n=14 and heterozygous knock-out n=13 (Het). All had electrodes implanted in the visual and auditory cortices. The electrophysiological activity was recorded with wireless Taini (Jiang et al., 2017) transmitters at the age of 10 weeks and again at the age of 22 weeks. The animals were exposed to gating paradigms of light flashes and tones presented at different inter-stimulus-intervals.

Spontaneous activity was recorded for four hours in the home cage environment. Semi-automatic scoring was carried out with custom scripts in matlab. Statistics were carried out using estimation statistics and the DABEST package in R studio.

Results:

The results showed the full-KO being sensitized to light flashes compared to the WT. The results from the auditory paradigm showed the heterozygous KO exhibiting more gating than both the full-KO and the WT.

Recording of spontaneous activity with subsequent scoring revealed statistically significant changes in the proportion of time spent in each state, see the figure below. The delta-dominated awake state was increased in both the heterozygous 0.147 [95CI: 0.0582; 0.254] and the homozygous knock-out 0.131 [95CI: 0.0414; 0.218] at the age of 22 weeks, where the delta-dominated slow wave sleep was decreased in both genotypes and at both ages (Het (-0.0636 [95CI: -0.106; -0.0246]) at w10 and (-0.0861 [95CI: -0.137; -0.0377]) at week 22, KO was decreased (-0.103 [95CI: -0.15; -0.0524]) at week 10 and (-0.139 [95CI: -0.181; -0.101]) at week 22). REM sleep was decreased at the later age in both Het (-0.0711 [95CI: -0.115; -0.0249]) and KO (-0.0685 [95CI: -0.111; -0.0299]). Curiously, then the fast NREM was increased in the homozygous knock-out at both ages (week 10 (0.0352 [95CI: 0.00446; 0.069]) and week 22 (0.032 [95CI: 0.003; 0.0594]). Overall, there would be an expectation of decreasing amounts of sleep with age, however the wildtypes did not differ significantly across time.

Conclusions:

Taken together this suggests hyperexcitability caused by knocking out Nrxn1, and this in turn affects not only the over-all amount of sleep, but also the composition of sleep.
Sleep Onset Problems in Infancy Associates with Later Increased Sensory Sensitivity and Autism Spectrum Disorder Symptomatology

Background:
Sleep problems have been implicated in neurodevelopmental disorders, such as Autism Spectrum Disorder (ASD), persisting from early development to adulthood (Rydzewska et al., 2020). Previous research examining prospective longitudinal cohorts have found that infants with a family history of ASD, and those that go on to have an ASD diagnosis, demonstrate reduced levels of night sleep (i.e., reduced sleep durations, increased night awakenings and increased sleep onset problems), with reduced night sleep in infancy associating with later increased ASD symptomatology and reduced social communication skills (Begum Ali, Gosse et al., in press; MacDuffie et al., 2020). Further, sleep disturbances in ASD cohorts have been associated with increased sensory atypicalities (e.g., Holway et al., 2013; De Laet et al., 2022). As such it is important to examine sleep in development and its relation to emerging sensory differences.

Objectives: To examine sleep and sensory behaviours concurrently and longitudinally in the first 2 years of life in infants and toddlers with a family history of ASD.

Methods:
We collected parent-report questionnaires from a sample of 247 infants; 170 infants with an elevated likelihood of ASD (ASD-L) and 77 infants with a typical likelihood of ASD (TL). We assessed sleep using the Infant Sleep Onset Problem score (ISOP; MacDuffie et al., 2020) derived from the Infant Behaviour Questionnaire Revised (Putnam et al., 2014) at 4, 6-10 and 12-15 months of age. To examine sensory behaviours, we used the Perceptual Sensitivity subscale (PSS) from the IBQ-R (4-15 months) and the Early Childhood Behaviour Questionnaire (24-months; Putnam et al., 2006).

Results:
Sleep Onset Problems did not vary by familial likelihood of ASD \(F(1, 314) = .25, p = .62\) or ASD Outcome at 3 years \(F(1, 403) = 1.31, p = .25\). To investigate the relationship between sleep and sensory behaviours, we used a cross lagged structural equation model. We found that increased Sleep Onset Problems at 12-15 months associated with increased Perceptual Sensitivity at 2 years \(\beta = .14, p = .03\) and increased ASD symptomatology (Social Responsiveness Scale scores: \(\beta = .2, p = .004\)) at 3 years; see Figure 1.

Conclusions:
Our findings show that increased levels of sleep problems in infancy associate with increased sensory sensitivity and ASD symptomatology in toddlerhood. Interestingly, we find no group differences in the sleep measure used.

Sleep Profiles and Their Association with Clinical Features in Individuals with Rare Synaptic Gene Conditions from the AIMS-2-Trials Synaptic Gene Study (SynaG)

Background:
GABA and glutamate are critical for maintaining excitation/inhibition (E/I) balance in the brain, and are also involved in sleep and wake regulation (Ballester et al., 2020). Altered synaptic biology is implicated in autism, which may in turn contribute to changes in sleep-wake
mechanisms (Bourgeron 2007; Tong et al., 2016). The Synaptic Gene Study assesses autism-related synaptic gene conditions, or synaptopathies, to better understand underlying biological mechanisms that may contribute to autistic traits and associated features (Cooke et al., 2022). Disturbances in sleep have been reported in synaptopathies such as Phelan McDermid Syndrome (PMD; Smith-Hick et al., 2021; Bro et al., 2017), however, their relationships with autistic features and functional outcomes have not yet been explored.

Objectives: We characterise sleep profiles of individuals with PMD (compared to matched autistic/typically developing individuals) and how sleep behaviours relate to autistic features and functional outcomes.

Methods: 54 individuals aged 1-19-years (16 Phelan-McDermid Syndrome, 21 idiopathic autistic, 17 neurotypically developing individuals matched for mental age) were included in this analysis. Sleep behaviour and disturbance was assessed using the parent-report Children's Sleep Habits Questionnaire (CSHQ). Autistic traits were measured using researcher-rated Autism Diagnostic Observation Schedule – 2nd Edition (ADOS-2)/Autism Diagnostic Interview – Revised (ADI-R); and the Sensory Experiences Questionnaire (SEQ) for sensory processing differences. Adaptive functioning was measured using the Vineland Adaptive Behaviour Scales – 2nd Edition (Vineland-II); and frequently co-occurring mental health features via the REISS scales (anxiety/depression scores) and Aberrant Behaviour Checklist (ABC; irritability/hyperactivity scores). Analyses were conducted to establish a) sleep profiles across the cohort, and whether these differed by subgroup; and b) associations between sleep behaviours/ disturbance with autistic traits, particularly sensory features

Results: NTD children slept more at night (Mdn = 11 hours, \( p = .01 \)) than their PMD (Mdn = 10 hours) and iAutism (Mdn = 9.5 hours) counterparts. Between 48-50% of PMD and iAutistic parents reported their child getting too little sleep as problematic, versus 0% of NTD parents. 19% of iAutism parents reported that their child frequently struggled at bedtime, versus 6% of both PMD and NTD parents. 28% of Autism versus 13% and 6% of PMD and NTD parents respectively, considered the bedtime struggles they experience to be problematic. Total sleep disturbance did not differ between groups (\( p = .162 \)), but was positively associated with sensory experience (\( r(41) = .440, p < .01 \)) and hyperactivity (\( r(54) = .229, p = .028 \)).

Conclusions: Our results show, for the first time, that increased sleep disturbances in a matched sample of individuals with PMD, iAutism and NTD associate with sensory sensitivities and hyperactivity, as perceived by parents. While both PMS and iAutism groups were reported to be getting too little sleep on average, as compared to their NTD peers, the iAutism group were reported to have the most sleep difficulties across the groups. This provides support to the hypothesis that altered synaptic biology implicated in autism may influence sleep-wake mechanisms but that other factors (including e.g., parental perceptions of sleep difficulties) may also be relevant when working with questionnaire-rated sleep data.

224.004 (Panel Discussion) Feasibility Study of Brief Parental Sleep Guidance for Toddlers with Prodromal ASD
A. Kylliainen, V. Jokitalo, T. Makeja, S. Erme, E. Lehtonen, E. Jones, J. E. Paavonen, L. Wiggins and O. Saarenpaa-Heikkila, (1)Faculty of Social Sciences/Psychology, Tampere University, Tampere, FINLAND, (2)Faculty of Social Sciences/Psychology, Tampere University, Tampere, FINLAND, (3)Department of Paediatrics, Tampere University Hospital, Tampere, Finland, (4)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (5)Public Health and Welfare, Finnish Institute for Health and Welfare, Helsinki, Finland, (6)The Centre for Psychological Research, Oxford Brookes University, Oxford, United Kingdom, (7)Center for Child Health Research, Faculty of Medicine and Health Technology, Tampere University; Tampere University Hospital, Tampere Finland, Tampere, Finland

Background: Sleep problems are common in ASD and are among the first concerns of parents whose toddlers are likely to develop autism spectrum disorder (ASD). It seems essential to offer parental support as early as possible, in the hope of preventing sleeping difficulties from becoming more severe and/or longstanding. Studies of sleep support for parents of toddlers with prodromal ASD are, however, sparse although there is research evidence of effective behavioural sleep interventions for autistic children and typically developing toddlers.

Objectives: This study obtains feasibility data of the brief parental sleep guidance for toddlers with prodromal ASD at a stage before formal diagnoses. The specific aims are to investigate the practical feasibility of the procedure, evaluate the developed fidelity measures, and gather a participatory view of the guidance.

Methods: To date, parents of three toddlers with prodromal ASD have participated in our ongoing feasibility study. The sleep guidance is implemented as a part of the Gaze@Toddler project, in which toddlers are screened from the general population at the age of 16-18 months using a parental questionnaire (M-CHAT-R/F). The guidance consists of three in-person (60 min) and two remote (45min) sessions over three months (Fig 1). The interventionists are (neuro)psychologists and MDs specialised in paediatric sleep medicine. The feedback for feasibility purposes was gathered both from the parents and the interventionists. There were two fidelity rating scales completed by researchers assessing: 1) the interventionists’ delivery of the guidance and 2) the parents’ adherence to the guidance. The parents’ fidelity assessment also included evaluation of how the sleep diary was filled for each session.

The guidance is focused on supporting 1) diurnal rhythm, 2) regular bedtime routines and 3) the ability for self-soothing. The specific techniques are derived from previous studies (e.g., Sleeping Sound), such as a camping out, bedtime fading and visual support for bedtime routines (Fig 1).
Results: The number of sessions and their content were accessible and appropriate, according to both the parents and the interventionists. The parental feedback of the sleep guidance was very positive. They felt that the principles were easy to follow, and they were highly motivated to participate in the guidance. However, parents were divided in their opinions about the inclusion of remote sessions; some considered them to be ineffective, but others favoured the remote delivery as it was easier to fit within their hectic family lives. The fidelity scale for the interventionists was reported to be easy for the researchers to complete but the fidelity scale about the parents’ adherence needed modifications, being too complicated for the interventionist to complete. The parents were motivated to fill out the sleep diary.

Conclusions: The feasibility study of sleep guidance for parents of a toddler with prodromal ASD suggests high acceptability to the parents and interventionists. The acceptability of remote sessions was less clear, and results will be monitored as more parents participate in the feasibility study. A simplified version of the parent fidelity scale is being developed.
