Methods: Data were drawn from the Simons Simplex Collection database of individuals for whom both parent and teacher scores on the Social Responsiveness Scale (SRS) were available. The final sample included 388 individuals (50% male) matched on age ($M=8.88$, $SD=3.53$, range from 4 to 17.58 years) and full-scale IQ ($M=74.8$, $SD=27.14$, range from 19 to 142). Eighty percent of the included sample was white. The raw total and five subscale scores from the SRS were used. We opted to use raw scores over T-scores, which may mask sex differences through sex-normed data transformation. Parametric tests were used to evaluate sex differences in mean scores for parent and teacher responses and differences between parent and teacher scores.

Results: Mean total and subscale scores are reported in Table 1. Despite no reported sex differences from parents on the SRS, males received significantly higher scores (i.e., more indicative of autism) than females in the teacher-reported raw total score, $t(378) = -4.23$, $p<.001$, $d=.43$, and all teacher-reported subscales including Social Awareness, $t(380) = -3.23$, $p<.001$, $d=.33$, Social Cognition, $t(377) = -3.64$, $p<.001$, $d=.37$, Social Communication, $t(379) = -3.97$, $p<.001$, $d=.40$, Social Motivation, $t(381) = -2.84$, $p=.01$, $d=.29$, and Restricted Repetitive Behaviors, $t(384) = -4.23$, $p<.001$, $d=.44$. Additionally, parent-reported scores were significantly higher for females than teacher-reported scores on the Social Awareness, $t(373) = 2.34$, $p=.02$, $d=.24$, Social Cognition, $t(371) = 2.9$, $p=.004$, $d=.29$, and Restricted Repetitive Behaviors, $t(382) = 3.61$, $p<.001$, $d=.36$, subscales, as well as on the raw total score, $t(366) = 2.78$, $p=.006$, $d=.28$. There were no significant sex differences between parent-report and teacher-report for males.

Conclusions: The findings from previous studies that parents of autistic children tend to rate their child’s characteristics and traits as more indicative of autism compared to teachers were replicated in this study, but only for the female sample. This builds on previous research surrounding teacher observations towards autistic females and suggests a need for improved school assessment and parent-teacher collaboration for this population.

431.110  (Poster) The Impact of an Older Siblings Diagnosis on Parent Perceptions of Infant-Siblings Development and Behavior: And Exploratory Study

J. Lisle, K. Hayes, E. Choi, K. B. Brown, J. Sideris and G. T. Baranek, (1)Chan Division of Occupational Science and Occupational Therapy, Chan Division of Occupational Science at the University of Southern California, Los Angeles, CA, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA

Background:

Screening infants for likelihood of autism is imperative for connecting families with services. While screening is considered best practice, parents’ expression of concerns may initiate this process sooner (Becerra-Culqui et al., 2018). While parents of infant siblings at elevated familial likelihood of autism report concerns earlier and in greater quantity than parents whose older children have no diagnosis and those that are first-born (Herlihy et al., 2016; Sacrey et al., 2015), it is unclear whether behavioral nuances are also recognized by parents. Further, it is unknown how the experience of raising a first-born or older child with or without developmental delays informs parents’ reports of infant behaviors on autism screening measures.

Objectives:

This study aimed to determine if having an older child with autism, or a related neurodevelopmental condition, is associated with parents’ perceptions about developmental concerns and the frequency of risk signs reported on the First Years Inventory v3.1 (FYIv3.1).

Methods:

A community sample of infants (n=443), age 6 to 16 months, was recruited from the California state birth registry. Caregivers completed a demographics questionnaire, Developmental Concerns Questionnaire (DCQ), and FYIv3.1. Age-specific risk cutoffs for two FYIv3.1 domains, Social Communication (SC) and Sensory Reactivity (SR), were determined using normative data. Parents who expressed some or many concerns on the DCQ were categorized as having a concern. The sample was split into four subgroups: Infant siblings of children with autism (AUT-IS), infant siblings of children with another diagnosis (OD-IS), infant siblings of typically-developing children (TD-IS), and first-born (FB). We analyzed frequency distributions of parent-reported concerns (e.g., some concerns, many concerns, no concerns), FYI pass/fail rates, and the amount by which infants either missed or surpassed the two domain risk cutoffs for each subgroup.

Results:

Participants (N=443) ranged in age from 6 to 16 months (mean=10.3; SD=3.0). Approximately half were males. The sample consisted of AUT-IS(n=16; 4%), OD-IS(n=16; 4%), TD-IS(n=201; 45%), and FB(n=210; 47%).
Parents of AUT-IS had the highest rate of developmental concern with 19% expressing some or many concerns, followed by TD-IS (11%), FB (7%), and OD-IS (6%). Table 1 provides the breakdown of concerns and FYI pass/fails by group. Notably, 38% of AUT-IS parents and 31% of OD-IS parent expressed no concerns, yet they failed the FYIv3.1, indicating that the infant was at elevated likelihood for ASD.

Figure 1 shows how much the domain-specific mean scores deviated from the cutoffs. 63% of AUT-IS failed the FYI due to meeting threshold on social communication. Parents of AUT-IS that failed the social communication domain did not report any developmental concerns.

Conclusions:

These results do not support a hypothesis of increased sensitivity. Results suggest close monitoring of AUT-IS, particularly for social communication development, given the lack of concordance between parent-reported concerns and risk scores in this domain. Additionally, findings indicate the significance of defining “developmental concerns” prior to providing parent education and screening, as this imprecise language may lead to inaccuracy. Broadly, this study demonstrates the importance of screening all infants for autism, even when a parent does not express concerns.

Background: Prevalence rates of ASD are lower for Hispanic/Latinx children than non-Hispanic White and Black children (Maenner et al., 2020). Although this gap is closing, a disparity still exists in many locations within the US (Maenner et al., 2021). Clinical assessment of children with suspected ASD relies heavily on parent report of symptoms, including use of norm-referenced parent-report measures. However, ethnicity may affect parent report of child behavior. Hispanic/Latinx parents were found to report fewer overall concerns and fewer child behavior problems than White/Anglo parents (Blacher et al., 2014; Magana & Smith, 2013). Language background may also affect symptom reports. Blacher et al. (2019) found Spanish-speaking Hispanic/Latinx mothers reported greater severity of symptoms on an autism questionnaire than English-speaking Hispanic/Latinx mothers, even when clinician observational ratings of behaviors did not differ between the two groups. Considerations of language and ethnic background may be important to inform clinician interpretation of results from norm-referenced parent-report measures.

Objectives: To examine differences in parent endorsement of behavior difficulties on the English and Spanish versions of the Autism Spectrum Rating Scales (ASRS) and Behavior Assessment Scales for Children (BASC-3).

Methods: The sample is comprised of 90 Hispanic/Latinx children, ages 2 to 5, who received an ASD diagnosis at a university-based specialty autism diagnostic clinic in Florida. Children were referred through local Part C and Child Find services as part of a services grant providing no-cost evaluations for children suspected of having ASD. The sample consists of 44 females (48.9%) and 46 males (51.1%) who had a mean age of 46.07 months (SD=9.73) and a NVIQ of 72.56 (SD =24.71). Parents were English-speaking only (31.1%), Bilingual (51.1%), or Spanish-speaking only (17.8%). Parents completed the questionnaires based on their preferred language: English (n = 44, 48.9%) or Spanish (n = 46, 51.1%). The two groups did not differ significantly in terms of child age, gender ratio, NVIQ, or parent education.

Results: There were no group differences in DSM-5 clinician-assigned severity levels for social communication or restricted repetitive behaviors or in ADOS-2 Social Affect or Restrictive Repetitive Behavior Severity scores. However, lower ADOS-2 Total Severity scores were seen for children of families whose preferred language was Spanish (M=5.65, SD=2.532) compared to those families who completed assessment measures in English (M=6.66, SD=2.272), t (88) = 1.983, p=.050, d =0.418. No statistically significant differences were found between the two groups for scores on either the BASC-3 or the ASRS (see Table 1).

Conclusions: These findings add to a growing literature exploring the impact of language proficiency on the diagnostic process for Hispanic/Latinx children referred for autism evaluations. Among children who received a diagnosis of ASD, similar levels of behavioral difficulties were reported by parents who completed questionnaires in English versus Spanish. However, this was despite a higher level of overall symptom severity on the ADOS-2 for English dominant families in our sample, suggesting that additional research is needed to better understand how language preference and proficiency affects the diagnostic process.

431.112 (Poster) The Longitudinal Development of Cognition, Co-Occurring Conditions and Diagnostic Features in Children at Elevated and Typical Likelihood for Autism

Background:

Studies show that very preterm born children (VP-children) and younger siblings of children with autism are at elevated likelihood (EL) to develop autism or the broader autism phenotype (BAP) (Ozonoff et al., 2011; Vermeirsch et al., 2020). Prospective follow-up studies incorporating these EL-children have contributed to our knowledge on early trajectories of autism. Few EL-infant studies, however, have monitored their sample beyond age three, which is important to get a better understanding of the development of autism, subthreshold manifestations, co-occurring conditions, and differences between and/or within different EL-groups.

Objectives:

- Investigate whether community diagnoses and autism features at school-age are consistent with clinical best estimate (CBE) diagnoses of autism/BAP at age three in a sample of VP-children and EL-siblings;

- Examine cognitive development;

- Explore the presence and development of co-occurring conditions.

Methods:

A total of 224 children who took part in a prospective study until age 3, were invited for follow-up at school-age. Five of them could no longer be reached and 42 dropped out; data of 49 VP-children (22 girls; mean age=9.06 years), 57 EL-siblings (27 girls, mean age=11.23 years) and 56 children at typical likelihood for autism (TL-children; 21 girls, mean age=10.97 years) have been analyzed. Data of the remaining 15 children will be added in the next months. Assessments included intelligence testing, ADOS-2 and questionnaires on autism features and emotional and behavioural functioning.

Results:

Although quite some developmental differences could be observed in our preschool VP-sample –62.8% received a CBE outcome of autism, BAP or atypically developing– only 25.6% had one or more community diagnoses at school-age. For the EL-siblings this was respectively 43.4% and 50.9%. Table 1 provides an overview of the agreement between CBE at age 3 and community diagnoses at school-age, indicating moderate agreement in EL-siblings, but poor agreement in VP-children. This is further supported by the finding that SRS-2 scores at school-age are significantly correlated with CBE in EL-siblings (r=.551, p=.001) but not in VP-children (r=.169, p=.304).

Concerning cognitive development, the IQ-scores of all three groups differed significantly from each other (p<.001) at age three (TL-group scoring highest; VP-group lowest). At school-age only the difference between TL- and VP-group remained significant (p<.001). A repeated measures ANOVA showed a significant interaction between time and outcome-group at school-age (TL-children, VP_typical, VP_atypical, VP_autism, sib_typical, sib_atypical and sib_autism) (F(6,127)=5.534; p<.001).

The group of EL-children with a CBE and/or community diagnosis of autism had significantly more affective difficulties (p=.005) than the other groups (TL-children, EL_typical, EL_atypical) at age 3. At school-age, group differences for anxiety (p<.001), depression (p<.001) and ADHD-features (p<.001) emerged, each time with the EL_autism group scoring significantly higher than most other groups. For hyperactivity/impulsivity, additionally the EL_atypical group scored higher than the EL_typical group.

Conclusions:

This is the first study providing insight into the longitudinal development of autism and co-occurring conditions in EL-siblings and VP-children up to school-age. Preliminary results suggest distinct pathways over time for both groups and a higher incidence of co-occurring difficulties in EL-children with autism compared to TL-children and EL-children without autism.

431.113  (Poster) The Relationship between Adaptive Behavior and Age at Diagnosis for Individuals with Autism Spectrum Disorder

D. J. Magin, K. N. Drapalik, E. Wilkinson, K. V. Christodulu and M. Rinaldi, Center for Autism and Related Disabilities/University at Albany, Albany, NY
Background: Autistic individuals tend to exhibit lower levels of adaptive behavior than would be expected with their corresponding cognitive intelligence (Bertollo et al., 2020). Previous prospective research has demonstrated a curvilinear relationship between adaptive behavior skills and age for individuals with Autism Spectrum Disorder (Smith et al., 2012). Specifically, previous research has found that, in this population, daily living skills tend to improve through the early 20’s and plateau as the individual reaches their late 20’s (Smith et al., 2012). However, there has been less attention paid to the relationship between age at diagnosis and adaptive behavior scores, as measured by the Vineland Adaptive Behavior Scales- Third Edition (Vineland-3; Sparrow et al., 2016).

Objectives: The present study aimed to evaluate the relationship between Vineland-3 scores and age at evaluation for individuals who received a diagnosis of ASD from a community-based clinic setting.

Methods: Comprehensive psychological evaluations of 252 individuals aged 1-36 (Median= 8.00) with concerns of ASD were analyzed. Individuals were evaluated by clinicians at a community-based clinic setting. Evaluations were composed of formal assessments of intellectual, adaptive, and behavioral functioning. The present study used data from the Vineland-3.

Results: 51.6% (130 of 252) of the individuals who came for an evaluation received a diagnosis of ASD. Correlations between age, the various domains of the Vineland-3, and the Vineland Adaptive Behavior Composite were computed for the subset of the individuals who received an ASD diagnosis. Among these individuals, age and Vineland Socialization standard scores were found to be weakly negatively correlated, r(128)= -.267, p<.001; age and Vineland Daily Living Skills standard scores were found to be moderately negatively correlated, r(128)= -.396, p<.001; age and Vineland Communication standard scores were found to be moderately negatively correlated, r(128)= -.406, p<.001; and, finally, age and Vineland Adaptive Behavior Composite scores were found to be moderately negatively correlated, r(128)= -.406, p<.001. There was no significant correlation found between age and Vineland Motor standard scores, r(78)= -.174, p=.122.

Conclusions: There was a significant negative correlation between age at diagnosis and Vineland-3 adaptive behavior scores in all domains except for the motor domain. These findings point to a larger deficit in adaptive behavior for individuals with ASD who are diagnosed at an older age. They also replicate the findings of previous studies into the relationship between adaptive behavior scores and age at diagnosis and further support the development and maintenance of interventions aimed at addressing deficits in adaptive behavior (Klin et al. 2007).

431.114 (Poster) The Social, Adaptive and Cognitive Profiles of Girls and Boys Participating in a Prospective Longitudinal Study from Infancy into Mid-Childhood

Background: Sex differences in autism are well-established, and the possibility of a distinct profile in girls and women with autism has been widely investigated. Prospective longitudinal studies of children at elevated likelihood of autism diagnosis offer the potential to explore the developmental trajectory of autism symptomatology, as well as providing an unbiased context to explore the emerging profile of autism in girls.

Objectives: The current study aims to investigate the longitudinal patterns of adaptive and cognitive skills from infancy through mid-childhood, with a focus on differences between girls and boys later diagnosed with autism. We predict that children with autism will have lower socialisation skills than their non-autistic counterparts, independent of overall cognitive ability, that girls with autism will have higher socialisation skills over time than their male peers and that this advantage will be maintained into mid-childhood.

Methods: The British Autism Study of Infant Siblings (BASIS) is a prospective longitudinal study of children at elevated likelihood (EL) of autism diagnosis due to having an older sibling with autism and those at typical likelihood (TL) of autism with no family history. Children are assessed at approximately 10, 14, 24 and 36 months, and finally between 6 and 10 years of age. At each visit, parents complete the Vineland Adaptive Behavior Scales (VABS) and children’s overall cognitive ability is assessed directly using the Mullen Scales of Early Learning (MSEL) (visits 1 to 4) or the Wechsler Abbreviated Scale of Intelligence (WASI) at the final visit. Following the mid-childhood visit, a best-estimate research diagnosis of autism vs not-autism is made for children in the EL group (EL-Autism and EL-Not Autism, respectively), based on gold-standard autism diagnostic instruments, researcher observation and parent report.

Results: 162 children (83 girls; 79 boys) participated through to mid-childhood, 42 of whom (16 girls; 26 boys) were given an autism diagnosis. ANOVAs investigating the main and interaction effects of visit and outcome were conducted for VABS Communication, Daily Living and Socialisation subscales and MSEL ELC/WASI FS IQ scores (Figure 1), showing overall differences between outcome groups for all measures [all F(2,775)>32.850, p<.001, partial η²>.078] with EL-Autism VABS scores significantly lower than the two other groups by mid-childhood [all F(2,151)>13.807, p<.001, partial η²>.155]. For those with an autism outcome only, girls performed better than boys.
over time on all measures (Figure 2) [all \(F(1,195)>7.665, p<.006, \text{partial } \eta^2>.038\] but by mid-childhood differences were not significant for any measure [e.g. VABS Socialisation: \(t=.328, ns, \text{Cohen's } d=.109\)].

Conclusions: Whereas children later diagnosed with autism had lower cognitive performance than their non-autistic counterparts through infancy and early childhood, by mid-childhood the EL-Autism group was comparable to the EL-Not Autism group. Vineland scores showed a relative widening gap, with Daily Living and Socialisation standard scores in particular declining into mid-childhood. Autistic girls showed an advantage over autistic boys throughout infancy and early childhood, but all scores 'converged' to some degree by mid-childhood perhaps reflecting the increasing demands from everyday social situations. These demands may impact relatively high-functioning girls as much as their male counterparts.

### 431.115 (Poster) The Utility of Gold-Standard Autism Screening Tools in Adolescents: A Functional Analysis of the Social Communication Questionnaire & Social Responsiveness Scale

**J. McKenna, R. Handsman, A. Verbalis, L. Kenworthy and C. E. Pugliese,** (1)Neuropsychology, Center for Autism Spectrum Disorders, Children's National Hospital, Rockville, MD, (2)Center for Autism Spectrum Disorders, Childrens National Medical Center, Washington, DC, (3)Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC, (4)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC

Background: The Social Communication Questionnaire (SCQ, manual cut-off=15) and the Social Responsiveness Scale (SRS-2, total t-score= 65) are considered benchmark screening measures for autism, with good sensitivity and specificity in young children. However, the limited data from samples of older children and adolescents suggest that these measures perform less well during developmental periods. Often, autism diagnosis in non-white males is underrecognized, leading to later diagnosis. Since the SCQ and SRS-2 were published, autism diagnostic criteria have changed, leading to questions of its continued efficacy as a measure, particularly for older girls and women.

Objectives: Examine the sensitivity of the SCQ and SRS-2 in a community-based sample of adolescents with a confirmed autism diagnosis, and explore gender and race-related differences in resulting scores.

Methods: Participants included 156 autistic teens (n=37 female, n=107 white) between 14-21 years old (M=1.95, SD=1.25) with FSIQ > 70 (M=101.87, SD=14.89). Parents completed the SCQ and SRS-2 at baseline as part of large-scale community-based clinical trials. All participants met criteria for autism confirmed via clinical report, school classification on an IEP, and/or an ADOS administered by trained clinicians. Calculations determined which participants met criteria based upon the most commonly used clinical cutoff scores in literature (e.g., raw scores of 11, 12, and 15 on the SCQ, and t-scores of 65, 70, and 75 on the SRS-2). Chi-squared analyses examined the impact of gender and race on participants meeting the three cutoff points from both the SRS-2 and SCQ.

Results: Sensitivity calculations indicated that 17.9% (28.6% female/ 71.4% male) of participants did not meet an SCQ score of 11 (M=16.76, SD= 6.64). That increased to 21.8% who did not meet a score of 12, and 33.3% for a score of 15 on the SCQ. Sensitivity calculations indicated similar results on the SRS-2 with 32.1% of participants not meeting the cutoff of 65 (M=70.35, SD=10.93). This increased to 51.3% for the cutoff SRS-2 score of 70, and then 67.1% for an SRS-2 score of 75. Out of 159 participants, 20% of the participants did not me on the SCQ or SRS-2. Chi-squared analyses did not indicate a significant relationship between SCQ and SRS-2 criteria and gender and race.

Conclusions: While results did not yield statistical significance, likely due to small pool of non-male and non-white participants, the overall number of participants who failed to meet on the SCQ and SRS-2 are clinically significant, as all participants had community autism diagnoses confirmed by our trained research team. Some item-level content on the SCQ is not developmentally appropriate for adolescents (e.g., imagine play with peers) leading to aberrant reporting. Greater analysis of the SCQ is important for screening purposes, given the greater feasibility of administration due to reduced participant burden (e.g., fewer items). The sensitivity of both the SCQ and SRS-2 is important to note when considering its efficacy for adolescent populations. One limitation of this project was the inability to calculate specificity. Discussions regarding the SCQ and SRS-2 should consider their efficacy for adolescents as diagnostic criteria continue to change.

### 431.116 (Poster) Virtual ASD Diagnostic Evaluations: Provider Perspectives on Differences and Adaptations from In-Person

Background: Delay in receiving an ASD diagnosis is a great public health concern (Dahiya et al., 2021); yet accessing an ASD diagnostic evaluation has historically been challenging (Wiggins et al., 2006), especially for families from underserved communities (e.g., rural, low-income, ethnically/racially diverse populations; Bishop-Fitzpatrick & Kind, 2017). The use of virtual diagnostic assessment, accelerated by the COVID-19 pandemic, has potential to fundamentally alter the ASD service landscape by addressing the significant disparities in access (Berger et al., 2021; Drahota et al., 2020). One common virtual assessment delivery method for young children is caregiver-mediated
synchronous virtual assessment (CMSVA), in which the provider coaches the caregiver through the implementation of specific assessment activities combined with a virtual clinical interview and feedback (Berger et al., 2021). Very limited research has been conducted on stakeholder attitudes about CMSVA.

Objectives: The current study examined interview data from community providers conducting CMSVAs, specifically investigating perceived differences and adaptations made as part of the virtual evaluation process, as well as the perceived outcomes (of differences) and/or intended goals (of adaptations).

Methods: Six psychologists contracted by San Diego Regional Center (SDRC) to provide ASD diagnostic assessments for young children were invited to participate. All participants had experience conducting in-person evaluations prior to switching to CMSVAs for the past 12 months. Virtual interviews were recorded and transcribed. Coding was conducted by members of the research team with over-arching themes of differences (i.e., between in-person and CMSVA) and adaptations (i.e., changes made by the provider during the evaluation) as well as corresponding coder-perceived difference outcomes and/or intended adaptation goals. Consensus coding was used to ensure agreement among coders.

Results: Most differences were noted in pre-evaluation preparation and the child assessment. Providers reported differences in data collection methods in that both providers and caregivers experienced a greater reliance on the caregiver. Both context/setting (i.e., virtual nature of the assessment) and data collection methods differences were associated with the outcome of collecting ecologically valid information, equally split between comments pertaining to collecting more information. Of note, differences in the context/setting was associated with an overwhelmingly positive outcome on evaluation reach and impact; providers noted how virtual assessment reduced several barriers to the evaluation. Overall, outcomes of differences were either overwhelmingly positive or equally positive and negative.

Regarding adaptations, the most common adaptation was adding components (time, strategies, contacts, etc.) to the evaluation. Adaptations to the evaluation process or structure were mostly associated with the goals of increasing evaluation validity and increasing caregiver comfort and engagement. During pre-evaluation preparation, adaptation goals included facilitate evaluation completion, improving evaluation validity, and increasing caregiver comfort and engagement.

Conclusions: Key findings included: psychologists perceived CMSVAs to increase both engagement and reach, and that many adaptations appeared to be designed to increase evaluation validity or caregiver comfort and engagement. These results suggest that CMSVAs may be an acceptable long-term method for evaluating, including equitable evaluation access, ASD in children. Future resources developed to support this evaluation method should focus on supporting evaluation validity and caregiver comfort and engagement.

431.117 (Poster) Towards the Improved Characterization of Minimally Verbal Children with Autism: Applications of Item Response Theory to Analyze the ESCS

A. J. Schlink and C. Kasari, (1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA

Background: Minimally verbal children are considered the enigmatic and, unfortunately, the neglected end of the autism spectrum (Tager-Flusberg & Kasari, 2013). This subpopulation has likely garnered this title due to their exclusion from research studies, which has inevitably affected their evidence base. The paucity of proper measurement tools that sensitively and accurately assess behaviors has been one limiting factor in the improved knowledge of these children. To address this issue, this study took an alternative quantitative methodological approach by repurposing item response theory (IRT) models to analyze social communication data generated by the ESCS.

Objectives: To create a hierarchy of social communication gesture difficulty.

Methods:

The final sample consisted of 453 minimally verbal children culled from four different intervention studies. The Rasch Poisson Count Model (RPCM; Rasch, 1960/1980) and its extensions (negative binomial model and its zero-inflated counterpart) were fit to the frequency of the ten initiation skills as measured by the ESCS (Mundy et al., 2003). Despite the separate functions of these skills (joint attention vs. behavior regulation), their intent of initiation was deemed as an acceptable justification to include all gestures in a single unidimensional model. Additionally, for assessments like the ESCS that have been historically analyzed using classical test theory, the RPCM is a logical progression into the IRT framework (Doebler & Holling, 2016).

Nested models were objectively compared with an LRT test, and non-nested models were compared with a Vuong test. AIC and BIC were used as additional indices to evaluate model fit.

The RPCM was estimated using the lme4 package (Bates et al., 2017). The negative binomial model was handled with lme4, but the zero-inflated model was estimated using the GLMMadaptive package (Rizopoulos, 2022). All the above analyses were conducted in R (R Core Team, 2022).
Results: The best-fitting and final model was a zero-inflated negative binomial model (ZINBM), which determined that joint attention gestures were, on average, more difficult than behavior regulation gestures. Joint attentional shows and gives were especially difficult, and behavior regulation reaches were the easiest gestures for this sample. The ZINBM separately modeled children with some gestures versus children who did not present with any gestures and determined that behavior regulation reaches and gives were likely the first gestures a child will eventually exhibit among children who currently do not exhibit gestures.

Conclusions: This study demonstrated that the use of IRT models can extract additional variability from the ESCS, thus, providing a more nuanced evaluation of the heterogeneity of social communication presentation within minimally verbal children, the vast majority who also present with profound intellectual disability (below 50 DQ). With the improved characterization of minimally verbal children, we can move towards the next phase of tailored interventions and understanding their treatment effects among subpopulations of the minimally verbal status.

431.118 (Poster) Use of Visual Aids during Caregiver Interviews to Screen for Autism Spectrum Disorder

J. Jung, D. Y. Song, G. Bong, J. H. Han and H. Yoo, (1)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Department of Psychiatry, Seoul National University, Seoul, MD, Korea, Republic of (South), (3)Psychiatry, Seoul National Univ Bundang Hospital, Seongnam, Korea, Republic of (South)

Background: Early diagnosis and interventions are critical factors that influence the prognosis of autism spectrum disorder (ASD). While caregiver interviews are an important source of information, they can often be subjective to bias, such as parental beliefs about their child’s development, awareness of risk signs related to ASD, and other misleading information (Eaves, Wingert, Ho, & Mickelson, 2006; Miller, Perkins, Dai, & Fein, 2017; Robledo, & Jankovic, 2017). To overcome such shortcomings, studies have suggested using visual aids to increase the accuracy during caregiver interviews by showing key social behaviors in children with and without ASD (Marrus et al., 2015; Young et al., 2020).

Objectives: To eliminate bias during caregiver interviews, we created short videos to support caregivers in understanding key social behaviors. This study explores the effectiveness of using visual aids in screening for ASD compared to pre-existing standardized caregiver interviews.

Methods: Key behaviors, composed of joint attention, echolalia, pointing behavior, use of gestures, social referencing, use of others’ hands, interactive social play, eye contact, social smiles, and restricted and repetitive behaviors (RRBs), were selected from the Behavior Development Screening for Toddlers (BeDevel; Bong et al., 2021). Caregivers were asked to select between videos showing the behaviors of a child with ASD and a child without ASD that their child resembled the most. The best clinical estimate diagnosis was based on the acquired information from the Autism Diagnostic Observation Schedule-2 (ADOS-2), the Autism Diagnostic Interview (ADI-R), and other questionnaires. The predictive value in screening for ASD was measured with the ROC curve analysis. Comparisons between the video and standardized interview (BeDevil-I) were analyzed using kappa values (k). Additionally, we explored whether the combination of visual aids with standardized interviews would improve effectiveness in screening for ASD.

Results: 91 children with ASD (M = 36.24, SD = 5.86) and 30 children without ASD (M = 32.37, SD = 7.06) were included for analysis. Social referencing, interactive social play, eye contact showed good predictability (AUC range = 0.708-0.773). There was a trend in visual aids being more effective in assessing interactive social play compared to the BeDevel-I (p = .054). However, RRBs measured by the standardized interview were better in predicting ASD (p < .01). Kappa values were highest in pointing behavior (k = 0.482) and eye contact (k = 0.480), while lowest in use of others’ hands (k = 0.134), interactive social play (k = 0.172), and social referencing (k = 0.174). The combination of visual aids and standardized interviews were found to be more effective than individual screening measures (p < .01) (Figure 1).

Conclusions: Visual aids can be helpful when interviewing caregivers. Among the selected key behaviors, complicated and sequential behaviors like interactive social play were better understood with visual references. Therefore, using such videos in combination with standardized caregiver interviews should be considered to improve screening for ASD.

431.119 (Poster) Use of the Psychomotor Vigilance Task (PVT) with School-Aged Autistic and Neurotypical Children and Its Relation to Sleep Problems: A Pilot Study

Background: Sustained attention measured by the Psychomotor Vigilance Task (PVT) is one of the primary outcomes in research on the impact of sleep deprivation in adults (Lim & Dinges, 2010). The PVT is highly sensitive to sleep deprivation and demonstrates psychometric advantages over other cognitive tests (Basner & Dinges, 2011). Attention is highly affected in neurotypical children and adults with reduced sleep, but as far as we know, no study to date has investigated the use of the PVT in autistic children (Kaida et al., 2006).

Objectives: This study primarily aimed to determine whether the PVT is feasible and accessible to school-age autistic and neurotypical children in the context of a home-based sleep study. A secondary aim was to examine preliminary relationships between sleep patterns and sustained attention using the PVT in school-age autistic children with high likelihood of autism spectrum disorder (HL+ASD), high likelihood children without autism spectrum disorder (HLnoASD), and low likelihood of autism spectrum disorder (LL).

Methods: As part of a multisite study and the longitudinal Infant Brain Imaging Study (IBIS), 73 children, age 6 to 14 years (HL+ASD n = 14, HLnoASD n = 28, and LL n = 31; Table 1), completed measures of cognitive ability (DAS-II general cognitive ability standard score) and sustained attention (PVT reaction time) and parents reported concerns about their child's sleep (CSHQ total sleep problems). Participants were also directly assessed for clinical best estimate of autism diagnosis using gold-standard measures multiple times starting at 24 months.

Results: Increased total sleep problems (CSHQ) significantly predicted increased mean reaction time (p = 0.019). We conducted a multivariate regression analysis of PVT reaction time that included participant age, general cognitive ability, total sleep problems, and diagnostic group as predictors (see Table 2). This analysis demonstrated that increased participant age significantly predicted lower mean PVT reaction time (RT, p < .001). General cognitive ability (GCA) was not a significant predictor of mean PVT reaction time (p = 0.723). Group did not improve this model. The full model significantly predicted PVT reaction time (overall R^2 = .45).

Conclusions: Greater parental sleep concerns were related to slower PVT reaction times. This is consistent with previous literature demonstrating sleep deprivation is related to increased reaction times. Additionally, results showed that as age increased reaction times decreased (i.e., children became faster), suggesting age is an important consideration in future pediatric PVT research. Furthermore, cognitive ability did not significantly impact reaction time. This is an important finding as it suggests the PVT can be used in the broader ASD population. The PVT is clearly feasible for in-home completion in pediatric autistic and neurotypical populations. Future research is needed to evaluate the relationship between sleep problems and sustained attention in autistic children using objective measures of total sleep time and in a larger sample.

431.120 (Poster) Using Endocrine Profile to Identify Subgroups Among Transdiagnostic Neurodivergent Children and Adolescents

(1)Institute of Medical Science, University of Toronto, Toronto, ON, Canada, (2)Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Department of Psychiatry and Behavioural Neurosciences, McMaster University, Hamilton, ON, Canada, (4)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Department of Pediatrics, University of Toronto, Toronto, ON, Canada, (6)Wellcome Centre for Integrative Neuroimagining, University of Oxford, Oxford, United Kingdom, (7)Mouse Imaging Centre, The Hospital for Sick Children, Toronto, ON, Canada, (8)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (9)Diagnostic Imaging, Hospital for Sick Children, Toronto, ON, Canada, (10)Department of Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (11)Department of Psychiatry, University of Western Ontario, London, ON, Canada, (12)Department of Psychology, Queen’s University, Kingston, ON, Canada, (13)Department of Psychiatry, Queen’s University, Kingston, ON, Canada, (14)Division of Endocrinology, The Hospital for Sick Children, Toronto, ON, Canada

Background:

Autism is part of a complex group of neurodevelopmental conditions (NDCs). Emerging evidence suggests 1) high individual variability within NDCs and 2) significant overlap in clinical and biological characteristics among NDCs. The within-condition/diagnosis heterogeneity and between-condition/diagnosis overlap warrants transdiagnostic investigations that extends beyond a case-control design. To date, such studies have demonstrated genetic, neural, and behavioural overlap among NDCs. Despite implications of endocrinological factors in NDC etiology and symptomatology, the field lacks transdiagnostic investigations of hormonal and endocrine-related phenotypic characteristics.

Objectives:

We used a data-driven, transdiagnostic approach to identify and characterize NDC subgroups with distinct endocrine profiles. We then examined endocrine-profile subgroups for differences in dimensional behavioural phenotypes, including externalizing and internalizing symptoms, across NDC diagnostic categories and typically developing children and adolescents.

Methods:
This study was conducted using clinical and bio-banked serum data from the Province of Ontario Neurodevelopmental Disorders (POND) Network, Canada. Participants (N=196) included children and adolescents between 3-21 years of age with a diagnosis of autism (N=117; 92 males, 25 females; mean age=10.3 years); ADHD (N=29; 27 males, 2 females; mean age=12.0 years); other NDCs, including sub-threshold ADHD, OCD, or intellectual disability (N=12; 6 males, 6 females; mean age=11.2 years); and typically developing individuals (N=38; 20 males, 18 females; mean age=14.1 years). Using liquid chromatography–mass spectrometry and immunoassay, we measured 16 endocrine analytes from hormonal systems including growth and metabolism, hypothalamic-pituitary-adrenal (HPA), and hypothalamic-pituitary-gonadal (HPG) axes (Figure 1). We used principal component analysis (PCA) for data-reduction for 16 analytes, and then used k-means clustering to identify subgroups with distinct endocrine profiles across diagnostic groups (Figure 1). Kruskal-Wallis H test was used to determine between-subgroup differences in externalizing and internalizing symptoms (measured by the Child Behavior Checklist, CBCL).

Results:

Cluster analyses consistently identified three diagnosis-agnostic subgroups with distinct endocrine profiles. There were significant between-subgroup differences in externalizing symptoms (H(2)=12.04, p=.002), but not internalizing symptoms among these endocrine-related subgroups (H(2)=2.96, p=.227). The three subgroups differed in NDC diagnoses composition, sex composition, and age range. Pairwise comparisons showed that the subgroup with significantly higher externalizing symptoms had lower growth factor (IGF-1) and lower stress-related hormones (cortisol and corticosterone) compared to the other two subgroups (p<.01 for all comparisons). Due to potential confounding effects of NDC diagnosis and sex, we repeated the subgroup-comparison analysis using only those with a diagnosis of autism and only males, respectively. The endocrine-profile subgroup differences in externalizing symptoms persisted among those with autism (H(2)=13.88, p=.001) and among males (H(2)=7.96, p=.02). Age had a negative correlation with externalizing symptoms (r(141)=-.34, p<.001). Thus, despite subgroups differ by age, we further performed the Quade’s test to covary for age to explore remaining between-subgroup differences; here the endocrine-profile subgroup differences in externalizing symptoms were observed when comparing across endocrine-profile subgroups among those with autism (F(2,114)=6.863, p=.002).

Conclusions:

Our findings suggest that distinct endocrine profiles may serve as potential stratification markers for externalizing behaviour challenges across children and adolescents with/without NDCs, with most robust findings in those diagnosed with autism.

431.121 (Poster) Utility of the Screening Tool for Autism in toddlers & Young Children (STAT) in Autism Diagnosis

Background: The combination of high autism prevalence and dearth of qualified evaluators results in families routinely waiting 1 to 2 years for diagnostic assessment. This puts children in a holding pattern during critical developmental periods when early intervention can capitalize on brain plasticity to optimize outcome. Traditional evaluation tools contribute to the problem of long wait times due to considerable training requirements and extensive administration and scoring times. This study explores the diagnostic utility of the Screening Tool for Autism in Toddlers & Young Children (STAT) as one possible solution to patient backlog. The STAT is a Level Two screener for autism detection in children 24 to 36 months of age with extended norms down to age 14 months. The STAT takes approximately 20 minutes to administer and assesses key social and communicative behaviors including imitation, play, requesting, and directing attention.

Objectives: Determine the agreement of the STAT in differential diagnosis of autism in an outpatient clinical population, compared to the more time and resource-intensive Autism Diagnostic Observation Schedule-Second Edition (ADOS-2). Examine the sensitivity and specificity of the STAT to refine clinic models and reduce wait time for evaluation.

Methods: Neurodevelopmental Disorders Clinic patient log and EPIC software were used to identify 317 consecutive patients between the ages of 14 and 36 months seen for diagnostic evaluation in our outpatient clinic between September 1, 2019 and April 30, 2022. Patients were referred from primary care or self-referred. Demographic information and test results for the variables of interest (STAT and ADOS) were abstracted from the chart. Comparative statistical analysis was completed on 44 patients who were administered both the STAT and the ADOS.

Results: A total of 44 patients (75% male) were administered both the STAT and ADOS. Agreement was 90.9% (40/44; 95% CI 78.3-97.5%) between the two measures (identified as not at risk by the STAT and non-spectrum by the ADOS-2, or at risk by the STAT and autism spectrum disorder or autism by the ADOS-2, Table 1). Using clinical diagnosis as the measure of truth, 33 of the 44 received a clinical diagnosis of ASD. The sensitivity of the STAT was 90.9% (30/33; 95% CI 75.7-98.1%) and the sensitivity of the ADOS was 100%
Conclusions: The STAT showed high sensitivity and specificity in differentiating children with autism from those with other neurodevelopmental disorders in this outpatient clinic population. There was excellent agreement between the STAT and ADOS-2. The STAT may be an acceptable diagnostic tool in children 14-36 months of age who present with concerns for autism. Using the STAT for children at lower and higher risk for autism based on clinical judgment of initial symptom presentation may decrease the risk of false positives and false negatives. The more time and resource-intensive ADOS-2 might be reserved for children with more complex or borderline autism presentations.

Results: A total of 51 participants expressed interest in the study, with 39 invited to complete round 1 of the Delphi (with 36 responses received). For the second round, 31 participants were invited, 26 responded, and 25 participants were invited and responded to the final round. Participants had a median of 13 (range: 5-31) years of experience and included paediatricians, occupational therapists, speech pathologists and psychologists. Across the sample, participants had worked with all NDC diagnoses included in the DSM-5.

By the final round, of the 113 0-5 early NDC items assessed, 103 (91%) were deemed relevant with only 4 (4%) deemed irrelevant. For the specific 0-5 core sets, 68 (92%)of the Autism, 43 (91%) of the ADHD, 27 (93%) of CP, and 68 (94%) of EDD were deemed relevant. Only 1-4% of the specific 0-5 Core Sets’ codes were deemed irrelevant, with most being environmental factor codes. Of the codes included in the comprehensive NDC Core Sets but not the 0-5 specific Core Sets, only 27 (47%) were deemed relevant, while 19 (33%) were deemed irrelevant. Most of the codes deemed relevant from outside the 0-5 Core Sets were Body Functions or Activity and Participation codes.

Conclusions: The ICF Core Sets for young children with NDCs are appropriate to use to guide the assessment of functioning in the Australian context, supplemented by additional codes from the broader NDC Core Sets.

431.122 (Poster) Validation of the International Classification of Functioning, Disability and Health Core Sets for Young Children with Neurodevelopmental Conditions in the Australian Context
E. D’Arcy1,2,3, K. Evans4,5, B. T. Milbour, S. Bolte5 and S. J. Girdler5,10,11,12, (1)School of Allied Health, Curtin University, Bentley, Western Australia, Australia, (2)School of Psychology, University of Western Australia, Crawley, Western Australia, Australia, (3)Autism Research Team, Telethon Kids Institute, Subiaco, Australia, (4)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (5)Curtin Autism Research Group, Curtin University, Bentley, Australia, (6)Telethon Kids Institute, The University of Western Australia, Perth, Western Australia, Australia, (7)School of Allied Health, University of Western Australia, Crawley, Western Australia, Australia, (8)School of Allied Health, Curtin University, Perth, Australia, (9)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (10)Curtin Autism Research Group, Curtin University, Bentley, Western Australia, Australia, (11)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (12)Karolinska Institutet, Stockholm, Sweden

Background: Being able to complete accurate and valid assessments of functioning for young children (under 6 years) with NDCs is vital for access to funding, diagnosis and services in the Australian context. The International Classification of Functioning, Disability, and Health (ICF) and ICF Core Sets provide a useful foundation for such assessments. These ICF Core Sets present a shortlist of ICF Codes (across body functions and structures, activities and participation and environmental factors) relevant to functioning in specific populations. ICF Core Sets have been developed for Autism, Attention-Deficit/Hyperactivity Disorder (ADHD), Cerebral Palsy (CP) and Early Delay and Disability (EDD), including specific sets for those aged 0-5 years. However, these Core Sets have not yet been validated to determine their appropriateness for the Australian context.

Objectives: To validate the ICF Core Sets for 0-5-year-olds with NDCs (Autism, ADHD, CP, and EDD) in the Australian context from the perspective of clinical and research professionals.

Methods: The ICF 0-5 Core Sets for NDCs were validated through an online Delphi survey incorporating the item level Content Validity Index (I-CVI). Australian clinicians and/or researchers who were experienced in assessing young children with, or suspected of, NDCs were invited to participate through convenience sampling. The Delphi was completed across three rounds, where participants were asked to rate each code of the Comprehensive Core Sets for NDCs on a scale of relevance. Prior to data collection, the threshold for agreement was set at 80% (I-CVI of 0.8), for deeming codes relevant or irrelevant. If a code did not meet the threshold for relevant or irrelevant, it was re-assessed in the subsequent round.

Results: A total of 51 participants expressed interest in the study, with 39 invited to complete round 1 of the Delphi (with 36 responses received). For the second round, 31 participants were invited, 26 responded, and 25 participants were invited and responded to the final round. Participants had a median of 13 (range: 5-31) years of experience and included paediatricians, occupational therapists, speech pathologists and psychologists. Across the sample, participants had worked with all NDC diagnoses included in the DSM-5.

By the final round, of the 113 0-5 early NDC items assessed, 103 (91%) were deemed relevant with only 4 (4%) deemed irrelevant. For the specific 0-5 core sets, 68 (92%)of the Autism, 43 (91%) of the ADHD, 27 (93%) of CP, and 68 (94%) of EDD were deemed relevant. Only 1-4% of the specific 0-5 Core Sets’ codes were deemed irrelevant, with most being environmental factor codes. Of the codes included in the comprehensive NDC Core Sets but not the 0-5 specific Core Sets, only 27 (47%) were deemed relevant, while 19 (33%) were deemed irrelevant. Most of the codes deemed relevant from outside the 0-5 Core Sets were Body Functions or Activity and Participation codes.

Conclusions: The ICF Core Sets for young children with NDCs are appropriate to use to guide the assessment of functioning in the Australian context, supplemented by additional codes from the broader NDC Core Sets.
Background: Although there is no difference among racial/ethnic groups in age of parents’ first concern about autism (Jang et al., 2014) or for overall prevalence (Maenner et al., 2021), disparities in average age of autism identification and treatment initiation persist (Maenner et al., 2020). To help address these disparities and equitably serve all children, diagnostic tools should be examined for their validity in different racial/ethnic groups.

The Toddler Autism Symptom Inventory (TASI) is a novel semi-structured diagnostic interview for clinicians interviewing caregivers of children aged 12-36 months with suspected autism. We previously compared the validity of the TASI in non-Hispanic White and Black toddlers (Coulter et al., in press) and found that the TASI worked comparably well in both groups. In the current project, we compare the TASI performance in Hispanic and non-Hispanic White toddlers.

Objectives: Determine the validity of the recommended TASI cutoff score of 7 in Hispanic and non-Hispanic White toddlers.

Methods: Children (n=415) aged 12 to 36 months were referred for a diagnostic evaluation after a positive screen or pediatrician concern. Caregivers reported their toddler’s race and ethnicity; 50.4% of the sample was White (n=209). The remainder reported other racial identities. Of the White participants, 75.6% reported a non-Hispanic ethnicity (n=158), 20.6% a Hispanic ethnicity (n=43), and 3.8% did not report ethnicity (n=8). Of the non-White Hispanic participants, the different racial groups were small (n<15). Children whose parents reported a race other than White, and those who did not report ethnicity were not examined here.

Diagnostic evaluations included measures of developmental functioning (Mullen Scales of Early Learning Composite, ELC) and autism symptoms (Autism Diagnostic Observation Schedule-2 Calibrated Severity Score (ADOS-2 CSS)). Clinicians either administered the TASI before the ADOS, or these measures were administered by different clinicians. There is a strong positive correlation between ADOS-2 CSS and TASI total score (Table 1).

Children were assigned diagnoses of ASD, other developmental delay (DD), or typical development/no diagnosis (TD/ND).

Results: Significant differences between the non-Hispanic and Hispanic White toddlers were found in mean developmental level (Mullen ELC) and SES measured by maternal education. These group-level differences must be considered in the following results.

There were no significant group differences in age at evaluation and rate of ASD diagnosis. Among children with non-ASD classifications, more Hispanic children were diagnosed with DD and fewer with TD/ND compared to the non-Hispanic group. In the ASD group, there were no differences in autism severity as measured by ADOS CSS; and TASI score (Table 1).

Validity of the TASI is similar in both groups (Table 2). Area under the curve in ROC analyses was over .9 for both groups, which is considered outstanding. Sensitivity was .88 and specificity ranged from .78-.84. The TASI was slightly less specific for Hispanic participants, as some DD participants were positive on the TASI.

Conclusions: The TASI appears to have similar validity in both non-Hispanic and Hispanic White toddlers; however, the group difference in SES is an important consideration when interpreting the differences in developmental delay.

431.124 (Poster) Verbal IQ and Socioeconomic Status Predict Autism Diagnostic Timing for Individuals Assigned Female at Birth

A. B. Ratto, J. V. Smith, G. A. McQuaid, A. Khout, K. Pelphrey, L. Kenworthy and A. Jack, (1)Center for Autism Spectrum Disorders, Children's National, Washington, DC, (2)Psychology, Children's National Hospital, Rockville, MD, (3)George Mason University, Washington, DC, (4)Autism and Neurodevelopment Disorders Institute, University of Virginia School of Medicine, Washington, DC, (5)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC

Background: Timely autism diagnosis is crucial for access to needed supports. Initial data links female sex assigned at birth to late diagnosis (Kavanaugh et al., 2021), and late autism diagnosis may be associated with verbal strengths in those assigned female at birth (AFAB; Salomone et al., 2016). Socioeconomic status (SES) predicts higher verbal skills (Noble et al., 2007), yet access to resources may facilitate diagnosis; thus, SES likely contributes to diagnostic timing in complex ways. Understanding factors contributing to diagnostic timing is important for autistic well-being, as late-diagnosed individuals report lower quality of life (Atherton et al., 2022).

Objectives: To better understand the roles of verbal IQ and sex assigned at birth in autism diagnostic timing, we examined these factors in two independent cohorts: a sex-balanced research sample (N=164, AFAB: 71) and a large clinical sample (N=641, AFAB: 177). We hypothesized that higher Verbal IQ (VIQ) would predict later diagnosis, particularly among AFAB individuals. Greater socioeconomic,
phenotypic, and etiological diversity in the clinical sample also permitted us to **explore the contribution of SES and sample inclusion/exclusion criteria** to these models.

**Methods:**

The **research sample** included previously-diagnosed youth aged 8-17 years \( [y] \) \((M[SD] = 12.5[2.88] y; \text{diagnostic age} = 5.84[3.58] y)\). Cohort exclusion criteria included full scale IQ\(\leq70\) or non-idiopathic autism. The **clinical sample** included individuals aged 2-25y \((M[SD] = 9.80[3.90] y)\) whose data was obtained during initial diagnostic assessment. Child Opportunity Index (COI; Noelke et al. 2020) scores were available for this cohort; higher scores reflect greater financial, health, and educational resource availability in the child’s neighborhood. All research questions were tested by fitting multiple linear regression models with diagnostic age as the outcome.

**Results:**

**Research Sample.** A model including the interaction between sex and VIQ \((F(2, 161) = 6.94, p = 0.001)\) indicated that VIQ positively predicted age of diagnosis for participants assigned female \((β = 0.39, p = 0.001)\) but not male \((β = 0.16, p = 0.101)\) at birth (Fig.1). **Clinical Sample.** In a model \((F(7, 633) = 3.58, p = 0.001)\) including VIQ, COI, sex, and their interactions, VIQ \((β = 0.14, p = 0.002)\) and VIQ×COI \((β = 0.10, p = 0.028)\) were significant predictors of diagnostic age. Fitting the same model in a subsample that applied the exclusion criteria from the research sample to the clinical cohort \((N = 484, \text{AFAB: } 110; \text{age: } 9.88[3.92] y), the three-way interaction among VIQ×COI×Sex became statistically significant \((β = -0.26, p = 0.013; \text{Fig.2})\); for AFAB participants, higher VIQ was associated with later diagnosis, with this association strengthening as COI decreased, while those assigned male at birth with low COI showed no association between VIQ and diagnostic timing.

**Conclusions:**

In samples with idiopathic autism diagnoses and no intellectual disability, higher verbal IQ predicted later diagnosis for AFAB individuals. SES may be especially relevant in these samples, with varying impacts depending on assigned sex at birth. For AFAB individuals, lower SES may exacerbate the association between higher VIQ and later diagnosis. When intellectual disability and syndromic autism were represented in analysis, the impact of sex assigned at birth was reduced, and VIQ and COI alone interacted to predict diagnostic timing, suggesting that these features may invite clinical attention in a way that potentially mitigates sex-based ascertainment bias.

---

**431.125 (Poster)** Time Is of the Essence: Age of Diagnosis Drives Psychopathology in Autism

**Background:**

Age of autism diagnosis has known links to sex assigned at birth (hereafter, “sex”), such that assigned female at birth (AFAB) versus assigned male at birth (AMAB) individuals are delayed or “missed” entirely in the diagnostic process. Later diagnosed individuals, especially AFAB individuals, demonstrate increased anxious and depressive symptoms. Unpacking the linkages among sex, age of autism diagnosis, and co-occurring psychopathology requires consideration of ascertainment methodology, which has been documented to impact reported sex ratios in autism diagnosis (e.g., D’Mello et al., 2022; Loomes et al., 2017).

**Objectives:**

Using regression-based mediation models to understand individual pathways and the overall model, we hypothesized age of autism diagnosis would mediate the relationship between sex and anxious/depressive symptoms.

**Methods:**

Youth \((N = 1163)\) from two samples were included in the present study: one from an outpatient autism/neuropsychology evaluation clinic \((n = 1035; 22.9\% \text{ AFAB})\) and the other research-based recruitment that prioritized a sex-balanced sample \((n = 128; 43.0\% \text{ AFAB})\). Anxious and depressive symptoms were assessed through: the Child Behavior Checklist, 1.5-5 \((n = 611)\) or 6-18 \((n = 546)\), or the Adult Behavior Checklist \((n = 6)\). To evaluate anxious and depressive symptoms without utilizing sex-normed \(t\)-scores, the average of both male- and female-normed \(t\)-scores were calculated and used for analyses. All data from the clinical sample were collected at the time of diagnosis.
Because diagnostic age was caregiver-reported through structured interview at the time of participation in the research sample, age at participation was added as a covariate to all relevant analyses.

Results:

Age of autism diagnosis was significantly later in the clinical ($M=6.75$, $SD=4.20$, range: 1.3-19.7 years) than the research sample ($M=6.12$, $SD=3.75$, range: 1.3-17 years), $t(169.06)= -1.77$, $p > .001$. Results from the two samples converged in two ways: later diagnostic age predicted greater anxious and depressive symptoms, and sex did not predict anxious symptoms (see Figures 1 and 2). In the clinical sample, despite sex not being predictive of anxious or depressive symptoms, there was a significant indirect effect of sex on anxious and depressive symptoms through age of autism diagnosis (95% BCa CI$_{anx}$ [0.0844, 1.3604]; 95% BCa CI$_{dep}$ [0.0624, 1.06]), such that later-diagnosed AFAB individuals had greater symptoms. Findings from the research sample indicate no such mediation, and sex did not predict diagnostic age (95% BCa CI$_{anx}$ [-0.0187, 0.1872]; 95% BCa CI$_{dep}$ [-0.1796, 1.6561]). See Figures 1 and 2 for all model coefficients.

Conclusions:

Through two different samples, age of autism diagnosis emerged as a potent predictor of psychopathology. Diagnostic age acted as a driver of the association between sex and psychopathology only in the clinical sample. This suggests research samples, even those with intentionally sex-balanced designs, diverge from clinically-based samples in ways that alter findings related to the impact of sex. Limitations of this study include: reliance on cross-sectional data and the lack of data on gender identity. Nonetheless, it provides an important impetus for accelerating autism diagnosis, enhancing tools for recognizing autism in AFAB individuals, and grounding research with real-world ascertainment strategies.

431.126 (Poster) Location Is Everything: Unpacking the Link to Age of Autism Diagnosis

J. V. Smith and M. O. Mazurek, University of Virginia, Charlottesville, VA

Background:

Diagnostic timing is a vital public health priority as early diagnosis facilitates access to early intervention, which leads to better outcomes for autistic individuals. Geographic factors likely relate to diagnostic timing due to uneven distribution of autism resources and specialists across the United States. There is some evidence that those living in the Northeast may have greater access to diagnostic resources and that those living in rural areas have more limited access to healthcare services and specialists compared to those in urban areas.

Objectives:

Aiming to better understand geographic factors’ association to diagnostic timing, we hypothesize: 1) those living in non-metropolitan areas will have a later age at autism diagnosis, 2) those living in census-designated regions outside of the Northeast will have a later age at autism diagnosis.

Methods:

The sample included participants from the National Survey of Children’s Health (NSCH) 2021 caregiver-report survey, which is conducted by the US Census Bureau to assess the health/well-being of US children ages birth-17. Participants with a caregiver-reported autism diagnosis who had not moved (i.e., lived in same geographic location) were included in analyses ($n=308$). The majority of the sample was male (79.2%), White (74.4%), and non-Hispanic/Latinx (83.1%). Current child age ranged from 1-17 ($M=8.65$, $SD=4.85$). Variables of interest included: whether/not participants lived in a metropolitan statistical area (MSA: high population density and urbanized area), and census-designated regions (Northeast, Midwest, South, West). Known predictors of late diagnosis were included as covariates: assigned sex, household income, race and ethnicity, and autism severity.

Results:

There was a significant difference in diagnostic age for those living in a MSA ($M=4.21$, $SD=3.13$) versus those who did not ($M=5.26$, $SD=3.80$), $t(306)=-2.02$, $p < .05$ (see figure 1). Results from a univariate ANCOVA revealed a significant difference in diagnostic age by census-designated regions, $F(3,299) = 3.31$, $p < .05$. After adjusting for multiple comparisons, pairwise comparison illuminated significant differences between the Midwest ($M=5.08$, $SD=3.37$) and South ($M=4.68$, $SD=2.47$) census-designated regions ($p = .02$). In a linear regression to predict diagnostic age from MSA status, census-designated regions, and the interaction between the two, the interaction term was significant ($B = -0.32$, $p = 0.04$), and the overall model (including covariates) accounted for 15% of the variance in diagnostic age.

Conclusions:
Overall, these findings are consistent with previous literature that those living in urban areas are diagnosed earlier, likely as a function of increased availability of providers and access to services. Inconsistent with previous literature, those living in the Northeast did not have an earlier diagnostic age compared to other regions; in fact, those living in the South had the youngest diagnostic age. The intersection of urbanicity and region emerged as a significant predictor of diagnostic age, suggesting those living outside of MSAs in certain regions may experience a compounding factor leading to later diagnosis. Future research should examine mechanisms underlying these differences, specifically the role of access to services.

431.127 (Poster) Reliability and Acceptability of the Vineland-3 for Australian Children and Youth with Neurodevelopmental Conditions

A. Chamberlain1,2,3, E. D’Arcy1,3,4,5, A. J. Whitehouse2,6,7, M. Hayden-Evans1,6, S. J. Girdler1,6,7, B. T. Milbourne1,6,7,8,9 and K. Background:

The Vineland-3 is used to assess the functioning of children and youth with neurodevelopmental conditions, including autism, attention deficit hyperactivity disorder, communication disorder, global developmental delay, intellectual disability and motor disorder. Despite widespread use as a clinical and research measure, there is a paucity of psychometric evidence for the current version, and comparison with the International Classification of Functioning, Disability and Health has demonstrated limited content validity.

Objectives:

This study explored the reliability and acceptability of the Vineland-3 using a large Australian sample. Specifically, it evaluated internal consistency; test-retest reliability of the Parent/Caregiver Form; inter-rater reliability of the Interview Form; and parallel forms reliability between the Parent/Caregiver and Interview Forms. Acceptability was explored from the perspective of caregivers as the informants.

Methods:

Caregivers of 172 children and youth with neurodevelopmental conditions participated in clinical assessments. Of these, 141 participants completed Assessment 1, which involved the administration of the Vineland-3 Parent/Caregiver Form. Based on a randomisation process, participants proceeded to either Assessment 2a to repeat the Vineland-3 Parent/Caregiver Form, or Assessment 2b to complete the Vineland-3 Interview Form. To boost sample sizes, additional recruitment resulted in another 31 participants being streamed directly into Assessment 2b. Caregivers of 46 children and youth completed a semi-structured interview exploring the acceptability of the Vineland-3.

Results:

The Vineland-3 demonstrated good to excellent internal consistency (for sub-domains where analysis was possible), and moderate to excellent test-retest reliability and inter-rater reliability. Parallel forms reliability showed significant correlations between the Parent/Caregiver and Interview Forms, ranging from moderate to good in strength. However, t-tests showed a significantly lower Adaptive Behavior Composite, as well as Communication and Socialization domain scores for the Interview Form. Acceptability of the Vineland-3 was mixed, with both positive and negative feedback. Overall, caregivers found the measure to be relatively accurate, providing a comprehensive depiction of functioning. Caregivers who reported that the Vineland-3 did not accurately measure functioning, suggested possible reasons including it was too generalised, had too few response options, and did not capture fluctuations in functioning across time and environmental contexts.

Conclusions:
The Vineland-3 was found to have adequate reliability; however, the Interview Form specified a greater level of impairment than the Parent/Caregiver Form. Evaluation of acceptability revealed that most caregivers considered the Vineland-3 as an accurate and comprehensive measure of functioning.

431.128 (Poster) Reliability, Validity and Acceptability of the Pedi-CAT with ASD Scales for Australian Children and Youth on the Autism Spectrum  
A. Chamberlain,1,2,3, E. D’Arcy,1,4,7, A. J. Whitehouse,6,8,9, K. Wallace,1, M. Hayden-Evans,1, S. J. Girdler,2,3,10,11, B. T. Milbourn,12,13, S. Bolte,12,13,14, and K. Evans,12,14, (1)School of Allied Health, Curtin University, Bentley, Western Australia, Australia, (2)Curtin Autism Research Group, Curtin University, Bentley, Western Australia, Australia, (3)Telethon Kids Institute, Nedlands, Western Australia, Australia, (4)Cooperative Research Centre for Living with Autism, Long Pocket, QLD, Australia, (5)School of Psychology, University of Western Australia, Crawley, Western Australia, Australia, (6)Autism Research Team, Telethon Kids Institute, Sibciaco, Australia, (7)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (8)Curtin Autism Research Group, Curtin University, Bentley, Australia, (9)Telethon Kids Institute, Perth, Western Australia, AUSTRALIA, (10)Telethon Kids Institute, University of Western Australia, Perth, Australia, (11)School of Occupational Therapy, Speech Pathology and Social Work, Curtin University, Perth, Australia, (12)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (13)School of Allied Health, University of Western Australia, Crawley, Western Australia, Australia, (14)Karolinska Institutet, Stockholm, Sweden, (15)School of Allied Health, Curtin University, Perth, Australia, (16)enAble Institute, Curtin University, Perth, Australia, (17)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (18)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, QLD, Australia, (19)Curtin Autism Research Group, Curtin School of Allied Health, Curtin University, Perth, Australia, (20)Center for Psychiatry Research, Region Stockholm, Stockholm, Sweden, (21)Telethon Kids Institute, The University of Western Australia, Perth, Western Australia, Australia

Background:

Autism is associated with diverse functional outcomes that cannot be described by diagnosis alone, thus, an assessment of functioning is recommended to inform the provision of supports. One measure currently used for this purpose in children and youth under 21 years of age is the PEDI-CAT(ASD); however, psychometric evidence is limited.

Objectives:

This study aimed to explore: 1/ Reliability (internal consistency, test-retest reliability, and parallel forms reliability with the original PEDI-CAT); 2/ Validity through comparison with the Vineland-3 (convergent validity) and the International Classification of Functioning, Disability and Health (ICF) Core Sets for Autism (content validity), and 3/ Acceptability from the perspective of caregivers.

Methods:

Caregivers of 134 children and youth on the autism spectrum participated in clinical assessments. Of these, 117 completed Assessment 1, involving the administration of the PEDI-CAT(ASD) and Vineland-3 Parent/Caregiver Form. Participants were randomised to either Assessment 2a or 2b, both involving the repeat administration of the PEDI-CAT(ASD), with Assessment 2b also involving administration of the Vineland-3 Interview Form. Additional recruitment to boost sample sizes resulted in another 17 participants being streamed directly into Assessment 2b. Caregivers of 47 children and youth completed Assessment 3, involving administration of the PEDI-CAT(Original) and/or a semi-structured interview exploring the acceptability of the PEDI-CAT(ASD). PEDI-CAT(ASD) content was compared to the ICF Core Sets for Autism to summarize areas of functioning assessed and relevance to autism.

Results:

The PEDI-CAT(ASD) demonstrated good to excellent internal consistency and test-retest reliability. Parallel forms reliability showed good to excellent correlations with the PEDI-CAT(Original), however, t-tests showed significantly higher Social/Cognitive scores for the ASD version. Concurrent validity results demonstrated significant correlations between the PEDI-CAT(ASD) and Vineland-3 core domains. The strength of these relationships ranged from poor to good with the Vineland-3 Parent/Caregiver Form, and poor to moderate with the Vineland-3 Interview Form. Content analysis of the full item bank revealed that the PEDI-CAT(ASD) covered 41% of the ICF Core Sets for Autism, 1% more than the PEDI-CAT(Original). Most were Activities and Participation codes; no Environmental Factors codes were represented. Just over half of the codes assigned to the PEDI-CAT(ASD) were represented in the ICF Core Sets for Autism, a 4% increase in relevance compared to the PEDI-CAT(Original). Content analysis of items administered to participants aged 0-5 years revealed that the median of 24% of the ICF Core Sets for Autism (0-5) was assessed. For participants aged 6-11 and 12-16 years, a median of 25% of the ICF Core Sets for Autism (6-16) was assessed. When compared against the full ICF Core Sets for Autism, median percentages were higher (28-30%), demonstrating greater relevance than the age specific ICF Core Sets for Autism. Feedback on the acceptability of the PEDI-CAT(ASD) was mixed in terms of accuracy, but overall, it was considered user-friendly and efficient.
Conclusions: The PEDI-CAT(ASD) was found to have adequate psychometric properties and acceptability as a measure of Activities and Participation codes. However, it lacks comprehensiveness and relevance when compared to the ICF Core Sets for Autism and has the potential to overestimate functioning.

Early Development (< 48 months)

Panel Chair: Alexandra Hendry, Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom

Difficulties with Executive Functions (EFs) impact quality of life, mental health and social and economic outcomes amongst autistic people. Early intervention may be key to reducing EF difficulties amongst autistic people, but to do so effectively requires understanding when, in what sub-domains, and for whom, EF difficulties emerge. This panel draws together 4 programmes of research using advances in the early measurement of EF to examine EF-autism associations in samples enriched for high autism traits, either by virtue of family history (Presentations 1, 3 & 4), or screening of prodromal behaviours (Presentation 2). Presentations 1 and 2 examine how autism traits associate with day-to-day EF behaviours in infancy and toddlerhood captured through parent report. Presentations 2, 3 and 4 examine how autism traits associate with behavioural measures of EF captured in the lab. In combination, these studies indicate that EF difficulties are evident for toddlers with elevated autism traits by the 3rd year of life, and highlight key areas of vulnerability.

202.001 (Panel Discussion) Toddlers (but not infants) with Elevated Autistic Traits Show Lower Executive Function Scores
M. Nosyk and A. Hendry, (1)University College London, London, United Kingdom, (2)Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom

Background:

Extensive research with children aged 3 years and above has demonstrated an association between autistic traits and difficulties with executive functions such as inhibitory control (the ability to stop or redirect a response), working memory (the ability to hold multiple items in mind, whilst manipulating those items) and cognitive flexibility (the ability to respond flexibly to a changing situation), particularly when these difficulties are captured via parent report of day-to-day behaviours. Due to a paucity of appropriate measures of everyday executive functions in infancy and toddlerhood, it is not clear whether associations between executive functions and autistic traits are evident prior to preschool age.

Objectives:

Using a recently-developed parent report measure of executive functions suitable for 9- to 36-month-olds, we aim to address the question of whether associations between autistic traits and day-to-day executive function ability are evident in infancy or toddlerhood, within a sample enriched for high variation in autistic traits (infants with a family history of autism or ADHD).

Methods:

136 UK parents of 9- to 37-month-olds with a family history of autism or ADHD contributed valid data about their child. Parents were recruited via a university babylab volunteer database, social media and the Prolific recruitment platform. Parents reported on their child’s autistic traits using the Autism Parent Screen for Infant (Bryson et al. 2006) (9- to 23-month-olds; n=85) or the Quantitative Checklist for Autism in Toddlers (Allison et al., 2008) (24- to 35-month-olds; n=51), and on their child’s executive function abilities using the Cognitive Executive Function (CEF) composite (23 items, α=.833) and Regulation scale (8 items, α=.904) of the Early Executive Questionnaire (all ages). Within each age group (i.e. infants/toddlers), linear regression was used to estimate the association between autistic traits and CEF score, after accounting for the linear effect of age. Hypotheses were pre-registered.

Results:

For 9- to 23-month-olds, the hypothesised associations between autistic traits and CEF scores (β=.118, p=.301) and between autistic traits and Regulation scores (β=-.126, p=.255) were not significant. As hypothesised, amongst 24- to 35-month-olds there was a significant negative association between autistic traits and CEF scores (β=-.808, p<.001) and between autistic traits and Regulation scores (β=-.595, p<.001); see Figs 1 and 2.

Conclusions:
Our results indicate that children with high levels of autistic traits may struggle, relative to their peers, with executive functions from as early as toddlerhood. These difficulties are observed in both the cognitive and regulatory aspects of executive function. Given the importance of executive functions for language development, as well as social, academic and mental health outcomes, these findings highlight the importance of providing early support in executive function development to toddlers displaying autistic traits.

Future research should consider whether executive function-autism associations may be detected even earlier than age 2 years when autistic traits are measured using trained observers rather than parent report.

202.002  (Panel Discussion) Early Cognitive Executive Functions in Toddlers with Prodromal ASD

F. Takio, T. M. Helminen, E. Lehtonen, H. Saarimaki and A. Kylliainen, (1)Tampere University, Tampere, Finland, (2)Faculty of Social Sciences/Psychology, Tampere University, Tampere, FINLAND, (3)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland, (4)Faculty of Social Sciences/ Welfare Sciences, Tampere University, Tampere, Finland

Background: The period between late infancy and early toddlerhood could be a sensitive period of the development of cognitive executive functions (EF), such as inhibitory control, flexibility and working memory. It has been suggested that in typical development, the ability to inhibit prepotent responses may be the first functions to emerge, already before the age of 12 months. Cognitive flexibility may be the latest EF to emerge. Existing evidence suggests that EF deficits may be present in autism spectrum disorder (ASD) before formal diagnosis, already before 3 years of age. It is less clear when and how EF deficits emerge and how EF unfold over time highlighting the importance of investigating EF skills in young children with prodromal ASD.

Objectives: The aim of the present study was to investigate cognitive executive functioning in early development at the prodromal stage of ASD. More precisely, we investigated association between early EF and ASD symptom severity.

Methods: Twenty-three participants between 13-30 months-of-age, screened with M-CHAT-R/F from the general population, have participated in the on-going Gaze@Toddler study. ADOS-2 for Toddlers was applied by professionals to evaluate ASD traits. Parents filled online the 31-item Early Executive Functions Questionnaire (EEFQ) suitable for 9-to 30-months old targeting cognitive and regulatory capabilities. From 31-items, 28 were questions concerning a wide range of activities from everyday life. Three items were behavioral games for parents to play with their children to elicit particular behavior. Four scales were calculated: Inhibition, Working memory, Flexibility and Regulation. In the present paper, statistical analyses were conducted for the EEFQ Cognitive Executive Function (CEF) factor including questionnaire items from Inhibition, Working memory and Flexibility (table 1). The internal consistency for CEF was evaluated with Cronbach’s alpha and the possible associations between total score of ADOS-2 and CEF and CEF subscales were evaluated with Pearson’s correlation coefficients.

Results: The internal consistency evaluated by the Cronbach’s alpha was for the CEF factor score .826 (table 1). Since the ADOS-2 score was positively correlated with age ($r(21)= .433, p=.039$), partial correlation was run to determine the relationship between ADOS-2 score, CEF factor, Inhibition, Working memory, and Flexibility whilst controlling for age. A moderate, negative partial correlation between Working memory and ADOS-2 score whilst controlling for age was observed ($r(20)=- .431, p=.045$) indicating that stronger ASD symptoms were associated with weaker working memory skills.

Conclusions: Among screened positive toddlers between 13-30 months, age was associated with prodromal ASD symptoms: the older the toddler was, the more severe prodromal ASD symptoms were observed. The internal consistency for CEF was good and equivalent to typically developing toddlers. When controlling the effect of age, the negative association between observed ASD symptoms and working memory skills evaluated by parents indicate that early EF deficits may be present already before the age of three in children with prodromal ASD. The small sample size means that the present result can only be considered preliminary. However, our on-going study will enable us to confirm these findings with a larger sample size.

202.003  (Panel Discussion) Associations between Autistic Traits and Executive Functions Amongst Two- and Three-Year-Olds with a Family History of Autism or ADHD

Background: Since autism and ADHD are highly heritable and overlapping, children with a family history of autism or ADHD are at elevated likelihood of showing autistic traits. Thus, research with this population affords the possibility of investigating how differences in cognitive development relate to autistic traits, early in development. Executive Functions (EF) enable us to work towards goals by coordinating thought and action and are of critical importance to social, academic and mental health outcomes. Autistic children and adults often experience EF difficulties but it is not known how early in development these difficulties emerge, due to a paucity of appropriate measures of early EF to date.
Objectives: We examine whether EF-autism associations are evident at age 2 or 3 years, in a sample at elevated likelihood of showing autistic traits, using a novel battery of EF measures.

Methods: 132 children with a first-degree relative with autism and/or ADHD completed an EF battery at age 2 (n=125), and 3 years (n=123). At age 2, the EF battery comprised an object-based inhibitory control task (‘Prohibition’), a touchscreen working memory game (‘Delayed Alternation’), and 3 eyetracking tasks indexing inhibitory control, working memory and cognitive control. At age 3, the EF battery additionally comprised a touchscreen inhibitory control game (‘GoNoGo’), a touchscreen cognitive flexibility game (‘Switch’), and an object-based working memory game (‘Spin-the-Pots’). Data processing of the eyetracking tasks is ongoing and will be included in the final presentation. Additionally, children were assessed with the Autism Diagnostic Observation Schedule–Second Edition, and parents reported on their child’s autistic traits using the Quantitative Checklist for Autism in Toddlers (age 2), and the Social Responsiveness Scale-Second Edition (age 3). Spearman rank correlations between autistic traits and performance on each EF task are presented. Missing data (due to the task not being attempted, or insufficient valid trials being completed) was excluded pairwise. In the full dataset, EF data will be reduced to latent factors to minimise multiple comparisons.

Results: Two-year-olds with high autistic traits showed lower inhibitory control on the Prohibition task compared with toddlers with low autistic traits, when traits were measured via behavioural assessment (\(r_s=-.269, p=.011\)) and via parent report (\(r_s=-.273, p=.007\)). No significant association between autistic traits and working memory was found at age 2. Three-year-olds with high parent-reported autistic traits showed lower working memory performance on Spin-the-Pots (\(r_s=-.337, p=.003\)). Similar associations were observed between parent-reported autistic traits and working memory (\(r_s=-.230, p=.052\)) and cognitive flexibility (\(r_s=-.299, p=.033\)) performance on two touchscreen tasks, but did not survive correction for multiple comparisons. Autistic traits were not significantly associated with inhibitory control at age 3; see Tables 1 and 2.

Conclusions: Autistic traits are linked to variation in behavioural markers of EF from as early as 2 years. EF difficulties appear first for inhibitory control, but are more evident for working memory by age 3. Planned latent-factor analysis with a more-comprehensive battery may reveal whether these findings are measure-specific, but these preliminary results indicate that toddlers already displaying autistic traits may benefit from early support with the development of EF.

202.004 (Panel Discussion) Executive Functions and Adaptive Behavior in 3 Year Olds: Associations to Autism and ADHD

L. Konke, T. Falck-Ytter and K. Brocki, (1)Uppsala University, Uppsala, Sweden, (2)Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden, (3)Department of Psychology, Uppsala University, Uppsala, Sweden

Background:

Difficulties with Executive Functions (EF) are common in children with autism and ADHD and have been suggested to be most impaired in children with co-occurring conditions. EFs are essential skills in order to function in everyday life, with associations to academic success, mental health and social relations (Diamond, 2002). However, a better understanding of both specific and shared neurocognitive markers would improve not only theory but also clinical practice particularly for children with co-occurring conditions. Given the high co-occurrence of autism and ADHD and the deficits in executive functioning commonly associated with ADHD it is important to disentangle autism and ADHD-specific contributions to the association of EF.

Objectives:

To investigate EF in relation to concurrent autism and ADHD in 3-year olds and if EF differs with respect to a family history of autism, a family history of autism and co-occurring ADHD, or with no family history of autism/ADHD. Moreover, we will also examine if specific EF components affect (moderate) the associations between autism vs ADHD-traits and adaptive functioning. However, the analyses which include adaptive functioning (e.g., moderation analyses) are only planned (pre-registered) and will be included at a later step.

Methods:

The sample consisted of 78 children at 36 months with a family history of autism (\(n=31\)), autism and co-occurring ADHD (\(n=27\)), and children with no family history of autism or ADHD (\(n=19\)). Adaptive behavior was assessed by VABS II. Executive functions were assessed by lab-tasks: day/night stroop, reversed categorization, beads, prohibition task, delay of gratification. Clinical best estimates of autism and ADHD-diagnosis assessed by clinical psychologists. Symptoms of autism and ADHD by ADOS-2 scores and ADHD-RS.

Results:

We found significant differences between groups based on family history in most of the EF-tasks, with lower scores for the FH-ASD and FH-ASD/ADHD groups. Children in the FH-ASD and FH-ASD/ADHD groups showed similar performance in Reversed categorization and the day/night Stroop, but slightly different performance in the Beads task (only children with FH-ASD had significantly lower scores...
Background: Atypical selective visual attention to social stimuli is a prominent feature of autism spectrum disorder (ASD; DSM-5-TR, 2022). One mechanism that contributes to selective attention in neurotypical individuals is reward value learning (RVL; Anderson, 2013; Gottlieb et al., 2014). Our group has demonstrated that unlike typical and developmentally-delayed controls, ASD preschoolers exhibit attenuated RVL in the social domain, indexed by lack of attentional bias for faces previously reinforced with social rewards (Wang et al., 2018, 2020). It remains unclear when RVL arises in infancy and whether it is related to social attention differences in infants with familial history of ASD (elevated-likelihood; EL infants). The present study investigates RVL in the social domain longitudinally, targeting EL infants and infants without familial history of ASD (low-likelihood; LL).

Objectives: Examine RVL in the social domain longitudinally at 4-, 6-, 8-, and 12-months of age. Data collection regarding developmental outcomes in this sample is ongoing.

Methods: Eighty-nine (66 LL, 23 EL) unique infants participated in at least one timepoint: 50 4-month-olds (M_{age}=4.27, SD=0.41, %Male=54.00), 49 6-month-olds (M_{age}=6.27, SD=0.51, %Male=59.18), 48 8-month-olds (M_{age}=8.35, SD=0.40, %Male=52.08), and 39 12-month-olds (M_{age}=12.27, SD=0.44, %Male=58.97). Participants viewed a gaze-contingent eye-tracking RVL task (Wang et al., 2020; see Fig. 1 for details) where specific faces were paired with a smile as a gaze-contingent reward (high-value; HV face) or remained neutral upon gaze (low-value; LV face). Visual preference for the HV face (HV dwell time/(HV dwell time+LV dwell time)) was computed before (baseline phase) and after (test phase) training. One-sample t-tests conducted at each age level compared mean HV preference to chance-level (0.5) at baseline and test phases (Fig. 2).

Results: Eye-tracking sessions with validation error $\leq 2^\circ$ and percent looking time $>20\%$ per trial were used for analysis. At baseline, 4-month-olds’ ($t(49)=0.29, p=0.773$), 6-month-olds’ ($t(47)=0.63, p=0.534$), 8-month-olds’ ($t(46)=1.19, p=0.238$), and 12-month-olds’ ($t(38)=-1.58, p=0.123$) mean HV preference was at chance-level, suggesting the absence of inherent stimulus biases (Fig. 2A). At test, 4-month-olds’ mean HV preference was at chance-level ($t(36)=-0.58, p=0.567$); however, 6-month-olds’ ($t(42)=3.98, p=0.001$), 8-month-olds’ ($t(42)=2.58, p=0.014$), and 12-month-olds’ ($t(33)=4.52, p=0.001$) mean HV preference were significantly above chance-level (Fig. 2B), indicating effects of training on visual selection in 6-12-month-old infants.

Conclusions: RVL in the social domain is robust by 6-months of age. Although prior studies have demonstrated infant RVL when non-social stimuli were paired with non-social or social rewards (Tummeltshammer et al., 2014, 2019), this is the first study to investigate RVL longitudinally and use an ecologically-valid paradigm, as both the stimuli and reward are social, capturing an essential, real-world skill. Considering RVL’s crucial role in selecting relevant stimuli for processing, RVL may be a prerequisite for the development of joint attention and social referencing, which emerge at 9-12-months of age (Mundy et al., 2007; Walden & Ogan, 1988) and are impaired in ASD. This longitudinal study is ongoing: we plan to evaluate associations between developmental trajectories of RVL in the social domain and developmental outcomes in EL and LL infants for the INSAR 2023 Annual meeting.
Background: Preferential orienting and looking at faces are present at birth and have been linked to atypical heritable neurodevelopmental conditions such as autism. According to one theory, face looking draws on two distinct neural processes: a subcortical one that promotes initial and fast orienting to faces appearing in the periphery, and a cortical route linked to top-down and sustained attention to the attended face (Johnson, Senju, and Tomalski, 2015). So far, no study with infants has probed whether face looking, when in competition with other objects, is a heritable phenotype, or whether orienting to faces versus sustained looking at faces have shared or distinct genetic etiologies.

Objectives: We investigated the contribution of genetic and environmental factors to individual differences in early life orienting and preference for faces (versus non-facial objects), and whether there were shared or distinct genetic etiologies between these measures. We also tested their associations with later developmental outcomes and common genetic variants (using genome-wide polygenic scores) associated with neurodevelopmental (autism spectrum disorder and attention deficit hyperactivity disorder) and mental health (bipolar disorder, major depressive disorder, and schizophrenia) conditions.

Methods: Our study included 536 infant twins assessed at 5 months of age (293 monozygotic and 243 dizygotic pairs) in the lab, using a Tobii TX300 eye-tracker to record attention to faces in two ways: initial orienting to faces at the start of the trial (thought to reflect subcortical processing) and sustained face preference throughout the trial (thought to reflect emerging attention control). We used 6 face pop-out displays of 20 seconds each, each consisting of static images of a face and 4 non-face competitors (including a ‘noise’ stimulus generated from the same face, a mobile phone, a bird, and a car) – see an example in Figure 1 Zygosity and GPSs were estimated based on DNA samples. Later developmental outcomes were assessed using standardized parent-rated questionnaires. The analysis plan for this study was pre-registered in OSF (https://doi.org/10.17605/OSF.IO/5FBVK).

Results: We showed that face looking was heritable, both face preference (the maintenance of attention to the face as the preferred target of attention, \( h^2 = .46, CI: .33-.57 \)) and face capture (the orienting to the face as the first target of attention, \( h^2 = .19, CI: .04-.33 \)). Face capture was not associated with later developmental outcomes, but higher face preference was associated with higher parental ratings of verbal competence in toddlerhood (\( b = 0.14, p = .014 \)). The phenotypic association between face capture and face preference (\( r_{pm} = .30 \)) was mostly explained by shared genetic factors – see Figure 2.

Conclusions: This study shows that individual differences in young infants’ selection of perceptual input – social versus non-social – are heritable, providing a new developmental perspective on gene-environment interplay occurring at the level of eye movements.

Background: Over the first year of life, infants engaged with infant-directed speech (ID-speech) gradually transition their gaze from the eyes to the mouth of the caregiver, as the mouth contains audio-visual cues that support language development (Tenenbaum 2015). Previous research has identified a positive relationship between mouth-looking and language outcomes in typically developing (TD) infants, but not siblings with an elevated likelihood of developing autism (Chawarska et al. 2022). Infant-directed song (ID-song) extends the features of ID-speech through increased rhythmic predictability, audio-visual synchrony, and smiling, as well as reduced tempo, capturing the attention of TD and ASD infants for longer durations than ID-speech (Macari et al. 2020). However, how TD and ASD infants allocate attention to the face during ID-song and ID-speech in relationship with language outcomes and feature sensitivity is unknown.

Objectives: Examine visual fixations to the mouth over the first year of life across ID-speech and ID-song conditions in TD and ASD infants with varying language outcomes.

Methods: TD infants (n=163) and ASD infants (n=64) were eye-tracked at 3, 4, 5, 6, 9, and 12 months of age while watching videos of caregivers singing (ID-song) or speaking (ID-speech). We quantified mouth-looking the proportion of face-looking time (PFLT) spent on the caregiver’s mouth (PFLT-mouth). Infants’ expressive language (EL) skills were assessed at 24 months using the Mullen Scales of Early
Learning (MSEL). We used a median split to separate ASD infants with higher (mean EL T=55.4 (9.6)) versus lower (EL T=31.9 (7.2)) EL outcomes. (TD infants EL T=57.4 (11.5)). Linear mixed models assessed changes in mouth-looking based on age, diagnostic group (TD, ASD-HighEL, ASD-LowEL), and condition (ID-speech, ID-song). Follow-up mixed models examined which stimuli features were associated with mouth-looking in each group.

**Results:** Across diagnostic groups, mouth-looking was higher in ID-song than ID-speech ($\beta = 0.099, p < 0.001$) and increased with age ($\beta = 0.075, p < 0.001$). PFLT-mouth increased at a faster rate in ID-song than ID-speech ($\beta = 0.032, p < 0.001$). When considering language outcomes, ASD-HighEL increased mouth-looking over the first year at a slower rate than TD or ASD-LowEL infants ($\beta$'s > 0.06, p's < 0.05), who exhibited more similar mouth-looking trajectories (Figure 1). However, which features drove mouth-looking differed across the three groups. Greater mouth-looking was predicted by slower stimuli tempo and increased rhythmic predictability, smiling, and mouth audiovisual synchrony in TD; by tempo and rhythm in ASD-HighEL; and by tempo in ASD-LowEL.

**Conclusions:** Over the first year of life, infants with and without ASD allocate more facial visual attention to the mouth, though this effect is attenuated in ASD-HighEL infants. This effect is greater during ID-song compared to ID-speech potentially due to features associated with song. The differing sensitivity to stimuli cues associated with mouth-looking in ASD and TD infants suggests differing processes regarding whether and how mouth-looking adaptively supports expressive language development across diagnostic groups. Individual differences in feature sensitivity may impact response to early language intervention and suggest differing mechanistic processes to be targeted.

**306.004 (Oral) Language, Visual Attention to Faces and Temporal Frequency: A Prospective Longitudinal Study of Infants with a Family History of Autism and ADHD**

**M. A. Agyapong, M. H. Johnson**: T. Charman; E. Jones; & The BASIS-STAARS Team; (1) Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (2) Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3) Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (4) Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (5) Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (6) Department of Psychology, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom

**Background:**
Neurodevelopmental conditions like autism and attention deficit hyperactivity disorder (ADHD) are diagnosed in early childhood and frequently co-occur. It is important to understand the early mechanisms that could contribute to later difficulties in these neurodevelopmental conditions through prospective studies. Throughout infancy, there are developmental changes in infant’s face-scanning patterns, which shapes and reflects their processing of social information like language. Another important component in early learning is how temporal structure of events influences attention. Syllabic speech occurs at 6Hz frequency, but it is unclear how mouths moving at different frequencies affects visual attention. Here, we explore looking patterns to faces at various temporal frequencies, in infants with and without autistic and/or ADHD first-degree relatives.

**Objectives:**
To investigate attention to faces, temporal structure (i.e. information presented at different frequencies), and language outcomes in infants with and without a family history of autism and/or ADHD.

**Methods:**
This prospective study included 161 infants (70 females) from the Studying Autism and ADHD Risks Study (STAARS); 29 typical-likelihood (TL) controls, 80 elevated-likelihood (EL) Autism, 31 EL-ADHD and 21 EL-Autism+ADHD. At 5-10- and 14-month timepoints, infants completed an eye-tracking paradigm (‘Frequency Task’). Three 10-second videos of face pairs were presented to the infants (Figure 1A). Each video flashed at low, mid or high frequencies, to show the mouth opening and closing in every other frame. An eye-mouth index (EMI; see Figure 1B) was calculated as: upper-face-looking time/(upper-face-looking time + lower-face-looking time).

Additionally, infant's language skills were assessed from 5- to 36-months using the Mullen Scales of Early Learning (MSEL). We used a median split to separate ASD infants with higher (mean EL T=55.4 (9.6)) versus lower (EL T=31.9 (7.2)) EL outcomes. (TD infants EL T=57.4 (11.5)). Linear mixed models assessed changes in mouth-looking based on age, diagnostic group (TD, ASD-HighEL, ASD-LowEL), and condition (ID-speech, ID-song). Follow-up mixed models examined which stimuli features were associated with mouth-looking in each group.

**Results:**
While EMI decreased with age ($\beta = -1.07, z(1939) = -8.88, p < .001$), temporal frequency did not affect eye-mouth looking over time ($ps > .22$). There was a marginally significant interaction between familial likelihood status and EMI ($\beta = -1.15, z(1939) = -1.93, p = .054$). Infants with EL for autism had a larger EMI compared to infants at TL for autism, but only when they were also TL for ADHD (OR = 0.50, SE = 0.18, p = .055); see Figure 2. At 14-months, infants who had acquired first words looked more at the mouth than infants without first words ($\beta = -0.14, r(58.43) = -2.47, p = .016$). However, language skills at 36-months did not associate with developmental changes in eye-mouth looking ($ps > .14$).

**Conclusions:**
Infants showed no preference for stimuli presented at the frequency of syllabic speech. The primary developmental shift in visual attention from looking at the eyes towards the mouth was consistent with emerging expressive language. Eye-mouth looking in infants with EL or
TL for autism varied depending on ADHD likelihood status. Nevertheless, individual differences in infant’s face scanning patterns did not associate with later language outcomes. This work adds to the existing knowledge by highlighting similarities and differences in visual attention and language development in autism and co-occurring conditions like ADHD. Future work will explore associations between EMI, language and autism outcomes in these children.

**ORAL SESSION — EARLY DEVELOPMENT (< 48 MONTHS)**

**322 - Early Emerging Neurodevelopmental Differences in Autism**

*Moderator: Ilan Dinstein, Psychology Department, Ben Gurion University, Beer Sheva, Israel*

**322.001 (Oral)** Using the Baby Connectome Project to Inform Early Autism – Explorations of Sleep, Brain Anatomy, and Social Communication

P. L. H. Chong¹, J. T. Elison¹, M. Styner¹, M. D. Shen¹ and A. J. Schwichtenberg⁴, (1)Purdue University, West Lafayette, IN, (2)University of Minnesota, Minneapolis, MN, (3)University of North Carolina, Chapel Hill, NC, (4)Human Development and Family Studies, Purdue University, West Lafayette, IN

**Background:** Using a developmental psychopathology perspective to inform early autism social communication development, this study assesses a typically developing sample with particular attention to two areas of noted interest in autism: sleep problems and extra-axial cerebrospinal fluid (EA-CSF). The developmental correlates of early, consistent sleep disturbance are well-documented across multiple domains, including complex behaviors such as social communication. Recent studies (Shen et al., 2017; 2018) highlight the potential role of elevated EA-CSF in individuals with autism and sleep problems; however, the nature of these developmental relations are not well understood.

**Objectives:** To inform our understanding of the longitudinal associations between early sleep problems, EA-CSF volumes, and social communication development in the first two years.

**Methods:** Data from the Baby Connectome Project (n = 318), a hybrid longitudinal cohort study documenting typical neurodevelopment in the first five years (Howell et al., 2019), was utilized for this study. See Table 1 for sample and data descriptive information. Based on parent reports of sleep in the first two years, children were classified into two groups: (1) consistent sleep problems (n = 35; 11%) and (2) inconsistent or no sleep problems (n = 283; 89%), Social communication competence at 24 months was indexed with the Mullen Scales of Early Learning, Video-Referenced Rating of Reciprocal Social Behavior, and Vineland Adaptive Behavior Scales, 2nd Edition. Volumetric EA-CSF and the ratio of EA-CSF to total cerebral volume (TCV) at 24 months were measured via T1- and T2-weighted MRI.

**Results:** Using path analysis (Figure 1), higher EA-CSF/TCV ratios were associated with lower receptive language skills and reciprocal social behavior at 24 months. Contrary to our hypotheses, robust connections between consistent sleep problems and later brain anatomy (EA-CSF/TCV ratios) and social communication were not apparent.

**Conclusions:** Consistent with previous work in autism, EA-CSF/TCV ratios were associated with aspects of social communication. This study builds on a line of work that highlights EA-CSF/TCV ratio as a developmentally meaningful anatomical index that can inform typical and atypical social communication development. Inconsistent with previous research, sleep problems were not clearly connected to the indices of interest; however, this may reflect the low levels of sleep problems present in this sample. Further research examining longitudinal trajectories and objective measures of sleep is needed to address the roles of brain morphology and sleep on social communication development.

Background:
Neurodevelopmental conditions such as Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD) are typically diagnosed in early/middle childhood through a combination of clinical interviews and observer-reports. The genetic factors that predispose an individual towards these highly heritable conditions likely act predominately prenatally, affecting brain development for years before the consolidation of the full clinical phenotype (Faraone & Larsson, 2019). Identifying the brain changes that precede the onset of behavioural symptoms could help with earlier identification of individuals who require additional support, and could provide useful outcome measures for early interventions.

One such neural change is the balance of theta and higher frequency oscillations (typically theta-beta ratio; TBR). Previous research has shown that a subset of children with ADHD show differences in TBR and its use as a prognostic indicator has been suggested (Arns et al.,...
Atypical Neural Responses to Language at 9 Months of Age Predict Delayed Language Trajectories in Infants at High and Low Likelihood for Autism

L. E. Wagner, M. Banchik, N. J. Okada, N. M. McDonald, S. Jeste, S. Y. Bookheimer, S. A. Green and M. Dapretto, (1)University of California, Los Angeles, Los Angeles, CA, (2)Harvard Medical School, Cambridge, MA, (3)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (4)Children's Hospital Los Angeles, Los Angeles, CA, (5)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (6)Dept of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA

Background: Language delays and impairments are common in autism spectrum disorder (ASD). Toddlers with a diagnosis (Redcay & Courchesne, 2008; Lombardo et al., 2015) and infants at high familial likelihood (HL) for ASD (Blasi et al., 2015) display atypical neural responses to speech, suggesting that the neural substrates of ASD-associated language delay are present well before behavioral signs can be detected. However, HL infants are a clinically and behaviorally heterogeneous population, which hinders efforts in identifying early biomarkers of ASD. Behavior-based stratification has proven useful in parsing the heterogeneity of HL samples (Longard et al., 2017; Okada et al., 2022), but has not yet been applied to investigate atypical brain activity associated with native/non-native language processing in infancy.

Objectives: To investigate the neural antecedents of aberrant language development in a sample of infants at varying familial likelihood for ASD using a data-driven clustering approach.

Methods: Infants at high (HL) and low (LL) familial likelihood for ASD were recruited as part of a longitudinal study of ASD biomarkers. Receptive language skills were periodically assessed (6, 9, 12, 18, 36 months) with the Mullen Scales of Early Learning (MSEL). Using the KmL package in R, infants who completed at least two MSEL assessments, with at least one conducted at 12 months or later (N=135), were clustered into three groups (Typical, Late-Blooming, and Atypical) based on their receptive language trajectories. At 9 months of age, a subset of participants successfully completed a stimulus-evoked fMRI paradigm in which alternating blocks of their native language (English) and a novel language (Japanese) were presented during natural sleep. After MRI quality control, the Typical, Late-Blooming, and Atypical group included 23, 18 and 8 infants, respectively. The fMRI scans were preprocessed and analyzed with FSL; differences in neural activity were evaluated across groups and language conditions.

Results: The Typical and Late-Blooming groups showed robust activation in classical fronto-temporal language networks in response to both languages. Moreover, these groups both showed extensive activity in additional frontal and occipital areas for the non-native language, with the Typical group also activating additional parietal association areas implicated in language. In contrast, the Declining group displayed considerably weaker neural activity in response to either language and, importantly showed no significant neural discrimination between languages. Finally, the extent of activation for Japanese vs. English was significantly higher in the Typical group than in the Late-Blooming group, suggesting a stronger novelty response for the non-native language.

Conclusions: This is the first demonstration that alterations in TBR are present in infants with a family history of ASD, extending the findings of Begum Ali, Goodwin et al. (2022), who found differences in TBR at 10 months only in infants with an elevated likelihood of ADHD. Interestingly, our NF1 cohort showed no alterations in TBR. We will discuss the developmental trajectories of TBR alterations and the implications for each neurodevelopmental condition.
with stronger responses to the novel/non-native language. The hypoactivation observed in the Atypical group for both native and non-native languages may reflect diminished salience of and/or attention to human speech, while the lack of neural differentiation between the two languages in this group suggests limited uptake of their native language well before overt autism-related delays can be observed.

Background: DSM-5 describes several behaviours within each domain and criteria for autism. The descriptions range from motor-, sensory-, perceptual-, language-, and socio-communicative behaviours to social cognition, intense interests and insistence on sameness. The developmental perspective on autism describes the condition as a delay of typical milestones on the one hand and, as early typical restricted and repetitive behaviours remaining instead of attenuating, on the other. If proven right, this perspective could open up for a new understanding of autism and the impact autism has on developmental trajectories. Moreover, interventions could be adapted to behaviours and milestones reached. However, the developmental perspective has not been fully evaluated in relation to descriptions in DSM-5 and gold-standard protocols. As yet, we do not really know if all autistic behaviours can be associated with typical development. Also, according to this perspective, milestones in autism emerge with other timing or rates than in typical development. To evaluate this, we need to make sure that we have good insights into the timing and rates of typical development. For the social domain, we often have a fairly good estimate about the emergence of different pro-social behaviours in typical development, even if not in detail. Our knowledge of milestones of restricted and repetitive behaviour in typical development is however often very limited, most likely because these behaviours have not been looked upon as part of typical development.

Objectives: The first aim was to search for research studies, indicating early milestones being delayed in autism. The second aim was to investigate if the restricted and repetitive behaviours, described in DSM-5 could be associated with behaviours in typical development. The third aim was to explore the feasibility to map early typical behaviours and milestones which are relevant to autism onto a developmental timeline.

Methods: As a first step, inventory of clinical charts and descriptions of early typical behaviours and milestones was made and compared with autistic behaviours according to the DSM-5. As a second step, search for research findings for more in-depth descriptions of typical developmental behaviours and trajectories, relevant for autism was performed.

Results: Findings indicated that typical socio-communicative behaviours are present but delayed in many autistic individuals. Moreover, restricted and repetitive behaviours found in autism, are also found in typical development, often remaining for a longer time in autism.

Conclusions: Findings indicate strong support for the developmental perspective of autism. Typical socio-communicative and restricted and repetitive behaviours can be mapped onto a time-line, easy to compare with the presence and absence of autistic behaviours.

Background: Language development is highly variable in autistic children and children at elevated likelihood (EL) for autism. There is some evidence suggesting that atypical sensory processing (SP) may trigger a cascade of direct and indirect effects on language development (e.g., Feldman et al., 2021). Atypical SP may change how children play and interact with objects, which may influence language development. This cascade has however not yet been studied.

Objectives: Using a mediation model of development, the current study investigates whether SP at 10 months influences language at 24 months through object play at 14 months in EL-children (younger siblings of autistic children and children born before 30 gestational weeks, N=112).
Methods: As part of a prospective longitudinal study, parents rated SP of their 10-month-old child on three domains (hyporesponsiveness, sensory seeking and hyperresponsiveness) using the Infant/Toddler Sensory Profile (ITSP), wherein lower scores were indicative of increased presence of the behaviors of interest. Scaled scores of the subscale Object Use of the Communication and Symbolic Behavior Scales Developmental Profile Caregiver Questionnaire (CSBS-DP) were used to assess play at 14 months. Parent-reported language was assessed using the short-form version of the MacArthur Communicative Development Inventories (MCDI) at 24 months. Three multiple regression models were conducted. Percentile-based bootstrap intervals were calculated for testing indirect effects using the “lavaan” R package.

Results: Three domains of SP accounted for 12.09% of the variance in play ($F(3,108) = 4.95, p = .003$). SP and play accounted together for 13.57% of the variance in language ($F(4,99) = 3.89, p = .006$). The total effect, representing the relationship between three domains of SP and language without the mediation of play, was not significant. The relationship between sensory seeking and language was fully mediated by play (bootstrapped unstandardized indirect effect 95%CI (-0.060: -0.006). For each additional point on the sensory seeking domain, participants scored .11 points lower on the CSBS-DP ($p = .006$), which in turn led to a decrease in language: per decreasing point on the CSBS-DP, MCDI scores decreased with 22.17% ($p = .001$). Although the effect of hyporesponsiveness on play was significant ($B = .11, t = 2.11, p = .03$), the (in)direct effects of hyporesponsiveness on language were not. No significant (in)direct effects of hyperresponsiveness on language were found.

Conclusions: This prospective study provides novel information on the association between SP and language through play in EL-children. No direct effects between early hyporesponsiveness, sensory seeking and hyperresponsiveness and later language were found. Contrary to results found in older children with (EL for) autism (e.g., Watson et al., 2011), parents who reported more sensory seeking behavior in their 10-month-old child, reported better play skills at 14 months, which was associated with better parent-reported language at 24 months. Our results support previous research showing that early play is related to later language, which emphasizes that play opportunities are indeed meaningful and important childhood experiences. More advanced play skills may be protective, amongst other variables, for language difficulties especially when children show little interest to perpetuate or intensify a sensory experience before their first birthday.

413.187 (Poster) Association between Cumulative Psychosocial Adversity in the Family and Neurodevelopmental Disorders: A Family-Based Cohort Study

A. Kanina, M. Rosenqvist, H. Larsson, A. Sjölander, A. Butwicka, M. Martini, M. Taylor and P. Lichtenstein, (1)Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, (2)Medical Epidemiology and Biostatistics, Karolinska Institute, Stockholm, Sweden

Background: Cumulative exposure to psychosocial adversity at an early age has been shown to be a risk factor for developing neurodevelopmental disorders, such as attention-deficit hyperactivity disorder (ADHD) and autism. However, few studies have investigated the effect of cumulative psychosocial adversity on neurodevelopmental outcomes and the role of unmeasured confounding. A scale for psychosocial adversity created by Rutter et al. consists of several factors: severe marital discord, low socioeconomic status, large family size, paternal criminality, maternal mental disorder, and foster care placement. Rutter et al. found that aggregation of those factors increases the risk for ADHD. Exposure to psychosocial adversity in early childhood is also associated with increased risk of autism. One major limitation of previous studies of psychosocial adversity and neurodevelopmental disorders is that most were unable to adjust for unmeasured familial (i.e., genetic and shared environmental factors) confounding.

Objectives: The aim of this study is to investigate the association between cumulative psychosocial adversity during the first year of life in the family and neurodevelopmental disorders in offspring, using family-based study designs to control for unmeasured confounding, and to assess if psychosocial adversity is specifically associated with ADHD or autism.

Methods: We used a population-based cohort of 1,877,901 individuals born in Sweden between 1990 and 2009. Participants were followed from the age of 3. Based on the information on 7 registers we created a cumulative index based on 7 psychosocial adversity factors and identified the diagnoses of ADHD and autism. We used Cox regression to estimate the hazard ratios (HRs) relating neurodevelopmental disorders to cumulative psychosocial adversity. To address familial confounding, the analyses were repeated in groups of relatives of different kinship: siblings, half siblings and cousins.

Results: A dose-response relationship was observed between cumulative exposure to psychosocial adversity and ADHD at a general population level (covariate adjusted HRs with 95% confidence intervals ranged from 1.55 [one adversity; 1.52 - 1.58] to 2.61 [≥4 adversities; 1.95 - 3.49]). No clear dose-response relation was seen for autism (covariate adjusted HRs ranged from 1.06 [1.60 - 1.87] to 1.34 [1.30 - 1.38]). HRs of ADHD and autism decreased with increasing level of kinship in the analysis of groups of relatives. Sex stratified analysis showed that boys and girls had similar risks of developing ADHD with the dose-dependent effect related to experiencing cumulative psychosocial adversity while girls had a higher risk of being diagnosed with autism compared to boys.

Conclusions: Cumulative exposure to psychosocial adversity was associated with both ADHD and autism in the general population. However, the association was attenuated towards the null with increasing level of genetic and environmental sharing, indicating that the association was partly explained by unmeasured familial confounding. This highlights the need for using family-based designs in studies of risk factors for neurodevelopmental disorders.
Background: Anxiety is one of the most common co-occurring conditions in youth with autism spectrum disorder (ASD; Leyfer et al., 2006). Both conditions share similar behavioral presentations, especially insist on sameness (IS), and both are associated with early temperament (Buss et al., 2013; Russel et al., 2019). Although behavioral inhibition (BI; fearful temperament) represents one of the most robust predictors of childhood anxiety, the relationship between infancy fearfulness and school-age anxiety among younger siblings of autistic children and typically developing children is found to be unique in children with ASD and not present in others (Degnan et al., 2010; Lasch et al., in preparation). The finding suggested that there are possible mechanisms linking autistic presentation and anxiety behaviors early in development; however, the behavioral manifestation and underlying mechanisms remain unclear.

Objectives: This study aims to examine the relationships between early temperament (measured by the Infant Behavior Questionnaire-Revised, IBQ-R, at 12-month-old), higher-order repetitive behavior (Repetitive Behavior Scale-Revised, RBS-R, at 24-month-old), and internalizing symptoms in toddlerhood (Child Behavior Checklist, CBCL, at 24- or 36-month-old).

Methods: Infants with higher autism likelihood (HL, having an older sibling diagnosed with autism; N = 62, 58% male) and lower likelihood (LL, no family history of autism in first-degree relatives; N = 39, 56% male) were examined at 12, 24, and/or 36 months of age. Caregivers completed IBQ-R (Approach and Fear), RBS-R (Ritualistic and Sameness Behavior), and CBCL 1.5 to 5 Years Form (Internalizing Problem) at 12-month, 24-month, and/or 36-month visits, respectively. Generalized mixed models were first used to examine the association between early temperament, higher-order repetitive behavior, and internalizing symptoms, controlling sex and familial likelihood. Causal Mediation Analyses were implemented next, bootstrapping with 5000 resamples to generate more reliable, robust results.

Results: Results suggested that early ritualistic behavior (β = 1.555, p < .05) and sameness behavior (β = 2.264, p < .001) were associated with later internalizing symptoms after controlling for familial likelihood and sex and considering early temperament. Causal mediation analyses revealed that the effect of early temperament on internalizing symptoms was fully mediated by insist on sameness. Specifically, the effect of infancy approach on internalizing symptoms (b = -4.759, p < .001) was fully mediated by sameness behavior, accounted for 47.7% of the total effect (95% CI [0.162 – 1.515]); the effect of fear on internalizing symptoms (b = 3.093, p < .001) was also fully mediated by sameness behavior, accounted for 48.5% of the total effect (95% CI [0.095 – 1.098]); the effect of infancy approach on internalizing symptoms (b = -4.759, p < .001) was fully mediated by sameness behavior, accounted for 47.7% of the total effect (95% CI [0.162 – 1.515]). Other restricted, repetitive behaviors, including compulsive behavior, restricted interests, self-injurious behavior, and stereotypic behavior, did not mediate the relationships between early temperament and toddlerhood internalizing symptoms.

Conclusions: The association between early temperament and later internalizing presentation was fully mediated by insist on sameness, suggesting IS may play a critical role in the development of anxiety. Elevated and persistent IS behaviors may be the main barrier that impedes the emergence of more developmentally appropriate modes of self-regulation, which result in elevated internalizing symptoms.

Background: Evidence suggests an interlink between sensory challenges and anxiety. Sensory related difficulties are known to be core of autism symptoms and earlier models link anxiety to Restrictive Repetitive Behaviours (RRB). A previous study with infants at elevated likelihood of autism indicated that infant anxiety and perceptual sensitivity traits were related both to later RRB and to later Social Communication Interaction (SCI) traits. We attempt to replicate this model in a separate cohort and examine whether separating hypersensitivity and hyposensitivity may show greater specificity, as it may be more attuned to determine different mechanisms that underpin sensory processing.

Objectives: This study aims to examine the associations between infant sensory hypersensitivity and anxiety and three-year autism characteristics.

Methods: Caregivers completed IBQ-R (Approach and Fear), RBS-R (Ritualistic and Sameness Behavior), and CBCL 1.5 to 5 Years Form (Internalizing Problem) at 12-month, 24-month, and/or 36-month visits, respectively. Generalized mixed models were first used to examine the association between early temperament, higher-order repetitive behavior, and internalizing symptoms, controlling sex and familial likelihood. Causal Mediation Analyses were implemented next, bootstrapping with 5000 resamples to generate more reliable, robust results.

Results: Results suggested that early ritualistic behavior (β = 1.555, p < .05) and sameness behavior (β = 2.264, p < .001) were associated with later internalizing symptoms after controlling for familial likelihood and sex and considering early temperament. Causal mediation analyses revealed that the effect of early temperament on internalizing symptoms was fully mediated by insist on sameness. Specifically, the effect of infancy approach on internalizing symptoms (b = -4.759, p < .001) was fully mediated by sameness behavior, accounted for 47.7% of the total effect (95% CI [0.162 – 1.515]); the effect of fear on internalizing symptoms (b = 3.093, p < .001) was also fully mediated by sameness behavior, accounted for 48.5% of the total effect (95% CI [0.095 – 1.098]); the effect of infancy approach on internalizing symptoms (b = -4.759, p < .001) was fully mediated by sameness behavior, accounted for 47.7% of the total effect (95% CI [0.162 – 1.515]). Other restricted, repetitive behaviors, including compulsive behavior, restricted interests, self-injurious behavior, and stereotypic behavior, did not mediate the relationships between early temperament and toddlerhood internalizing symptoms.

Conclusions: The association between early temperament and later internalizing presentation was fully mediated by insist on sameness, suggesting IS may play a critical role in the development of anxiety. Elevated and persistent IS behaviors may be the main barrier that impedes the emergence of more developmentally appropriate modes of self-regulation, which result in elevated internalizing symptoms.
Objectives:

The study aims to: 1) replicate the association between infant anxiety and perceptual sensitivity and later autism traits in an independent sample. 2) examine longitudinal associations between infant anxiety and hypersensitivity and hyposensitivity and later RRB and SCI symptoms.

Methods:

As part of the Studying Autism and ADHD Risks (STAARS), 161 infant-siblings participated in a longitudinal study. All participants had at least one older-sibling with a diagnosis of autism (elevated-likelihood-Autism (EL-ASD; N=80)), or first degree relative with Attention Deficit Hyperactivity Disorder (ADHD) (elevated-likelihood-ADHD (EL-ADHD; N=31)) or both (elevated-likelihood-autism&ADHD (EL-ASD/ADHD; N=21)). All typical-likelihood (TL) participants (N=29) had no known immediate family members with a diagnosis of autism or ADHD. Parents rated infant’s traits of early anxiety and perceptual sensitivity using the Infant Behavior Questionnaire at 10 and 14-months, and the Early Childhood Behavioral Questionnaire at 24-months. The Infant Toddler Sensory Profile (ITSP) was used to separate hyposensitivity and hypersensitivity at all timepoints. RRB and SCI were assessed using subscales of the parent-rated Social Responsiveness Scale at 36-months. Structural equation models tested 1) predictive pathways from fear (infant anxiety) and perceptual sensitivity at 10-24-months, 2) bidirectional pathways between fear, hyposensitivity, and hypersensitivity quadrants of ITSP between 10-24-months, 3) Cross-lag models tested directionality of the pathways from fear and hypo/hypersensitivity at 10, 14 and 24 months, and RRB and SCI at 36 months.

Results:

Replication analysis provided a moderate fit along with within domain continuity for both fear and perceptual sensitivity between 10-14 and 14-24-months as seen before. The cross-lagged model with ITSP indicated within domain continuity to next timepoint for fear, hyposensitivity and hypersensitivity. Higher levels of hypersensitivity at 14 months were associated with both fear and hyposensitivity at 24 months. Increased hypersensitivity at 14 and 24 months were associated with higher levels of SCI at 36 months, and hypersensitivity at 24 months associated with RRB at 36 months, but fear was not.

Conclusions:

Our findings did not replicate the associations between early anxiety and perceptual sensitivity to later RRB and SCI. The novel model with the ITSP found that developmental continuity of traits and association of infant anxiety was specific to hypersensitivity compared to hyposensitivity. Hypersensitivity also related to later RRB and SCI. Our findings indicate that hypersensitivity plays an important role in development of later autism characteristics.

413.190 (Poster) Behavioral Differences between Infants at Community and Elevated Risk for Autism during a Contingency Learning Paradigm

M. R. Rosales1, J. C. Pulido2, N. S. Bradley3, M. J. Mataric4 and B. A. Smith5, (1)Division of Biokinesiology and Physical Therapy, University of Southern California, Los Angeles, CA, (2)Universidad Carlos III de Madrid, Madrid, Spain, (3)Division of Biokinesiology and Physical Therapy, University of Southern California, Los Angeles, CA, (4)Department of Computer Science, University of Southern California, Los Angeles, CA, (5)Children's Hospital Los Angeles, Los Angeles, CA

Background: Infants having a family history of autism are at elevated risk for autism (ER). Based on current literature, infants at ER and later diagnosed with autism display delayed motor development, atypical visual behaviors, and difficulties with motor control (Johnson et al. 2015). Despite these descriptions, we do not know if infants at ER have difficulties learning or executing motor skills. A better understanding of motor skill acquisition and execution will aid in developing behavioral interventions.

Objectives: The aim of this study was to determine and describe the motor behavioral differences between infants at community risk (CR) and ER for autism during a contingency learning paradigm (CLP).

Methods: To date, 21 full-term infants (6-9 months of age) at CR (n=14, 6 male) or ER (n=7, 5 male) participated in a CLP. An infant-sized humanoid socially assistive robot provided reinforcement by clapping and laughing when the infant produced a right leg movement with an acceleration ≥ 3.0 m/s² (GIF 1). The CLP contained a 2-minute baseline (no reinforcement), 8-minute contingency (robot reinforcement), and 2-minute extinction (no reinforcement). The infant’s limb movements were captured by wearable sensors (Opal) and concurrent gaze by a head-mounted eye tracker (Positive Science). The number of robot activations during each 2-minute block of the contingency phase were counted, as well as the number of times the infant would have activated the robot during baseline. An infant was classified as a performer if they activated the robot 1.5 times more during any block of the contingency phase than during baseline. Using a frame-by-frame analysis, two assessors determined the start and end of each gaze centered on the robot to estimate look duration. Assessors were
Results: Preliminary results showed that fewer infants at ER were classified as performers (ER = 29%, CR = 43%, Table 1). However, infants at ER tended to produce more robot activations during the contingency phase (M±SD; ER=92±28, CR=79±37). Average look duration appeared to be similar; ER (N=2) (301 and 306 sec) and CR (M±SD, N=6) (279±40 sec).

Conclusions: Our preliminary data suggest that fewer infants at ER may increase their limb movements in response to a reinforcement than infants at CR for autism. However, our measures of motor behavior suggested infants at ER may increase their overall level of motor activity over an extended period of robot reinforcement. Given similar average look durations, robot reinforcements may have offered similar levels of interest for infants at ER compared to infants at CR. We plan to explore our data further by examining the baseline phase of the contingency paradigm. Additionally, we plan to further analyze our visual gaze and movement data by examining visual anticipation on the reinforcement and evidence of “sticky attention”. A more detailed analysis of motor learning could indicate potential learning differences between the two groups.

413.191 (Poster) Blink Rate Reveals Distinctive Patterns of Attentional Engagement in Young Autistic Toddlers Via Digital Phenotyping Tool

Background:
Spontaneous blink rate has been used to index attentional engagement, with lower blink rates reflecting increased engagement. The evolutionary basis of varying blink rate stems from the idea that real-time assessments of the salience and value of information unconsciously change blink rate to increase or decrease the amount of visual information processed. Prior studies indicate that the blink rate and attention engagement were reduced or distinct in autistic (AUT) children compared to their neurotypical (NT) counterparts. Here, we use computer vision analysis (CVA) for automatically quantifying patterns of attentional engagement in young autistic children based on facial orientation and blink rate.

Objectives:
To develop a digital phenotyping tool for scalable, objective, and quantitative estimates of attentional engagement in toddlers. This requires implementing and designing robust CVA methods to detect blink rate and facial orientation in primary care settings.

Methods:
Participants were 474 toddlers (17–36 months old), 43 of whom were diagnosed with autism. Movies containing social or nonsocial content (screenshots in Figure 1) were presented on a tablet whose camera recorded the children’s behavior while they watched the movies. Nonsocial movies contained dynamic objects while social movies had human actors. Tools such as OpenFace and IntraFace were used to track blinking events and facial orientation (respectively), to obtain blink rate and total facing forward proportion for the duration of each movie. The estimated gaze using a deep neural network model was used to ensure that the toddlers were looking toward the screen.

Results:
Overall, autistic children spent less time facing the screen (NT: P<.0001, r=0.68, AUT: P=.043, r=.33) and had a higher mean blink rate compared to neurotypical children (Figure 1 and Figure 2), who also blinked at a lower rate during the social movies compared to the nonsocial movies (NT: P<.0001, r=0.55, AUT: P=.21, r=.17). On average, neurotypical children faced the screen more often during social movies than autistic children, whereas the two groups did not differ in their tendency to face toward the nonsocial movies. For all the social movies, significant P-value and medium-large effect sizes (see Figure 2) were found for both total facing forward proportion and blink rate, unlike for nonsocial movies (except “Toys”). The observation is consistent with eye tracking studies that reported the autistic toddlers exhibit lower overall sustained attention to any dynamic stimuli.

Conclusions:
Blink rate and orientation automatically measured via CVA using an app on a smart tablet offer an objective, quantitative, scalable method for detecting distinct patterns of social and nonsocial attentional engagement in autistic toddlers. Our findings are consistent with past work performed with high-grade tools; in contrast to these, our method does not require per-subject calibration or laboratory equipment. Autistic and neurotypical toddlers displayed distinctive patterns of attentional engagement with the social compared to the nonsocial movies. This work is a step towards developing scalable and robust phenotyping tools to objectively quantify behavior related to autism and the assessment of the response to early interventions.

413.192 (Poster) Change in Developmental Functioning for Young Children in Early Intervention: The Contributions of Child Social-Emotional and Behavioral Functioning and Autism Diagnosis

M. Troxel, A. E. Chavez, A. Eisenhower, R. C. Sheldrick and A. S. Carter, (1)Department of Psychology, University of Massachusetts Boston, Boston, MA, (2)Boston University School of Public Health, Boston, MA

Background: The U.S. federal Part C Early Intervention (EI) program provides services for autistic children, as well as children with developmental disabilities, under three-years-old. Delays in social-emotional and behavioral (SEB) functioning are higher in young autistic children. However, little is known about how SEB functioning impacts developmental gains for children diagnosed with autism spectrum disorder (ASD) receiving EI services.

Objectives: This study addressed how ASD diagnosis and SEB functioning are associated with developmental gains in EI.

Methods: Data were drawn from Department of Public Health records for 610 children receiving services from EI agencies participating in an ASD screening study from 2011-2019 and who had a repeated developmental evaluation following screening. The sample was restricted to children with a documented ASD diagnosis, or who remained in EI until 30 months (or longer), so that there was greater opportunity for ASD identification. About a third of children in the sample received a diagnosis of ASD (n = 187). Most children were male (67.4%), non-White (77%), and had a primary household language of English (61%). On average, children were 19-months-old at the time of EI entry. The Battelle Developmental Inventory, Second Edition (Battelle-2) assessed developmental functioning at EI entry and exit, or follow-up. The Brief Infant Toddler Social Emotional Assessment (BITSEA) was used to operationalize SEB functioning in terms of SEB problems and competencies. Covariates included: developmental functioning at EI entry, child sex, child age at EI entry, family race/ethnicity, and primary household language. Hierarchical multiple regression was used to assess the contribution of SEB functioning and ASD diagnostic status on change in developmental functioning while controlling for covariates.

Results: A hierarchical multiple regression model predicting exit Battelle-2 scores was conducted with entry Battelle-2 scores at step 1; child-level covariates at step 2; family-level covariates at step 3; ASD diagnostic status at step 4; SEB problems at step 5; SEB competencies at step 6; three two-way interaction terms at step 7 (ASD group X problems/competencies and problems X competencies); and a three-way interaction term at step 8 (ASD group X problems X competencies). The final model (step 7) accounted for 49.8% of the variance in developmental functioning at the time of EI exit. The model showed that the following predictors were significantly associated with greater developmental gains: higher developmental functioning at the time of EI entry ($\beta = .31$), being a female ($\beta = .08$), identified as White ($\beta = .11$), not having an ASD diagnosis ($\beta = .23$), and having more SEB competencies ($\beta = .24$). Age, household language, and SEB problems did not significantly contribute. Of the interaction terms, only BITSEA problems by competencies was significant ($\beta = -.09$). See Figure 1.

Conclusions: EI is an important resource for families of young autistic children. Yet, findings highlight child- and family-level factors associated with gains in developmental functioning during EI, including diagnostic status. Focusing on enhancing SEB competencies may be one strategy for increasing the developmental gains of autistic children. Racial/ethnic disparities in EI services also need to be addressed.

413.193 (Poster) Characteristics of Gesture Communication in Young Children with Autism during Naturalistic Play Interactions

M. Mastrogiuseppe, E. Leonardi, S. Aiello, F. Fama, A. Campisi, C. Carrozzi, C. Bladino, F. Marino, G. Tartarisco, G. Pioggia, O. Capirci and L. Ruta, (1)University of Trieste, Trieste, Italy, (2)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy, Messina, Italy, (3)National Research Council of Italy, Institute for Biomedical Research and Innovation (IRIB), Messina, Italy, (4)Institute of Cognitive Sciences and Technologies, National Research Council of Italy, Rome, Italy

Background: One of the earliest signs of autism is the absence or the delayed onset of non-verbal communication, such as gesture behaviors. While there is a large body of literature showing the importance of gestures in predicting and supporting language development in typically developing (TD) children and in other clinical populations, there are still many open questions about this topic in autism. Very limited studies, with relatively small sample sizes, and in school-aged children with autism have explored gesture behaviors. For this reason, the paper proposes to investigate early socio-communicative development in very young children with autism under the lens of gesture behaviors, using a fine-grained microanalytic coding system. The theoretical framework is the Embodied Cognition, according to which social communication has roots in motor behaviors and early sensorimotor interactions. Since infancy, early motor schemes, scaffold
the emergence of gestures that in turn act as supporting links toward social communication and language during daily child-caregiver communicative interactions.

Objectives: The aim of this study was to explore how gestural communication is expressed in toddlers and young children with autism, compared to TD children, during naturalistic play interaction. The main goal was to detect whether possible differences in gesture behavior could be expressed not only quantitatively (e.g. absence or lower level of gestural production in autism), but also qualitatively (e.g., production of different types of gestures and with a different pragmatic function).

Methods: The study had an cross-sectional design and was conducted on a group of 30 toddlers and young children with and without autism (N=15 per group, 8 F). Children with autism and TD were individually matched according to the autism child’s developmental age (mean = 23 months). To explore gestural communication, we used a detailed micro-analytic system from video footage of naturalistic mother-child interactions. Relevant behavioral information from video contents were extracted using a moment-by-moment coding strategy and a detailed coding scheme specifically developed to capture the amount and types of gestures, and their pragmatic functions.

Results: Results showed that, compared to the TD group, the autism group: (i) produced a significantly lower number of total gestures (Z = 100, p = 0.003); (ii) tended to produce a lower proportion of conventional gestures with a trend towards statistical significance (Z = 50, p = 0.052); (iii) produced a significantly lower proportion of showing gestures (Z = 69, p = 0.013); (iv) produced gestures mainly for expressing the pragmatic function of request (Z = -73, p = 0.007 ), while TD children used significantly more gestures for declarative purposes (Z = 93, p = 0.006). Interestingly, among different gesture types, only children with autism produced instrumental gestures.

Conclusions: Overall these preliminary findings suggest a specific deficit in social sharing and declarative functions (i.e. lower production of conventional gestures and showing) in autism, with a preferential use of gestures to direct others behavior and address their requests (exclusive use of instrumental gestures and greater use of requestive function).

413.194 (Poster) Characterizing Associations between Quantitative Autistic Traits and Language Development in Toddlers

K. Lineback, H. C. Baer*, N. Marrus* and J. N. Constantino*; (1)Washington University School of Medicine, St. Louis, MO, (2)Washington University in St. Louis, St. Louis, MO, (3)Children's Hospital of Atlanta, Atlanta, GA

Background: Language delay is a common co-occurring condition in autism spectrum disorder (ASD), which has been shown to manifest prior to the age of diagnosis (Swanson et al., 2016), to be associated with familial liability for ASD (Marrus et al., 2018), and to predict long-term neurodevelopmental outcomes in children with ASD (Magiati et al., 2014). At the same time, abilities contributing to social communication that are disrupted in ASD, such as joint attention, are known to influence language outcomes (Morales et al., 2000). Characterizing early developmental relationships between language function and quantitative autistic traits (QATs), i.e., subthreshold levels of heritable ASD traits encompassing a continuous range across typically developing and atypically developing populations, can be informative for clarifying the developmental progression of these interrelationships and the optimal timing for ASD interventions targeting these domains.

Objectives: Examine concurrent and longitudinal relationships between expressive language and quantitative autistic traits (QATs) across toddlerhood in a general population sample, which affords the advantage of characterizing interrelationships across a range of language ability and ASD trait levels that span the continuum of typical to atypical development.

Methods: Epidemiologically sampled toddler twins (n=699; 112 monozygotic pairs, 237 dizygotic pairs, 1 unmatched twin) from the general population were longitudinally assessed as part of the Early Reciprocal Social Behavior Study (HD068479) between the ages of 18 and 36 months. At 18- and 24-month time points, quantitative autistic traits (QATs) were quantified using the “Video-referenced Rating Scale of Reciprocal Social Behavior” (vrRSB), a metric indexing QATs as deficits in reciprocal social behavior (Marrus et al., 2015). The vrRSB represents a downward extension of the Social Responsiveness Scale-2 (SRS-2), a QAT measure applied at age 36 months. Expressive language was quantified at 18, 24, and 36 months using age-appropriate versions of the MacArthur Communicative Development Inventory. Pearson correlations assessed relationships between QATs and expressive language within and across time points. Generalized estimating equations (GEE) accounting for twin relatedness tested interrelationships between 18-month QATs and 36-month expressive language, as well as 18-month expressive language and 36-month QAT outcome.

Results: QATs showed concurrent inverse associations with expressive language scores at 18, 24, and 36 months, with the highest magnitude correlations observed at 18 months (r=-0.44, p<.001; r=-0.38, p<.001; r=-0.15, p<.001). The correlation of 18-month QATs to 36-month expressive language (r=-0.28, p<.001) was nominally larger than that for 18-month expressive language with 36-month QATs (r=-0.19, p<.001). GEE models showed that 18-month expressive language, 18-month QATs, and their interaction each contributed significant variance to 36-month expressive language outcome (Figure 1). GEEs examining relationships of 18-month expressive language and QATs to 36-month QATs found that only 18-month QATs contributed significant variance to the model (Table 1).

Conclusions: QATs additively and interactively contributed to expressive language in early childhood, whereas associations between expressive language and QATs were largely concurrent rather than predictive. While individualized interventions targeting both QATs and
Background: Research has shown that infants at increased likelihood for autism spectrum disorder (ASD) have difficulties regulating their emotional states, which is often characterized by atypical behavioral expression and physiological arousal. Yet, the relation between behavioral and physiological indices of emotion regulation and their association with ASD symptoms remains unclear. Thus, a behavioral-physiological approach is warranted to study the role of emotion regulation in the emergence of ASD.

Objectives: The objectives were to (1) determine whether indices of behavioral affect and heart-rate were congruent (i.e., significantly correlated) during negative activities of an emotion regulation task, and (2) examine the relations between congruence and later ASD symptoms in an infant sibling cohort.

Methods:

Participants: Participants were 103 infants at increased likelihood (IL; have an older sibling with ASD) and 52 infants at low likelihood (LL; no family history of ASD) for ASD. Infants were assessed at 6, 12, 18, and 24 months of age.

Emotion Regulation: At 6, 12, and 18 months, infants were assessed on the emotion regulation task, which is comprised of activities designed to elicit negative emotions (toy removal, masks, grooming; Sacrey et al., 2021). Behavioral affect was coded for valence (positive, negative, neutral) and intensity (to differentiate mild from intense displays of affect) using Noldus Observer software. Raw heart-rate was recorded and extracted from an electrocardiogram signal and the data were processed and transformed into a metric of average change in heart-rate from baseline.

ASD Symptom Expression: At 24 months, infants underwent the Autism Diagnostic Observation Schedule 2nd Edition Toddler Module (ADOS-2-T) to measure ASD symptoms.

Analytical Approach: Behavioral affect and heart-rate were collapsed into 5-second time intervals during the negative activities of the emotion regulation task. To assess congruence, data were analyzed using Spearman’s rank-order correlations. Group differences (IL, LL) in congruence (rho values) across the negative activities at 6, 12, and 18 months were explored using Mann-Whitney U tests. Kruskal-Wallis tests examined if negative activities at 6, 12, and 18 months were associated with 24-month ASD symptoms.

Results: There were no group differences in congruence during the negative activities at 6 (U=362.000, p=0.437), 12 (U=1048.000, p=0.132), or 18 (U=358.000, p=0.973) months, thus group was collapsed for the remainder of the analyses. There was a significant association between participants characterized by negative congruence and ASD symptoms, such that increased negative affect and greater heart-rate at 6 (q’s=0.017–0.050) and 12 months (q’s= 0.025–0.050) was associated with greater ASD symptoms at 24 months.

Conclusions: The absolute level of agreement between behavioral affect and heart-rate was low in infants at IL and LL of ASD. Moreover, no significant differences in congruence between IL and LL infants were seen. It is important to note that this does not preclude the possibility that affect and heart-rate might separately predict subsequent ASD symptoms or diagnostic status. Overall, the study highlights the complexities entailed in examining temporal relations between behavioral and physiological indices of emotion regulation during infancy. Future work will investigate how affect and heart-rate differentially impact the emergence of ASD.

413.196  (Poster) Defining Resiliency in 6-Month-Old Infants with and without Siblings with Autism: A Data-Driven Approach from the Baby Siblings Research Consortium

Background: Convergent evidence highlights biological and nonbiological factors associated with resilience from atypical neurodevelopment in infants with and without familial history of ASD (Elsabbagh, 2020). A primary challenge involves defining the axes upon which both outcomes and potentially associated precursors to those outcomes may be established (Masten & Coatsworth, 1998).

Objectives: To use data-driven approaches to define developmental status at ages 6 and 36 months in infants with siblings with ASD (ASIB) and without (NSIB) from the Autism Science Foundation’s Baby Siblings Research Consortium with the goal of identifying factors associated with functional outcomes.

Methods: We used principal component analysis (PCA) on Mullen Visual Reception, Fine Motor, Receptive Language, and Expressive Language domains at 6 months (NSIB N=391) and Mullen and ADOS (CSS-Total, SA, and RRB) at 36-months (NSIB N=618) to define axes of developmental performance. The first principal component (PC#1), accounting for the greatest variance in behavioral measures, defined a threshold separating the top 85% of the NSIB group (“upper”) from the bottom 15% (“lower”) at each timepoint. In 1035 infants (ASIB N=679, NSIB N=356; Table 1a) seen at both 6 and 36 months, relationships between infant sex, sibling group (ASIB or NSIB), 6-month PC#1 status (upper or lower), and 36-month PC#1 outcomes (upper or lower) were examined using Chi-square tests. This was followed by BIC-driven stepwise model simplification of exploratory logistic regression considering factorial effects of sex, sibling group, PC#1 6-month status, and 6-month PCs #2-4.

Results: Derived principal components at 6 and 36 months are shown in Figure 1a. The probability of upper group membership at 36 months was greater in (Table 1b) NSIB compared to ASIB children for those with 6-month lower (X(1,N=198)=15.9, p<.001) and upper status (X(1,N=837)=73.1, p<.001). 6-month upper status was associated with higher probability of 36-month upper membership in ASIB (X(1,N=679)=9.4, p<.002) but not NSIB (X(1,N=356)=3.0, p=.082). The probability of upper membership at 36 months was greater for girls than boys for both ASIB (X(1,N=679)=31.0, p<.001) and NSIB (X(1,N=356)=6.9, p=.008) infants, and greater for ASIB as compared to NSIB infants for both girls (X(1,N=475)=32.1, p<.001) and boys (X(1,N=560)=57.7, p<.001). Stepwise reduction of unified logistic regression predicting 36-month upper status yielded additive main effects of sex (X(1,339)=33.9, p<.001), sibling group (X(1,977)=97.7, p<.001), and 6-month PC#1 status (X(1,128)=9.9, p=0.002). In girls, 36-month upper status was negatively associated with 6-month PC#4 interaction (X(1,452)=9.6, p=.002). In girls, 36-month upper status was negatively associated with 6-month PC#4 (M=-.252, 95% CI: -.512, .008) suggesting stronger visual reception than fine motor was advantageous, whereas for boys the opposite was observed (M=.293, 95% CI: .070, .517).

Conclusions: Results suggest additive effects associated with likelihood of data-driven clinical composites of 36-month outcomes in infants. These effects include well-known female protective effects against atypical neurodevelopment, developmental vulnerabilities associated with ASIB, and persistence of earlier observable developmental concerns. Exploratory findings also suggest sex-specific interactions with the tension of nonverbal domains, with males benefiting from stronger fine motor skills, and females benefiting from stronger visual reception. Subsequent research is needed to further investigate and confirm these findings.

413.197 (Poster) Delay of Gratification Performance in Preschoolers with Autism or Risk for ADHD

Background: Autism and attention-deficit/hyperactivity disorder (ADHD) likely share developmental pathways (Johnson et al., 2015). Children with autism and ADHD show difficulties in self-regulation which are predictive of problems later in life (e.g., social and cognitive difficulties, academic underachievement) making it important to identify difficulties in this area as early as possible. However, questions remain regarding similarities and differences in self-regulation behaviors in young children with autism or those who are showing clinically relevant concerns for ADHD during the preschool years.

Objectives: To examine self-regulation behaviors using a delay of gratification task in preschoolers with autism and those showing clinically relevant concerns for ADHD (i.e., ADHD Concerns) compared to children without these concerns.

Methods: Participants (n=180) were originally enrolled as infants into one of three familial likelihood groups: family history of autism (i.e., elevated likelihood of autism; n=91), family history of ADHD (i.e., elevated likelihood of ADHD; n=40), and no family history of either

Table 1a
| Table 1b |
(i.e., low likelihood of autism/ADHD; \(n=49\)). At the 36-month visit, participants were classified into one of the three outcome groups: autism (\(n=26\)), ADHD Concerns (\(n=24\)), and a Comparison group (i.e., not meeting criteria for either of the other groups, \(n=130\)).

As part of the 36-month battery, children were administered a delay of gratification task in which they were presented with a snack and instructed to wait for unspecified amounts of time (5, 10, 20, 30 seconds) before they could eat the snack. Survival analysis for the longest wait trial (30 sec) was used to examine the association between outcome group and likelihood of eating the snack, with and without adjusting for Mullen Scales of Early Learning-derived verbal Developmental Quotient (DQ).

Results: By 30 seconds, 60% of participants in the autism group, compared to 16% in the Comparison group ate the snack (HR=5.03, \(p<.001\)). Additionally, 35% of participants in the ADHD Concerns group ate the snack (HR=2.32, \(p=0.04\) vs Comparison and HR=0.46, \(p=0.08\) vs autism group). Adjusting for verbal DQ attenuated these associations, although the autism group continued to show greater likelihood of eating the snack sooner at 30 seconds relative to the Comparison group (aHR=2.87, \(p=0.01\)). The adjusted likelihood of the ADHD Concerns group eating the snack sooner was not significantly different from the Comparison (aHR=1.61, \(p=0.28\)) or autism groups (aHR=0.56, \(p=0.23\)).

Conclusions: Participants in the autism and ADHD Concerns groups had more difficulty delaying gratification relative to the children without these conditions. Language abilities accounted for some of these differences, indicating that language skills may play a role in behaviors underlying self-control and, in some cases, poorer understanding of the task may have impacted children’s performance. Because self-control difficulties are associated with poorer outcomes, the next step is to identify early indices that may predict 36-month self-control skills with the aim of determining vulnerability to such problems and providing interventions early in life.

413.198 (Poster) Designing Toys for Autism: Integrating Clinical and Developmental Science into a Professional Design Curriculum

S. J. Sheinkopf, P. Locastor, P. Vivier, J. Quinn, C. Sassir and J. Ellis; (1)Thompson Center for Autism & Neurodevelopment, University of Missouri, Columbia, MO, (2)Toy Design Department, Fashion Institute of Technology, New York, NY, (3)Public Health and Community Medicine, Tufts University, Boston, MA, (4)The Autism Project, Johnston, RI

Background: Play is a core function of early childhood and is impacted by Autism Spectrum Disorders. It is a context that supports social learning, language and communication development, and other aspects of early development. Play is also intrinsically fun and motivating and supports quality of life for young children. Developmentally informed toy designs can support the ability of autistic children to engage in play. Baccalaureate and post-baccalaureate programs in toy design do not typically focus on special populations.

Objectives: The objective of this presentation is to describe a toy design program that integrates knowledge about autism and developmental approaches to supporting play and social communication into an undergraduate curriculum.

Methods: Students were enrolled in an established and specialized toy design program at an urban public university. The program includes theory, practical applications, and mentored hands-on training to prepare students for work in industry, with most students placed in design roles at companies that design toys and other consumer products for children. In their senior year, students participated in a year-long sequence that included the following elements: 1) readings and didactics on autism in early childhood, developmental and autism-specific aspects of play, and evidence based supports for play in children with autism and 2) observations in a school for children with autism and developmental disabilities. Parallel to these experiences, each student engaged in a semester-long capstone design project that included development of product rationale, determining overlap with existing products, detailed artistic renderings, and ultimately a scale model prototype of the toy. Feedback from toy design faculty and from the collaborating autism content experts was provided at sessions in the second semester and informed final designs.

Results: Four cohorts of students have completed the program (12 – 15 per cohort). Students produced designs for toys, defined as products that can be used as objects in play routines. Several themes emerged from the designs, including: 1) degree of specificity to autism; 2) endpoint goals of teaching specific skills or knowledge (instrumental) or on supporting play itself (intrinsic); 3) a focus on supporting play routines (instrumental or intrinsic) or on supporting the child (e.g., products intended to help with coping or stress reduction); 4) degree of focus on autism phenotypic characteristics, and if so a focus on social communication behaviors or sensory needs; and 5) a focus on how individual children interact with the toy versus a focus on dyads or groups interacting with a toy. Examples of artistic renderings are presented in the accompanying figures. Ongoing work will involve a survey of students to assess engagement in the program and impact on post graduate activities.

Conclusions: Translational approaches often focus on using medical and behavioral science knowledge to develop treatments or programs administered by professionals or in therapeutic, educational, or professional settings. This collaboration, with representation from clinical service, developmental and clinical research, stakeholder groups and toy design faculty, is an example of another model of translation that has the potential to support autism-friendly design into commercially available and viable products.

413.199 (Poster) Development of Lateralized Brain Oscillations in Infants at Risk for Autism
Background: One of the common early features of Autism Spectrum Disorder (ASD) is language delay. It is estimated that nearly 50% of toddlers with ASD present language impairments, yet the biological mechanisms underlying these deficits are not fully understood. Recent studies suggest that differences in language abilities may be attributed to atypical brain lateralization during development. Language processing activates the left hemisphere in 96% of the population, but studies on autistic children indicate diminished hemisphere dominance. Thus, more research is needed to assess 1) whether atypical lateralization emerges early in infancy, and 2) whether lateralization patterns are associated with language outcomes in ASD.

Objectives: The goal of this study is twofold. First, we explore the developmental trajectories of brain lateralization in infants at risk for autism during the first two years of life. Second, we examine the relationship between brain lateralization, and receptive and expressive language abilities in toddlerhood. We hypothesize that autistic infants will have less lateralization than the control group.

Methods: This study used data from the International Infant EEG Data Integration Platform (EEG-IP); a multi-site cohort study of infants at risk for ASD and age-equivalent controls (London: 7, 14 months; Seattle: 6, 12 months). Participants were either in an at-risk group (n=98) or a control group (n=94) by virtue of having an older sibling with autism. Of the at-risk infants, 39 were later diagnosed with ASD based on the Autism Diagnostic Observation Schedule (ADOS) at 36 months and clinical evaluation. Resting-state high-density EEG recordings were preprocessed for artifacts and cortical sources were estimated to identify brain regions associated with EEG activity. Finally, lateralization scores were correlated to receptive and expressive language scores extracted from the Mullen Scales of Early Learning (MSEL) at 6 and 12 months.

Results: Consistent with the literature, all groups exhibited predominantly left-hemisphere lateralization at 6 months. However, a three-way ANOVA revealed a statistically significant interaction between the diagnostic outcome and EEG frequency band at 12 months of age (F (2,184) = 7.85, p = .001). At 12 months, autistic infants showed an increase in left-hemisphere lateralization while the control group shifted towards symmetry. Moreover, source estimation revealed that differences between autistic infants and controls were accentuated in the superior temporal gyrus (STG). In terms of language skills, we found a statistically significant correlation between left-hemisphere dominance of the STG and expressive language at 12 months of age across all groups. Additionally, infants with more left-hemisphere lateralization had higher expressive language scores.

Conclusions: Establishing the development of brain lateralization and autism risk is an important first step toward improving our understanding of the etiology of ASD. Overall, our study showed that by 12 months of age, autistic infants had more lateralization in the STG compared to controls. The STG is a region thought to be important for phoneme discrimination, auditory attention, and based on our results it can potentially be a precursor for language learning. Language is a key part of development and our study elucidates the neural mechanisms that contribute to language learning during infancy.

413.200 (Poster) Developmental Impacts of the COVID-19 Pandemic Among Infants at High and Low Likelihood for Autism or ADHD

M. Miller, G. Kadlaskar, K. Marrs, J. Morales-Martinez, A. Piergies, J. P. Sandler, A. Schneider, C. Silver, M. M. Soller, K. G. Tena and Y. Yu, (1)Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)MIND Institute and Psychiatry & Behavioral Sciences, University of California, Davis - M.I.N.D. Institute, Sacramento, CA, (3)MIND Institute and Psychiatry & Behavioral Sciences, University of California, Davis, Sacramento, CA, (4)MIND Institute and Department of Pediatrics, University of California, Davis, Sacramento, CA, (5)MIND Institute and Psychiatry & Behavioral Sciences, Center for Autism Research, Children’s Hospital of Philadelphia, Sacramento, CA

Background: Recent work has suggested pandemic-related developmental decrements among infants (Deoni, 2022; Imboden et al., 2021). Infants with family histories of neurodevelopmental conditions like autism or ADHD are already at risk for developmental concerns (Miller et al., 2021; Ozonoff et al., 2010). Whether developmental impacts of the pandemic differentially affect infants with higher genetic risk for autism or ADHD is unknown.

Objectives: We evaluated pre- and peri-pandemic differences in development among 12-month-olds recruited into two prospective longitudinal studies of the early autism and ADHD phenotypes (one pre-COVID, one peri-COVID), and examined whether such impacts interact with genetic susceptibility for these conditions based on family diagnostic history.

Methods: Both studies used identical protocols and measures; Pre-COVID cohort data were collected between 2017-2019, while Peri-COVID cohort data were collected between 2021-present. Participants included 122 12-month-olds: n=88 in the Pre-COVID cohort (n=23 low likelihood [LL], n=37 elevated likelihood ASD [EL-ASD], n=28 elevated likelihood ADHD [EL-ADHD]) and n=34 in the Peri-COVID cohort (n=18 LL, n=6 EL-ASD, n=10 EL-ADHD). Peri-COVID cohort data collection is ongoing. Development was evaluated using the Mullen Scales of Early Learning Visual Reception, Fine Motor, Receptive Language, and Expressive Language subscales (T-scores). Verbal, Nonverbal, and overall Developmental Quotients (DQs) were also calculated. Consistent with public health guidance and institutional policies, examiners were masked during Peri-COVID cohort data collection.
A series of ANOVAs were conducted with developmental subscale/composite score as the dependent variable and Cohort and Recruitment Group (LL, EL-ASD, EL-ADHD) as independent variables, examining main and interaction effects.

Results: Results are displayed in Figure 1/Table 1. With the exception of Visual Reception, there were main effects of cohort for each developmental subscale/composite. In all cases, the Peri-COVID cohort exhibited lower scores than those evaluated pre-COVID. There was a main effect of Recruitment Group for the Receptive Language subscale, with the EL-ASD group (M=43.12, SD=8.81) exhibiting marginally lower scores than the EL-ADHD group (M=46.68, SD=7.86), $p=0.06$. The Recruitment Group*Cohort interaction was not significant for any subscale/composite.

Conclusions: Consistent with work in other samples, our findings suggest developmental impacts of the pandemic on infants in nearly all domains. Still, scores were, at a group level, generally still in the average range (with VDQ scores on the cusp of the Below Average range in the Peri-COVID cohort). Our findings also suggest these developmental impacts operate similarly across genetic risk for neurodevelopmental concerns. However, Peri-COVID cohort data collection is ongoing (anticipated additional 100 12-month visits by April 2022), and inspection of group means suggests potential differential susceptibility of verbal development in the EL-ASD group. Whether pre-/peri-COVID developmental differences are the result of reduced social learning opportunities over the first year of life due to physical distancing, and/or the impact of examiner masking during developmental testing on auditory and/or visual cues related to language comprehension, requires further investigation. Moreover, additional work is needed to evaluate whether such decrements are time-limited or persist over the first several years of life. Such questions will be addressable with ongoing follow-up of these samples.

### 413.201 (Poster) Developmental Profiles of Infants with Different Types of Neurodevelopmental Risk

**N. M. McDonald, C. Ferrario, S. Pena, S. Iyer, and S. Jeste**, (1)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)Children's Hospital Los Angeles, Los Angeles, CA

**Background:** Much of our understanding of early development in children with autism spectrum disorder (ASD) comes from studies of infants with a family history of autism. Extending this knowledge to infants with medical histories or genetic conditions that make autism and related neurodevelopmental issues more likely can broaden our understanding of autism as it first emerges. Here, we directly compare early developmental profiles of infants with a family history of ASD (FamHx), extended Neonatal Intensive Care Unit hospitalizations (NICU), tuberous sclerosis complex (TSC), and low-risk controls (LR controls).

**Objectives:** To better understand the development of 12-month-old infants with differing backgrounds, we will (1) assess inter-correlations among developmental measures, (2) compare scores on developmental measures among FamHx, NICU, TSC, and LR control groups, and (3) examine group differences in rates of delay.

**Methods:** Infants were enrolled in a prospective study examining early biological and behavioral markers of autism and developmental delays. The current sample consisted of 106 infants ($n$ varied by analysis). FamHx infants ($n=49$) had at least one older sibling with ASD. NICU infants ($n=22$) had a NICU hospitalization and medical condition that qualified them for the state-funded High-Risk Infant Follow-up Clinic (e.g., born<32 weeks, neurological and/or cardiovascular concerns). TSC infants ($n=14$) had a clinical diagnosis. LR controls ($n=21$) had a neurotypical older sibling, no major medical issues, and no known first-degree relatives with ASD. Groups differed by race/ethnicity but not gender (see Table). Measures included: Vineland Adaptive Behavior Scales-3rd Edition (Vineland-3), Mullen Scales of Early Learning (MSEL), Ages & Stages Questionnaire-3rd Edition (ASQ-3).

**Results:** (1) Moderate to high correlations were found between the direct measure (MSEL), parent interview (Vineland-3), and parent report (ASQ-3) within domains, suggesting consistency across scales (e.g., MSEL & ASQ-3 Gross Motor, $r=.796$; MSEL Receptive Language & Vineland-3 Communication, $r=.690$). (2) Group differences were found in motor ($Eta^2=.125-.320$), early nonverbal cognition ($Eta^2=.196-.241$), communication/language ($Eta^2=.159-.195$; exception: MSEL Expressive Language $p=0.115$), and social skills ($Eta^2=.095-.192$). Differences were largely driven by developmental delays in the TSC group. Generally, LR controls had the highest scores, TSC the lowest, and FamHx and NICU fell in between with wide variability within these groups. (3) Using ASQ-3 cutoff categories, associations were detected between risk group and rate of delay across areas ($ps<.001$; see Figure).

**Conclusions:** Measurements of development level by domain were quite consistent across the varied measures used. TSC infants were much more likely to show clinically significant developmental delays at this young age, which is expected given that all infants in this group were known to have a neurogenetic condition. FamHx and NICU infants tended to have lower scores and higher rates of developmental delays than the LR controls, but these differences were not always significant and most were developing as expected at 12 months. Higher rates of gross motor delays were observed in the NICU group, while FamHx infants tended to show higher rates of delay in ASD-associated domains (communication and social). Increased incidence of delays and autism concerns are expected as the infants age. Data collection is ongoing.

### 413.202 (Poster) Developmental Trajectories of ADOS-2 Scores in Toddlers at Elevated Likelihood of Autism

Background:

Core characteristics of autism develop slowly and subtly during infancy and toddlerhood and are sometimes hard to grasp. Developmental trajectories differ between individual children, and early administration of ADOS-2 could be valuable in predicting evolution of characteristics in toddlers at elevated likelihood (EL) of developing autism.

Objectives:

The aim of the current study is to cluster trajectories of repeated ADOS-2 scores in EL-toddlers. This will allow us to pinpoint if and when trajectories might start diverging and at what age ADOS-2 administration would be most informative for future outcome.

Methods:

ADOS-2 was administered at the ages of 14, 24 and 36 months in a sample of 112 EL-toddlers, as part of a prospective longitudinal study. These toddlers were either younger siblings of autistic children (N=64), toddlers born before 30 weeks gestational age (N=38) or toddlers with medically insufficiently explained feeding or eating difficulties (N=10). Calibrated severity scores (CSS) were calculated, to enable comparison between the scores resulting from different ADOS-2 modules at different ages and language levels. Due to COVID-19 interruptions, only 246 observations were collected. To avoid issues caused by missing data, a feature-based clustering approach was used. After plotting individual linear regression lines, participants were clustered based on individual intercepts and slopes, using k-means clustering (Figure 1). This process was repeated for the Total CSS and the subscales of Social Affect (SA) and Restricted and Repetitive Behaviors (RRB). Descriptive statistics were used to describe and compare the clusters. At the time of the INSAR conference, additional analyses including the best estimate research diagnoses will be available. Individual cluster-profiles, i.e. the combination of the Total CSS, SA CSS and RRB CSS clusters per participant, were investigated.

Results:

Each cluster analysis resulted in three clusters of trajectories. In the Total (Figure 2a) and SA CSS, similar trajectories were found: (1) low start – steep increase, (2) low start – stable, (3) high start – slow decrease. In the RRB CSS (Figure 2b), (1) a similar stable and (2) a similar decreasing trajectory were found, besides (3) an earlier increasing trajectory. None of the clusters differed based on sex or on composition of different EL-toddler groups. Analysis of individual cluster profiles showed that the most prominent profile (24.1% of participants) was a stable trajectory profile on all three scales.

Conclusions:

Feature-based cluster analysis of repeated ADOS-2 administration in a heterogenous group of EL-toddlers reveals three distinct trajectories for all CSS scales. Clustered trajectories for the Total CSS and SA CSS are more similar than the trajectories in the RRB CSS, as expected based on psychometric properties. Previous research in siblings of autistic children showed largely similar results, however often a severe persistent and a stable non-spectrum group were found, instead of one stable group. Differences between trajectories in the Total and SA CSS were more prominent after the age of 24 months, implying that administration of ADOS-2 at 14 months, is less informative. Limitations include the inability to walk of some participants at 14 months and the use of face masks during about half of the administrations.

413.203 (Poster) Developmental Trajectories of Adaptive Functioning in Toddler with Developmental Disabilities

C. Y. Lee, T. T. Lin and C. C. Wu, (1) Kaohsiung Medical University, Kaohsiung, Taiwan, (2) Department of Psychology, Kaohsiung Medical University, Kaohsiung, Taiwan

Background: Previous studies have shown that adaptive behavior or adaptive functioning plays an important role for outcomes and prognosis in individuals with developmental disabilities, including autism spectrum disorder (ASD) and developmental delays (DD). However, ASD is a fairly heterogeneous group, with some individuals with normal cognitive development or language skills and others with significant impairments, while children with DD also have shown different types of impairments.
Objectives: The purpose of this longitudinal study was to examine the developmental trajectories of adaptive behavior and the relationships between adaptive behavior and mental abilities and autistic symptoms in toddlers with developmental disabilities. By analyzing the characteristics of adaptive behavior development subgroups, effective intervention can be planned for toddlers with different developmental disabilities.

Methods: The current study recruited 102 toddlers with developmental disabilities who were assessed when they were between 16 and 35 months of age (Time 1, T1) and were followed up 18 (Time 2) and 36 months (Time 3) after the first assessment. The current study applied the Adaptive Behavior Assessment System-Second Edition (ABAS-II), a parent-report questionnaire to assess the adaptive behavior of toddlers with developmental disabilities.

Results: There were three distinct developmental trajectories of general adaptive composite in toddlers with developmental disabilities. Group 1 (n = 36, 35%) had higher functioning and a maintaining trajectory, group 2 (n = 50, 49%) showed moderate functioning and an improving trajectory, group 3 (n = 16, 16%) had lower functioning and a maintaining trajectory. There were two distinct developmental trajectories of conceptual adaptive behavior in toddlers with developmental disabilities: Improving trajectory (n = 52, 51%) and worsening trajectory (n = 50, 49%). There were three distinct developmental trajectories of social adaptive behavior in toddlers with developmental disabilities: higher functioning and a maintaining trajectory (n = 35, 34%), moderate functioning and a maintaining trajectory (n = 11, 11%), and lower functioning and a worsening trajectory (n = 56, 55%). There were two distinct developmental trajectories of practical adaptive behavior in toddlers with developmental disabilities: higher functioning and a worsening trajectory (n = 23, 23%) and lower functioning and an improving trajectory (n = 79, 77%). The trajectory class assignments in general adaptive composite were related to diagnostic outcomes three years later. The improving trajectories of adaptive behavior in toddlers with developmental disabilities showed better mental abilities at T1 compared to the worsening trajectory group. And, the improving trajectories of adaptive behavior in toddlers with developmental disabilities also showed mild autistic symptom at T1 compared to the worsening trajectory group.

Conclusions: The findings of this longitudinal study indicated that the heterogeneity of adaptive behavior in toddlers with developmental disabilities. Most of the toddlers with developmental disabilities showed impairments in adaptive behavior. However, part of this sample, which showed better adaptive behavior comparable to typically developing toddlers. The findings of the current study provide the implications for practitioners to design early intervention for toddlers with developmental disabilities.

413.204 (Poster) Did Covid Shelter-in-Place Alter Early Clinical Profile in Autism? a Natural Experiment in Exploring Nature Versus Nurture

B. S. Siegel, Autism Center of Northern California, San Francisco, CA

Background:

Due to Covid-19, most autism diagnostic centers internationally were closed for in-person assessments for at least a year beginning March, 2020. When our center resumed in-person assessment in Spring 2021, many parents expressed concerns about potential sequelae of Covid Shelter-in-Place (CSiP) having delayed diagnostic assessment and access to early intervention. We ask: Did CSiP children (index sample) diagnosed with ASD in the first year post-CSiP have more severe ASD signs and/or more developmental delays than children diagnosed at the same ages pre-CSiP (comparison sample)? What were parent concerns about the possible effects of CSiP on their children and was this supported by assessment data?

Objectives:

We hypothesized that if CSiP-related delay in diagnosis and treatment negatively influenced markers of development related to ASD, baseline scores at initial diagnosis would be higher for autism severity, and lower for 1) receptive language, 2) expressive language, and 3) adaptive behavior than age-matched comparisons diagnosed before CSiP.

Methods: We reviewed qualitative data coded from narratives of parent concerns about their child’s presentation as due to CSiP as well as quantitative scores including DSM-5 ratings, ADOS score, and adaptive behavior (DP-4 or Vineland).

Results:

Index Sample: Between March 2020 and October, 2022, N=176 18-42 month-olds were seen for initial diagnostic assessment. Of these, 25 cases received telehealth diagnostic assessments, with 20 receiving an ASD diagnosis. We resumed in-person diagnostic assessment in April 2021, N=151, with 31% (N=55) not meeting criteria for ASD. Of the N=176, the home language was English (N=62), Spanish (N=70), Chinese/Vietnamese (N=32), or another language (N=12).

Comparison Sample: Between January 2018 and February 2020, N=144 18 to 42 month-olds were seen for initial diagnostic assessment. 77% (N=110) were diagnosed with ASD, and 23% (N=33) were assessed, but did not meet criteria for ASD. Of the N=144, home language was English (N=58), Spanish (N=50), Chinese/Vietnamese (N=29), or another language (N=7).
Preliminary analyses indicate that subsequent to CSiP, more children received a false-positive referral, \( \chi^2 (1, N=261) = 6.23, p = .012 \). In the future, we plan to examine differences in cognitive and adaptive abilities across groups, along with analysis of home language as a barrier to receiving diagnostic assessment subsequent to CSiP.

Conclusions:

Our data suggest many themes about the effect CSiP on young children with ASD in the short and long term. Parents expressed concern regarding potential regression or developmental stalling, and fear that a crucial period of neural plasticity had been passed over. Many parents experiencing telehealth assessment questioned accuracy/validity, and those experiencing telehealth treatment were concerned about efficacy. ESL families continued to receive telehealth treatment after programs had resumed ‘in-person’ for English-speaking families in their areas. Ongoing concerns included a flight of ABA service providers and special education aides so that long-delayed IEPs could not be implemented. While initial differences in diagnosis and access to services were explored in this study, young children diagnosed with ASD during CSiP will need to be followed longer term to more fully ascertain potential longer-term effects of the themes identified in this study.

C. V. Tran, H. T. Ngo and N. H. Nguyen, (1)Department of Educational Sciences, Vietnam National University, Hanoi, Viet Nam, (2)VNU University of Education, Hanoi, Viet Nam

Background:

In recent years, adverse childhood experiences (ACEs) have begun to be systematically studied in Vietnam. However, current research focuses on children with typical development. For example, it lacks studies on children with autism spectrum disorders (ASD), who have difficulty self-reporting their experiences in the present and the past.

Objectives:

This study was implemented to identify common patterns of ACEs among children with ASD and the variables associated with these experiences as reported by caregivers.

Methods:

This is a cross-study. A questionnaire was given to more than 150 parents with children with ASD. There were 12 factors of ACEs, including physical abuse; emotional abuse; sexual abuse; family members with drug addiction/mental health disorders/imprisoned; domestic violence; parents divorced/death; emotional neglect; physical neglect; school violence; community violence.

Regarding children with ASD whose caregivers participated in the study, 72.2% were male, 27.8% were female; the mean age was 3.87 years; the mean age when diagnosing ASD was 28.06 months, the earliest is 14 months, and the latest is 48 months. 67.3% were the first child, 21.8% were the second, etc.; 70.9% lived with only parents, 14.5% lived with grandparents, and the left was with both parents, grandparents, and siblings.

Results:

The result shows that emotional neglect is the most common form of ACEs in children with ASD, followed by family members with mental health disorders, parents divorced/death, and family members imprisoned or addicted to drugs. Meanwhile, the less common forms included: emotional abuse, sexual abuse, and community violence (A lower mean score indicates a greater degree of ACEs). There was no significant difference in the degree of ACEs between male and female children with ASD or who lived in different areas.

In many children with ASD, the more frequently family members play with the child, the less likely the child will experience emotional abuse and domestic violence, with \( r=0.30^* \) and \( r=0.31^* \), respectively. In addition, the greater the number of siblings a child has, the less likely the child will experience emotional neglect (\( r=0.27^* \)). However, in some cases, the more siblings a child has, the more the child experiences school (\( r=-0.42^* \)) and community violence (\( r=-.032^* \)). In addition, children with older parents also experience community violence (\( r=-0.27^* \)).

The other results show that the higher the child's ability to self-serve, the lower the experience of living with divorced/dead parents (\( r=0.27^* \)), the higher the child's communication ability, the lower the child's experience of community violence (\( r=0.32^* \)). In addition, the
better the children’s motor skills, the lower the experience of living with a family member addicted to drugs, going to prison, and having parents divorced, with a correlation coefficient of \( r = 0.29*, r = 0.44*, \) and \( r = 0.47**. \)

Conclusions:

Family members’ care and proactive interactions with children with ASD seem to be protective factors against ACEs in the family. Meanwhile, the child’s skills play a role in avoiding ACEs in the community. However, future studies with larger samples need to be performed more for reliability and to explore other relevant variables.

**413.206 (Poster) Disability Versus Difference Autism Subtypes in Early Childhood**

**V. Mandelli, I. Severino and M. V. Lombardo**, (1)University of Trento, Centre for Mind Brain Sciences (CIMeC), University of Trento, Italy, Rovereto, Italy, (2)Italian Institute of Technology, Rovereto, Italy, (3)Center for Neuroscience and Cognitive Systems, Istituto Italiano di Tecnologia, Rovereto, Italy

Background: Early developmental difficulties in the domains social-communication-interaction and restricted repetitive behaviors are the core of autism. While these features are important for maximizing clinical consensus and reliability, they fail to reveal important individual differences between autistic individuals that may be most relevant for explaining variability in the biology, outcomes and treatment responses. Alternatively, differences between autistic individuals in non-core domains such as early language, motor, intellectual and adaptive functioning may be key elements that separate out autism subtypes characterized by profound ‘disability’ versus ‘difference’ from typically-developing norms.

Objectives: We aim to test whether ‘disability’ versus ‘difference’ subtypes are present in early childhood and whether identification of such subtypes can be made in robust, stable, and objective manner with unsupervised data-driven stratification methods. If early subtypes can be identified, we will further test whether the subtypes are differentiated in terms of outcome and developmental trajectories throughout early childhood.

Methods: Vineland (VABS) and Mullen (MSEL) data from \( n = 773 \) autistic children less than 68 months old were identified within the National Institute of Mental Health Data Archive (NDA). VABS standard domain scores (communication, daily living skills, socialization, motor) and MSEL subscale developmental quotients (visual reception, VR; fine motor, FM; receptive language, RL; expressive language, EL) were input as features to reval stability-based relative clustering analysis (Landi et al., 2021). The optimal number of subtypes and generalization accuracy of the subtypes are tested within the reval framework. Subtype labels from reval are then used in longitudinal linear mixed effect models to test for age*subtype interactions on MSEL age-equivalent scores.

Results: VABS and MSEL data measuring language, motor, intellectual and adaptive functioning can be used to identify two early autism subtypes with highly stable out-of-sample prediction accuracy (98%). These subtypes can be described by individuals with very low scores across both MSEL and VABS (e.g., disability subtype) that are well below clinically-meaningful cutoffs for developmental disability versus individuals with much higher scores (e.g., difference subtype) that would not typically be considered as profound disability compared to the other subtype. Longitudinal analyses through the first 6 years of life show that the subtypes differ in rate of growth (i.e. age*subtype interaction) for all MSEL subscales (VR: \( F = 181, p < 0.001 \); FM: \( F = 185, p < 0.001 \); RL: \( F = 155, p < 0.001 \); EL: \( F = 188, p < 0.001 \)), with the disability subtype showing much slower growth than the difference subtype.

Conclusions: This work demonstrates that disability versus difference autism subtypes are highly stable and can be objectively identified with high accuracy in a data-driven manner in early childhood from patterns of language, motor, intellectual and adaptive functioning measured by routine standardized clinical assessment tests such as VABS and MSEL. These subtypes are developmentally and outcome-sensitive, as longitudinal results show that these groups show different rates of growth and highly differentiated outcomes by 6 years of age.

**413.207 (Poster) Do Children with Sex Chromosome Trisomies Display Features of Autism Spectrum Disorder in a Free Play Caregiver-Child Interaction?**

**C. Ferrante, C. Chiesa, E. Ceriani, G. Silibello, P. Vizziello, L. Zampini and E. Salomone**, (1)Department of Psychology, University of Milan-Bicocca, Milan, Italy, (2)Unità Operativa Neuropsichiatria dell’Infanzia e dell’Adolescenza, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Children with Sex Chromosome Trisomies (SCTs), genetic syndromes characterized by an additional sex chromosome, have been reported to display social-communication difficulties similar to those of Autism Spectrum Disorder (ASD) more frequently than typically developing (TD) children (Bouw et al., 2022a; Bouw et al., 2022b). However, existing data are mostly limited to self-report and parent-report measures collected from clinical samples and therefore potentially prone to referral bias (Bishop et al., 2011).

Objectives: To compare social communication profiles of children with SCTs, ASD and TD on direct observational measures.
Methods: We compared 15 children of 24 months with prenatal diagnosis of SCTs (mean age in months 24.27, sd=0.59), with 15 TD children of 24 months (mean age in months 23.93, sd=0.59) and 15 children with ASD of comparable developmental age measured on the Griffiths Scales of Child Development, Third Edition (mean age in months 40.53, sd=9.73, developmental age 22-25 months). A free play caregiver-child interaction with a standard toy kit suitable for a range of developmental play levels was videorecorded and ten consecutive minutes were rated for child autism symptoms severity with the Brief Observation of Social Communication Change (BOSCC, Grzadzinski et al., 2016) and child engagement states and expressive language level with the Joint Engagement Rating Inventory (JERI, Adamson et al., 2020). To check agreement, 22% of the corpus was independently rated by a second observer. The inter-rater reliability on the double-coded videos was good on the BOSCC Total score (intraclass correlation coefficients, ICC=.71) and the JERI items (range of weighted Kappas: 0.72-1.0).

Results: Children with ASD showed significantly higher levels of symptoms severity than children with SCTs and TD children on the BOSCC Total Score and across all symptom domains. With regard to the JERI rating of child’s engagement states, the groups did not significantly differ on Unengaged and Object Engagement states. Significant group differences on Joint Engagement state were examined with post hoc analyses, performed with Bonferroni, showing lower scores, close to significance, in children with ASD than both TD children (p=.055) and children with SCTs (p=.074). Children with SCTs showed lower Expressive Language skills than TD children (p=.003) but did not differ from children with ASD (p=.480).

Conclusions: Consistently with previous evidence (Zampini et al. 2022), children with SCTs displayed lower expressive language levels than TD children, however they showed significantly lower autistic symptoms than children with ASD, not differently from TD children. In addition, we showed a non-significant trend for higher levels of joint engagement in children with SCTs than in children with ASD. The use of a direct observation measure and the characteristics of our sample (children with a prenatal diagnosis) arguably explain our findings, which are in contrast with previous evidence of increased rates of ASD-like symptoms in this population. The results must be interpreted cautiously due to the small sample size. In conclusion, possible social communication difficulties should be distinguished from linguistic impairments in children with SCTs, particularly for those identified with a prenatal diagnosis.

413.208 (Poster) EIP Participation Leads to a Diagnosis One Year Earlier for Children with Autism
J. Lazzarino, W. Zahorodny, J. Shenouda and K. Sidwell, (1) Pediatrics, Rutgers New Jersey Medical School, Newark, NJ, (2) Department of Pediatrics, Rutgers--New Jersey Medical School, Newark, NJ, (3) Department of Pediatrics, Rutgers University, Newark, NJ

Background: Many children with autism spectrum disorder (ASD) are qualified for federally mandated (IDEA, Part C) Early Intervention Program (EIP) services due to developmental delays. These services can include evaluation and provision of interventions, potentially leading to better ASD outcomes, including earlier identification of ASD. A recent study showed that children participating in EIP were more likely to be diagnosed earlier with ASD. Professional evaluation leading to ASD diagnosis may expedite access to ASD specific services, programs, and interventions. The extent to which EIP facilitates the timing of ASD diagnosis has not been fully examined.

Objectives: To determine whether ASD children who received EIP services are diagnosed earlier than ASD children who did not participate in EIP and to describe differences in the distribution of individuals receiving intervention.

Methods: Data was collected from an active population-based surveillance system (NJ Autism and Developmental Disabilities (ADDM) Monitoring Network) in a large diverse US population (NY-NJ Metropolitan Area), across multiple cohorts between 2006 and 2016. Data was restricted to 1) children identified as ASD by the surveillance, 2) have a clinical ASD diagnosis after age 30-months. Case data included: functional characteristics, evaluations and diagnoses, services by EIP and special education systems, as well as: demographic and related information determined through systematic analysis of information contained in professional evaluations. Descriptive statistics are provided and linear regression models, adjusted for sociodemographic (sex, race/ethnicity, socioeconomic status) and clinical factors (intellectual ability and degree of impairment), were utilized to identify associations.

Results: Overall, 4050 8-year-old children were identified with ASD between 2006 and 2016. Of those, 2,607 met the study criteria. Diagnosis age ranged from 30 to 107 months. Median age of ASD diagnosis was 54 months; however, median age of ASD diagnosis among EIP participating children was 49 months compared to 62 months for non-EIP participating children. After adjusting for sex, race/ethnicity, socioeconomic status, comorbid intellectual disability, and degree of impairment, average age of ASD diagnosis among EIP participating ASD children was 41 months, while average age of ASD diagnosis among non-EIP participating ASD children was 53 months. Additionally, in our model ASD diagnosis age did not vary by sex or race and ethnicity but varied by socioeconomic status, the presence of intellectual disability, and degree of impairment.
Conclusions: EIP- participating ASD children received the diagnosis 1-year earlier than non-EIP participating children (41 months vs. 53 months), even after adjusting for multiple covariates. The findings show that EIP participation facilitates early ASD diagnosis. Additionally, our findings show that EIP participation reduces race-based disparities in ASD diagnosis age; however, income disparities remain evident even when we account for EIP participation. Early diagnosis of ASD and EIP participation may be advanced by universal autism specific screening, between 18 and 36 months.

413.209 (Poster) Predictive Utility and Degree of Correspondence between Parent- and Examiner-Reported Concerns for ASD and ADHD in the First Years of Life

R. Aishworiya1, S. Ozonoff and M. Miller, (1)Paediatrics, National University Hospital, Singapore, Singapore, (2)UC Davis MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (4)Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA

Background: Autism spectrum disorder (ASD) and ADHD commonly co-occur, with research suggesting shared developmental pathways (Johnson et al., 2015). While parent concerns for ASD by 12 months of age have been associated with eventual diagnosis (Ozonoff et al., 2009), research on early ADHD concerns and their relation to ASD is sparse. The degree of correspondence between early parent and clinician concerns is also unclear.

Objectives: We examined parent- and examiner-reported concerns (PC/EC) for ASD and ADHD between 12-36 months among infants developing ASD or elevated ADHD symptoms in a sample enriched for both outcomes. We also explored PC/EC correspondence.

Methods: This study included n=225 infants with an older sibling with ASD (ASD-risk, n=116), an older sibling/parent with ADHD (ADHD-risk, n=52), or ≥1 typically developing sibling and no family history of ASD/ADHD (low-risk, n=57). Participants were enrolled no later than 18 months (89.3% by 12 months) and followed prospectively at up to 4 visits, depending on enrollment age (12, 18, 24, 36 months). At the final visit, participants were classified into one of 3 outcomes: ASD (DSM-5 diagnosis), ADHD Concerns (elevated symptoms), or Comparison (i.e., not meeting criteria for ASD/ADHD Concerns). At each visit, PC were elicited by a standardized interview; EC were rated at the end of the visit. Concerns were coded into pre-defined categories by trained examiners. For each respondent (examiner, parent), communication, social, stereotyped behavior, and unspecified autism concerns were combined into an “ASD concerns” composite. Concerns about hyperactivity, impulsivity, and/or inattention were combined into an “ADHD concerns” composite. Generalized estimating equations compared PC/EC from 12-36 months based on 36-month outcome. Spearman’s correlations assessed correspondence between PC and EC.

Results:

The effects of outcome, visit, and their interaction on PC-ASD were significant (ps<0.003, Figure 1). The ASD group had higher PC-ASD and EC-ASD than the other two by 12 months, persisting through 36 months. The ADHD Concerns group had higher PC-ASD than the Comparison group at 36 months and higher EC-ASD relative to Comparison group from 18–36 months. For PC-ADHD, only the effect of outcome was significant (p=0.037) with marginally higher PC-ADHD in the ADHD Concerns group relative to the Comparison group (p=0.05). For EC-ADHD, the effects of outcome, visit, and their interaction were significant (ps<0.009). There were no group differences at 12-18 months, but the ADHD Concerns group had marginally higher EC-ADHD at 24 months relative to the Comparison group, and higher EC-ADHD at 36 months relative to the other two groups. Correspondence between parent and examiner ASD concerns were stronger compared to ADHD-related concerns, though still significant for the latter between 18-36 months (Table 1).

Conclusions: Examiner concerns about ASD in infancy are associated not only with an eventual ASD diagnosis but also with ADHD Concerns outcomes in the absence of ASD by 18 months. Examiner (but not parent) concerns for ADHD at 24 months were associated with ADHD Concerns outcomes by 3 years. Further characterization of these concerns, and whether degree of correspondence relates to eventual outcome, may facilitate earlier identification for ASD and ADHD.

413.210 (Poster) Early Joint Attention Behaviors in Infants at High Familial Risk for Autism Spectrum Disorder: Association with Brain Development

J. Montenegro1, D. Seguin1 and E. Duerden1, (1)Faculty of Education, University of Western Ontario, London, ON, Canada, (2)Western University, London, ON, Canada, (3)Western University, London, ON, Canada

Background:

Autism Spectrum Disorder (ASD) is a heritable neurodevelopmental disorder that includes deficits in social communication and interactions, as well as the presence of deficits in restricted and repetitive behaviors. Early signs of ASD can be detected in the first year of life, and impairments in early social gaze and Joint Attention (JA) are one of the earliest indicators of later ASD diagnoses. JA is
characterized by the ability to follow the gaze of others and share common interests with other individuals or objects. In individuals with an ASD diagnosis, the ability to initiate JA (IJA) can be more impaired than the ability to respond to JA (RJA).

Objectives:

In this study, we aimed to examine behavioral measures of Joint Attention and the association between subcortical brain volumes, and ASD diagnosis in infants with a familial risk for ASD.

Methods: In this longitudinal study, data from 101 high-risk infants (62% males) were collected as part of ACE Study and IBIS Network from the National Database for Autism Research (NDAR). Infants underwent MRI scans at either 4 or 6 months of age, or both. Using Infant FreeSurfer, subcortical volumes from the thalamus, the hippocampus, the amygdala, the basal ganglia, the ventral diencephalon, and the cerebellum were automatically extracted. Behavioral data from assessment tools such as the Vineland Adaptive Behavioral Scale-II (VABS-II) and the Autism Observational Scale of Infants (AOSI) were used to examine early gaze and JA behaviors. Using Principal Component Analysis, data from both assessment tools were classified identifying 5 components. Two components related to JA, responding to joint attention (RJA), and initiating joint attention (IJA), were identified, and used for further analysis. The other three components that described visual tracking and auditory processing were excluded.

Results:

It was found that the majority of infants were IJA non-responders (n=93, 92%), and over half were RJA non-responders (n=50, 52%). For both non-responder groups, models accounting for age, sex, and total cerebral volumes tested the association among subcortical volumes with later ASD diagnosis. Using a regression method, it was found that, in the non-responder IJA group, subcortical volumes of the left hippocampus (B=-0.009, aOR=0.991, p=0.025), the right thalamus (B=-0.016, aOR=0.984, p=0.026), as well as the left thalamus (B=0.015, aOR=1.015, p=0.019) were predictive of later ASD diagnosis. In the non-responder RJA group, no associations amongst brain volumes and later ASD diagnosis were found.

Conclusions:

Findings suggest that brain regions such as the thalamus and hippocampus may be more vulnerable early in life. The absence of IJA and altered subcortical development may be key predictors of later ASD development. A better understanding of early signs of social gaze and JA in infants with ASD familial risk as well as the neural mechanisms underlying those behaviors could aid in identifying intervention targets and biomarkers to promote improved social and behavioral outcomes.

413.211 (Poster) Early Language-Specific Developmental Differences in Young Children with and without Autism.

A. Campisi, M. Mastrogiuseppe, S. Aiello, E. Leonardi, F. Fama, C. Carrozza, F. Marino, G. Tartarisco, G. Pioggia, O. Capirci and L. Ruta, (1)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy, Messina, Italy, (2)University of Trieste, Trieste, Italy, (3)Institute for Biomedical Research and Innovation (IRIB), National Research Council of Italy, Messina, Italy, (4)University of Messina - Italy; National Research Council, ISASI, Messina - Italy, Messina, ITALY, (5)National Research Council of Italy, Institute for Biomedical Research and Innovation (IRIB), Messina, Italy, (6)Institute of Cognitive Sciences and Technologies, National Research Council of Italy, Rome, Italy

Background:

The state of the art about autism poses important unsolved questions, such as the heterogeneity in the onset, clinical presentation and developmental trajectories of the condition. Early language development is particularly affected by this heterogeneity and it is a fundamental predictor of longer-term outcomes.

However, although global domains of language such as lexical, morphosyntactic, semantic and pragmatic have been studied in relation to language proficiency, very limited studies, with relatively small sample sizes, have explored, the early precursors of speech in a developmental framework and through a fine-grated qualitative and quantitative perspective.

Objectives:

For this reason, the paper aims to explore language heterogeneity in autism under the lens of early expressive language development, by using a detailed micro-analytic system, within a naturalistic setting of parent-child play interaction.

Methods:
We conducted a cross-sectional analysis of speech (vocalizations, words) and pragmatic functions (request, denial, declarative) in a sample of 30 children with and without autism (N=15 per group, 8 F). Children with TD were matched according to the developmental age of the autistic child, aged 12 to 48 months. All the children were tested using a naturalistic paradigm of free parent-child interaction (PCI). The PCI was video-recorded for a 10-minute time and the video footage was analyzed using an open-source behavioral annotation tool for audio and video recordings, which allows an unlimited number of textual annotations, supports creation of multiple tiers and tier hierarchies (ELAN). Speech production, both vocalizations and words were annotated and their pragmatic function identified. 

Results:

Results showed that, although the two groups are similar in terms of total amount of speech, they significantly differ in terms of speech repertoire (i.e. the proportion of vocalizations and words over the total speech production). Compared to the TD group, the ASD group: (i) produced significantly fewer words (W(30)= 84, p= .015); (ii) produced significantly more vocalizations (W(30)=76, p=.030); (iii) produced speech mainly for expressing the pragmatic function of request, while the TD children used significantly more words for declarative purposes (W(30)=85, p=.005).

Conclusions:

Speech production during naturalistic play interaction and from a developmental perspective in young children with and without autism was investigated using a microanalytic quantitative and qualitative approach. Our results highlight, since very early development, the language gap and the impairment in social sharing and declarative function in autism. Delays and atypicalities in early speech production can provide novel and predictive behavioral markers of an autism condition, very early on, contributing to dissecting autism language heterogeneity.

413.212 (Poster) Early Motor Features Successfully Decode Autism Spectrum Disorder: Findings from a Longitudinal Study through Parent Questionnaire

F. Fulceri, A. Caruso, M. Micai, A. Ciaramella, L. Gila, M. L. Scattoni and N. NIDA (on behalf of the NIDA Network), (1)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (2)NIDA Network, Rome, Italy

Background:

Early motor impairments have been reported in children with autism spectrum disorder (ASD), but it is unclear how early such impairments might be detected. Tracking motor development through reliable and inexpensive tools is strategic in the clinical and research fields. Findings on motor development may contribute to the early diagnosis of ASD and thus hasten referral for early intervention.

Objectives:

To investigate whether a parent-report measure of motor development might effectively predict the developmental outcome of infants at high risk (HR) for developing ASD

Methods:

The Italian Network for early Detection of autism spectrum disorders (NIDA Network) is the largest multi-center and multi-disciplinary network aimed to guide observational studies and surveillance programs for the early detection of ASD and neurodevelopmental disorder (NDD). The NIDA Network has enrolled 1436 HR infants (890 siblings, 328 infants born preterm, 218 small for gestational age) and 120 low risk (LR) infants. The Early Motor Questionnaire (EMQ), a parent-report measure of motor development, has been administered as part of a wider clinical evaluation protocol at 6, 12, 18, 24, and 36 months (mth). EMQ is an easy to complete 3 sections (gross motor, fine motor, and perception-action integration skills) parent-report. EMQ motor scores of 17 LR infants with typical development were compared with 150 siblings grouped according to their clinical outcome at 24-36 months [14 HR infants with ASD diagnosis (HR-ASD); 20 HR with other NDD diagnosis (HR-NDD); 118 HR with typical development (HR-NoDiagnosis)].

Results:

ANOVA analyses showed that HR-ASD and HR-NDD infants had lower EMQ scores compared to LR infants (HR-ASD vs LR, p< 0.001 at 18, 24, 36 mth; HR-NDD vs LR, p < 0.01 at 18, 24 mth). Significant differences were observed for EMQ total and subscales scores (perception-action integration skills at 18, 24, 36 mth, gross motor and fine motor skills at 24, 36 mth). HR-NoDiagnosis and LR infants did not differ at each time point. The area under the curve (Receiver operating characteristic ROC curve analysis) for EMQ total scores predicting ASD outcome was 0.83 (at 18 mth) and 0.84 (at 36 mth), whereas NDD outcome was 0.86 (at 18 mth) and 0.84 (at 36 mth).
Conclusions:

The motor skills of HR infants diagnosed with ASD and NDD early differed from LR infants typically developing. EMQ scores moderately/highly discriminated HR infants later diagnosed with ASD or NDD from LR infants already at 18 and 24 months. The EMQ parent-report of motor development might be effective in predicting the diagnostic outcome of HR infants earlier than the clinical diagnosis confirmation. EMQ may be an informative, helpful, and low-cost tool to early detect neurodevelopmental outcomes. In the future, EMQ can be also a valuable remote telehealth approach for the early assessment of HR infants.

413.213 (Poster) Early Signs of Autism in Infants with TSC Is Associated with Reduced Language Production and Nonverbal Communication during the Second Year of Life

Background:

Tuberous sclerosis complex (TSC) is a rare, multisystem genetic disorder which presents a considerably increased risk for autism, with up to 60% of infants with TSC meeting the criteria for an autism diagnosis by 3 years of age. TSC can also have pervasive effects on cognitive, behavioural, intellectual and psychosocial development. Given that autism is characterised by receptive and expressive language impairments and reduced nonverbal communicative skills, we might expect to observe such delays in infants with TSC. Despite this, very few studies explore autism emergence in TSC, and whether impaired verbal language and communication is linked to early signs of autism. Diagnosis of TSC before the onset of atypical socio-communication allows for prospective investigation of autism emergence, and may inform the development of targeted interventions.

Objectives:

We aimed to explore: (1) whether early autism traits present on or before 24 months of age in infants with TSC, and (2) whether group differences (TSC versus typically developing infants) in early language/communication skills are associated with autism emergence.

Methods:

Data were collected as part of the Early Development in Tuberous Sclerosis Study, which prospectively tracked development of infants with TSC (n=32) and typically developing (TD) infants (n=34). Standardised parent report questionnaires, interviews and child observational measures were administered at 3, 5, 8, 10, 14, 18 and 24 months old. Verbal language skills were measured using Macarthur Communicative Developmental Inventories (MCDI) which generated vocabulary production and comprehension scores at 10, 14 and 24 months old. Mullen Scales of Early Learning (MSEL) verbal developmental quotients for expressive and receptive language were collected at all time points. Nonverbal communication was measured using MCDI early gestures scores. Developmental ability (a covariate) was measured using the Mullen Scales of Early Learning composite score. Early autism traits were measured using the Quantitative Checklist for Autism (Q-CHAT) at 10, 14 and 24 months old at outcome.

Results:

Infants with TSC demonstrated higher Q-CHAT scores at 14 months (p=.004), 18 months (p=.006) and 24 months old (p=.01) compared to TD infants. Lower language production scores were found in TSC infants, and at 14 months (p=.019) and 24 months old (p=.005) they predicted Q-CHAT scores at 24 months old, however this effect was not present when controlling for developmental ability. No association was found between language comprehension scores and Q-CHAT scores. Verbal developmental quotients were lower in TSC infants compared to TD infants from 10 months old (p<.001). Reduced early communicative gestures were observed in the TSC group at 14 months (p=.01) and 24 months old (p=.004), and both were associated with Q-CHAT scores at 24 months old. There were no group differences in gesture use at 10 months old.

Conclusions:

Early signs of autism were consistently observed in TSC infants from 14 up to 24 months old, which supports earlier autism screening in TSC. Reduced language production and nonverbal communicative skills from 14 months old predicts later autism emergence in infants with TSC, however should take into account developmental ability when defining early markers of autism.
**413.214 (Poster) Early Social Communication Skills in 12-Month Old Infants with Sex Chromosome Trisomy (SCT): Results from the Extraordinary Babies Study**

**R. Wilson**, S. Takamatsu, T. Thompson and N. Tartaglia, (1)Developmental Pediatrics, University of Colorado Childrens Hospital Colorado, Aurora, CO, (2)Pediatrics, University of Colorado School of Medicine, Aurora, CO, (3)University of Colorado School of Medicine, Aurora, CO, (4)Endocrinology, Children's Hospital Colorado, Aurora, CO, (5)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO

**Background:** Sex Chromosome Trisomies (SCT) including Klinefelter/XXY, XXX, and XYY syndromes occur in approximately 1:500 births. SCTs are associated with broad spectrum of neurodevelopmental outcomes, including increased risks for developmental delays, speech-language and learning disorders, executive dysfunction, anxiety disorders, social deficits and autism spectrum disorder (ASD), with studies showing ASD rates ranging from 12-35%. Preliminary studies of toddlers with SCTs show evidence of early deficits in language and social communication, although more systematic study is needed from infancy. The eXtraordinarY Babies Study is a natural history study of health and neurodevelopment in infants with a prenatal diagnosis of SCT, and aims to identify early predictors of poor neurodevelopmental outcomes in SCT, including early predictors for a later diagnosis of ASD.

**Objectives:** To describe the profile of early social communication development in the SCT population, and to evaluate the relationship of social communication skills to neurodevelopmental skills.

**Methods:** A subset of 56 participants with confirmed SCT diagnoses (XXY=43, XYY=4, XXX=9) from the eXtraordinarY Babies Study were evaluated using the Bayley Scales of Infant and Toddler Development-3, and the ADOS-2 Toddler Module at 12-months of age. Analyses were limited to those who completed the assessments prior to COVID19 mask/shield requirements. ANOVA with post-hoc Tukey analysis was used to compare demographics and Bayley-3 subdomain scaled scores between SCT conditions (XXY, XYY, and XXX), and one-tailed T-tests compared to normative sample. Proportions of 0, 1, and 2 scores on ADOS-2 social affect and restrictive/repetitive behavior items were calculated and ranked, and algorithm total scores for each domain were correlated with Bayley-3 subdomain scores.

**Results:** There were no significant differences in demographics or Bayley subdomain scales between SCT groups. Bayley-3 results showed lower Receptive Language (scaled score 8.2±2.4), Expressive Language (8.9±3.0), and Gross Motor (7.9±3.0) scores compared to normative sample, while Cognitive (10.8±1.9) and Fine motor (9.3±2.3) domains did not differ. High rates of delayed or atypical development of early social communication skills were identified, with >75% showing scores of 1 or 2 in frequency of babbling, spontaneous vocalizations, gesture use, and pointing. 58% of the sample showed unusual eye contact and facial expressions directed to others. Participants showed few restricted and repetitive behaviors. Results of ADOS-2 total scores: Little-no concern 50%, Mild-Moderate concern 35.7%, Moderate-severe concern 14.3%. No one was assigned a clinical diagnosis of ASD. Receptive language scores negatively correlated with ADOS-2 Social Affect (r= -.38, \( p < .001 \)) and Overall Total (r= -.41, \( p < .001 \)).

**Conclusions:** Even at an early age, toddlers with SCT are at increased risk for language, communication, and social delays. While no participants were diagnosed with ASD at 12 months of age, social communication and reciprocal social interaction deficits or “red flags” for later diagnosis of ASD were seen in a subset of young children with SCT and correlated with receptive language skills at 12 months. Prospective follow-up will allow us to determine the trajectory of these deficits and whether findings at 12-months of age predict later social communication deficits and ASD diagnosis.

**413.215 (Poster) Emotion Regulation and Family Risk Factors in Young Children with Autism**

**Background:**

A growing body of research has emerged exploring the role of emotion regulation (ER) in autistic children. ER refers to any process that a person uses to influence the onset, magnitude, duration, intensity, or quality of one or more aspects of an emotional response. ER research shows that autistic individuals generally present more ER difficulties than non-autistic persons and are less effective at using ER strategies (e.g., avoidance or distraction). Less is known about ER of very young autistic children. More research is needed to better understand ER in young autistic children and its potential association with family risk factors.

**Objectives:**
The objectives of the study were to (1) Identify whether significant differences exist between autistic and non-autistic children (12-72 months) in ER and to (2) Investigate whether family risk factors (i.e., maternal education, family income, family status) are related to children’s ER skills while simultaneously considering autism diagnosis.

Methods:

The sample consisted of 94 children aged 12-72 months, including a group of 41 autistic children matched on age with a group of 53 non-autistic children. Children’s ER skills were evaluated using the French version of the Emotion Regulation Checklist, a parent report questionnaire. Each item on the scale is rated from 1 (rarely) to 4 (almost always) and greater scores indicated greater ER skills. The level of familial risk was calculated from self-reported sociodemographic information completed by mothers. Factors such as maternal education, family income and family status (nuclear family, single parent household, etc.) were combined to create a composite score representing the level of familial risk. To answer aim 1, the group difference in ER was calculated using a one-way analysis of variance (ANOVA). For aim 2, a multiple regression was used to investigate if familial risk and diagnosis status (0= control group, 1=autistic group) predict ER skills.

Results:

Autistic children had significantly lower ER skills ($M = 2.64, SD = .41$) compared to non-autistic children ($M = 3.37, SD= 0.28; p < .001; \eta^2 = .52$). The overall regression model was statistically significant and explained 53% of ER skills in the sample, $R^2 = .53, F(2,83) = 49.6, p < .001$. The presence of familial risk negatively predicted ER skills ($\beta= -.17, p = .028$), whereas having an autism diagnosis negatively predicted ER skills ($\beta= -.684, p < .001$).

Conclusions:

This study adds to the current literature showing that young autistic children present less developed ER skills compared to non-autistic children. Importantly, familial risk predicted ER skills even when considering autism diagnosis. More research is needed to understand the role of family risk on ER, and whether other variables may account for variations in ER skills in autistic children (e.g., intellectual disability).

413.216 (Poster) Examining Parent-Infant Interaction Trajectories in Infants with and without an Elevated Likelihood for Autism – a Replication Study

E. Papageorgopoulou, M. W. Wan, M. H. Johnson, T. Charman, E. Jones and &. The BASIS Team; (1)Birkbeck, London, United Kingdom, (2)University of Manchester, Manchester, United Kingdom, (3)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, UNITED KINGDOM, (5)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (6)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom

Background: It has been suggested that developmental antecedents of autism may bidirectionally affect parent-infant social interactions, amplifying social skills difficulties (Dawson, 2008; Elsabbagh & Johnson, 2007). Previous research using a sample from the British Autism Study of Infant Siblings (BASIS) found differences in several areas of parent-infant interaction for 7 and 14 months with lower ratings for infants with versus without elevated likelihood (EL) for autism (defined by having an older diagnosed sibling), and prediction of 3-year autism outcome based on 14-month interaction (in mutuality, positive affect and attentiveness; Wan et al., 2013).

Objectives: We sought to replicate previous work by Wan and colleagues in a more recent, larger sample to examine the consistency and predictive value of the parent-infant interaction aspects in relation to autism likelihood and later autism outcome (infants at EL with and with no autism outcome, EL-autism, EL-no autism; infants at typical likelihood, TL).

Methods: Using the Manchester Assessment of Caregiver-Infant Interaction (MACI) global rating scales, we evaluated 6-minute videotaped laboratory-based unstructured parent-infant free-play interaction in a larger independent prospective cohort from the BASIS at 8-10 (100 infants at EL, 24 infants at TL) and 10-15 months (104 EL and 26 TL infants). Coding was blind to participant information. Assessment of autism outcome was conducted at 36 months.

Results: Linear mixed-effects models replicated previous findings showing significant differences in parent sensitive responsiveness, parent non-directiveness and dyadic mutuality ($ps<0.004$) between the autism likelihood groups (EL-no autism, EL-autism, TL) with scores on these variables being lower in the EL-autism group compared to the other two groups. Additionally, an age-by-group interaction effect showed that infant attentiveness to parent decreased from 8 to 14 months in the EL-autism group compared to the other two groups ($p=0.02$). 14-month infant attentiveness to parent and mutuality predicted autism outcome; this also replicated previous effects. We failed to replicate the group effects in infant liveliness, positive affect and dyad engagement intensity. Furthermore, we found earlier (8m) predictive effects of autism outcome in infant positive affect and parent nondirectiveness ($ps<0.02$) than reported by Wan et al.
Conclusions: This study strengthens the existing evidence base for emerging alterations in parent-infant interaction, starting from 8 months, especially among infants subsequently diagnosed with autism. These robust longitudinal analyses of the largest sample to date measuring parent-infant interaction to 3-year diagnosis reinforce the predictive value of parent-infant interaction qualities and suggest divergence in attentiveness to parent from 8 months, not seen in the previous 7-month sample. Further work should examine whether changes represent an affirmative parenting style, or could provide options for supportive interventions.

413.217 (Poster) Examining the Profile of Visual Attention Eye-Tracking Markers in Children and Their Association with Autism Traits and Child Development

Background:

Visual attention is a key gateway for learning during early development, and which may show an altered trajectory in autism. Objective markers of visual attention have been identified using eye-tracking technology in infants and children; individual markers have been associated with specific autistic traits. Eye-tracking offers the potential to objectively observe developmental trajectories before the appearance of overt behaviours. Investigating multiple measures from eye-tracking tasks can improve our understanding of the underlying structure of cognitive processes, and how they may be associated with child development and autism traits.

Objectives:

We aim to: 1) examine the underlying structure of visual attention with multiple measures from a battery of eye-tracking tasks in children at 3 years; 2) Identify groups of children with similar visual attention patterns across eye-tracking tasks; 3) Investigate whether visual attention profiles are associated with child development and autism trait measures.

Methods:

Data from 120 children at 3 years were analysed, from STAARS: a cohort including children with an elevated likelihood of Autism Spectrum Disorder and/or Attention Deficit Hyperactivity Disorder, by virtue of having a first degree relative with a diagnosis. Measures from four eye-tracking tasks were included in the analysis: fifty faces (ff – dynamic social stimuli), pop out (pop – static social stimuli), non-social contingency (ns), gap-overlap task (gap). Structural Equation Modelling (SEM) examined the underlying structure of visual attention. Latent profile analysis (LPA) then identified sub-groups of children with similar visual attention patterns across tasks. Multiple regression models investigated whether these visual attention profiles were associated with: 1) child development (Mullen ELC); and 2) autism trait scores (ADOS-2 CSS).

Results:

The SEM model was estimated with two latent factors, social attention and exogenous orienting (RMSEA = 0.077 (CI = 0.047-0.105, p = 0.068); CFI = 0.945; TLI = 0.925; c² (48) = 81.59, p = 0.002). For the LPA, a five-profile solution was chosen (Figure 1); profiles were described as: (1) “High Social Attention”, (2) “Fast Exogenous Orienting”, (3) “Low Social Attention”, (4) “Slow Exogenous Orienting”, (5) “Slow Exogenous Orienting and low social attention to dynamic stimuli”. Multiple regression revealed that slow exogenous orienting was associated with higher Mullen scores (R²=0.31, F(7, 94)=6.14, p<0.001). Further, profiles showing “High Social Attention” had significantly lower Social Affect ADOS scores than all other profiles (AdjR²=0.15, F(7, 94)=2.4, p=0.027).

Conclusions:

The underlying structure of visual attention measured using eye-tracking markers from multiple screen-based tasks conducted with children at 3 years, and based on previous models of visual attention, confirmed two latent constructs: Social Attention and Exogenous Orienting. Five-profiles of visual attention were identified from this cohort that primarily varied in social attention and exogenous orienting, thus further confirming these as underlying constructs of visual attention. Both constructs were associated with childhood autism trait scores (social attention eye-tracking profile), and developmental measures (exogenous orienting eye-tracking profile). By identifying subpopulations based on eye-tracking markers from multiple domains, and further investigating their association with cognitive development and autism traits, could ultimately enable us to provide more individualised and tailored support within sub-populations.

413.218 (Poster) Executive Dysfunctions in Toddlers with ASD: A Brief-P Profile
Background:

Children with Autism Spectrum Disorders (ASD) often have impaired Executive Function (EF) skills. This concerns problems in the domains of inhibition, emotional control, initiation, working memory, planning and organizing, and monitoring, with the most profound problems in cognitive flexibility (Blijd-Hoogewys et al., 2014). Little EF research has been done in toddlers with ASD. While their EF problems are linked with lower social, communication, and daily living skills (Powell et al., 2022).

Objectives:

The present study aimed to investigate whether a specific BRIEF-P score profile can be found in toddlers with ASD. The BRIEF-P is a parent-completed questionnaire that screens for EF-problems in daily life.

Methods:

Retrospective BRIEF-P and other diagnostic data from a clinical sample of 201 toddlers with ASD (n = 147 boys, age: M = 3.65 years, SD = 0.87 years; n = 54 girls, age: M = 3.80 years, SD = 0.94 years) were analyzed. The norm group from the original Dutch BRIEF manual was used as a reference group. Mean T-scores of the research group were compared to a mean T-score of 50, a subclinical elevated T-score of 60 and a clinical elevated T-score of 65.

Results:

The internal consistency of the BRIEF-P total score was excellent (Cronbach’s α = .942); and good for the clinical scales (Inhibition, Cronbach’s alpha = .887; Shift, Cronbach’s alpha = .843; Emotional control, Cronbach’s alpha = .893; Working memory, Cronbach’s alpha = .879), except for Plan/Organize, which had an acceptable internal consistency (Cronbach’s alpha = .799).

Autistic toddlers had (see Table 1), compared to the BRIEF-P norm group, elevated scores (T > 50) on all clinical scales for both the total group and for boys/girls separately (p < .001, Cohen’s d = .850-1.627). They had clinical elevated scores (T-score > 65) for Shift (boys: p < .004, Cohens’ d = .222; girls: p < .001, Cohens’ d = .567) and borderline clinical elevated scores (T-score = 60-65) for Inhibition (boys: p < .001, Cohens’ d = .291; girls: p = .002, Cohens’ d = .416). Concerning Emotional control, girls had clinical elevated scores (p < .001, Cohens’ d = .708), boys had borderline clinical elevated scores (p < .001, Cohens’ d = .363). Concerning Working memory, boys had borderline clinical elevated scores (p < .001, Cohens’ d = .317).

Conclusions:

There was a BRIEF-P profile obvious in toddlers with ASD. Their parents reported the most pronounced EF problems in cognitive flexibility. Also, inhibition problems were obvious. This is in concordance with findings from older children with ASD.

Parents reported more pronounced emotional control problems in girls with ASD. This is consistent with the clinical impression that girls with ASD are more likely to evidence emotion regulation problems. Also, often the primary referral reason for seeking diagnostic assessment in toddler girls and not immediately a suspicion for ASD.

Note that most findings concern small effect sizes, expect for the findings concerning cognitive flexibility and emotional control in girls with ASD, which concerned medium effect sizes.

413.219 (Poster) Exploring the Relationship between Child Attachment, Parent Child Interaction and Parental Reflective Functioning: Preliminary Results from DAN-PACT Pilot Study

(1)Reseach Unit for Child and Adolescent Psychiatry, Research Unit of Child and Adolescent Psychiatry, Aalborg, Denmark, (2)University of Southern Denmark, Odense C, Denmark, (3)Center for Autisme, Herlev, Denmark, (4)The Research Unit - Child and Adolescent Mental Health Centre, The Capital Region of Denmark, Hellerup, Denmark, (5)Department of Child and Adolescent Psychiatric, Region Zealand, Slagelse, Denmark, (6)Department of Child and Adolescent Psychiatry, Research Unit, Aarhus University Hospital, Psychiatry, Aarhus N, Denmark, (7)Research Unit for Child and Adolescent Psychiatry, The North Denmark Region, Aalborg University Hospital, Aalborg, Denmark

Background: The social communication problems in children with autism may impact the quality of parent-child interactions. Parents’ sensitivity to the child’s atypical communication pattern, through parental reflective functioning and achievement of synchronicity may
improve parent-child interactions. This may also nurture secure attachment in younger children with autism. Relationships between child attachment, parental reflective functioning and parent-child interaction measures such as synchronicity in dyadic communication have not yet been investigated in parent-child dyads in children with autism. Results from the baseline assessment in a pilot study of the intervention Paediatric Autism Communication Therapy will be analyzed and presented.

Objectives: This study aims to explore the relationship between child attachment security, parental reflective functioning, and measures of parent-child interaction such as synchronicity in dyadic communication in children with autism.

Methods: Participants were 18 parent-child pairs recruited from child and adolescent psychiatric hospital units in Denmark after the child had received a diagnosis of autism spectrum disorder (pervasive developmental disorder according to ICD-10 criteria). The parents filled out the questionnaires Parental Reflective Functioning Questionnaire (PRF-Q), and Maternal Perception of Child Attachment (MPCA). The PRF-Q includes three subscales reflecting different aspects of mentalizing: 1) Pre-mentalizing Modes, 2) Certainty about Mental States and 3) Interest and Curiosity in Mental States. Twelve-minute playtime sessions between parent and child were videotaped to assess parent-child interaction using the Dyadic Communication Measure of Autism (DCMA). The DCMA is scored by a certified rater on three areas of interaction: parental synchronicity in communication, child initiations and mutual shared attention. The mean age of the children, 17 boys and 1 girl, was 4.4 years (range 2.7-6.4 years). The parents in the playtime videos were seven fathers and eleven mothers.

Results: In this underpowered pilot-sample there was a positive correlation with a moderate effect size (0.36), p=0.15 between parental synchronicity in DCMA and parents’ perception of child attachment (MPCA). The linear regression of DCMA synchronicity and MPCA results in a regression coefficient of 1.86 with SE 1.21 and 95% CI (-0.72 ; 4.43), p=0.15 (Fig. 1). This is consistent with previous research in normative samples indicating parental sensitivity as a mediator of secure attachment. There was no immediate correlation between neither of the three subscales of PRF-Q and parental synchronicity, e.g., PRF-Q Certainty in Mental States and DCMA synchronicity correlation (-0.15), p=0.55. More analyses of the data will be presented on the poster.

Conclusions: The study indicated a correlation between child attachment and parental synchronicity in communication. No association between parental synchronicity and parental reflective functioning was found in this sample of parent-child dyads. Given the small sample size this is not surprising. We look forward to gaining deeper insights into these explored relationships when more data becomes available with the completion of the DAN-PACT trial.

Figure 1 Linear regression of DCMA parental synchronicity as independent and MPCA as dependent variable

413.220 (Poster) Factors Contributing to a Change in Diagnosis from 24 to 36 Months in Younger Siblings at Elevated Likelihood of Autism Spectrum Disorder

H. Davies, A. Buck, S. Shultz, W. Jones, A. Klin, S. P. White and C. Klaiman, (1)Marcus Autism Center, Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Emory University, Atlanta, GA, (4)Emory University, Atlanta, GA

Background: Autism spectrum disorder (ASD) is a heritable developmental disorder, with higher rates of ASD in families with older affected sibling(s). Earlier screening is beneficial for younger siblings at elevated likelihood (EL) of ASD, as 86.3% of cases diagnosed before 36 months maintain an ASD diagnosis over time (Rondeau et al., 2011). The remaining false positive participants often have co-morbid disorders which benefit from early intervention (Greene et al., 2021). On the contrary, false negative rates can reach over 40% in EL samples which poses a problem for accessing necessary services (Ozonoff et al., 2015). Assessing children with these borderline phenotypes, we investigated phenotypic trends at 24- and 36-months which might influence final diagnostic outcome in order to minimize future misdiagnoses.

Objectives: Identify the phenotypic characteristics driving diagnosis change from 24- to 36-month evaluations.

Methods: EL younger siblings (n=63) completed 24-month (Mage(SD)=24.44(±1.00) months) and 36-month (Mage(SD)=37.46(±2.09) months) assessments. Clinician best estimate (CBE) of diagnosis was made using: (1) Autism Diagnostic Observation Schedule-2 (ADOS-2); (2) Mullen Scales of Early Learning (MSEL); and (3) overall diagnostic impressions (Lord et al., 2012, Mullen, 1995). CBEs from 24- and 36-month appointments were collected to generate four independent groups: (1) true positive, ASD CBEs (TP, n=18); (2) true negative, non-ASD CBEs (TN, n=33); (3) false negative CBEs (FN, n=7); and (4) false positive CBEs (FP, n=5). Influence of ADOS-2 sub-scores [social affect (SA) and restricted and repetitive behavior (RRB)] and MSEL sub-scale scores [visual reception (VR), fine motor (FM), receptive language (RL), and expressive language (EL)] on CBE change were determined by between group ANOVAs and Bonferroni-corrected multiple comparisons.

Results: There was a significant effect of 24- and 36-month ADOS-2 sub-scores (all p<0.001) and MSEL sub-scale scores (all p<0.036) on CBE change. FN participants had significantly lower SA and RRB scores than TP participants at 24 months (p_{SA}=0.001, p_{RRB}=0.010) and significantly higher SA and RRB scores and significantly lower EL scores than TN participants at 36 months (p_{SA}=0.003, p_{RRB}=0.001, p_{EL}=0.033). FP participants had significantly higher SA and RRB scores than TN participants (p_{SA}=0.032, p_{RRB}=0.004) at 24 months and
Background: Previous studies have shown atypical gaze patterns in autistic individuals during video viewing: they gaze less on-screen and show larger within-group heterogeneity in gaze patterns than typically developing individuals. Also, autistic individuals do not fixate typically to social content of videos, including faces.

Objectives: We investigated whether atypical gaze might be evident already in prodromal autism. We focused on gaze patterns to social and non-social videos in toddlers divided into two groups according to their ADOS-2 scores. We hypothesized that toddlers with high ADOS scores indicating more autism-related behavior tend to look more outside the screen, especially during social videos, and that there is more variability in gaze patterns within the high ADOS group. Finally, we ran an explorative analysis to investigate the epochs within videos where gaze similarities differ most between groups.

Methods: We recruited 32 toddlers (20 males, mean age 18 months, range 13–31 months) in the longitudinal Gaze@Toddler study (Tampere University, Finland) from child welfare clinics. Eye-tracking data and ADOS-2 ( toddler module) were obtained during their first lab visit. We divided the participants into high (N=15, total ADOS ≥13 points) and low (N=17, total ADOS <13 points) ADOS groups. Participants passively viewed a video stimulus consisting of eight video clips from Finnish-language children's TV shows. Four clips had social content (people, conversation), and four had non-social content (vehicles, animals). We compiled the video clips into a single video (dur. 5:10min) with an abstract fixation video (dur. 2.5s) for recalibration between each video clip. Participants were seated on the caregiver's lap while watching the videos on a 27” screen placed at a 60cm distance. We investigated the effects of ADOS group membership (high vs. low) and video category (social, non-social vs. fixation) on percentage of gaze on screen with a 2 x 3 mixed-effects ANOVA. To investigate the within-group similarity of gaze patterns, we used 1-s-long non-overlapping time windows to calculate dynamic inter-subject synchrony during the videos using pairwise gaze heatmap correlations. We estimated group differences in mean inter-subject correlations for each clip using Cohen's d and bootstrapping to estimate distribution parameters.

Results: High ADOS scores were associated with less gaze on screen (F(1,30)=8.27, p=.007, η^2=.22; M_high=71.7%, SD_high=14.6%; M_low=85.2%, SD_low=7.9%). Groups also differed in the effect of video category on the percentage of gaze on screen (F(2,60)=5.17, p[HF]=.009, η^2=.15): low ADOS group gazed more on screen during social videos than during fixation or nonsocial videos, but this effect was absent in the high ADOS group. Low ADOS group had higher within-group gaze synchrony during both social and nonsocial videos (Table 1), indicating more homogeneous gaze patterns. We identified higher synchrony within the low ADOS group to scenes with people and intentional actions, and higher synchrony within the high ADOS group during scenes with objects (Figure 1).

Conclusions: Overall, toddlers with high ADOS scores look less on the screen and show more heterogeneous gaze patterns than toddlers with low ADOS scores. Our longitudinal study will follow gaze pattern development in larger samples with diagnostic outcome.
Background: Early detection of ASD is essential for initiating support and minimizing cascading negative effects on development. Psychophysiological responses to direct gaze might serve as one potentially useful predictive marker of ASD in young children. Previous study by Helminen et al. (2017) showed that while young, 2 to 5-year-old children without ASD show stronger heart rate deceleration response to gaze shifts to direct vs. averted direction, a similar physiological orientation response is not seen in young children with ASD.

Objectives: The objective was to investigate heart rate orientation responses in toddlers with prodromal ASD to faces vs. objects, and to gaze shift to direct vs. averted direction. Specifically, we wanted to investigate whether toddlers showing different levels of ASD-related symptoms differ in their orientation responses.

Methods: Participants of this on-going study were 20 toddlers (Age $M=18.95$ months, $SD=4.47$), who were screened positive with the parent-report screening tool (M-CHAT-R/F). They were recruited in Gaze@Toddler (Tampere University, Finland) study from child welfare clinics. Toddlers were divided into two groups according to their ADOS-2 toddler module score; lower ($M=11.2, \text{Range}=6-15, N=13$) and higher symptoms group ($M=23.3, \text{Range}=20-26, N=7$). Toddlers were presented with dynamic pictures of faces (direct and averted gaze directions) and clocks on a computer screen. Heart rate (bpm) change between prestimulus baseline (-500 to 0 ms) and stimulus presentation (0 to 3000 ms) was analyzed in 500-ms intervals.

Results: Preliminary analysis (Stimulus X Time X Group ANOVA) revealed a significant three-way interaction, $F(2.8;50.7)= 3.95, p=.015, \eta^2_p = .180$. This interaction was explained by the Low ADOS group showing stronger heart rate deceleration to faces vs. cloks while the high ADOS group showed a stronger heart rate deceleration to clocks vs. faces (Fig 1 & 2). No other significant effects were found. Analysis showed no statistically significant effects of gaze direction (Gaze Direction X Time X Group ANOVA) on the strength of heart rate orientation responses in the two groups.

Conclusions: Preliminary results indicated stronger orienting response to objects than to faces in toddlers with higher level of ASD-related symptoms while toddlers with lower level of symptoms showed stronger orienting response to faces. Gaze direction was not found to have an effect on the strength of orienting response. It might be that differences in orienting responses to gaze directions are not seen at this early stage of development, but larger sample, also including toddlers with no signs of prodromal ASD, is needed to clarify this conclusion. Also, the effect of age needs to be studied more closely. However, the preliminary findings suggest that orienting responses to faces vs. objects, regardless of gaze direction, might aid in early detection of ASD together with other sources of information such as parental concern and other early markers. Further investigation of this area will be conducted as a part of the longitudinal Gaze@Toddler -project. Data collection of both, prodromal ASD and control group (typically developed toddlers screened negative on M-CHAT-R/F) is currently in progress.

413.223 (Poster) Higher Prevalence of Autistic Features in Children with Agenesis of the Corpus Callosum Compared to Familial High Likelihood Children

Background: Agenesis of the Corpus Callosum (ACC), a congenital disorder in which the corpus callosum is completely or partially absent, occurs in ~1 in 4,000 live births. ACC has been identified as a major risk factor for autism spectrum disorder (ASD). Although 35%–45% of children and adolescents with ACC may ultimately meet screening criteria for ASD, there are no published studies of early ASD screening (under age 4) with this population. The Parent Rated Observation of Communication, Emotion, and Social Skills (PROCESS) has been shown to be useful for predicting ASD outcome in children with familial high likelihood (HL) for ASD, but its utility has not yet been studied in children with ACC.

Objectives: We aimed to characterize the presentation of early autistic features in children with ACC at ages 18-24 months compared to HL children using the PROCESS. Additionally, we explored item-level differences that may be contributing to group differences on the PROCESS.

Methods: Parents of infants diagnosed with ACC and no other unrelated brain pathology completed the PROCESS for their children at ages 18 and/or 24 months ($n=75$). The familial HL group comparison data were obtained from a sample of 18–to 24-month-olds who had an older sibling with an ASD diagnosis ($n=588$). Mixed model analyses were conducted to test the effect of group (ACC vs. HL) as a predictor of PROCESS Total score as well as of two conceptually derived subdomain scores targeting social communication and restricted & repetitive behaviors. To investigate item-level differences between groups, a series of chi-square tests was run on the response category proportions for each item at the 18-month and 24-month timepoints.

Results: An effect of group (ACC vs. HL) on the PROCESS score was detected, such that children with ACC consistently scored higher than familial HL children ($\beta = -3.13, SE = 1.24, p = 0.021$). A similar pattern was seen at the subdomain level, such that the ACC group
scored higher than the HL group in both social communication ($\beta = -3.94$, SE = 0.91, $p < .001$) and restricted & repetitive behaviors ($\beta = -2.09$, SE = 0.54, $p < .001$). At the item level, items showing the greatest distributional differences between groups (in which the ACC group endorsed higher scores) involved visual tracking, eye contact, motor control, and use of gestures.

Conclusions: Compared to children at familial HL for ASD, 18- to 24-month-old children with ACC presented higher levels of parent-reported autistic features. Specifically, items with a visual or motor control component appear to contribute most to differences between the two groups. This may indicate that early motor and coordination delays, which are common in the ACC population, may underlie their higher PROCESS scores. More work is needed to parse which aspects of an ASD phenotype are shared between ASD and ACC, and which are specific to ASD.

413.224 (Poster) Using Factor Analysis and Mixture Models to Elucidate the Broad Autism Phenotype in Infancy

Background: Characterizing the broad autism phenotype during infancy may illustrate key targets of familial heritability prior to developmental, environmental, and stochastic processes that yield consolidated phenotypes in older individuals. One study made such an effort using the Autism Observation Scale for Infants (AOSI) in 12-month-olds (Georgiades et al., 2013). We sought to extend this work in the Infant Brain Imaging Study (IBIS) Network.

Objectives:

1. Evaluate the factor structure of the AOSI to determine whether the items map onto SC and RRB domains in a sample of infants at high- and low-likelihood for developing autism (total N = 523, of whom 308 were males).
2. Identify clusters or subgroups of infant siblings of autistic children who do not meet DSM criteria for ASD at 24 or 36 months (N = 396, of whom 216 were males), based on the factors derived from step 1.
3. Determine whether subgroups identified at 12 months differ as a function ASD-related symptoms at 36 months.

Methods: An exploratory factor analysis (EFA) specifying two factors was conducted on AOSI items. Social communication (SC) and restrictive and repetitive behavior (RRB) scores were then calculated by summing scores of the Items with significant loadings for factor 1 and factor 2. K means cluster analyses on these two normed variables were then completed specifying two, three, and four cluster solutions. Finally, we evaluated whether subgroups based on SC and RRB scores at 12 months varied as a function of 1) verbal developmental quotient (VDQ) and 2) nonverbal developmental quotient (NVDQ) from the Mullen Scales of Early Learning and 3) externalizing and 4) internalizing from the Child Behavior Checklist (CBCL) at 24 months.

Results: The EFA resulted in item loadings on two factors consistent with separate SC and RRB domains, and this solution ($RMSEA = 0.05$) fit as well as a one factor ($RMSEA = 0.059$) or three factor ($RMSEA = 0.041$) solution. In the subsequent cluster analysis, the four cluster solution fit the data best, with a higher Calinski-Harbasz statistic (431.87) than the three cluster (382.90) or two cluster (303.05) solutions. In each cluster solution, groups differed by both SC and RRB (smallest $p > 0.01$). In the best-fitting four cluster solution, clusters differed significantly on Mullen VDQ ($p = .031$), CBCL externalizing ($p = .046$), and CBCL internalizing ($p = .002$) and marginally on Mullen NVDQ ($p = .052$).

Conclusions: Findings from the EFA suggest that the AOSI is multidimensional, which aligns with the established SC and RRB symptom domains in ASD. These multiple dimensions may better index the broader autism phenotype than a unidimensional model, as evidenced by the subgroups derived from the two AOSI factors among children without an ASD diagnosis. Using longitudinal data, we validated the utility of these subgroups, showing that clusters differed not only in SC and in RRB at 12 months, but also in ASD-related symptoms at 24 months. Further work is still needed to elucidate the broader autism phenotype during infancy and the trajectory of development of ASD-related symptoms across groups.

413.225 (Poster) Early Developmental Pathways in Infants at Elevated Likelihood of Developing Autism: Towards an Innovative Biomarker Approach to the Study of Audio-Visual Sensory Integration

V. Riva, E. M. Riboldi1, E. Capelli1, C. Cantani1 and M. Moltetti1, (1)Child Psychopathology Unit, IRCCS Eugenio Medea, Bosisio Parini, Lecco, Italy, Italy, (2)Scientific Institute IRCCS Medea, Bosisio Parini, Italy, (3)Child Psychopathology Unit, IRCCS Eugenio Medea, Bosisio Parini, Italy, (4)Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy

Background:
Early identification of autism spectrum disorder (ASD) is crucial for the formulation of specific supports to be applied at young ages. The heterogeneity of ASD is expressed in individual variation not only in core symptoms but also in cognitive, language and behavioral skills, which show different trajectories. Moreover, there is strong interest in identifying reliable behavioral/brain-based predictors, which may constitute useful tools for detection of at-risk cases. Although it is well-known that autistic individuals perform poorly during conditions that require integration across multiple sensory modalities, as audiovisual integration (AVI), the study of AVI in early stages of life using experimental techniques is still scarce. Here, we report the findings of a large longitudinal study: we characterize the clinical outcome of our sample of infants at higher likelihood of developing autism (HL-ASD) and then provide early measures of AVI and their associations with clinical outcome.

Objectives: Specific objectives of this study include: (1) the characterization of clinical outcome in HL-ASD infants monitored from 6 to 36 months (2) the comparison of early AVI skills (measured by eye-tracking and EEG) in HL-ASD and typically developing (TD) infants, and (3) the association between early AVI and the clinical measure of infant neurodevelopment.

Methods:

HL-ASD (n=185) and TD infants (n=85) are monitored from 6 to 36 months with a multi-observational protocol including clinical and experimental measures (Figure 1a). Clinical outcomes were determined following the 36-month assessment (n=104, the recruitment is ongoing). Autistic children were classified if they had a clinical best estimate diagnosis of ASD by expert clinicians and an ADOS score above the clinical threshold. The non-autistic group was split into a typical and atypical group. A subgroup of the larger sample (n=54) underwent an experimental task (preferential looking paradigm) on AVI skills at 6-9-12 months. Infants' looking behavior was recorded using the Tobii ProSpectrum, and we calculated the proportion of total looking time for (in)congruent conditions in the two groups. A new experimental task on AVI integrating EEG/eye-tracking will be additionally presented (Figure 2b).

Results: Figure 1b shows the recurrence risk of ASD in our sample: the proportion of children in the three groups (ASD, typical, atypical) is shown for the whole sample and separated for males and females. Relating to the experimental task, ANOVA on looking time toward the mouth area of interest showed a main effect of Time-Point F(6,334)=27.67, p<.001 and of Group F(6,334)=13.24, p<.001. In both groups, looking behavior toward the mouth increased during development, and this pattern is stronger in TD infants (Figure 1b). Clinical measures will be available for all infants. Finally, future directions and preliminary data on the changes in AVI skills (measured by integrated EEG-eye tracking) following an early intervention in 18-month-old HL-ASD infants will be presented.

Conclusions: Future work should continue to investigate individual variability in AVI, potentially distinguishing between infants who later develop autism and those who do not receive a diagnosis. These findings may allow researchers to better understand (a)typical trajectories and clinical implications in the development of more individualized supports.

413.226 (Poster) Differentiating Early Sensory Profiles in Infants at Elevated Likelihood for Autism and Association with Later Socio-Communicative Skills
E. M. Riboldi1, E. Capelli1, M. Molteni2, C. Cantiani3 and V. Riva4, (1)Scientific Institute IRCCS Medea, Bosisio Parini, Italy, (2)Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy, (3)Child Psychopathology Unit, IRCCS Eugenio Medea, Bosisio Parini, Italy, (4)Child Psychopathology Unit, IRCCS Eugenio Medea, Bosisio Parini, Lecco, Italy, Italy

Background:

Atypical sensory responses are included in the diagnostic criteria of autism spectrum disorder (ASD). It has been proposed that early differences in sensory responsiveness may produce “cascading effects” on later development. However, the relations between sensory processing and social communication in the earliest stages of development have not been well established.

Objectives:

The purposes of this study are (1) to evaluate the presence of different sensory profiles in infants at elevated likelihood of autism (i.e., infants with an older autistic sibling; EL-ASD) at 18 months of age and (2) to assess the potential association of the sensory subgroups and ASD-related traits.

Methods:

116 EL-ASD toddlers (males=56; females=60; age mean=17.33 months; SD=2.25) took part in the study. Inclusion criteria were: (1) gestational age ≥36 weeks, (2) birthweight >2000 grams, (3) Griffiths general quotient > 65, (4) absence of known medical, genetic or neurological conditions; (5) absence of major complications in pregnancy and/or delivery likely to affect brain development. Clinical measures of sensory processing (Seeking, Registration, Avoiding, Sensitivity) were measures by the Sensory Profile-2 Questionnaire (Dunn et al., 2014). To identify similar sensory subgroups, we used Latent Class Analysis (LCA) estimated in Mplus. In a longitudinal
framework, we also investigated sensory subgroups in relation to later socio-communicative skills and restricted/repetitive behaviors, as measured by ADOS Calibrated Severity Scores, CSS).

Results:

LCA defined three sensory subgroups (best fitting model, AIC=1079.477; BIC=1129.041; Entropy=.951): class 1 (n=65; 55.8%), class 2 (n=29; 25.7%), class 3 (n=22; 18.5%; see Figure 1). Interestingly, the results showed that only the subgroup with higher registration and sensitivity sensory scores (class 3) obtained higher socio-communicative difficulties at 24 months (F(2,100)=9.98; p<.001; ADOS Social Affect CSS: M=4.70, SD=2.83) compared to subgroup with lower sensory seeking scores (class 1: M=2.41, 1.49). No association were found between sensory groups and restricted/repetitive behaviors (F(2,100)=.599; p=.551; see Figure 2).

Conclusions:

This study supports that differences in sensory responsivity may be evident in infants with later social communication difficulties. These findings provide new insights into the nature of early sensory responsiveness and its association with later socio-communicative skills in early toddlerhood.

413.227 (Poster) Use of Multiple Biometrics during an Objective Paradigm to Evaluate Social Arousal in Infants

Background: Parents of infants who go on to develop autism spectrum disorder (ASD) report atypical sensory reactivity as early as 6 months of age. These reactivity, or arousal, patterns precede differences in social motivation and cascading deficits in social communication that are associated with ASD. Identification of objective markers of atypical arousal in infancy has the potential to re-envision early diagnosis and intervention.

Objectives: To evaluate the feasibility and validity of a novel paradigm developed to quantify arousal responses via multiple biometrics (pupillary, cardiac, and respiratory dynamics).

Methods: We developed the Stimuli for Early Social Arousal and Motivation in Infants (SESAMI) paradigm to evaluate multiple metrics of arousal to well-controlled social and non-social stimuli. Infants at low likelihood for ASD (no first degree relative with ASD) viewed SESAMI, while an eye tracker (Tobii Pro Spectrum) acquired gaze-tracking and pupillary dynamics, and a chest monitor acquired heart and respiratory data (Bittium Faros). SESAMI includes 9 trials of social (adult female face with speech) and non-social (pixelated, musical patterns that mimic human tones without the elements of speech) components. All data is validated and processed through an established pipeline that involves normalization to allow for comparisons across individuals and integration of available and valid data across trials. Time-series data are examined to evaluate the presence of unique social and non-social arousal patterns in infants.

Results: SESAMI pilot data has been gathered on 42 (98% success rate) infants between 6-24 months yielding valid arousal biometric data. Infants fixate on social faces more than non-social pixelated faces. Pupillary dynamics indicate that arousal responses are similar across social and non-social stimuli, highlighting the validity of SESAMI in eliciting well-controlled arousal responses. Distinct biometrics are not yielding significant differences between social and non-social stimuli and also have different onsets and durations during a stimulus presentation trials.

Conclusions: Arousal may provide the backdrop for how an infant samples information from and learned within a multi-sensory environment. The SESAMI paradigm may provide a new method to evaluate arousal biometrics in infants at risk for ASD, which can transform early diagnosis and intervention. The varied arousal responses across metrics highlights the need for analyses that integrate multiple time-series data to determine the utility of various metrics. Arousal biometrics are conserved across species, highlighting the utility of this work for preclinical models of ASD.
432.131 (Poster) How Do Infants with Later Autism Look at Other Children's Interactions?

C. Viktorsson, S. Bolte and T. Falck-Ytter, (1) Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden, (2) Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (3) Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden

Background: When observing other people during naturally paced and dynamic interaction, it is essential to look at the most informative locations at the right time. While viewing interactive social scenes, both children and adults with autism have been found to orient less towards faces than typically developing peers (Rice et al., 2012; Rigby et al., 2016), which might be related to the difficulties understanding and anticipating others’ actions that have been found in autism (Schneider et al., 2013; Senju et al., 2010). However, few studies have focused on how infants or children view other children interacting. This is a common social situation for children who are observing siblings at home or spending time in childcare settings, a situation in which it is important for social development to attend to the actions of other children.

Objectives: To investigate the looking behavior when viewing other children interact in typically developing infants and infants with later autism.

Methods: The sample was part of a prospective sibling study, in which infant siblings of typically developing children and children with autism are followed into early childhood. The final sample consisted of 98 infants; 22 in the low-likelihood (LL) group, 60 in the elevated likelihood group who did not receive an autism diagnosis (EL-noASD group), and 16 in the elevated likelihood group who did receive an autism diagnosis (ASD group). They did an eye tracking task at 18 months of age and were assessed for diagnostic outcome at 36 months. We tracked the infants’ gaze while they were shown eight stimuli videos, consisting of two children interacting, where a boy reaches out for a toy and a girl refuses to give it to him. An earlier study using the same stimuli found that typically developing children look at the girl’s face shortly after the boy reaches for the toy (Falck-Ytter et al., 2013), presumably because the girl holding the toy decides what happens next, and looking at her facial expression might provide important social cues.

Results: The LL group showed an expected increase in ratio of looking at the girl’s face during a 2.5 second time window, starting one second after the reach for the toy, as compared to the 2.5 seconds before (t(21) = -3.337, p = .003). There was a significant group difference in the ratio of looking at the face of the girl during the time window after, but not before, the reach (F(2,91) = 3.698, p = .029), where the ASD group showed a significantly lower ratio of looking at the girl’s face, as compared to the other children.

Conclusions: This study suggests that when observing other children, infants with later autism may sometimes fail to look at locations that are maximally indicative of what is going to happen next. This may lead to altered information processing and may make it more difficult to predict, understand and learn from social interaction.

432.132 (Poster) How Infants Respond to Others’ Direct Gaze: A Prospective Study of Associations to Autism

M. Rudling, P. Nyström, G. Bussu, S. Bolte and T. Falck-Ytter, (1) Department of Psychology, Department of Psychology, Uppsala University, Uppsala, Sweden, (2) Uppsala University, Uppsala, Sweden, (3) Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden, (4) Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden

Background: Being looked at is an important and salient signal for typically developing infants. Attenuated behavioural responses to such direct gaze could be an early sign of autism spectrum disorder (ASD), yet this has not been tested empirically. This study is a follow-up based on our previous findings, reported in Nyström et al., 2017, but here we included ASD outcome.

Objectives: To investigate the looking behavior when viewing other children interact in typically developing infants and infants with later autism.

Methods: The sample consisted of 169 infants: 35 with elevated likelihood of ASD and subsequent diagnosis (EL-ASD), 94 with elevated likelihood of ASD without subsequent diagnosis (EL-notASD), and 40 with typical likelihood of developing ASD and no diagnosis (TL). At approximately 10-, 14-, and 18 months age we measured how much and how quickly infants looked back towards an adult’s face after the adult looked at them. The analysis was pre-registered.
Results:

Independent of age, ASD likelihood and subsequent diagnosis, all infants were likely to look more towards the adult’s face shortly after the direct-gaze event compared to before. Compared to the TL group, infants in both EL groups looked less towards the adult's face shortly after the adult looked towards the infant (TL - EL-ASD: t(157) = 2.01, p = .046; TL - EL-notASD: t(159) = 2.45, p = .015). Yet, neither how much nor how quickly the infants responded to other’s direct gaze differentiated between EL-notASD and EL-ASD groups at follow-up. Additional, explorative analyses indicated that infants with subsequent ASD diagnosis look away quicker from faces with direct gaze than infants without ASD.

Conclusions:

The current results suggest that infant direct-gaze responses, as operationalized here, are not clinically meaningful early markers of ASD. Instead, our results suggests that differences in this phenotype could reflect familial factors linked to neurodevelopmental conditions more generally, irrespective of the individual’s later development.

432.133 (Poster) How to Measure the Life of a Child: Optimal Sampling Strategies for Detecting Pivotal Transitions in Early Vocal Development in Infants with ASD

G. Ramsay, Marcus Autism Center, Children’s Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA

Background: The recent availability of large data sets of densely sampled longitudinal measures collected from birth across multiple domains of infant behavior has provided compelling evidence that prodromal symptoms of autism emerge and can be detected within the first year of life by monitoring change over time in specific trajectories of development. Although gold-standard reference samples collected through years of research have finally provided the temporal resolution and statistical power needed to pinpoint significant changes in early development related to later outcome in autism, it is unlikely that intensive longitudinal designs developed for research will ever be appropriate or feasible for large-scale, cost-effective, community-viable screening. However, the information that cascades through the course of a child's development is not uniformly distributed. Dense uniform sampling over long periods of time may not be necessary if, with appropriate calibration from reference data, pivotal transitions can be localized using carefully chosen non-uniform subsamples. Accordingly, in this study we investigate new methods for systematically constructing sparse non-uniform sampling strategies for developmental profiling with equivalent performance to dense longitudinal designs.

Objectives: The goal of this research is to design and evaluate developmental sampling strategies that optimize detection of autism from trajectory biomarkers using sparse non-uniform sampling, in the context of early vocal development.

Methods: As part of an NIH Autism Center of Excellence (NIH P50 MH100029), we tracked vocal development in 40 children later diagnosed with autism and 40 typically developing controls, as part of a larger sample of more than 400 infants. Each child wore a LENA recorder one day every month from 0-24 months to provide audio recordings of their vocal environment. Using multitaper harmonic analysis, we identified the onset and offset of each infant and caregiver vocalization. From the mean rate of event markers, we determined an index of volubility for infant and caregiver; by calculating the transfer entropy between event marker sequences, we derived an index of infant-caregiver vocal contingency. Using Functional Data Analysis, we determined developmental trajectories for these measures for each infant-caregiver dyad, and mean trajectories for each outcome group. Permutation tests were used to identify significant (P<.05) differences between groups. We repeated our analysis using 10000 randomly selected subsamples of time points, and we determined the number and distribution of subsamples that continued to yield significant differences. We then used sparse coding techniques to reconstruct full developmental trajectories from these subsamples.

Results: Replicating our previous analyses, we identified significant differences in trajectories of vocal contingency within the first year, based on our full sample of up to 24 timepoints per child. Significant differences could still be detected in subsamples containing on average only 6 samples within 12 months, or 4 samples out to 18 months, with optimal performance from 3 samples centered around 12 months.

Conclusions: Sparse non-uniform sampling of infant development can be used to detect differences between autism and typical development with fewer samples than dense uniform designs, if the optimal sampling distribution can be derived from a densely sampled reference.

432.134 (Poster) Identifying Sex and Diagnostic Differences in the Emergence and Frequency of Social Smiling in Infants with and without Autism Spectrum Disorder through Parent and Clinician Reports

A. Koksal1, H. Davies2, A. Buck2, M. Pileggi2, W. Jones2 and S. Shulz2, (1)Marcus Autism Center, Children’s Healthcare of Atlanta & Emory School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA
Background: Social smiles emerge at around 1-2 months of age according to parental and experimental reports and are a fundamental milestone for social communication (Anisfeld, 1982; Messinger and Fogel, 2007). Smiling expression has been shown to diverge in atypically-developing infants: though at 6 months, frequency of smiling is comparable between children on the Autism Spectrum and their typically-developing (TD) peers, it declines significantly until 12 months of age (Ozonoff et al., 2010). Additionally, it has been shown that females with ASD have stronger non-verbal communication skills than males in childhood (Park et al., 2012). Retrospective parent reports and prospective clinical assessments may be valuable to understand the effect of diagnosis and sex on the emergence of smiling.

Objectives: To examine the relationship between primary caregiver-reported developmental milestones and behavioral characteristics at 9 months of age and indicators of autism risk at 12 months of age in a population-based birth cohort.

Methods: Participants included 109 children (66 females) from an ongoing longitudinal birth cohort study. At 9 months, primary caregivers completed the Survey of Well-being of Young Children (SWYC). The SWYC includes questions and cutoff scores for infant developmental milestones and behavior concerns (three subscales: Adaptability, Temperament, and Sleep). At 12-15 months, primary caregivers completed the First Year Inventory–Lite (FYI-Lite, v.3.1b), a parent report measure designed to identify children at possible risk for a later autism diagnosis. The FYI-Lite includes 25 questions from the full FYI and yields two subscales: Social Communication (SC) and Sensory Regulatory (SR). We hypothesized that the 9-month behavior ratings would be more sensitive to autism risk than the developmental milestone screening at 9 months. The SWYC behavior checklist and the FYI-Lite SR scale have thematically similar items (e.g., the SWYC asks how infants react to new people and the FYI-Lite asks about responses to new situations; both ask about infant sleep behaviors).

Results: In this sample, 52% of infants (n = 57) were classified as at risk on the developmental milestone questions on the SWYC at 9 months. Infants who failed the 9-month SWYC developmental milestone screener did not differ from those who passed the FYI SC (p >0.1) or SR (p >0.8) scores at 12-15 months. A moderate positive correlation (r = 0.22, p <0.05; Table 1) was found between the 9-month

Conclusions: The interaction effect of sex and diagnosis on the age of smiling emergence, whereby females on the spectrum smile earlier per parent reports and more frequently in clinical contexts than their male counterparts, may have implications on social compensation mechanisms in females on the spectrum, and on the divergent diagnosis rates between sexes. Future analyses may look at the interactive development of smiling with other milestones such as crawling, sitting up and first words, dimensional analyses using other diagnostic tools such as the Mullen Scales of Early Learning and Autism Diagnostic Observation Schedule, and the internal validity of retrospective parent reports over time.

432.135 (Poster) Infant Adaptability Associated with Autism Risk in the First Year of Life

**E. M. Andres, I. Camillone, S. P. Brady, C. A. Cragin, M. A. Clark, D. A. Savitz, B. M. Lester and S. J. Sheinkopf; (1)Thompson Center for Autism & Neurodevelopment, University of Missouri, Columbia, MO, (2)Women & Infants Hospital, Brown Center for Children & Families, Providence, RI, (3)Women and Infants Hospital, Brown Center for Children & Families, Providence, RI, (4)Brown University School of Public Health, Providence, RI, (5)Department of Psychiatry and Human Behavior, The Warren Alpert Medical School of Brown University, Providence, RI**

Background: Autism is not diagnosed until the toddler or preschool period or later. Yet identification of prodromal indicators of autism in infancy has the potential to open doors for early supports and interventions. Research on autism in infancy has often utilized enriched risk cohorts such as infant sibling designs. Tracking developmental trajectories of behaviors in relation to autism outcomes in general, population-based cohorts of infants will help identify early behavioral signs of autism risk in broader pediatric populations.

Objectives: To examine the relationship between primary caregiver-reported developmental milestones and behavioral characteristics at 9 months of age and indicators of autism risk at 12 months of age in a population-based birth cohort.

Methods: Participants included 109 children (66 females) from an ongoing longitudinal birth cohort study. At 9 months, primary caregivers completed the Survey of Well-being of Young Children (SWYC). The SWYC includes questions and cutoff scores for infant developmental milestones and behavior concerns (three subscales: Adaptability, Temperament, and Sleep). At 12-15 months, primary caregivers completed the First Year Inventory–Lite (FYI-Lite, v.3.1b), a parent report measure designed to identify children at possible risk for a later autism diagnosis. The FYI-Lite includes 25 questions from the full FYI and yields two subscales: Social Communication (SC) and Sensory Regulatory (SR). We hypothesized that the 9-month behavior ratings would be more sensitive to autism risk than the developmental milestone screening at 9 months. The SWYC behavior checklist and the FYI-Lite SR scale have thematically similar items (e.g., the SWYC asks how infants react to new people and the FYI-Lite asks about responses to new situations; both ask about infant sleep behaviors).

Results: In this sample, 52% of infants (n = 57) were classified as at risk on the developmental milestone questions on the SWYC at 9 months. Infants who failed the 9-month SWYC developmental milestone screener did not differ from those who passed the FYI SC (p >0.1) or SR (p >0.8) scores at 12-15 months. A moderate positive correlation (r = 0.22, p <0.05; Table 1) was found between the 9-month
SWYC Adaptability subscale ($M = 1.61, SD = 1.53$) and FYI-SR subscale average ($M = 1.91, SD = 0.49$). A simple linear regression further evaluated this association ($R^2 = 0.04, F[1,107] = 5.64, p = 0.02$) and poor Adaptability was a positive predictor of higher FYI-SR risk ($\beta = 1.79, p < 0.0001$; Figure 1).

Conclusions: At 9 months of age, behavioral characteristics may be more sensitive to autism risk than are delayed developmental milestones at that age. An unexpectedly high rate of failed screens was found on the SWYC milestone screener at 9 months; the context of the COVID-19 pandemic may have impacted parental responses in ways that are not yet understood. This is an initial analysis of data from a large longitudinal study of autism outcomes in a general birth cohort. The association of 9- and 12-months ratings suggest stability in infants’ responses to new people and situations. Results will help to refine planned models predicting 36-month autism outcomes.

432.136 (Poster) Investigating the Association between Proband ASD Affectedness and Younger Sibling Social Visual Engagement across the First Three Years of Development

M. Adebogun, S. P. White, A. Klin, C. Klaiman, S. Shultz, and W. Jones, (1)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Emory University, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA, (4)Emory University, Atlanta, GA, (5)Marcus Autism Center, Atlanta, GA

Background: ASD is a highly heritable neurodevelopmental condition. One in 3-5 younger siblings of individuals with ASD (proband) also receive an ASD diagnosis by the age of three (McDonald et al., 2020; Ozonoff et al., 2011). A recent study by Girault et al. (2022) linked early brain MRI phenotypes of ASD in younger siblings with proband ASD traits, representing one approach to investigate inherited genetic liability in ASD. Previous research identifies social visual engagement as a neurodevelopmental endophenotype for ASD and suggests patterns of social visual engagement are highly heritable (Constantino et al., 2017). However, social visual engagement has yet to be leveraged in studying the heritability of ASD traits within families. Furthermore, the degree to which genetic influence on social visual engagement varies over developmental time is unknown.

Objectives: To investigate heritability of ASD traits within families across development, we examine whether proband ASD affectedness is associated with the percent of time younger siblings spend looking at the eyes, mouth, and body (EMB) at 3, 4, 5, 6, 9, 12, 15, 18, 24, and 30 months of age.

Methods: With a sample of 122 proband-sibling pairs, the association between proband ASD affectedness–as indicated by scores on the Social Communication Questionnaire (SCQ), Autism Diagnostic Observation Schedule (ADOS-2), and Social Responsiveness Scale (SRS)—and patterns of social visual engagement in younger siblings (85 male, 37 female) was examined. EMB percent fixation, calculated using data collected from eye-tracking sessions, was used to index younger siblings’ social visual engagement. Linear regressions tested the predictive power of probands’ assessment scores on younger siblings’ EMB fixation at 3, 4, 5, 6, 9, 12, 15, 18, 24, and 30 months. Proband-sibling pairs were included in analyses if relevant proband assessment scores were available and the younger sibling completed an eye-tracking session at the appropriate time point.

Results: Results of sensitivity analyses in our sample indicate that for cross-sectional analyses detecting associations between probands’ level of affectedness and variation in social visual engagement in younger siblings, we are able to detect associations having medium effect size, $\rho \geq 0.3$, for SCQ-based levels of affectedness. Additionally, we are able to detect associations having medium to large effect sizes, $\rho \geq 0.43$, for ADOS-2 and SRS-based levels of affectedness. Subsequent analyses indicate possible associations between probands’ SRS total scores and younger siblings’ social visual engagement at months 4, 5, and 6; however, these findings must be interpreted with caution given results of sensitivity analyses.

Conclusions: Preliminary analyses indicate possible relationships between proband traits and younger sibling social visual engagement, but small effect sizes require additional analyses to support or reject this hypothesis. One important consideration is the diagnostic outcome of younger siblings, which is expected to produce variability in patterns of EMB fixation (Constantino et al., 2017). Moreover, because trends in heritability across development are of particular interest, time varying associations between trajectories of younger siblings’ EMB fixation and probands’ ASD traits will be analyzed to provide a temporally sensitive perspective on the genetic heritability of ASD traits within families.

432.137 (Poster) Investigating the Impact of Intervention Time on Development in African American Children with Autism Spectrum Disorder

M. Hines-Wilson, S. P. White, A. Abbacchi, J. Lowe, J. N. Constantino, A. Klin, W. Jones, D. Geschwind, and C. Klaiman, (1)Marcus Autism Center, Children’s Healthcare of Atlanta & Emory School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Emory University, Atlanta, GA, (3)Washington University School of Medicine, St. Louis, MO, (4)Semel Institute, University of California, Los Angeles, Los Angeles, CA, (5)Children’s Hospital of Atlanta, Atlanta, GA, (6)Marcus Autism Center, Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA, (7)Marcus Autism Center, Atlanta, GA, (8)Emory University, Atlanta, GA

Background: Compared to non-Hispanic white children, African American (AA) children experience a persistent delay in receiving an autism spectrum disorder (ASD) diagnosis (Constantino et al., 2020). AA children with ASD also have double the likelihood of having co-
occurring intellectual disability (ID) (Meanner et al., 2021). It is thus imperative for AA children to receive comprehensive assessments and interventions as early as possible. Prior studies have yet to investigate the average amount of intervention time AA children receive per week post-ASD diagnosis and how this impacts development.

**Objectives:** Investigate the impact of intervention time on development among AA toddlers with ASD.

**Methods:** Participants included AA toddlers with ASD (n= 46, M_age(SD)=27.26 (4.65) months) enrolled in a longitudinal genetics study. Developmental skills at time 1 (T1) and at a follow-up visit (T2) 18 months later were assessed with the Mullen Scales of Early Learning (MSEL), Social Responsiveness Scale (SRS-2), and the Vineland Adaptive Behavior Scale (Vineland-3) which are standardized for developmental age. The Autism Diagnostic Observation Schedule (ADOS-2) was also performed. T1 and T2 intervention hours looking at therapies like speech-language therapy (ST) and occupational therapy (OT) were assessed by surveying caregivers using the ACE 3 Intervention History survey. The average amount of intervention time the participants received every week was assessed at T1 (i.e., from age 1 to T1) and at three time points post-diagnosis (i.e., from T1 to T2).

**Results:** Paired-samples t-tests were used to compare the toddlers at T1 and T2. Intervention ranged from 0-1.75 hours at T1 and 0-20.00 hours at T2. At T2, the toddlers received significantly more (t(45)=4.91, p<.001) intervention time (M_intervention(SD)=4.13(4.96)) compared to T1 (M_intervention(SD)=0.45(0.60)). There were no significant changes on the Vineland-3 or SRS-2. MSEL domain age equivalent scores were used to assess changes in the brief period between T1 and T2. These scores were significantly higher at T2. Visual reception increased from 17.62(SD=5.82) months to 30.59(SD=1.41) months (t(36)=7.09, p<.001). Fine motor increased from 18.93(SD=5.17) months to 31.48(SD=11.38) months (t(41)=9.60, p<.001). Receptive language (RL) increased from 12.05(SD=6.97) months to 24.95(SD=13.98) months (t(41)=6.35). Expressive language (EL) increased from 13.08(SD=6.99) months to 25.94(SD=14.04) months (t(38)=6.99, p<.001). ADOS-2 total and social affect scores were significantly (t(25)=2.72, p=.012; t(25)=3.48, p=.002, respectively) lower at T2 (M_ADOS2(SD)=19.08(5.58); M_ADOS2(SD)=14.04(4.52), respectively) than T1 (M_ADOS2(SD)=21.62(5.10); M_ADOS2(SD)=16.81(3.80), respectively). Within-group correlations showed more ST and OT hours were positively associated with increased RL(r=.393, p=.029; r=.736, p=.001, respectively) and EL(r=.384, p=.033; r=.719 p=.002, respectively) t-scores at T2.

**Conclusions:** Findings suggest that increased intervention time can aid in comprehensive development in AA children with ASD. Specifically, ST and OT significantly improved language development. Given the benefits from a modest increase in intervention post-diagnosis, it is probable that an increase would result in even greater gains and reduce the burden of ID. Given that the average amount of intervention received was less than 5 hours/wk and the average recommended by the American Academy of Pediatrics (Hyman et al., 2020) is 20-25 hours/wk, more effort is needed to ensure children are receiving adequate intervention to help them reach their potential.

**432.138 (Poster) Link between Early Intervention Program Participation and Use of Preschool Disability Services By Children with Autism Spectrum Disorder**

**V. Vought, M. J. Conlan, C. Molfetta, K. Sidwell, J. Shenouda and W. Zahorodny, (1)Department of Pediatrics, Rutgers--New Jersey Medical School, Newark, NJ, (2)Department of Pediatrics, Rutgers University, Newark, NJ**

**Background:** In New Jersey, interventions are provided to preschool-age children with disabilities including autism spectrum disorder (ASD) under the auspices of the preschool disability (PSD) classification for special education. Though PSD services are universally available through local school districts, little is known about the utilization of the PSD (intervention) system by children with ASD. In addition, it is unknown to what degree an ASD child participating in Early Intervention Programs (EIP), a federally mandated program focused on children ages 0-36 months with disabilities and/or developmental delays, impacts linkage to PSD services.

**Objectives:** The study objectives were to determine the extent to which ASD children received PSD services in New Jersey and to identify factors affecting the utilization of PSD services. The influence of EIP participation, sociodemographic and clinical factors on PSD receipt were assessed.

**Methods:** Five consecutive cycles across a decade (2006-2016) of active population-based ASD surveillance by the New Jersey Autism Study (NJAS) focused on 8-year-olds with ASD from Essex, Hudson, Ocean, and Union counties. A two-phase ascertainment method was used. First, relevant information was reviewed and abstracted from medical and educational evaluations. Then, experienced clinicians using a reliable, DSM-referenced, and comprehensive method scored and analyzed the case information and determined ASD status. Demographic variables, including sex, race, and socioeconomic status (SES), were considered, along with clinical features, including intellectual status and degree of impairment as well as EIP participation. PSD participation was verified from multiple sources in the case record and referenced to EIP participation between birth and 36 months. Pearson Chi-square tests assessed differences between those receiving and not receiving PSD services. Standard logistic regression models were fit to examine the factors associated with PSD participation. Adjusted odds ratios (AOR) and 95% confidence intervals (CI) were estimated.

**Results:** 4050 8-year-old children satisfied ASD criteria. 2,667 (65.9%) received PSD services. Among children participating in EIP, 88.0% (n=1,661) received PSD services compared to 46.5% (n=1006) PSD participation by ASD children who did not receive EIP. No sex-based differences in PSD utilization were observed. SES was a significant factor in bivariate analysis, but was not significant when we adjusted
for covariates. Non-Hispanic Black children had higher odds of PSD utilization (AOR: 1.4; 95%CI: 1.1-1.8) compared to non-Hispanic White children. Similarly, Hispanic children had higher odds of PSD utilization (AOR: 1.3; 95%CI: 1.1-1.6) compared to Non-Hispanic White children. There was also variation in PSD utilization by county. After adjusting for multiple factors, EIP participation was strongly associated with the future receipt of PSD services (AOR: 8.7; 95%CI: 7.3-10.3). The proportion of ASD children receiving PSD services declined slightly, over time.

Conclusions: Two-in-three ASD children received PSD services, indicating a high rate of utilization. Slight decline in PSD utilization at the end of the study period suggests that maximum system capacity was being reached. Additional resources to the special education system for educating preschoolers with ASD are needed. EIP participation increased the odds of PSD service usage. Early universal use of an effective ASD screener may increase EIP participation and PSD enrollment.

432.139 (Poster) Measurement of Developmental and Behavioral Concerns in Young Children with Tuberous Sclerosis Complex

S. L. Jacobs, C. Hyde, S. Jeste and N. M. McDonald; (1)UCLA, Los Angeles, CA, (2)Semel Institute, UCLA Medical Center, Los Angeles, CA, (3)Children's Hospital Los Angeles, Los Angeles, CA, (4)UCLA Center for Autism Research and Treatment, Los Angeles, CA

Background: Tuberous sclerosis complex (TSC) is a genetic disorder caused by mutations in the TSC1 or TSC2 gene, which code for regulatory proteins involved in cell growth and division. The TSC phenotype often involves associated neuropsychiatric disorders (TAND), including autism, as well as medical complications, such as seizures. The TAND Checklist is a commonly used measure designed to assess the development and behaviors of individuals with TSC and impacts on families. This measure has been used to analyze and describe TAND phenotypic clusters of school-age children and broader age groups (de Vries et al., 2021; Alperin et al., 2021), but it is much less studied in younger populations. Here, we examine the degree to which the TAND Checklist is appropriate for use during the first years of life in children with TSC.

Objectives: To describe the utility of the TAND Checklist and characterize the areas of concern most commonly reported by caregivers in 12- to 36-month-old children with TSC.

Methods: Participants were enrolled in a larger early intervention study. Eligibility criteria included a clinical diagnosis of TSC and age between 12-36 months at entry. Data presented here are from the baseline visit (median age=23 months, n=53, 27 males). The TAND Checklist was collected via caregiver report. We separated participants into two age bins: 12-23 months (n=33) and 24-36 months (n=20) and examined patterns of response and non-response within the measure.

Results: Questions 1-5, which asked about milestones, current ability levels, behavioral concerns, psychiatric diagnoses, and intellectual development, had high response rates. Questions 6-9, which gathered data on academics, executive functioning, and impacts of TSC on daily life had lower response rates. The overall rate of concerns was higher in the 24-36 month cohort. The most commonly reported concern across both ages was absent/delayed onset of language (12-23 months=73%, 24-36 months=95%). Using the clusters from de Vries et al. (2021), dysregulated, overactive/impulsive, and ASD-like behavior were most common across both age groups, although more commonly reported among the older children (see Figure). Mood/anxiety concerns were more rarely noted at these younger ages. Open-ended responses revealed that top caregiver priorities were: communication and language skills (63%), mobility and motor skills (30%), behavioral/emotional management (26%), and daily living skills (26%). Behavioral/emotional management was primarily reported for the 2-year-olds, whereas mobility and motor skills were more frequently noted for the 1-year-olds.

Conclusions: While some question areas may be less relevant to younger cohorts, the TAND Checklist was found to provide meaningful information regarding early behavioral concerns and parent priorities, suggesting its general utility in clinical and research settings with younger children with TSC. Findings also reveal particular areas of need around early language development and behavioral regulation, highlighting the importance of further investigation of early interventions focused on these areas in TSC. We will continue to collect the TAND Checklist longitudinally in this cohort as part of the larger early intervention study.

432.140 (Poster) Monitoring Cognitive Development in Toddlers Using Automatic Eye-Tracking Based Technology

R. Sifre, J. C. Stallworthy, A. Klin and W. Jones; (1)Data Science, EarliTec Diagnostics, Decatur, GA, (2)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA

Background: Treatment progress for individuals with ASD varies considerably. One challenge is the lack of adequate tools for objectively measuring progress in social and cognitive skills. These processes are mediated by how a child engages differentially with the surrounding environment, attending to relevant signals while disregarding those that are not.

Objectives: To test the hypothesis that a direct eye-tracking-based monitoring biomarker can be used to assess change in social and cognitive skills over time.
Methods: Data were collected as part of a larger longitudinal study at the Marcus Autism Center, with visits at 15-, 18-, and 24-months. To leverage a sample in which developmental progress can be expected, 28 TD toddlers with data from at least two visits (20 with two time-points, 8 with three time-points, comprising a total of 64 visits) were included in analysis. Toddlers watched four video scenes of unscripted social interactions (Figure 1A) while undergoing eye-tracking. Time-varying kernel density estimation was used to quantify visual fixation and scanning patterns during each moment of collected eye-tracking data (Figure 1B-D). Using models previously validated (n=475) in a multi-site, prospective, double-blind clinical trial (Jones et al., under review), we used each child’s scan paths to calculate their 1) Social Disability Index (proxying ADOS-2 Total Scores, r=-0.70 [-0.75, -0.66]), 2) Verbal Learning Index (proxying MSEL verbal ability age equivalent scores, r=0.61 [0.55, 0.66]), and 3) Nonverbal Learning Index (proxying MSEL nonverbal cognitive ability age equivalent scores, r=0.60 [0.54, 0.66]). We hypothesized significant growth in the Verbal Learning and Nonverbal Learning Indices (processes that show rapid development in the first years of life) and no significant change in the Social Disability Index, as TD children should show low and stable levels of these values. We used linear mixed effects models to test these predictions.

Results: Children watched an average of 118.33 seconds of video during each session (range=30.77-177.03, SD=33.49). The Verbal and Nonverbal Indices were sensitive enough to monitor the age-expected increases in these skills over time (Verbal: FE$_{Age}$=1.6, $\chi^2$=25.96, p=3.48e-7; Nonverbal: FE$_{Age}=2.06$, $\chi^2=35.95$, p=2.02e-9) (Figure 2). As expected, Social Disability Indices did not exhibit age-related change (FE$_{Age}=1.729$, $\chi^2=2.92$, p=.09), providing divergent validity for our eye-tracking-based monitoring biomarkers.

Conclusions: These findings provide evidence of convergent and divergent validity of our eye-tracking-based monitoring biomarkers. TD children are expected to show marked development in Verbal and Nonverbal learning; as hypothesized, there was significant growth in these Indices in the first years of life. As expected, there was no significant change observed in the Social Disability Index scores. It should be noted that an average of 118.33 seconds of eye-tracking data provided enough signal to monitor change in Verbal and Nonverbal learning over the first years of life. These findings have important implications for the development of objective treatment monitoring tools for children with ASD-related disabilities. Future work will validate these monitoring biomarkers in an ASD cohort undergoing treatment and compare rates of change in children whose clinicians reported significant improvements against those whose clinicians reported no significant improvement.

432.141 (Poster) Object Exploration and Fine Motor Skills in Infants at an Elevated Likelihood for ASD

E. Platt, A. Federico’ and J. Bradshaw, (1)University of South Carolina, Columbia, SC, (2)The University of South Carolina, Columbia, SC

Background: While motor delay is not a core feature of ASD, growing research has identified a predictive association between early fine motor (FM) delays and later ASD outcomes (LeBarton & Landa, 2019). Infants at an elevated likelihood (EL) for ASD have demonstrated poorer FM skills by 6 months (Bhat et al., 2012), however, it is not yet understood the impact of this early delay on infant play and exploratory behaviors. FM skills, such as reaching and grasping, increase opportunities for a variety of object exploration behaviors. Object exploration plays a critical role in development as it enhances learning opportunities (Tamis-LeMonda et al., 2013) and increases word learning (Yu & Smith, 2012). If early FM skills enhance object exploration, this may be one pathway through which FM delays disrupt other domains of infant development and contribute to later ASD outcome.

Objectives: The present study aims to investigate the impact of early FM skills on concurrent object exploration and examine the predictive associations of these two constructs with later ASD symptoms.

Methods: Longitudinal data was collected at 6, 9, and 12 months from LL (n=49) and EL (n=35) infants. At 6 and 9 months, infants completed a 4-minute object interaction task followed by an assessment of motor skills using the Bayley Scales of Infant and Toddler Development (Bayley-3). At 12 months, infants were screened for ASD symptomology using the First Year Inventory (FYI) questionnaire. The object interaction was recorded and coded for exploratory touching and mouthing (Table 1).

Results: Multiple regressions were used to examine the relationship between 6- and 9-month Bayley-3 FM scores and concurrent object exploration across all participants. Model results showed that at both 6 and 9 months, FM skills were not associated with exploratory touching or mouthing ($p$'s>.05). Linear regressions were used to examine the associations between early motor measures and later ASD symptoms. Across all participants, FM skills at 6 months were significantly associated with 12-month ASD symptoms ($R^2=0.19$, $p<0.01$). This relationship was only significant in EL infants ($R^2=0.22$, $p<0.01$) and not LL infants ($R^2=-0.02$, $p=0.74$; Figure 1). At 9 months, this relationship was no longer significant for either group. No association was found between early object exploration and later ASD symptoms ($p$'s>.05).

Conclusions: No association was observed between early FM skills and concurrent object exploration. While previous studies have observed FM delays in EL infants, our results suggest that this does not diminish their quality of object exploration compared to LL infants. Similarly, FM skills, but not object exploration, at 6 months were negatively associated with later ASD symptoms at 12 months. This finding further builds on the established relationship between FM skills and ASD and suggests that object exploration does not follow a similar pathway to ASD outcome. Future studies could examine infant exploration of objects that require more refined FM skills, such as puzzles and blocks. This type of object exploration may be more dependent on the infant’s concurrent motor ability and play a larger role in...
Background: Majority of children with autism spectrum disorder (ASD) have language delay in their early development. Previous studies showed that early social communication skills, i.e., joint attention(JA), imitation, are associated with later language development in children with ASD, however, the results were inconsistent and most were from Western languages. Moreover, there were few studies examined these early predictive factors of language ability separately for children with high-functioning ASD (HFASD) and low-functioning ASD (LFASD).

Objectives: According to the heterogeneity in children with ASD, it is important to distinguish the different influential factors in language development between children with HFASD and LFASD. Therefore, the aim of this study was to investigate the role of JA and imitation in language development in children with HFASD and LFASD children respectively.

Methods: Participants included 99 children with ASD aged 18 to 35 months and were followed up (Time 2) 18 months after initial assessment (Time 1). Participants were divide into HFASD and LFASD groups by the Time 2-assessed developmental quotient (DQ) of 70. Screening Tools for Autism in Two-Year-Olds Taiwan Version (T-STAT) was modified to measure high levels of initiating joint attention (H-JJA), low levels of initiating joint attention (L-JJA), responding joint attention (RJA), object imitation and manual imitation. Mullen Scales of Early Learning (MSEL) was used to measure language ability, comprising receptive language, expressive language, and overall language.

Results: At Time 1, both HFASD and LFASD groups showed that RJA and receptive language, and L-JJA and expressive language were positively intercorrelated, respectively. At time 2, it was found that imitation ability was positively correlated to language ability in HFASD group, and LFASD group showed that receptive language was positively correlated to L-JJA and RJA respectively, and expressive language was positively correlated to RJA and object imitation respectively. After controlling chronological age, HFASD group showed that only Time 1 manual imitation predicted Time 2 expressive language, and LFASD group showed that only Time 1 RJA predicted Time 2 receptive language.

Conclusions: The current study included different types of JA and imitation to investigate their role of language development in children with HFASD and LFASD. Both children under 3 years old with HFASD and LFASD showed that RJA and IJA play a critical role in language ability. Furthermore, this study suggests that children with HFASD and LFASD may rely on different ways to enhance their language development: for children with HFASD, well-developed manual imitation is an important indicator of improving expressive language ability. This may show that imitation involved intentional social intention can help children with HFASD to express more well; for children with LFASD, they rely more on mapping strategies and understanding others’ communicative intention to acquire language knowledge. The current findings note the different directions of early intervention for children with ASD in different cognitive levels.

Predictors of Language Ability in Young Children with HFASD and LFASD in Taiwan
T. L. Lin1 and H. J. Yang1, (1)Institute of Behavioral Medicine, National Cheng Kung University, Tainan City, Taiwan, (2)E-DA Hospital, Kaohsiung City, Taiwan

Objectives: In this cross-sectional study we use the Social Responsiveness Scale-2 (SRS-2) to characterize social communication skills and restricted interests/repetitive behaviors (RRBs) in 3-4 year old children with ACC and a large community comparison sample.

Methods: Primary caregivers of n = 69 infants who had received a diagnosis of ACC completed the SRS-2 at 36 or 48 month timepoints (age range 33-50 months; M = 42.16, SD = 5.5; 39% female). The age-range matched comparison group represents a convenience community sample (n = 689; M = 44.1 months, SD = 5.5; 46% female) from three studies on early development. The SRS-2 provides results across multiple scales including Social Awareness, Social Cognition, Social Communication, Social Motivation and RRBs, as well as a total score.

Background: Agenesis of the Corpus Callosum (ACC), a congenital brain malformation in which the corpus callosum is partially or completely absent, occurs in ~1 in 4,000 live births. ACC has been identified as a major risk factor for Autism Spectrum Disorder (ASD). Although 35%-45% of children and adolescents with ACC may ultimately meet screening criteria for ASD, very little is currently known about social development or signs of ASD in early childhood. Currently there is no published information about how young children with ACC score on many of our most used measures of early ASD symptomatology. Consequently, there is a lack of guidance for pediatricians, neurologists, therapists and neuropsychologists regarding early assessment and optimal targets for intervention and treatment planning in this population.

Objectives: In this cross-sectional study we use the Social Responsiveness Scale-2 (SRS-2) to characterize social communication skills and restricted interests/repetitive behaviors (RRBs) in 3-4 year old children with ACC and a large community comparison sample.
Results: The ACC group had significantly higher raw scores than the community sample across all SRS-2 scales, as well as the total SRS-2 score ($p < .001$). See Figure 1 for box & whisker plots. When examining T-scores, the SRS-2 total scores for the majority of participants in both groups fell within the Normal to Mild range (77% ACC group, 98% community). However, a significantly greater proportion of ACC participants' SRS scores were in the Mild (13% ACC, <1% community), Moderate (3% ACC, 1% community) and Severe (7% ACC, <1% community) range.

Conclusions: Our study suggests that by ages 3 - 4, children with ACC are more likely to show early signs of social challenges and RRBs than a community sample. Given that there is initial evidence for early ASD behaviors in the ACC population on experimental measures, this study additionally provides initial support for using the SRS-2 to assess for early social difficulties in children with ACC. Longitudinal follow-up and a full diagnostic evaluation are the next steps in determining the predictive value of the SRS-2 in this medically complex population.

432.144 (Poster) Profound Developmental Delay Among Minimally Verbal Autistic Children
J. Panganiban and C. Kasari, (1)Semel Institute, University of California Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA

Background: A hallmark of autism spectrum disorder (ASD) is the diversity in ability among autistic individuals, ranging from savant skills to profound disability. This can lead to complications in understanding ways to support autistic individuals, particularly for those at highest risk. Individuals with IQ’s below 50 and/or minimal expressive language form a group which will be identified as profoundly autistic by the age of eight and will likely need a lifetime of support. Due to the challenges of working with this population, little is known about their skills and challenges, resulting in a significant gap in our knowledge.

Objectives: Our objectives are to characterize autistic children at risk for profound autism.

Methods: This is a secondary analysis of 156 minimally verbal preschool age autistic children. Children were assessed using the Mullen Scales of Early Learning (MSEL), administered at the start of the study and after one year. The children completed the Early Social Communication Scales and the Structured Play Assessment, measures of social communication and play development. Children were filmed for ten minutes playing with a caregiver, and videos were coded for joint engagement and expressive language.

Results: At entry, 70% percent of the sample tested below the range needed to determine a valid early learning composite, the equivalent to an IQ score, on the MSEL. This subset of the overall sample we considered to be profoundly developmentally delayed. We explored the relationship between profound delay and measures of social communication, play, joint engagement, and expressive language. Accounting for the child's age, regression analyses showed a significant relationship between profound delay and child initiated joint attention ($p < .001$), play diversity ($p < .001$), joint engagement ($p < .01$), and number of distinct word roots (NDWR; $p < .001$). Autistic children with profound developmental delays were likely to have lower scores across all measures. Analysis of the profoundly delayed subset shows great variability. Child initiated joint attention ranged from 0 – 28, play diversity from 1 – 43, percent of time joint engaged from 0 – 92%, and NDWR from 0 – 34. At the 12 month follow up of the MSEL 58% of the sample continued to test in the profoundly delayed range.

Conclusions: Autistic children that also present with profound developmental delay are underrepresented in research. Seventy percent of the children in our sample did not score in the testable range of the MSEL, providing little information about skills and challenges. Assessments of core skills, such as joint attention, play, engagement, and language, provided a clearer picture of these children. While they were all more likely to score lower across domains, there is still great variability in their skills. High scores in child initiated joint attention and play diversity are important for target setting and have been shown to predict expressive language gains through intervention. Finally, 12 month follow up assessment showed that fewer children tested in the profoundly delayed range. Future work should examine factors that may predict these improvements or potential targets for early intervention.

432.145 (Poster) Pupil Dilation Indicates Atypical Physiological Reactivity to Facial Expressions during Late but Not Sensory Processing Stages in ASD
L. Polzer, S. K. Kleber; N. Rajji; C. Lemler; J. Kitzerow-Cleven; Z. Kim; C. M. Freitag and N. Bast, (1)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany, (2)Autism Research and Intervention Center of Excellence Frankfurt, Dept. Child and Adolescent Psychiatry, Psychosomatics & Psychotherapy, Goethe-University Frankfurt, Frankfurt, Germany, (3)Autism Research and Intervention Center of Excellence Frankfurt, Goethe Universitat Frankfurt am Main, Frankfurt, GERMANY, (4)Autism Research and Intervention Center of Excellence Frankfurt, Goethe University Frankfurt / Department of Child and Adolescent Psychiatry, Frankfurt, Germany

Background: Individuals with ASD show atypical physiological reactivity to emotional stimuli. Underlying processes of these aberrations are unknown. Pupil dilation (PD) reflects sympathetic activation and can be used as a physiological measure for emotional arousal. PD time course components were suggested to reflect differential neural processes such as sensory vs. cognitive processing. Previous studies reported inconsistent findings on PD to emotional expressions in ASD, which may be a consequence of heterogeneous research.
Quantitative and Qualitative Analyses of Preverbal Production of Infants with High-Likelihood of ASD at 6 and 18 Months

M. Weyland, P. Maes and M. Kissine, (1)ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium, (2)ACTE — Center of research in Linguistics — ULB Neuroscience, Université libre de Bruxelles, Brussels, Belgium

Background: Siblings of autistic children have higher likelihood of autism spectrum disorder (HL-ASD). Tracking their early vocal production allow 1) to describe early linguistic trajectories of HL infants with a later diagnosis of ASD (HL-ASD) at 24-months and those who don’t (HL-Neg) 2) to monitor early signs of atypical language development. In typical language development, the first preverbal milestones are expected to emerge around 6 months, and words and two-word combinations around 18 months. Researchers can rely on detailed analyses of the quality and quantity of these preverbal and verbal productions to investigate early (pre)linguistic development and describe individual trajectories.

Objectives: The present study, investigates whether at 6 and 18 months of age, infants with low likelihood of ASD (LL), HL-Neg infants and HL-ASD’ infants follow different trajectories in terms of total amount of production and type of production.

Methods: The present corpus correspond to two cross-sectional time-point (6-months: HL-ASD=3; HL-Neg=9; LL=18; 18-months: HL-ASD=11; HL-Neg=9; LL=19) from a longitudinal study following 55 infants with HL-ASD and 37 infants with LL-ASD between their 6 and 36 months. Infants’ vocal production are naturalistic data, recorded at home, without an experimenter. The hour the most “talkative” has been selected, for each infant, and manually coded with a detailed coding procedure (osf.io/y2jxm). Negative binomial regression models were used to assess diagnostic group differences.

Results: No group differences in total amount of production neither in type of production were detected at 6 months. There is no group differences either in total amount of production at 18 months. The variability in term of quantity of production is extremely heterogeneous (Table 1.). At 18 months, diagnostic condition has an effect on certain type of production. Vocalic preverbal production, Syllabic production and Proto-word production showed no group differences whereas HL-ASD and HL-Neg produced significantly less two-combination ($p$’s < .01) and single word ($p$’s < .01) than LL group.

Conclusions: Findings suggest that cross-sectional analyses, with few variables, are not enough to describe group differences and individual trajectories. Both HL-ASD and HL-Neg are incredibly heterogeneous and showed difference from LL group only for “verbal” categories of type of production. Analyses with more granularity (phonetic level) must be done on preverbal type of production. All
information from assessment that will be available when the follow-up of these infants will be over for everyone (VABS-II, MB-CDI, Leiter, CELF and ADOS) should also add precious information to describe each individual. Exploration of individual differences within-group from a longitudinal perspective is desired (Graph 1.). This is precisely the aim of the broader study from where these two samples are a part.

432.147 (Poster) Refining Computational Facial Analysis of Infants to Advance Early Autism Screening

Background: Computational analysis of infants' socially-directed facial expressions holds promise as a highly precise and scalable new avenue for early autism detection. However, existing computer vision facial analysis methods, developed on adult samples, have not been validated for infant facial morphology. Moreover, existing methods were largely developed for front-facing images, rendering them a poor fit for assessing infants in natural contexts. Evaluation of state-of-the-art methods by our team uncovered significant inaccuracies in measuring facial expression in the presence of head movement and in 3D estimates of individual morphology. Consequently, analysis of infants has been limited to basic head movements because faces cannot be adequately characterized. In response, we have developed novel methods that can digitally represent infants’ facial shape and separate head pose from facial expression. This study provides an initial validation as a critical step toward applying these methods to a large dataset of infants during natural social interactions.

Objectives: Validate new computer vision algorithms designed to accurately capture and parse facial structure, pose, and expression on infant video data.

Methods: 2D facial video data were collected from 130 ~12-month-old infants with (n=60) or without (n=70) a sibling with autism, during a 5-minute face-to-face interaction with a caregiver designed to elicit natural social behavior. From a subsample, 216 3-sec. video clips were selected in which there were no occlusions of the face or extreme deviations from frontal pose. 3D reconstructions representing facial pose and expression were generated for each clip as quantified by a robust 3D morphable model fitting method. Original clips and reconstructions were viewed side-by-side and coded for presence of 1) change in facial pose (i.e., head orientation movement) and/or 2) change in facial expression (i.e., movement in facial features). When a change was present, the accuracy with which it was captured by the reconstruction was rated from 0-3 (Very Inaccurate, Fairly Inaccurate, Fairly Accurate, Very Accurate). 30% of clips were double-coded – 15% to establish consensus and 15% for reliability.

Results: Interrater reliability (percent agreement) ranged from 69.6% to 90.6%. 164 clips were coded as containing a pose change, with a mean accuracy rating of 2.66 (SD=0.60). 156 clips were coded as containing an expression change, with a mean accuracy rating of 2.52 (SD=0.74). 121 clips contained changes in both pose and expression. Accuracy ratings for expression reconstruction were strong even when there was also a pose change (M=2.50, SD=0.75), suggesting the method can parse expression and pose – a difficult problem for computer vision that is especially critical to overcome for infant analysis.

Conclusions: Results suggest that our novel computational method accurately represents both facial pose and facial expression changes in infants as they engage in natural social interactions, even when pose and expression changes co-occur. Thus, it overcomes shortcomings of existing methods, which have hindered their vast potential for quantifying infant behavior. This work paves the way for future analyses on our large dataset of infant-caregiver interactions, aimed at deriving computational biomarkers of atypical development to be leveraged for earlier, more effective autism screening.

432.148 (Poster) Relationship between Sleep Habits and Behavioral Problems in 3-Year-Old Children, and Differences in Sleep Habits with and without Social Development Delay

A. Terui1, Y. Sakamoto2, T. Mikami3, A. Osato4, K. Nakamura5 and M. Saito6, (1)Neuropsychiatry, Hirosaki University, Hirosaki, Japan, (2)Graduate School of Comprehensive Rehabilitation Science, Hirosaki University, Hirosaki, Japan, (3)Neuropsychiatry, Hirosaki University, Hirosaki, Japan

Background: Recently, there has been growing interest in the effects of children's sleep on their health and development. Children with sleep problems have more behavioral problems (Reynaud, 2018), and children with Autism Spectrum Disorder (ASD) have more sleep problems than without it (Johansson, 2018). Sleep habits differ between Western countries and Asia, and although interest in sleep habits has been growing in Japan, there are few reports of sleep habits in Asia.
Objectives: Therefore, our object in this study is to investigate the association between sleep habits and behavioral problems in 3-year-old children, and differences in sleep habits with and without social development delay (SDD).

Methods: Among the parents of 3-year-old children who underwent health checkups in a city in the Tohoku region in 2021-2022 and responded to a questionnaire, 1327 people who could be analyzed were included. We used the Child Sleep Habits Questionnaire (CSHQ) to assess sleep habits and the Child Behavior Checklist (CBCL) to assess behavioral problems. "14-item Social Development Screening"; cutoff value: 29 points, sensitivity 82.8, specificity 96.8, created by Hirosaki University from the Social Responsiveness Scale 2nd edition (SRS-2) and Strength and Difficulties Questionnaire (SDQ) was used to evaluate social development delay. All participants were examined for associations between sleep habits and behavioral problems. In addition, we examined differences in sleep habits between a group with social development delay (SDD group, n=154) and a group without social development (non-SDD group, n=1173). We used multiple regression analysis for statistical analysis, the χ² test and the Mann-Whitney test.

Results: As a result of multiple regression analysis (dependent variable: CBCL, independent variable: CSHQ), there was a moderate effect size association between total scores (β = 0.431, R² = 0.185). In other words, it became clear that sleep habit problems and behavioral problems were significantly correlated in 3-year-olds. In the subsections of CBCL and CSHQ, there were significant associations between sleep habits such as Sleep onset delay, Sleep anxiety, Parasomnias, and Sleep disordered breathing and behavioral problems such as Emotional reactive, Anxious/Depressed, Attention problems, Aggressive behavior, Internalizing, and Externalizing (Table 1). A chi-square test showed that the SDD group was significantly more likely to have some sleep problems (p<0.01). As a result of comparing the sleeping habits of both groups, the total score (p<0.001), each subitem; Bedtime resistance (p<0.01), Sleep onset Delay (p<0.001), Sleep duration (p<0.01). Sleep anxiety (p<0.05), Sleep disordered Breathing (p<0.001), and Daytime sleepiness (p<0.001) were all significantly higher in the SDD group. Therefore, children with social developmental delays were shown to have significantly more problems with sleep habits than children without delays (Figures 1, 2).

Conclusions: A community survey suggested a significant association between sleep habits and behavioral problems in 3-year-olds. Children with SDD also had more problems with sleep habits. It is also necessary to pay attention to the sleep habits of 3-year-old children with social and behavioral problems. In the future, we will further investigate sleep habits in ASD and other neurodevelopmental disorders.

432.149 (Poster) Sleep Duration and Sleep Challenges in Infants with Autistic Siblings

M. Foster and J. Bradshaw, University of South Carolina, Columbia, SC

Background: Evidence suggests sleep differences emerge in the first three years of life for autistic individuals (Horiuchi et al., 2020; MacDuffie et al., 2020). In order to understand sleep differences as a possible early indicator of ASD, it is important to determine the utility of different sleep data collection methods in infancy. Specifically, questions remain on the clinical utility of describing parent perceptions of their infant’s sleep challenges compared to tracking hours spent asleep.

Objectives: The current study uses prospective parent report to examine the how two different reports of sleep (sleep challenges and sleep duration) may be uniquely linked to future autistic traits among infants with an autistic sibling (elevated likelihood, EL) and those with no familial history of ASD (low likelihood, LL).

Methods: Participants (N = 71; EL, n = 32; LL, n = 39) were enrolled in a prospective longitudinal study on early autistic traits. At 6 months, caregivers completed the Infant Behavior Questionnaire Revised (IBQ-R) and a 24-hour sleep log. At 12 months, clinicians administered the Communication and Symbolic Behavior Scales-Behavior Sample (CSBS-BS: Wetherby & Prizant, 2003) and scored the Systematic Observation of Red Flags (SORF; Dow et al., 2016) from recordings of the CSBS-BS administrations. From the SORF, domain scores were calculated for social communication and restrictive and repetitive behaviors (RRBs). To measure sleep challenges, a new scale of Sleep Challenges was created with sleep-related items from the IBQ-R.

Results: At 6 months, EL infants (M = 5.12, SD = 1.70) spent significantly more time asleep during the day than LL infants (M = 3.87, SD = 1.21), (t(45) = 2.89, p < .01). There was no significant difference in time spent asleep at night or in the Sleep Challenges score between EL infants and LL infants. In examining the influence of sleep duration variables and likelihood status on the Sleep Challenge score, a multiple linear regression analysis was performed and found to be significant (F(3, 41) = 3.18, p = .03, R² = .19, R(adj) = .13). In this model, greater daytime sleep duration significantly predicted less sleep challenges (β = -.19, t(1) = -2.59, p = .01) while neither status nor nighttime sleep duration uniquely predicted the Sleep Challenges score. When assessing the role of status and sleep-related variables on future autistic traits in a general linear model, infants who spent less time asleep at 6 months demonstrated greater RRBs at 12 months (F(3, 10) = 15.26, p = .02), regardless of status. No association was observed when testing sleep challenges as a predictor or SORF social communication scores as the outcome.

Conclusions: The results of this study suggest that EL infants sleep more in the daytime at 6 months and increased daytime sleep predicts less sleep challenges in the overall sample. Findings of this study also indicate that reduced nighttime sleep at 6 months may signal future autistic traits. Additional research is needed to examine data collected from objective measures of sleep, such as actigraphy, and its
relationship to the etiology of ASD and related developmental outcomes.

432.150 (Poster) Sleep Patterns of Children with Prodromal Autism Spectrum Disorder

V. Jokitalo, T. Makela, E. Lehtonen, H. Saarimaki, J. E. Paavonen, O. Saarenpaa-Heikkila and A. Kylliainen, (1)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland, (2)Faculty of Social Sciences/ Welfare Sciences, Tampere University, Tampere, Finland, (3)Pediatric Research Center, Child Psychiatry, Helsinki University and Helsinki University Hospital, Helsinki, Finland, (4)Public Health and Welfare, Finnish Institute for Health and Welfare, Helsinki, Finland, (5)Center for Child Health Research, Faculty of Medicine and Health Technology, Tampere University; Tampere University Hospital, Tampere Finland, (6)Faculty of Social Sciences/Psychology, Tampere University, Tampere, FINLAND

Background:

During the prodromal phase of autism spectrum disorder (ASD), when behavioural symptoms begin to appear, sleep problems are a frequent concern of the parents. In general, sleep problems seem to get worse around 18 months of age when sleep starts to deviate from the normative sample. Studies in older ASD-children indicate that sleep difficulties such as reduced total sleep time are related to more severe symptoms. Understanding the sleep problems of prodromal ASD is essential so that support can be provided at the optimal time.

Objectives:

The aim of this study is to describe sleep problems in toddlers with prodromal ASD screened from the general population. We focus on sleep latency, night awakenings, time spent awake at night and the total night-time sleep duration. Another interest of this study was to investigate whether there is association between sleep patterns and autistic behaviour in children aged 12-24 months.

Methods:

Participants were recruited from on-going Gaze@Toddler -study in which toddlers are screened (M-CHAT-R/F) from the general population. Parents responded to a sleep questionnaire (BISQ & SDSC) about their toddler’s sleep. Within 1,5 months of completing the sleep questionnaire, children aged 13-28 months (N=23) were assessed with the ADOS-2 Toddler Module. The sample was divided into two categories; low (N=14, total ADOS < 16 points) and high groups (N=9, total ADOS ≥ 16 points) based on the median scores in total ADOS scores. The age was positively correlated (r= 0.597, p=.003) with the ADOS scores indicating that the toddlers with more autistic behaviour were older than the toddler with fewer ASD traits.

ADOS groups were compared to sleep latency, a number of night awakenings, time spent awake at night, and the total night-time sleep duration, and parents’ experience of the child’s sleep. We also compared the sleep patterns of children with prodromal autism to those of the general population at 12, 18, and 24 months old published by Paavonen et al., (2020).

Results:

The findings indicated that any of the sleep variables did not differ significantly between the high and low groups. There was a trend of significance (Fisher’s exact test, one-sided, p=0.06) indicating that the parents in high ADOS group reported their toddler having sleep problems compared to low ADOS group (Fig1). When toddlers’ sleep patterns were descriptively compared to the normative sample, the difference to the general population seemed to increase with age (Fig2).

Conclusions:

The preliminary findings suggest that sleep development deviates from average development during the second year of life in children with prodromal ASD. The parents of toddlers with clear autistic behaviour considered their toddlers to have sleep difficulties more often than the parents whose toddlers have milder autistic behaviour. The toddlers with clear ASD traits were also mostly over two years of age and this fact could partly explain our tentative finding. Nevertheless, it indicates that the parents need continuing support for sleep issues already before the formal diagnosis.

432.151 (Poster) Social Bids for Caregiver Attention in Infants at Elevated Likelihood for ASD

K. Rowland, A. Acosta, S. R. Edmunds and J. Bradshaw, University of South Carolina, Columbia, SC

Background: Young children with autism spectrum disorder (ASD) show significant differences in their initiations of social interaction compared to neurotypical children (Chiang et al., 2008). Previous studies suggest autistic children are less likely to socially engage in triadic interactions (child-parent-object) than typically developing children (Adamson et al., 2012); however, these findings have not yet
been studied in infants during a semi-structured interaction in which the caregiver intentionally withdraws their attention. The current study examines infant social bids to a caregiver whilst being ignored for infants at a genetically elevated likelihood (EL) for ASD and infants at low likelihood (LL) for ASD.

Objectives: This study aims to compare trajectories of social bids from 12 to 24 months between EL infants and LL infants.

Methods: At 12, 15, and 24 months of age, participants (n=21 LL, n=17 EL) engaged in a semi-structured triadic interaction. Caregivers were asked to play with their infant as usual for five minutes. Afterwards, caregivers were asked to sit back and ignore their infant (neutral face and avoid eye contact) for two minutes. Videos of this ignore period were coded for infant’s social bids towards their caregiver (based on definitions from the CSBS-BS). Social bids were studied using frequency scores for gestures, looks, and directed vocalizations. Effects of group and time were estimated using linear mixed models.

Results: All infants showed a significant effect of age on looks ($F(2, 57.13) = 5.86, p = .005$), gestures ($F(2, 60.55) = 8.13, p < .001$), and directed vocalizations ($F(2, 53.66) = 22.22, p < .001$), see Figure 1. A significant interaction emerged for gestures, with EL infants showing a faster rate of growth compared to LL infants, $F(2, 60.55) = 3.14, p = .05$. At 15 months, LL infants initiated marginally more gestures than EL infants ($t(29) = 1.95, p = .06$). There was no significant difference between groups at 24 months ($t(15) = -0.96, p = .35$).

Conclusions: Overall, EL and LL infants showed similar types and frequencies of social bids toward a caregiver when being ignored in a semi-structured interaction. All social bids increased over time from 12-24 months, regardless of status. The only differentiating feature between the groups was the frequency of gestures, where EL infants increased at a faster rate than LL infants. Intriguingly, 15 months was a critical time period, with EL infants producing fewer gestures than LL infants. By April 2023, n=10 participants will be added to the study, yielding final n=23 LL and n=25 EL, allowing additional stratification based on outcome. This study demonstrates that the quantity of social bids solicited by EL and LL infants is comparable between 12-24 months, suggesting that these infants were similarly aware of the social withdrawal and motivated to re-engage their caregiver. Additional research investigating the quality of bids, particularly for those with an eventual ASD diagnosis, may be helpful in understanding the complex picture of social awareness, motivation, and engagement in EL infants.

---

**432.152 (Poster) Social Communication As a Predictor of Treatment Gains in Autistic Preschoolers: Examining the UCLA PEERS® for Preschoolers Program**

Background: Social differences are a core component of autism spectrum disorder (ASD; American Psychiatric Association, 2013), frequently evident in early development (Paul, 2003). Specifically, social communication is often impacted, such that autistic individuals might develop social language later or have sustained communication differences (Sterley, 2021). Only a few comprehensive social skills programs exist for young autistic children (DeRosier et al., 2011; Reichow & Volkmar, 2010). The PEERS® for Preschoolers Program (P4P) is an evidence-based social skills intervention that addresses multiple aspects of social skills and has been shown to improve peer interactions (Park et al., 2022). While various interventions have been found to increase social communication (Nowell, 2019), baseline social communication as a predictor of other social skills post-P4P has not been studied.

Objectives: This study aims to examine how social communication skills prior to P4P are related to and might predict treatment gains post-P4P. We hypothesized that preschool-aged children with higher social communication would show greater treatment gains.

Methods: Participants included 43 preschoolers (79% male; $Mage=4.6; SD=8.0$) who had completed P4P, all of whom had historical autism diagnoses and Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2012) total scores $\geq 60$. Parents completed a battery of assessments pre- and post-intervention, including the SRS-2. This measure includes a total score and multiple subscales (i.e., social awareness, cognition, communication, motivation, and repetitive behaviors). Parents also completed the Social Skills Improvement System (SSiS; Gresham & Elliot, 2008), which has two main subdomains: Social Skills (SSiS-SS) and Problem Behaviors (SSiS-PB). Treatment gains were assessed using change scores pre- and post-intervention and Pearson correlations examined the relationship between social communication (measured on the SRS-2) and treatment gains.

Results: Paired samples t-tests indicated p-values from all SRS-2 subscales were significant when comparing baseline social communication and post-intervention subscales (all $p$ values $<.05$). Thus, there were gains in all SRS-2 subdomains. There were also significant correlations between baseline social communication and post-intervention SRS-2 total ($r=.48, p=.002$), social awareness ($r=.42, p=.008$), social cognition ($r=.47, p=.003$), social communication ($r=.45, p=.004$), and repetitive behaviors scores, ($r=.35, p=.029$).

However, the direction of the correlation indicated those with greater baseline social communication demonstrated higher post-treatment scores (i.e., more social difficulties). Significance was also evident between social communication and post-intervention SSiS-SS scores ($r=.43, p=.006$), where less baseline social communication difficulties also correlated with lower social skills.
Conclusions: Findings suggest baseline social communication is related to general treatment gains post-treatment in P4P, and all individuals benefited from this intervention. However, level of social communication is not a predictor of the magnitude of outcomes. Of note, P4P participants must speak in at least 4-word spontaneous phrases, which may decrease sample variation. Findings emphasize the importance of social communication in conjunction with other aspects of social skills targeted in P4P. Future research may examine additional domains as outcome predictors to better tailor the intervention to achieve the greatest benefits.

432.153 (Poster) Social Looking in Infants at Elevated Likelihood of Autism during Interaction with Parents
E. Thorup, S. Bolte and T. Falck-Ytter, (1) Uppsala universitet, Uppsala, Sweden, (2) Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (3) Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden

Background: Diminished social interest or functioning is a key feature of Autism Spectrum Disorder (ASD), and reduced social motivation, manifested as lower attention to faces and other social stimuli, has been suggested to represent a potential starting point for later autistic symptoms (Chevallier et al., 2012; Dawson et al., 2004). For infants, the faces of parents provide rich sources of information, and diminished attention to these may lead to missed opportunities for learning and development. Whether ASD is associated with lower attention to faces in infancy is not clear (Chawarska et al., 2013; Elsabbagh et al., 2013), and whether autistic infants pay less attention to the faces of their parents specifically has yet to be assessed. However, using head mounted eye trackers, Yurkovic-Harding et al. (2022) found no differences in terms of parental face looking between young (24-48 months) children with and without ASD. In line with previous studies of typically developing children (e.g. Yu & Smith, 2013) both groups spent remarkably little of their time looking at their parents faces. While these findings are interesting, the possibility remains that differences exist earlier in development.

Objectives: The main aim of this study is to assess whether the frequency of spontaneous looking to a parent’s face during free play in 10-month-old infants is related to later ASD status. As not all included infants have yet reached 36 months and been clinically assessed, we currently report a comparison between infants at elevated vs. low familial likelihood of ASD. By the time of INSAR 2023 all infants will be diagnostically assessed. We then plan to present comparisons based on diagnostic outcome status (i.e. ASD vs. typical development).

Methods: At 10 months of age, infants were videotaped while playing freely with a set of toys with a parent. The first 5 minutes of play were video coded for instances of infant looking at the parent’s face. Frequencies of face looking were compared between infants at elevated likelihood of ASD and infants with no familial history of ASD (i.e. low likelihood).

Results: A preliminary analysis of 63 infants at elevated likelihood of ASD and 17 infants at low likelihood revealed more frequent face looking in the low likelihood group, M = 8.29 (per 5 minutes), SD = 5.96, compared to the elevated likelihood group, M = 4.98, SD = 4.25, p = .044.

Conclusions: Less parental face looking in the high likelihood group could be considered in line with the social motivation hypothesis (Chevallier et al., 2012; Dawson et al., 2004). However, whether reduced face looking is associated with diagnostic outcome remains to be seen once we have complete data. It is also possible that rather than being primary, the difference in face looking may be a consequence of other differences in interaction. It is noteworthy that in line with previous studies (e.g. Yu & Smith, 2013), both groups of infants directed rather few looks at the faces of their parents, perhaps contradicting the idea of infants as diligent observers of their parents faces.

432.154 (Poster) Sustained Joint Attention in Response to Expected and Unexpected Referential Gaze in Toddlers and Children with and without ASD: A Longitudinal Study
A. Vernetti, V. Donthireddy, K. All, A. Boxberger, C. Bianco, E. Hong, E. V. Edgar, C. Morgan, F. Shi, S. Macari and K. Chawarska, (1) Child Study Center, Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2) Child Study Center, Yale University School of Medicine, New Haven, CT, (3) Yale Child Study Center, New Haven, CT, (4) Yale, New Haven, CT, (5) Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (6) Child Study Center, Yale School of Medicine, New Haven, CT

Background: Difficulty with joint attention, an ability typically acquired by 12 months of age (Mundy et al., 2007) is one of the earliest signs of ASD. Toddlers with ASD exhibit basic gaze-following behavior at the end of the first year (Bedford et al., 2012). However, sustained joint attention (SJA, attention to gaze-cued objects) during toddlerhood is reduced and is associated with cognitive abilities and ASD severity (Bedford et al., 2012; Naber et al., 2008). To date, the early developmental dynamics of SJA in response to gaze direction cues in both predictable and informationally noisy environments in children with ASD remain understudied.

Objectives: To investigate SJA in response to expected and unexpected audio-visual referential gaze at 18, 30 and 42 months of age in children with typical development (TD), with developmental delay (DD) and with ASD. We hypothesize that SJA will increase over time in TD/DD children in the Expected condition, but children with ASD will evidence pervasively suppressed SJA at all ages. In the Unexpected condition, due to its greater cognitive-attentional challenge, SJA will be higher in TD compared to ASD/DD children.
Methods: 188 unique TD, DD and ASD children participated at 18, 30 and/or 42 months (Table 1). Gaze behavior was recorded during a video of an actress surrounded by 4 toys. After engaging in child-directed-speech and eye-contact, the actress exclaimed “uh-oh!” and gazed at one toy (Expected condition; 4 trials) or gazed at a toy on the opposite side of a moving toy distractor (Unexpected condition; 4 trials). (Chawarska et al., 2012, 2013). Age x group linear mixed models examined %SJA to the cued toy (dwell time at cued toy / dwell time at all non-moving toys) in Expected and Unexpected conditions.

Results: In Expected condition %SJA was above chance-level at all ages (ps < 0.001) and increased from 18 to 42m (p < 0.047) in TD and DD groups. In the ASD group, %SJA was above chance-level at 30 and 42m (p < 0.001), but not at 18m. Although %SJA increased from 18 to 42m (p < 0.017) in ASD, it was lower than in both control groups at both timepoints (p < 0.040). %SJA of TDs in Unexpected was above chance-level only at 42m (p = 0.015) and it increased from 18 to 42m (p = 0.030). Although %SJA increased from 18 to 30m in the ASD group (p = 0.049), both ASD and DD groups performed at chance-level at all ages (ps > 0.101) (Figure 1).

Conclusions: Contrary to expectations, children with ASD at 36 and 42 months evidenced robust SJA in a distractor-free setting (Expected-condition), even though effects were muted compared to DD and TD controls. The condition in which referential gaze was directed opposite the location of a perceptually salient stimulus (Unexpected-condition) proved difficult for all; only TDs showed evidence of SJA at 42 months, while DD and ASD children did not exhibit SJA at any time point. Children with neurodevelopmental disorders may share difficulties in inhibiting attention to a salient distractor, preventing input from more relevant sources. Further research is warranted to understand the disruption of SJA in ASD and DD under informationally noisy yet ecologically-valid conditions.

432.155 (Poster) Testing Executive Functioning As a Predictor of Restricted and Repetitive Behaviors and Interests in Young Children with Autism Spectrum Disorder
N. Sheikhi, G. Schmar, A. Jones and S. Faja, (1)Laboratories of Cognitive Neuroscience, Boston Children’s Hospital, Brookline, MA, (2)Boston Children’s Hospital, Boston, MA

Background: Previous studies suggest that executive function (EF) is related to restricted and repetitive behaviors and interests (RRBIs) in older youth diagnosed with autism spectrum disorder (ASD). Pellicano (2013) found that early EF predicts later RRBI expression. However, few published studies examine EF and RRBIs in autistic toddlers and preschoolers.

Objectives: To examine whether EF subdomains (inhibition, set-shifting, working memory, and delay) predict higher-order and sensorimotor RRBI presentation in two- and four-year-old autistic children.

Methods: Participants were 140 (33 females) two- and four-year-olds diagnosed with autism spectrum disorder using the Autism Diagnostic Observation Schedule–Second Edition and the Autism Diagnostic Interview–Revised (ADI-R). Individual RRB items in the ADI-R were summed to calculate higher-order and sensorimotor RRBI composites. The Mullen Scales of Early Learning measured developmental levels in the two-year-olds (n=78; M=66.9 (16.7)) and four-year-olds (n=62; M=72.5 (22.3)). Children also completed several EF tasks to create composites for inhibition, set-shifting, working memory, and delay.

Results: We first examined whether RRBIs and EF differed between two- and four-year-olds. Higher-order RRBIs were more prevalent in the older group, t(140) = -2.64, p = .009, but sensorimotor RRBIs did not differ by age, t(140) = -0.35, p = .73. EF composites also differed by age for delay, t(140) = -5.52, p < .001, working memory, t(76) = 3.47, p = .001, and inhibition, t(98) = 2.85, p = .005, but not set-shifting, t(100) = -1.41, p = .163. Due to age differences in RRBI expression, we examined correlations in the two age groups separately. Within the two-year cohort, higher-order RRBI related to age, r(78) = -0.46, p < .001, and Mullen composite, r(76) = .28, p = .01, but not EF, ps > .18. Within the four-year cohort, higher-order RRBI related to Mullen scores, r(60) = .40, p = .001, inhibition, r(53) = .27, p = .05, and delay, r(60) = .27, p = .03, but not age, set-shifting, or working memory, ps > .14. Interestingly, cognitive ability was positively associated with higher-order RRBI expression, r(53) = .40, p = .001. In a regression model with the four-year cohort, EF scores did not significantly predict higher-order RRBIs when controlling for overall developmental level. Sensorimotor RRBI were not related to age, Mullen scores, or EF in the two-year (ps > .19) or four-year (ps > .11) cohorts.

Conclusions: Our preliminary findings suggest that executive function abilities do not relate to higher-order and sensorimotor RRBI in young autistic children beyond age and developmental level, which differs from previous studies with school-age autistic children but is consistent with the emergence of RRBI during toddlerhood. Other factors, such as anxiety and emotion regulation, may modulate RRBI presentation in early stages of development. Data collection is ongoing, and we plan to examine whether parent reported anxiety scores relate to EF or RRBI in this age range.

432.156 (Poster) The Development of Neural Tracking in Infants with and without an Elevated Likelihood for Autism: Links with Language Development
Background: The ability to acquire language relies on a sophisticated processing system, developing across the first years of life. The neural mechanisms underlying language processing are not yet fully understood. However, one candidate mechanism is the neural tracking of the amplitude envelope of speech – referred to as ‘neural tracking’. More specifically, the speech envelope contains acoustic information across multiple temporal-scales – for example, at the phonological (~30-50Hz), syllabic (~4-8Hz) and lexical/phrasal rate (<2 Hz). It has been shown that neurophysiological signals follow these amplitude fluctuations, which is thought to support the parsing of the speech signal into linguistically relevant units. Furthermore, there is some evidence that neural tracking may be reduced in autistic adults (Jochaut et al., 2015). Emerging evidence from one study including infants with an elevated likelihood for autism also suggests that early tracking may be linked to subsequent language development (Menn et al., 2022). However, given the paucity of studies in infant samples, our current understanding of the development of neural tracking and its role in language development remains relatively unexplored.

Objectives: The current study aimed to investigate: 1) differences in neural tracking across infants with and without an elevated likelihood for autism (i.e., younger siblings of autistic children and infants born very preterm), at 10- and 14-months; and 2) whether any differences in neural tracking relate to language development and joint-attention.

Methods: Electroencephalography signals were recorded at 10- and 14-months as infants listened to nursery rhymes of native Dutch speakers. To assess neural tracking, a backwards multivariate temporal response function model was employed (Cross et al., 2016). This approach is based on a ridge regression fit between the amplitude envelope of the speech signal and EEG response; providing a measure of the extent to which the EEG signal decodes the speech stimulus. The predictive accuracy of the model was assessed by computing the Pearson correlation coefficient between the actual speech stimulus, and that predicted by the model.

Results: Preliminary results in infants with an elevated likelihood for autism (n = 28) indicate that the highest predictive accuracy was observed at delta (\(M = 0.026 \ (SD = 0.027)\)) and theta (\(M = 0.017 \ (SD = 0.021)\)) frequencies, whilst lower \(r\) values were observed at alpha frequencies (\(M = 0.003 \ (SD = 0.008)\)). A series of Wilcoxon rank tests revealed significantly higher reconstruction accuracy at theta (\(z = 2.42, p = 0.16\)) and delta (\(z = 2.83, p = 0.005\)) frequencies, compared to alpha. No significant difference was found between delta and theta (\(z = 1.34, p = 0.181\)). In addition, frequencies at the theta band were associated with indices of language development at 14-months (moderate effect size).

Conclusions: Higher predictive accuracy was observed at delta and theta frequencies, compared to alpha. This is consistent with the literature suggesting greater neural tracking at delta/theta rate frequencies. The data presented at INSAR-2023 will be extended – comprising the full sample (\(N = 87\)) and group differences across infants with and without an elevated likelihood for autism.

432.157 (Poster) The Developmental Six-Component Model of Reward Processing: A Reconceptualization and Literature Review of Typical and Autistic Development

C. C. Clements, K. Ascunce and C. A. Nelson, (1)Labs of Cognitive Neuroscience, Boston Children's Hospital Labs of Cognitive Neuroscience, Brookline, MA, (2)Yale University, New Haven, CT, (3)Department of Developmental Medicine, Boston Children's Hospital, Boston, MA

Background: Differences in reward processing have been associated with numerous conditions, including autism and ADHD. Many attempts to understand reward processing characterize differences in neurodivergent populations in adolescence and adulthood; however, divergence may begin much earlier. In fact, the typical developmental progression of reward processing in infancy and early childhood is poorly understood. We reconceptualize classic infant developmental constructs such as preferential looking into a Six-Component Developmental Model of Reward Processing: an infant- and young child-focused framework to guide research and assessment of reward processing across development. The primary application of this transdiagnostic work is to autism, where the motivation hypothesis suggests differences between autistic and nonautistic individuals in what feels motivating and rewarding. These differences may manifest as hyperfocus, strong passions, and ability to develop highly specialized skills. Reward processing might lie at the core of these autistic features, but little is known about how or when reward processing develops. Understanding its development could allow us to support the development of beneficial related traits in both autistic and nonautistic individuals.

Objectives: To review current findings on components of reward processing in autistic and nonautistic development, then provide a conceptual framework and experimental paradigms to improve assessment of reward processing developmentally.

Methods: The extant developmental literature including recent textbooks, systematic reviews, and meta-analyses was reviewed to build a conceptual framework and estimate a timeline of each component’s emergence in the social and nonsocial domains. We describe and recommend new and existing experimental paradigms to assess each developmental component of reward processing longitudinally from infancy, filling gaps.
Results: Six components of reward processing were identified — association, discrimination, preference/valuation, effort, anticipation, and response (Figure). Selected evidence suggests emergence between birth and six months (Table). Application of this model to autism led to a reinterpretation of existing disparate results around the motivation hypothesis. For example, we found reported differences in discrimination abilities (slower habituation, reduced neural suppression) as early as 8-10 months in infants later diagnosed with autism, consistent with an ability to maintain interest in a stimulus long after nonautistic individuals may become ‘bored’. However, at odds with this idea are findings from other studies reporting a stronger novelty preference among infants later diagnosed with autism; this processing bias could manifest as heightened distractibility. On the other hand, we found almost no autism developmental research on anticipation nor contingency learning, two essential components of reward processing. Novel paradigms could fill this gap, such as adapting the conjugate mobile paradigm to incorporate the progressive ratio task (KickMORE).

Conclusions: The proposed framework reconceptualizes the extant literature and could be used to guide future research. Longitudinal studies of the suggested experimental paradigms could elucidate the developmental trajectory of the six components and timing of potential sensitive period(s) for each component. Given previous findings that only some aspects of reward processing differ between autistic and nonautistic individuals, it is important to identify which aspects lead to beneficial traits, and support development of such traits.
to infant siblings of children with ASD who are younger than 6 months can add to our understanding of the emergence of ASD by quantifying very early embodied social attention in naturalistic settings. Yet the feasibility of using HMET in younger infants or infants at elevated genetic likelihood for ASD has yet to be established. At this age, infant acceptability can be impacted by sensory challenges that decrease tolerance for wearing HMET headgear. Data quality can be negatively impacted by motoric actions, including reaching and rolling, that interfere with camera stability. The feasibility of mobile eye tracking in young infants, including acceptability and data quality, is important to document and compare across groups of interest.

Objectives:

This study aims to determine the feasibility of using HMET to study infant attention in 4-month-olds and compare feasibility between infants at elevated (EL) and low (LL) genetic likelihood for ASD.

Methods:

Infants and their caregivers (LL=10, EL=16) were enrolled in a longitudinal study of social attention prior to 4 months of age. At 4 months, participants completed four interactions that cut across two positions (supine and reclined) and two interaction contexts (infant-caregiver and infant-caregiver-toys) while wearing a HMET unit (see Figure 1). Two aspects of feasibility across groups were analyzed: infant acceptability of the procedure and eye image data quality (see Table 1). To examine motor ability as a possible contributor to data quality, infant reaching and rolling ability (in supine) were also assessed.

Results:

In regard to infant acceptability, infants completed between 2-3 of the 4 interactions during each study visit (M=2.77, SD=1.25); 96.15% (n=25) completed ≥1 full interaction and 46.15% (n=12) completed all 4 interactions. Results revealed no differences in acceptability based on group status (EL vs. LL: t(20.95)=1.21, p=.24), infant position (t(101.5)=.84, p=.40), or interaction contexts (t(101.88)=-.42, p=.67).

Similarly, there were no differences in data quality (%time with “good” eye image) based on group status (t(80.61)=.86, p=.39), position of the interaction (t(99.86)=.42, p=.68), or interaction contexts(t(88.92)=.50, p=.62).

In terms of motor abilities, 50% of infants were reaching. Reaching ability did not impact infant acceptability (t(22.86)=-.92, p=.37), but had a marginally significant effect on data quality (t(21.78)=1.80, p=.08). Similarly, 50% of infants were rolling from their back to their side. Rolling ability did not affect infant acceptability or data quality (p’s>.05).

Conclusions:

This study indicates that EL and LL infants show similar acceptability in completing an HMET session. Additionally, motoric ability had no effect on infant acceptability and a marginal effect on data quality. These findings demonstrate preliminary feasibility of collecting HMET data with 4-month-old infants and that data quality is comparable across infants with varying motor abilities and infants at elevated and low likelihood for ASD. HMET is a promising tool for studying very early social attention in EL infants.

432.160 (Poster) The Overlap and Distinction of Childhood Temperament Profiles for Autistic and ADHD Youth

H. E. Morton1, M. Kozlowski2, J. Nigg3 and S. Karalunas4, (1)Oregon Health & Science University, Binghamton, NY, (2)Oregon Health & Science University, Portland, OR, (3)OHSU, Portland, OR, (4)Purdue University, West Lafayette, IN

Background: Evolving criteria now permit co-occurring diagnoses of Autism and Attention-Deficit/Hyperactivity Disorder (ADHD), with 40-60% of autistic youth also meeting diagnostic criteria for ADHD (Minohar et al., 2018; Stevens et al., 2016). The combined autistic (AT)+ADHD neurotype is associated with more substantial support needs (Zablotski et al., 2020) and delayed autism diagnosis (Kentrou et al., 2018), highlighting the need for better understanding of the overlap and distinction of autism and ADHD. Childhood temperament may be useful to characterize heterogeneity within neurodivergent youth (Karalunas et al., 2019) and enhance understanding of autism and ADHD beyond diagnostic labels to inform tailored supports.

Objectives: To identify profiles of childhood temperament across a neurodiverse sample and examine the distribution of autistic and ADHD youth within these profiles.

Methods: Parent report of youth temperament was collected via the Temperament in Middle Childhood Questionnaire (TMCQ; Simonds et al., 2007; Simonds & Rothbart, 2004) within two, community-recruited samples (n=1698, Mage=9.85, SDage=1.92) enriched for autism.
Background: During the first 2 years of life, social-communicative abilities develop rapidly. These developmental changes in behaviour are accompanied by changes in the brain, which reflect the emergence of the so-called “social brain”. Oscillatory activity of the ongoing electroencephalogram (EEG) is one way to investigate how these new networks develop in infants. Spectral power in various frequency bands extracted by spontaneous EEG has been associated to different functional correlates. In particular, theta (4-6 Hz) has been associated with the processing of social stimuli and social behaviour in infants. Work in this area is important not only for testing theories of typical social development, but also for identifying new ways to study the mechanisms underlying the early emergence of social and communication difficulties, such as the ones associated with autism. Research on early biomarkers has reported atypical brain development in children with autism and infants at elevated likelihood for autism (namely siblings and preterms). Among these findings, EEG spectral power (both in resting state and in response to specific stimuli) has also been associated with autism and likelihood of autism.

Objectives: In the present study we investigate whether there are differences in the theta spectral power in response to social vs non-social dynamic stimuli in infants with elevated likelihood (EL) and typical likelihood (TL) for autism.

Methods: 32-channel spontaneous EEG signal was recorded with an ActiChamp amplifier and Brain Vision Recorder (Brain products, version 1.21.0402) from 5 EL (3 females) and 20 TL (10 females) infants between 10 and 14 months old. The children were presented with Social (4 nursery rhymes with gestures sang by two women) or Non-Social (5 vignettes of child-appropriate dynamic toys) videos of approximately 1-min duration. The videos were repeated 3 times during the session and the order of presentation was counterbalanced. The EEG signal was cut into 1-second segments and manually edited for artifacts. In order to obtain frontal theta (4-6 Hz) power indices, absolute power was extracted and averaged among frontal electrodes (F3 and F4).

Results: The current results are preliminary, as data collection is ongoing. Frontal theta power was significantly larger for the Social compared to the Non-Social condition in the TL children (\( p = 0.017 \)). This effect of condition seems to not be present in the EL group (\( p = 0.812 \)). Because of the currently limited sample and the unbalanced group sizes, we did not yet compare the two groups. Complete results of the full sample will be presented at the conference.

Conclusions: These preliminary results could: a) support findings from previous studies suggesting that theta power is sensitive to social stimuli in TL infants and might reflect activity of the emerging “social brain”; b) EL children might not show this pattern. However, final conclusions cannot be drawn until the full sample has been collected. Theoretical and clinical implications will be discussed.
Background: Studies have shown that spontaneous motor activity of infants later diagnosed with Autism Spectrum Disorder (ASD) appears to be impaired already in the first months of life. The research indicates that the motor patterns within this population are less developed and could potentially serve as early markers of ASD.

Objectives: In the present study, we aim to investigate the use of DeepLabCut (DLC), an open-source toolbox contained within a Python package, for recognizing the early motor development patterns of individuals later diagnosed with ASD or another neurodevelopmental disorder (NDD). Another goal of this work is to train a machine learning algorithm that could distinguish between individuals with and without an NDD diagnosis, based on the motor features considered to be meaningful for identification of pathological motion patterns, i.e., mean velocity and acceleration, as well as their cross-correlations, skewness of velocity distribution, periodicity in trajectories and velocities, area differing from moving average, and area out of standard deviation of moving average.

Methods: The longitudinal data was collected by the Italian Network for early detection of Autism Spectrum Disorder (NIDA) and consisted of infant videos recorded at 10 days, 6, 12, 18, and 24 weeks of life. We included 174 videos of individuals with elevated likelihood of ASD (86 females, 88 males) who have an older sibling with a clinical diagnosis of ASD. To track the trajectories of infants’ hands and feet in space, we used the DLC markerless pose estimation method. To check the reliability of DLC tracking performance the detected positions were compared with the results obtained by MOVIDEA software using the Percentage of Correct Key-points (PCKh) accuracy metric.

Results: The model trained within DLC can successfully track infants’ hands and feet movement with a mean accuracy of 3.84 pixels. We obtained satisfactory PCKh values of 96.6% (left foot), 96.2% (right foot), 80.9% (left hand), and 82.8% (right hand). Nevertheless, the infants’ back of the hand was often not visible. Therefore, the motor features were computed using only the feet trajectories.

Conclusions: DLC is a useful method that can be applied to track infant movement. It allows further computation and analysis of motor patterns that could be useful in early diagnosis of ASD. In the nearest future, we intend to feed the extracted features to a machine learning classifier and verify whether they could predict an NDD diagnosis.

432.163 (Poster) Visual Attention to the Face and Mouth during Infant-Directed Song and Speech across Development in Autism and Typical Development

C. Alviar1, M. K. Sahoo2, N. R. Fram3, C. Nicholson4, A. Klin5, W. Jones6, L. A. Edwards7, and M. D. Lense8, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA, (4)Marcus Autism Center, Atlanta, GA

Background: Infant-directed (ID) song and speech both promote children’s attention with ID song being particularly effective at sustaining infants’ attention in typically developing (TD) infants and those with ASD (Macari et al., 2020). However, specific patterns of social visual engagement across development and in relation to song characteristics are unknown. Probing children’s social visual engagement during ID song and speech may inform processes by which such activities scaffold social and communication development.

Objectives: Examine the trajectories of overall visual attention, attention to the face, and attention to the mouth for ASD and TD infants/toddlers across the first two years of life during infant-directed (ID) song with and without gestures, and ID speech.

Methods: 143 TD and 65 ASD male infants viewed audiovisual clips of naturalistic ID speech without gestures, ID song without gestures, and ID song with gestures, while eye-tracking data was collected longitudinally at 6, 9, 12, 18, and 24 months.

We ran 3 mixed-effects models with random intercepts and random slopes for age per subject predicting either total fixations, fixations to face, or fixations to mouth with a linear and a quadratic component of age, clip category, diagnosis, and all interactions.

Results: TD infants fixated significantly more than ASD infants overall (B=0.05, p<.001). However, both TD and ASD infants exhibited higher overall fixation rates for song over speech (B=0.03, p<.001), and for song with gesture over song without gesture (B=0.04, p<.001). Fixations increased with age overall during the first year across diagnostic groups, and continued to increase for speech during the second year for TD but not ASD infants (B=3.2, p<.05, Figure 1A).

Attention to the face increased over development across categories for TD but not ASD (B=2.6, p<.01). This group trajectory difference was most apparent for song with gestures (B=−4.5, p<.01), with attention increasing for TD, while decreasing for ASD. Fixations to the face, were also lower overall across diagnostic groups in song with gestures than in the other two contexts (B=−1.1, p<.001, Figure 1B).

Both TD and ASD infants’ overall attention to the mouth increased with age (B=2.9, p<.001), as in previous studies. Attention to the mouth was significantly higher overall during song without gestures than during song with gestures (B=−0.08, p<.001) or during speech (B=−0.12, p<.001) across diagnostic groups (Figure 1C).
Conclusions: Infants with and without ASD engage differently with ID song and ID speech across development. ID song potentiates overall visual engagement over a longer developmental time window in ASD. Song also promotes mouth-looking for both TD and ASD, of interest given mouth-looking’s association with expressive language skills (Habayeb et al., 2021). However, the group differences in overall attention and attention to the face indicate the mechanisms and adaptive value of attention to the mouth might vary across diagnostic groups. Future analyses will examine children’s individual differences (e.g., language skills, musical preferences), and stimuli level characteristics (e.g., gestures, tempo) to inform mechanisms by which song impacts attentional allocation and potential clinical implications in early intervention for ASD.

Background: Early detection of autism spectrum disorder (ASD) characteristics by parents or primary caregivers during infancy can lead to early diagnosis and interventions. While various ASD signs can appear within 6 to 18 months, the timing in which parents raise concerns about their children's ASD characteristics varies (Tanner & Dunavi, 2021). Understanding the factors that influence parents' perception of ASD characteristics in their children can help with early detection.

Objectives: To identify factors that influence the early detection of children's ASD signs, we explored various characteristics of the child and their caregivers.

Methods: Based on the data collected from Korean families, we explored the parents' age during pregnancy, educational background, occupational group, and family economic status as parental variables. The severity of ASD symptoms measured by the ADOS-2 comparison score and the timing of the child's first word was also included and evaluated using Pearson's correlation. Parental awareness of initial concerns was identified using the ADI-R question item and divided into five categories. Comparison between parents' perceived timing of risk signs and trained administrators were compared using t-tests.

Results: Data from 1608 individuals with ASD were analyzed (M=76.65, SD=51.21). The average age that parents perceived difficulties was 25.2 months (range=1~160month, SD=15.63), while experts perceived ASD-related risk signs around 20.2 months (range=1~84month, SD=9.47). Language development and communication (39.8%; language delay, etc.) were mostly reported, followed by social interaction (37.7%; eye contact, response to name, play alone, etc.), other developmental characteristics (10.6%; late walking, sleep problems, etc.), repetitive restricted behaviors (8.8%; repeated spinning, etc.), and cognitive difficulties (1.8%). 1.3% reported no concerns. We found that delays in first-word usage were correlated with earlier detection (r=-.096, p<.01). The age at which the mother was pregnant and the mother's occupational group showed a small but significant correlation with when concerns were raised (r=-.061, -148, p<.05, <.01). These variables were also related to the difference between the time of when the parent recognized the difficulties and when the expert evaluated them (r=-.067, -.082, p<.05). On the other hand, the severity of the current ASD symptoms did not correlate with the timing of detection (r=-.29).

Conclusions: The timing of parents' recognition of their children's ASD signs was not much different from that of experts, but considering the emphasis on early detection and early intervention before 24 months, it will be necessary to help them perceive their children's difficulties earlier. In the case of noticeable delays, such as the delay of the first word, led parents to recognize ASD signs early, and the mother's variables such as the pregnancy age and occupational group influenced early detection. While communication and social domains were prominent as factors perceived by parents, core symptoms on DSM-5 such as RRB were not well recognized. Therefore, explicit parental education on typical development in infancy and atypical development will be very important.

Background:

A meta-analysis of face processing studies reported that the latency of the N170 ERP component was larger in children and adults with Autism Spectrum Condition (ASC) compared to non-autistic children and adults (Kang et al. 2018). It was suggested that the N170 latency could serve as a possible stratification marker of ASD that is robust to age, sex, and cognitive functioning. However, the meta-analysis involved only three children younger than 5 years.

432.164 (Poster) When, Why, and What Causes Parents to Raise Concerns about ASD?

G. Bong1, H. Yoo1, D. Y. Song2, Y. Hong2 and J. Choi1, (1)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (3)Department of Psychiatry, Seoul National University, Seoul, MD, Korea, Republic of (South), (4)Bridgekids Behaviour Consulting, Richmond, BC

Conclusions: Infants with and without ASD engage differently with ID song and ID speech across development. ID song potentiates overall visual engagement over a longer developmental time window in ASD. Song also promotes mouth-looking for both TD and ASD, of interest given mouth-looking’s association with expressive language skills (Habayeb et al., 2021). However, the group differences in overall attention and attention to the face indicate the mechanisms and adaptive value of attention to the mouth might vary across diagnostic groups. Future analyses will examine children’s individual differences (e.g., language skills, musical preferences), and stimuli level characteristics (e.g., gestures, tempo) to inform mechanisms by which song impacts attentional allocation and potential clinical implications in early intervention for ASD.

Background:

A meta-analysis of face processing studies reported that the latency of the N170 ERP component was larger in children and adults with Autism Spectrum Condition (ASC) compared to non-autistic children and adults (Kang et al. 2018). It was suggested that the N170 latency could serve as a possible stratification marker of ASD that is robust to age, sex, and cognitive functioning. However, the meta-analysis involved only three children younger than 5 years.

432.165 (Poster) Are ERP Responses to Faces Atypical in Young Children at Elevated Likelihood for Autism Spectrum Disorder? a Meta-Analysis

K. Fico1, G. Bussu1, C. Tye2, M. A. Krol3, J. K. Buitelaar2 and S. Hunnius1, (1)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, Radboud University, Nijmegen, Netherlands, (2)Donders Institute for Brain, Cognition and Behaviour, Radboudumc, Nijmegen, Sweden, (3)Development and Neurodiversity Lab, Department of Psychology, Uppsala University, Uppsala, Sweden, (4)Department of Psychology, King's College London, London, United Kingdom, (5)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (6)Department of Cognitive Neuroscience, Radboud University, Nijmegen, NETHERLANDS, (7)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands

Conclusions: Infants with and without ASD engage differently with ID song and ID speech across development. ID song potentiates overall visual engagement over a longer developmental time window in ASD. Song also promotes mouth-looking for both TD and ASD, of interest given mouth-looking’s association with expressive language skills (Habayeb et al., 2021). However, the group differences in overall attention and attention to the face indicate the mechanisms and adaptive value of attention to the mouth might vary across diagnostic groups. Future analyses will examine children’s individual differences (e.g., language skills, musical preferences), and stimuli level characteristics (e.g., gestures, tempo) to inform mechanisms by which song impacts attentional allocation and potential clinical implications in early intervention for ASD.
Objectives:

To establish whether the N290/P400 complex – the developmental precursor of the N170 at later age – also indexes atypical neural mechanisms of face processing in very early childhood. Our first aim was to meta-analyze the literature investigating differences in N290 and P400 response to faces in infants and young children with an elevated likelihood (EL) of autism in comparison to low likelihood children (LL). Our second aim was to investigate whether the EL and LL children differ already in low-level visual processing (P1 component) to rule out any potential carry over effects in our later components of interest.

Methods:

The meta-analysis was conducted in line with the PRISMA guidelines and prospectively registered with PROSPERO (registration no. CRD42022302537). Across 5 databases 1139 records were identified, of which 20 studies met the inclusion criteria. Overall, data were collected from 280 EL children and 357 LL children (8 to 48 months old). Random effects meta-analyses were performed using the ‘meta’ package in R.

Results:

P400 amplitude (but not the latency) was significantly larger for EL compared to LL children ($g=-0.2$, $k=18$, $p<0.0001$). There was no evidence of publication bias and heterogeneity between effect sizes for the P400 component. No group differences were found for the P100 and N290 amplitude and latency. The only meta-analytic model that was powered enough to reach a precision of above the normative 80% threshold was the P400 amplitude model. The rest of models were all underpowered (average precision power of 23%).

Conclusions:

We found no differences in the amplitude and latency of P100 and N290 but a significantly smaller P400 amplitude for EL compared to LL children. This was in contrast to our hypothesis given that the N290 is thought to be a precursor of the adult N170 and one of the most frequently studied face-specific ERP components. The P400 has been associated with face processing as well as allocation of attention and may play a crucial role in novelty or saliency processing. In previous studies, group differences in P400 amplitude have only been reported when task demands are high, perhaps reflecting an impact of attention on the component, as attention is often impaired in ASD. This also might explain the lack of significant findings for the N290 component as attention may play a smaller role in N290 responses as it reflects a more automatic process of face detection.

432.166 (Poster) Examining the Agreement between Caregiver-Reported and Direct Assessment of Child Imitation

M. Howard, D. Oosting, W. L. Stone, A. Wainer, B. R. Ingersoll and A. S. Carter, (1)Psychology, Michigan State University Psychology Department, East Lansing, MI, (2)University of Massachusetts, Boston, MA, (3)Psychology, University of Washington, Seattle, WA, (4)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (5)Psychology, Michigan State University, East Lansing, MI, (6)Department of Psychology, University of Massachusetts Boston, Boston, MA

Background: Caregivers are important informants of child behavior beyond what is observed in the clinical setting; however, extant research is mixed on the degree of alignment of caregiver reports with direct observations. Low agreement between parent report and ratings of home-video observations of social-communication behaviors was reported in one study of autism symptom onset (Ozonoff et al., 2011). In contrast, agreement between caregiver-report and direct assessment of child language and fine motor abilities has been found (Miller et al., 2017). Early imitation skills are often reported on and directly assessed during developmental evaluations in early childhood because early imitation skills are related to later gains in language and social interaction skills (Pittet et al., 2022; Yoder et al., 2009). Yet, little is known about the agreement between caregiver reports and ratings of direct observations of child imitation skills, despite the measurement of this competency in diagnostic and intervention decision-making.

Objectives: We evaluated agreement between caregiver-reported and direct assessment ratings of child imitation in toddlers with social communication delays indicative of possible autism spectrum disorder.

Methods: Sixty-three caregivers (56 mothers, 6 fathers, 1 grandmother) and children (40 boys, age $M=26.30$ months) participated in a research study examining the effectiveness of caregiver-implemented Reciprocal Imitation Teaching, a Naturalistic Developmental Behavioral Intervention, delivered through the Part C Early Intervention system. Caregiver-reported imitation was measured using items from the Parent Interview for Autism-Clinical Version, Vineland Adaptive Behavior Scales-Third Edition, Brief Infant-Toddler Social and Emotional Assessment, and a new questionnaire called ‘My Toddler’s Social Communication’. The caregiver-reported measures were standardized and combined to create a composite imitation scale (Total Imitation Scale) that was used for analyses. Direct assessments of children’s prompted and spontaneous imitation were collected through an experimental caregiver-administered in-home assessment, the Communication Play Protocol (adapted from Adamson & Bakeman, 2016). First, we examined the internal consistency and subscales of the Total Imitation Scale. Next, we ran correlations between the Total Imitation Scale and the direct assessments of child imitation. We
hypothesized that the Total Imitation Scale would demonstrate adequate internal reliability and would be significantly related to direct child imitation measures.

Results: The Total Imitation Scale had strong internal reliability (Cronbach’s α = .87) and was significantly correlated with both direct measures of prompted child imitation ($r = .36, p = .003$) and spontaneous child imitation ($r = .69, p < .001$). These direct measures of prompted imitation and spontaneous imitation were also significantly related ($r = .35, p = .005$).

Conclusions: Caregiver reports of child imitation were significantly, positively correlated with direct assessments. This agreement between caregiver-reported and direct assessments of child imitation skills suggests that caregivers can be reliable informants during the evaluation process when assessing imitation. Interestingly, the correlation between caregiver-reported imitation and direct assessments was stronger for measures of spontaneous imitation. Future research should examine the validity and reliability of caregiver report for spontaneous versus prompted imitation, and whether there is change in agreement over time.

Epidemiology

PANEL DISCUSSION — EPIDEMIOLOGY

203 - I Am Not an "Other": Cross-Cultural Representation and Health of Indigenous, Immigrant, or Puerto Rican Autistic Individuals in Health Services Data

Panel Chair: Teal Benevides, Institute of Public and Preventive Health, Augusta University, Augusta, GA

Autism is represented in the literature by primarily young white males, creating a cycle of marginalizing work that fails to address needs of people outside of this demographic. Although strides in increasing diversity in autism research samples have occurred in recent years, limited work has addressed what is known about health of people generally left out of research studies: indigenous individuals, immigrants, non-English speaking individuals, and individuals from Puerto Rico. In demographic descriptions for race, ethnicity, and geographic location, individuals from groups with small samples are classified as “Other”. This panel’s sessions leverage existing data to capture health outcomes of groups who are infrequently described due to small samples or inadequate recruitment. We point to ways in which research can be modified to be more culturally relevant for autistic people and families. Panel topics are exploratory, and although panelists focus on data from the United States, we wish to begin a conversation with attendees about what we can learn when we disaggregate large data to understand needs and gaps as a path to conversations with community leaders and partners. We will emphasize the importance of this knowledge for international discussion because immigration and challenges for indigenous individuals exist worldwide.

203.001 (Panel Discussion) Health and Health Care Among Indigenous Pacific Islander, Alaska Native, and Native American Autistic Adults Enrolled in U.S. Medicare and/or Medicaid

T. W. Benevides and A. Roux, (1)Institute of Public and Preventive Health, Augusta University, Augusta, GA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

Background: Limited scientific knowledge in the field of autism has been generated with samples representing culturally and racially diverse individuals, including indigenous individuals from Pacific Islander, Alaska Native, and Native American communities. Indigenous autistic groups may be at risk for adverse health outcomes and receipt of inadequate health care.

Objectives: The purposes of this study were to 1) describe the demographic characteristics of indigenous autistic adults enrolled in U.S. Medicare and/or Medicaid, which frequently cover medical care for autistic individuals, and 2) quantify chronic health conditions and medical utilization compared to non-indigenous adults on the spectrum.

Methods: We used Medicare-Medicaid Linked Enrollees Analytic Data Source (MMLEADS-2012) data. MMLEADS are aggregated annual claims of all individuals in all U.S. states enrolled in Medicaid on the basis of disability, dually-eligible for both Medicaid and Medicare, and those enrolled in Medicare. MMLEADS-2016 exists but does not contain chronic health condition variables, making 2012 data the best source for this research. We included adults identified as American Indian or Alaska Native (AIAN; n=1,455) or Pacific Islander (PI; n=1,179). Chi-square and multivariate logistic regressions adjusting for age, sex, intellectual disability, geographical location, and rurality compared indigenous individuals with non-indigenous adults on the spectrum (n=185,954) on chronic conditions, annual emergency department (ED) use, and prescription drug use.

Results: See Table 1. Frequency of dual-eligibility was significantly lower among PI (29%) compared to AIAN (46.9%) or non-indigenous (44.2%) adults. AIAN adults were significantly more likely to have a chronic health condition compared to PI adults and non-indigenous individuals. Across age groups, AIAN individuals were significantly more likely to have a chronic condition compared to non-indigenous individuals at younger ages: 18-25-year-olds (OR=1.27, 95%CI: 1.07-1.50), 26-35-year-olds (OR=1.32, 1.08-1.62). PI
individuals were significantly less likely than non-indigenous individuals to have a chronic health condition at younger ages (18-25y, 26-35y). The odds of having a chronic health condition were 4 times higher among PI aged 56-65 years compared to same-aged non-indigenous individuals (OR=4.31, 1.00-18.63). AI/AN individuals had double the odds of having a chronic condition at ages 56-65 years compared to non-indigenous individuals (OR=2.21, 1.03-4.72). Rates of any annual ED use were significantly lower among PI (10.8%) compared to AI/AN (30.3%) and non-indigenous autistic adults (27.3%). PI autistic adults had significantly fewer prescription drug fills annually (median prescriptions=22) compared to AI/AN (median=32) and non-indigenous adults (median=38).

Conclusions: This is one of the first studies to identify healthcare conditions and service use among a large sample of indigenous autistic adults in the U.S. Unfortunately, most analyses of claims data collapse indigenous individuals together into a single group, or exclude them altogether, hindering understanding of individuals and care needs. Our findings suggest that types of coverage differ (Medicare, Medicaid, both), as well as rates of chronic conditions, use of the emergency department, and prescription drugs. Next steps should include mixed-method approaches to engage these communities about priorities and desired approaches for health outcomes to ensure research aligns with preferences for care and care outcomes.

203.002 (Panel Discussion) Autistic and Immigrant: An Analysis of Health of Autistic Immigrant Adults in the U.S. Medicaid Program
W. Song, L. Shea and S. Tao, (1) A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2) A.J. Drexel Autism Institute, Philadelphia, PA, (3) Drexel University, Philadelphia, PA

Background:

About 22.1 million immigrants, including lawfully present and undocumented, lived in the United States in 2020. Nonelderly noncitizens with disabilities were less likely to be insured than citizens, which poses challenges to accessing health care support. Eligibility restrictions for Medicaid and barriers to enrollment among eligible individuals, contribute to the higher uninsured rate among noncitizens. Previous studies have demonstrated that the states that choose to expand Medicaid coverage showed an increase in Medicaid enrollment among immigrant children. However, few policy efforts target immigrant adults. Medicaid is the largest insurer in the U.S. for autism services and may be the only available insurer for many disabled adults. To meet the needs of autistic immigrant adults, it is essential to understand the disparities in physical and mental health conditions by immigrant status among the Medicaid population in the U.S.

Objectives:

The purpose is twofold: (1) identify the prevalence of various health conditions, both mental and physical conditions, in the population of autistic immigrant adults enrolled in Medicaid in 2016; (2) compare the prevalence of co-occurring conditions in immigrants to the U.S. citizens among autistic adults.

Methods:

We utilized administrative claims from the Centers for Medicare & Medicaid Services (CMS) Transformed Medicaid Statistical Information System Analytic Files (TAF) data file, containing data from all 50 states and Washington DC. Our population of autistic adults (18-64 years old) was identified if they had at least two outpatient or one inpatient claim with an ICD-10 diagnosis (F84. x) who were Medicaid beneficiaries in 2016. The immigrant status was coded as (1) qualified non-citizen (QNC; N=2,952) and (2) U.S. citizen (N=240,037).

Results:

The sample characteristics and prevalence of co-occurring conditions are presented in Table 1. Differences in age, sex, and urbanicity between groups were modest. The QNC group had a higher percentage of Black, Hispanic/Latino, and Asian/Hawaiian/Pacific Islander than the citizen group. The QNCs were also more likely to have intellectual disabilities (p<0.001). Among the five co-occurring mental health conditions, the most diagnosed condition among QNCs was anxiety, followed by ADHD. The QNC group had a higher percentage of having Alzheimer’s disease than citizens (p<0.001). The physical health conditions with the highest prevalence among QNCs were epilepsy, hypertension, and hyperlipidemia. The QNCs were more likely to have epilepsy (p=0.003), diabetes (p<0.001), hyperlipidemia (p=0.003), and hypertension (p<0.001) than citizens.

Conclusions:

Our study is the first investigation of the health of autistic immigrant adults. Our analysis showed immigration status differences in some of the most common physical health conditions. These disparities are likely driven by environmental, behavioral, and psychosocial factors, which warrants future research efforts. Autistic immigrant adults may be at a double disadvantage, at higher risk of premature mortality and chronic health conditions associated with autism, yet also facing discrimination and lower access to services as members of immigrant groups. Understanding the increased risk for specific co-occurring conditions in immigrant groups can support the formulation of joint
access to services when there are multiple service needs to ensure health equity.

Background:

Calls to action from the autism community have underscored the need to center the experience of autistic individuals from multiple viewpoints and residence. Limited research has elevated the experiences of autistic individuals in US territories, including the oldest and most populous, Puerto Rico (PR). PR residents are US citizens who have nonvoting representatives in US governing bodies. Most of the PR population reports being Hispanic or Latino (98.9%). PR operates an island-wide public health insurance (Medicaid) program, the Government Health Plan or Vital, that was expanded under the Affordable Care Act. Eligibility is based on age, income, or disability. The CDC ADDM Network in the US does not include Puerto Rico, but it has identified that the number of Hispanic children with an autism diagnosis is lower than other groups.

The limited research base that has sought to understand the experiences of autistic individuals and their families or caregivers in PR has been focused on epidemiologically-focused research, such as prenatal exposures that utilized population-based sibling cohort studies. Efforts to identify mental health diagnoses and service usage among parents and relatives found higher rates of several MH diagnoses. Recent research in Puerto Rico recommended screening procedures in Latino populations to link to evaluation referrals.

Objectives: This study seeks to identify the characteristics of Medicaid-enrolled autistic individuals in Puerto Rico.

Methods: National (US) Medicaid claims for 2016 for all enrolled autistic individuals of all ages were utilized. Autism and intellectual disability were identified through validated algorithm from the Chronic Condition Warehouse (CCW) which aligns with the strategy deployed in the majority of autism research.

Results: Medicaid-enrolled autistic individuals in PR included mutually exclusive groups of individuals with co-occurring intellectual disability (ID, n=452) and without co-occurring intellectual disability (n=3,921). Comparison groups of individuals with intellectual disability only (n=5,479) and a random sample of other Medicaid enrollees (n=6,554) in PR were also compiled. Both autism groups were younger than the ID and other Medicaid enrollee groups. Almost half (44%) of the autism-only group was under the age of 10 and 36% were between ages 11 and 18. Fewer than one in five individuals in the ASD-only group were over age 18. The autism+ID group was older on average, with 12% under the age of 10, and 32% were ages 11 to 18. More than half (56%) of the ASD/ID group was over the age of 18. Ages were evenly distributed across the ID-only and random Medicaid sample population. With recently acquired data through 2019, groups will be updated across age and demographic/clinical characteristics.

Conclusions: Our initial analyses identified a robust group of autistic individuals enrolled in Medicaid in PR. Most individuals were youth or young adults, in contrast to their peers with ID. Population-level data, including Medicaid, presents a unique opportunity for next steps to identify their healthcare access and service use, as well as demographic and clinical characteristics. Examining the specific characteristics and healthcare service use of this group presents a new and needed set of data to drive important programmatic change.

203.004 (Panel Discussion) Health of Latinx Transition-Age Youth

K. Lopez, L. Shea and J. Ventimiglia*, (1)Arizona State University, Phoenix, AZ, (2)A.J. Drexel Autism Institute, Philadelphia, PA, (3)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA

Background: The Latine population has been rapidly growing in the US, reaching 62.5 million in 2021. The rapid growth has designated the Latine population as the largest ethnic group in the United States. Improved methods of diagnosis and heightened autism awareness, has increased the identification of autism among Latine children and youth in recent years. This improvement in early detection of autism and associated efforts in early intervention for Latine children have been promising for young children and families. Yet there is very little investment in understanding and supporting the growing youth and adult Latine autistic populations. Understandably, the greater number of early diagnoses, suggests an expected surge in youth and adult Latine autistic individuals in need of care. To serve their needs it is necessary that we have an understanding of their demographics, living circumstances, as well as physical and mental conditions. Large datasets, such as the National Medicaid claims database which provides substantial number of individuals with disabilities services across the lifespan, offers opportunities to explore these areas among racial/ethnic subgroups.

Objectives: The objective of this study is to explore the demographics of the Latine autistic subgroup within the 2016 National Medicaid claims database.
Methods: This study utilized national (US) Medicaid claims for the year 2016 from 50 states to explore demographics among the Latine subsample of autistic service users. Diagnoses of autism, ID, and chronic conditions were identified using validated algorithms from the Chronic Condition Warehouse (CCW), which have also been used in the majority of autism research to date. Tables were generated using data from the T-MSIS Analytic File Medicaid claims data.

Results: Of the total number of Medicaid beneficiaries (n=894,529), n=185,540 were Latine and had an autism diagnosis. White autistic Medicaid beneficiaries were the largest racial group (62.9%) followed by Black beneficiaries (18.6%) in the all other races group. Twenty percent of the Latine autistic subgroup were also classified with an intellectually disability. Ages ranged <18 to 65+y, with most of the sample (82.9%) falling in the <18 age group, followed by the 22-40 age group. Of the Latine autistic Medicaid beneficiaries, 78.8% were male, and 86.9% lived in urban areas. Most Latine autistic beneficiaries were eligible for Medicaid due to disability (56.9%), followed by eligibility due to poverty status (31.2%). Approximately 17% of the Latine autistic beneficiaries had one chronic condition, with 4.5% having 2 or more chronic conditions, and the remaining having none. Lastly, the majority of Latine beneficiaries resided in California (n= 47,647) with the fewest living in Idaho and West Virginia (suppressed).

Conclusions: The present study provides a glance of autistic Latine Medicaid beneficiaries. By exploring the demographics of this group we set the stage for future analyses of services and factors that contribute to service access among autistic Latine Medicaid beneficiaries. This study provides implications for state and national health care programs and policies. Despite the promise of the study, it includes several limitations. For instance, the scope of the data did not allow for separate analyses of Latine subgroups.
Conclusions: Racial and ethnic disparities in the quality of developmental assessment records may contribute to previous reports of excess prevalence of ASD among White relative to Black and Hispanic children in the United States and point to the need to improve health equity and quality of ASD diagnoses and services.

Background:

Every two years, the U.S. Centers for Disease Control and Prevention’s Autism and Developmental Disabilities Monitoring (ADDM) Network conducts cross-sectional, population-based surveillance of autism spectrum disorder (ASD) prevalence among 8-year-old children. The ADDM Network critically examines variation in ASD prevalence by race/ethnicity as significant differences in ASD prevalence across race/ethnicity may suggest under-identification in certain populations. Little is known about ASD prevalence among American Indian/Alaska Native (AIAN) children as the ADDM Network has not generally reported on prevalence due to low numbers of AIAN children preventing stable estimates. An improved understanding of ASD prevalence among AIAN is essential for meeting the service needs of individuals with ASD in AIAN communities.

Objectives:

To estimate ASD prevalence among 8-year-old AIAN children by study year, examine change in prevalence over time, and compare ASD prevalence among AIAN children with prevalence among children from other race/ethnicity groups.

Methods:

8-year-old children with ASD were identified in ADDM Network sites from 2002-2018, and categorized into five race categories (i.e. Asian/Pacific Islander (Asian), Black, non-Hispanic (Black), White, non-Hispanic (White), Hispanic, and AIAN). Population denominators were from the National Center for Health Statistics’ bridged-race postcensal population estimates using the most recent vintage available at the conclusion of each study year. Public school enrollment counts were used to adjust denominators in sites with subcounty surveillance areas. Overall and race/ethnicity-specific prevalence estimates were calculated by study year as the number of children with ASD divided by the number of children per group per 1,000 children. The Wilson score method with continuity correction was used to estimate 95% confidence intervals (CI). Prevalence ratios (PR) and 95% confidence intervals using Wald’s method were estimated across race/ethnicity and study years.

Results:

There were fewer AIAN children in the sample compared to other racial/ethnic groups (Table 1), and precision of ASD prevalence estimates among AIAN children was poor (Figure 1). ASD prevalence among AIAN children increased significantly from 2.8/1,000 8-year-old children in 2002 to 29.0/1,000 8-year-old children in 2018 (PR: 10.1, 95% CI: 4.5-22.5). ASD prevalence among other race/ethnicity groups did not show as large of an increase (Figure 1). Few significant differences in ASD prevalence were detected between AIAN children and other children with the exception of the AIAN:White ratio in 2002 (PR: 0.4, 95% CI: 0.2-0.8) and 2016 (PR: 0.7, 95% CI: 0.4-1.0), and the AIAN:Hispanic ratio in 2008 (PR: 1.6, 95% CI: 1.1-2.4; Table).

Conclusions:

These results should be interpreted with caution given low precision of prevalence estimates. Although ASD prevalence among 8-year-old AIAN children increased over 10-fold from 2002 to 2018, it rarely differed from the prevalence measured in other groups within study years. Even with pooling data across sites, sample sizes remained too small in most years to yield precise estimates impacting comparisons of ASD prevalence in AIAN children to other race/ethnicity groups. This suggests that additional efforts may be needed to increase the inclusion of AIAN children in population-based ASD surveillance systems such as ADDM to provide more precise ASD prevalence estimates.

309.003 (Oral) Prenatal Stress, Maternal Immigrant Status and Child Autistic Traits: Insights from a Population-Based Cohort Study.

A. E. Leeuw, W. A. Estér, K. Bolhuis, H. W. Hoek and P. W. Jansen, (1)Parnassia Groep, The Hague, Netherlands, (2)Sarr Expert Centre for Autism, Youz Child- and Adolescent Psychiatry, Parnassia Group, Rotterdam, Netherlands, (3)Department of Child and Adolescent Psychiatry, Erasmus Medical Center, Sophia Children’s Hospital, University Medical Center Rotterdam, Rotterdam,
Background: There is emerging evidence for an increased risk of Autism Spectrum Disorder (ASD) in children of immigrant parents. To date, the mechanisms underlying this relationship are poorly understood.

Objectives: To investigate prenatal exposure to maternal stress as a mediating pathway between maternal immigrant status and child autistic traits.

Methods: We applied a longitudinal mediation analysis embedded in the Generation R Study, a population-based cohort study from fetal life onwards in the Netherlands. Of the 4727 included participants, 1773 mothers had a migration background. Prenatal maternal stress occurring in various aspects of life was assessed, using questionnaires related to psychopathology, self-esteem, life events, family functioning, long-term difficulties, social support and perceived discrimination. Child autistic traits were measured at age 6 with mother reports on the Social Responsiveness Scale (SRS-short). Multiple mediation analysis was performed making use of a regression-based path analysis and of bootstrapping.

Results: Children of mothers with a migration background had higher scores on the SRS-short (n=1773, M=0.48, SD=0.25), thus indicating more autistic traits, compared to children of mothers with no migration background (n=2954, M=0.38, SD=0.23) (p <0.001). In addition, mothers with a migration background experienced significantly more stress in almost all aspects of life (p <0.05), except in relation to self-esteem. The total mediating effect of prenatal stress indicators on the relationship between maternal immigrant status and child autistic traits after adjusting for socioeconomic factors, birth weight, gestational age at birth and gender of the child was 31.3% (95% CI 29.6 to 32.2). Stress indicators with the highest mediating effect were poor family functioning (12.5%, 95% CI 11.5 to 13.7) and perceived discrimination (11.9%, 95% CI 8.8 to 13.9). In the group of mothers with a migration background from outside Europe (n=1390), the mediating effect of maternal stress indicators was 35.1% (95% CI 32.8 to 36.3), with an effect of perceived discrimination of 20.8% (95% CI 18.5 to 22.3, see also figure 1 and table 1).

Conclusions: Maternal stress during pregnancy, especially related to social discrimination and poor family functioning, seems to be an important mediator in the association between maternal immigrant status and child autistic traits in the Netherlands. Prevention programs and early interventions in clinical practice should focus on reducing the exposure to prenatal stress, in particular amongst women with a migration background.

309.004 (Oral) Risk Factors for Autism Spectrum Disorder on the Kenyan Coast
P. Kipkemoi1, A. Abubakar1, A. Gona, C. van der Merwe, E. B. Robinson and C. R. Newton1, (1)Neurosciences Unit, KEMRI/WTRP, Kilifi, Kenya, (2)Complex Trait Genetics Department, Center for Neurogenomics and Cognitive Research, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (3)Neurosciences Unit, KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya, (4)Department of Psychiatry, University of Oxford, Oxford, United Kingdom, (5)Institute for Human Development, Aga Khan University, Nairobi, Kenya, (6)KEMRI/Wellcome Trust Research Programme, Kilifi, Kenya, (7)Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, (8)Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA

Background: Evidence from population-based studies in the Global North has identified the role of environmental risk factors in the aetiology of neurodevelopmental disorders (NDDs), such as autism spectrum disorder (ASD). A limited number of case-control studies have identified various risk factors associated with NDDs in Africa. One such study by Mankoski and colleagues in 2006 found evidence of falciparum malaria as a possible antecedent to ASD in Tanzania. Widely researched risk factors such as pre-eclampsia, placental insufficiency, prolonged labour, induced labour, birth asphyxia, preterm birth and low birth weight are common in Africa. Bleeding and maternal infection during pregnancy and advanced paternal age have also been linked to ASD.

Objectives: This study aimed to identify unique prenatal, perinatal, and postnatal factors associated with ASD in Coastal Kenya, comparing children with ASD and other children with NDDs as well as typically developing children. The study combines data from two studies—an ongoing case-control study that aims to characterise the genetics and phenotypic architecture of children with NDDs (NeuroDev Study) and a concluded study that aimed at validating an ASD-specific screening tool and thereafter collected data on risk factors associated with ASD (Autism Study).

Methods: The study was conducted in Kilifi and Mombasa counties along the Kenyan Coast. We included 172 of the study participants from the Autism Study and 151 from the NeuroDev Study who had a diagnosis of at least one NDD (cases) and 112 and 73 with no NDD diagnosis (controls) from each study, respectively. Case participants were recruited from special schools, a database of participants from previous studies and the neurology clinic in Kilifi County. An unadjusted analysis of the potential risk factors was carried out using logistic regression. Risk factors with a p-value reaching 0.25 were included in the adjusted analysis. Analyses were conducted in STATA version 15.0.
Results: 25 possible medical and socio-demographic factors associated with ASD and NDDs compared to the typically developing group were explored in the unadjusted analysis. 13 factors were included in the preliminary adjusted analysis. Medical complications during pregnancy, labour and birth complications, and previous hospitalisations in childhood were associated with an increased risk for ASD and NDDs, reaching the statistically significant cut-off <0.05 with odds ratios ranging from 1.46 to 7.99. Infection during pregnancy and head injury/coma were linked to an increased risk associated with ASD, with odds ratios ranging from 1.89 and 2.59, respectively. Low birth weight and birth order showed a relatively reduced risk for ASD only, with odds ratios of 0.83 and 0.90, respectively.

Conclusions: This study contributes to the growing evidence of a link between prenatal, perinatal, and postnatal factors and ASD. Infection during pregnancy and head injury/coma were potentially unique factors associated with ASD. More research is needed to understand the biological mechanisms of these factors. Knowledge of the association between these factors and ASD could lead to an early assessment of ASD in children at risk and enhance early diagnosis and intervention.

### Oral Session — Epidemiology

#### 324 - Epidemiological Studies of Autism Traits & Comorbidities

**Moderator: Mayada Elsabbagh, McGill University, Montreal, QC, Canada**

**324.001 (Oral) Prevalence and Patterns of Co-Occurring Mental Health Conditions and Intellectual and Developmental Disabilities Among Autistic Youth and Young Adults**

Background: Compared to non-autistic people, research suggests that autistic people are at an increased risk for co-occurrence of mental health (MH) conditions and intellectual and developmental disabilities (IDD). However, few studies have large enough samples to examine multiple co-occurring MH conditions and IDD among autistic people (i.e., prevalence of 2+ co-occurring conditions) which may more appropriately reflect the lived experiences of autistic youth and young adults.

Objectives: Among autistic youth and young adults we sought to understand the prevalence of and common combinations of multiple co-occurring conditions within the domains of MH and IDD and the sociodemographic characteristics of those with multiple co-occurring conditions.

Methods: Using national public health insurance (Medicaid) data from 2016 (among the most recently available), we conducted a cross-sectional analysis of autistic youth and young adults across the US. Autistic individuals ages 8-25 enrolled in Medicaid were eligible. We used validated algorithms for identifying co-occurring conditions in claims data (1+ inpatient or 2+ outpatient claims with an ICD-10 code for that condition of interest). MH conditions and IDD of interest included: Attention-deficit/hyperactivity disorder (ADHD), anxiety disorder, bipolar disorder, depressive disorder, intellectual disability (ID), learning disability (LD), other developmental disability (DD), epilepsy, personality disorders, post-traumatic stress disorder, and schizophrenia. Prevalence of 0, 1, 2, 3, or 4+ co-occurring conditions was calculated as the number with the respective number of co-occurring conditions divided by total number of autistic youth and young adults. For each prevalence group (e.g., 2 co-occurring conditions), we ranked the frequencies of most common combinations of co-occurring conditions. Descriptive statistics were calculated for demographic and enrollment characteristics and compared between those with 4+ co-occurring MH conditions or IDD and those with less than four. We chose 4+ co-occurring conditions as our cutoff because in this insurance system and for this age group prevalence of more than 4 co-occurring conditions of interest was rare.

Results: Among autistic youth and young adults (N = 1,285,210), 10% had zero, 45% had one, 26% had two, 12% had three, and 7% had four or more co-occurring MH conditions or IDD. Table 1 provides the top 5 co-occurring conditions of interest autistic youth and young adults and one co-occurring condition of interest which were ADHD (32.9%), ID (29.9%), LD (14.5%), Anxiety (8.3%) and Epilepsy (5.4%). The five most common combinations of co-occurrence among those who had 2 conditions were: 1) LD & DD (15.6%), 2) ADHD & ID (10.1%), 3) ADHD & anxiety (9.6%), 4) ID & LD (9.3%), and 5) Epilepsy & ID (8.7%). A higher proportion of those with four or more conditions were females (39.2% vs 31.3%) and ages 13-17 (35.3% vs. 30.7%) compared to those with less than four conditions.

Conclusions: We observed a high prevalence of multiple co-occurring conditions in the domains of MH and IDD among autistic youth and young adults, dominated by ADHD, ID, and LD co-occurrence. Understanding the co-occurrence of these conditions can help policymakers to shape program access and service availability to match the needs of autistic youth and young adults.

Background: Children with ASD frequently have co-occurring medical and psychiatric conditions that can affect their longitudinal course and function. Parent-report rating-scales, such as the Child Behavior Checklist (CBCL), can be useful in characterizing behavior and emotional development in large population samples and have been examined in ASD. Several studies have explored if relationships between ASD and emotional/behavioral problems vary by child sex, and if severity of ASD-related traits is associated with increased behavioral and emotional problems.

Objectives: Our goals were to: 1) examine the occurrence of emotional and behavior problems in children with and without ASD in a large national sample, stratifying by sex, and 2) evaluate if children with increased ASD-related social communication deficits also experience more behavioral and emotional problems.

Methods: Participants (n=7,978) were drawn from 43 cohorts from the Environmental influences on Child Health Outcomes (ECHO) program. Information on demographic factors, parent-report of an autism diagnosis by clinician, Social Responsiveness Scale (SRS) scores, and CBCL scores were obtained for children aged 2.5-18 years by parental surveys. We examined mean differences in CBCL total and DSM-oriented subscale scores by ASD diagnosis and by child sex. Analyses using logistic regression were conducted to examine if ASD was associated with higher CBCL scores. We further examined if these relationships differed by child age category (<5 years, 6-11 years, 12+ years). The relationships between SRS score and CBCL total and subscale scores were examined using quantile regression models, with analyses adjusted for child sex.

Results: In ECHO, 552 children were reported by a parent to have a clinician diagnosis of ASD (n=431 boys, 121 girls). After adjusting for sex, children with ASD were more likely to have CBCL total problems scale score greater than the 50th percentile (50-70th percentile (OR=1.76, 95% CI (1.49-2.09), 71-90th percentile (3.23(2.39-4.38), or top 10th percentile (7.10(4.35-11.60))) compared to children without ASD. Among children with ASD, girls had a higher mean difference on the depression (beta=1.48, p=0.05) and anxiety (beta=1.35, p=0.03) DSM-5 oriented subscales compared to boys. These relationships were also present for the CBCL DSM-5 oriented subscales reflecting depression, anxiety, and ADHD, and were confirmed across age groups when stratified by age group in stratified analysis. In quantile regression analyses, we observed evidence of stronger associations between SRS and CBCL for those in higher quantiles of CBCL total problems scale score (beta representing 1-unit change in SRS associated with 1-unit increase in CBCL total problems scale score), among children in the 70-90th percentile (beta=1.60, p<0.01), or top 10th percentile (beta=2.43, p<0.01) of the CBCL total problems scale score distribution. Similar findings were seen for the DSM-5 oriented depression and anxiety subscales.

Conclusions: Results from this large national sample suggest increased behavioral and emotional problems among children with ASD compared to those without. Girls with ASD were more likely to have parent-reported depression and anxiety. High social communication deficits may warrant increased monitoring for co-occurring behavioral and emotional problems.

324.003 (Oral) Use of the Social Communication Questionnaire As a Measure of Autistic Traits in the General Population: Psychometric Properties and Measurement Variance By Sex and Autism Diagnostic Status

L. Hegemann, R. Bugge Askeland, S. Barbo Valand, T. von Soest, L. J. Hannigan and A. Havdahl. (1)Nic Waals Institute, Lovisenberg Diagonal Hospital, Oslo, Norway, (2)Department of Mental Disorders, Norwegian Institute of Public Health, Oslo, Norway, (3)Institute of Clinical Medicine, NORMENT Centre, University of Oslo, Oslo, Norway, (4)PROMENTA Research Center, Department of Psychology, University of Oslo, Oslo, Norway, (5)Medical Research Council Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom, (6)Department of Psychology, University of Oslo, Oslo, Norway

Background: The psychometric properties of the SCQ have primarily been assessed in clinical samples of children diagnosed with autism. However, it is also commonly used to assess for signs of autism in primary care settings and general population samples in research.
Additionally, concerns have been raised about potential sex differences in psychometric properties of autism screeners such as the SCQ, and these may be difficult to detect in clinical samples which may already have a sex bias in selection and ascertainment.

Objectives: We aim to explore the factor structure of the SCQ in a large population-based sample and compare it to other proposed factor structures from clinical cohorts. Additionally, we assess for potential measurement variance by sex and autism diagnostic status.

Methods:

Using data from the Norwegian Mother, Father and Child Cohort study (MoBa), we perform exploratory factor analysis in one-half of an eligible child sample at age 8 (n = 21,814) and confirmatory factor analyses in the other (n = 21,711) comparing our observed factor structure to other theoretical structures in the literature. We additionally compare these models in a subsample of children who received autism diagnoses in the Norwegian Patient Register between 2008 and 2018 (n = 436). Finally, we conduct measurement invariance testing by sex (ascertained from birth registry) in a general population and across registered autism diagnostic status.

Results: Factor analyses find that a 7-factor solution fits the data substantially better than any of the alternative theoretical models in both the full sample and the autism diagnosis subsample. Measurement invariance testing found the factors can be assumed to have the same structure, loadings, and thresholds between males and females. However, a few items show some evidence of differing effects in residual variances potentially biasing the measurement of the specific trait, the strongest example being for item 13 which measures having unusually intense special interests. The factors’ structure was found to be the same between the diagnosed and non-diagnosed subsamples but differed in the estimated loadings and thresholds of the items. For example, there were differences in the manifestation of the idiosyncratic speech factor, which was characterized primarily by repetitive speech in the diagnosed sample but had more uniform effects across all speech items in the non-diagnosed sample.

Conclusions:

Our results find high dimensionality underlying the SCQ in the general population, indicating that using sum scores based on broader domains may obscure more specific effects. We find evidence supporting that the factor structure is the same between autistic and non-autistic individuals but with some differences in the degree by which factors affect traits. Surprisingly, we find few significant sex differences in the structure, loadings, and thresholds of items measuring autistic traits in a general population. However, in the few areas where differences in estimated residual variances for traits between females and males were observed, we caution that sex differences in observed scores could be partially attributable to differences in the sensitivity of the instrument rather than in the underlying behaviors.

Background: Autistic individuals have an increased risk of self-harm, including an elevated risk of death from suicide. However, the pathways to suicide in this group, and whether they differ from that among non-autistic people, is not well known. Thus, while non-fatal self-harm is strongly associated with death from suicide in the general population, the relationship has not been thoroughly investigated among autistic people. It is also unclear if the relationship between self-harm and suicide in autism is different among females as compared to males, and whether it varies by the method of self-harm.

Objectives: This study examined whether the relationship between self-harm and risk of death from suicide differs between autistic and non-autistic individuals. It also set out to explore if sex and the method of self-harm further modifies this association.

Methods: We used the Swedish health and administrative registers to establish a total population cohort of 2,822,789 individuals who we followed from age 12 up to age 37 years, by 2021. Autistic individuals were identified by pre-existing diagnosis of autism (N=86,427) in the National Patient Register. Self-harm was also ascertained from this register and included any hospital admissions or emergency department visits for self-inflicted injury or poisoning. Death from suicide was identified from the Cause of Death Register. Parental level of education and psychiatric history were also assessed, as were other individual level neurodevelopmental disorders. We used Cox proportional hazard regression models to estimate adjusted hazard ratios (aHR) and confidence intervals (CI) for suicide in relation to a cross-classification of autism and any hospital presentation for self-harm overall and by method. The analyses were conducted in the total cohort and separately among males and females.

Results: We observed a strongly increased aHR of death from suicide in individuals who had presented to health services for self-harm. This risk was clearly more pronounced in autistic as compared to non-autistic individuals (adjusted Hazard Ratio [95 % Confidence Interval] : 22.9 [19.5-26.9]) and 16.2 [14.9-17.5], respectively), and particularly noticeable among autistic females and autistic individuals.
who presented with self-cutting. These associations were not explained by sociodemographic factors, family history of psychiatric disorders or other neurodevelopmental conditions among index persons.

Conclusions: Our findings underline the severity of clinical presentations of self-harm in young autistic individuals. These data demonstrate the need for further understanding and consideration of this issue in relation to research and clinical guidelines.

**422.116 (Poster) A Comparative Analysis of a Shortened Version of the Social Responsiveness Scale in Estimating an Established Autism Risk Factor Association in the Echo Program: Do We Get the Same Estimates?**

M. A. Patti\(^1\), L. A. Croen\(^2\), R. Joseph\(^3\), M. R. Karagas\(^4\), C. Ladd-Acosta\(^5\), R. Landar\(^6\), D. S. Messinger\(^7\), C. J. Newschaffer\(^5\), R. Nguyen\(^8\), S. Ozonoff\(^9\), T. M. O. O'Shea\(^10\), R. J. Schmide\(^11\), C. Trevino\(^12\) and K. Lyall\(^13\); \(^1\)AJ Drexel Autism Institute, Philadelphia, PA, \(^2\)Division of Research, Kaiser Permanente Northern California, Oakland, CA, \(^3\)Boston University Chobanian & Avedisian School of Medicine, Boston, MA, \(^4\)Dartmouth University, Hanover, NH, \(^5\)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, \(^6\)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, \(^7\)University of Miami, Coral Gables, FL, \(^8\)College of Health and Human Development, Pennsylvania State University, University Park, PA, \(^9\)University of Minnesota, Minneapolis, MN, \(^10\)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, \(^11\)University of North Carolina School of Medicine, Chapel Hill, NC, \(^12\)Department of Public Health Sciences, University of California Davis, Davis, CA, \(^13\)University of Washington, Seattle, WA, \(^14\)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

Background: While autism spectrum disorder (ASD) is characterized as a binary diagnosis, evidence suggests a continuum of core traits that extend beyond diagnostic boundaries into the general population. The Social Responsiveness Scale (SRS) is a 65-item informant-tool and widely used quantitative measure of the autism-related phenotype and has been previously validated against ASD diagnosis. Prior work developed a shortened 16-item version of the SRS from the original 65-item measure using item response theory. However, its properties for use as a quantitative trait measure, including in epidemiologic risk factor analyses, have not been fully examined.

Objectives: Here, we compared the associations between gestational age (as a previously established risk factor associated with ASD) with the 65-item “full” and 16-item “short” versions of the SRS to test the shortened version’s utility in epidemiologic analyses of ASD risk factors.

Methods: Participants (n=2,760 with available item-level SRS information at time of analysis) were drawn from the Environmental Influences on Child Health Outcomes (ECHO) Program. The ECHO Program is a United States (US) based consortium of 69 cohort studies investigating the effects of environmental exposures on child health. SRS scores were collected via caregiver report when children were aged 2.5-18 years, where higher scores indicate the presence of more autism-related traits. Total scores were scaled to enable comparison across the short and full SRS. We then compared estimates of associations between gestational age and preterm birth status between the full and short SRS using multivariable linear regression, prediction methods, and quantile regression. Crude and adjusted models, including maternal (education and race/ethnicity) and child factors (sex and age at SRS administration) were run.

Results: In all analyses, adjusted associations supported increases in SRS scores (whether according to short or full scores) with preterm birth, and decreases with increasing gestational age. Overall, associations based on full and short SRS scores were highly comparable. For example, we observed positive associations between preterm birth with both full (β: 2.8; 95% CI: 1.7, 4.0) and short (β: 2.9; 95% CI: 1.6, 4.3) SRS scores. Quantile regression analyses indicated similar direction and magnitude of associations across the distribution of SRS scores between gestational age and both short and full SRS scores. These analyses revealed stronger, increasingly negative associations between gestational age and SRS scores from the 50th percentile (Full SRS: β: -0.3; 95% CI: -0.4, -0.2) to the 90th percentile (Full SRS: β: -0.6; 95% CI: -0.8, -0.4; Short SRS: β: -0.8; 95% CI: -1.0, -0.5) of SRS scores.

Conclusions: We observed a high degree of similarity in associations between gestational age, an established ASD risk factor, with full and short SRS scores in a sample of US children participating in the ECHO Program. The similarities in the direction and magnitude of associations observed between the full and short SRS suggest comparability of these for use as quantitative trait measures in risk factor analyses, though further work should address associations with other types of risk factors.

**422.117 (Poster) A Preliminary Assessment of the National Autism Screening Program in Sultanate of Oman: Lesson Learned from a Single Tertiary Care Centre Data**

A. B. Idris\(^1\), W. S. Al Mamari\(^2\), S. Jalees and M. Al-Jahbi\(^3\); \(^1\)Child Health Department, Sultan Qaboos University Hospital, Muscat, Oman, \(^2\)Child Health, Sultan Qaboos University Hospital, AL-Khoud, Oman, \(^3\)Sultan Qaboos University Hospital, Muscat, Oman

Background:
The National autism screening program was launched in the Sultanate of Oman early in 2017. The program adopted the Omani version of Modified Checklist for Autism in Toddlers, Revised /Follow-Up (M-CHAT/RF) as a tool for screening for autism and other developmental disorders mandated at 18 months of age for all children. The national guideline for autism screening classified the referral of screened positive cases into three autism diagnostic clinics in tertiary care hospitals, namely; Sultan Qaboos University and Royal Hospitals.

Objectives:

Hereafter, we are presenting a primary analysis of cases in Sultan Qaboos University Hospital (SQUH) to explore the performance of the screening program as a pioneer project in the Middle East area.

Methods:

The data was incurred from hospital electronic system of all cases diagnosed as ASD and presented to the clinic during the study period. In order to label a child with Autism Spectrum Disorder, the tertiary care clinics in Oman are espousing gold standard diagnostic procedures involving multidisciplinary assessment, Autism Diagnostic Interview-Revised (ADI™-R) and Autism Diagnostic Observation Schedule, Second Edition (ADOS™-2).

Results:

Between January 2017 and January 2020, a total of 624 autism spectrum disorder (ASD) cases were diagnosed in SQUH. Among those, 46 (7.4%) cases stemmed from the national screening program, while 578 (92.6%) came through the regular referral system from other sources. Although the program was still expanding during the last 3 years and didn’t reach its full potential – plus the interruption caused by the COVID-19 pandemic-36% of cases who were diagnosed before the age of 3 years came through the ASD screening program. The mean age of ASD diagnosis among the screened cases was 2.70 ± 0.81 years, while the mean age of diagnosis among the non-screened cases was 5.46 ± 2.30 years. Interestingly, 69.6% of the screened cases had a diagnosis before 3 years of age which allowed them to start early intervention. The difference was statistically significant (p-value < 0.000) as only 9.9% of the non-screened cases reached diagnosis before 3 years of age.

Conclusions:

Despite the fact that the above data originates from a single centre, it highlights the importance of the screening program in detecting ASD cases early and facilitating their referral for early intervention. However, it is recommended to conduct a full program evaluation within 2 years to evaluate the project activities, rectify flaws and perform a cost-effectiveness analysis.

422.118 (Poster) Adaptive Skill Differences in Race and Ethnicity in a Metropolitan Autism Center

J. Mannheim1, F. Shic1, N. Ono1, D. Camenisch3, A. Persons-Geer4 and K. Bearss5, (1)Seattle Children's Autism Center, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Seattle Children's Hospital, Seattle, WA, (4)Department of Psychiatry and Behavioral Medicine, Seattle Children's Autism Center, Seattle, WA, (5)Psychiatry and Behavioral Sciences, Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

Background: Many state programs require scores from standardized measures, including adaptive skills, to qualify for benefits and services. Racial bias in standardized measures may differentially impact the ability of families of color to obtain services appropriate to the level and needs of their children.

Objectives: To conduct a top-down examination of differences between White children and children of other races to understand the presence and nature of inter-race differences in adaptive skill profiles in children seeking diagnostic evaluation in a high-throughput metropolitan hospital-based autism center.

Methods: Participants were n=793 children whose caregiver completed the Adaptive Behavior Assessment System, Third Edition (ABAS-3) as part of their visit. We examined differences in ABAS-3 composite and scaled scores dependent on the additive effects of race/ethnicity (American Indian n=23, Black n=80, Asian American/Pacific Islander n=93, Hispanic n=110, Unknown and Other Race n=54, and White n=433), insurance type (Medicare/Medicaid or non-Medicaid), and child age using linear regression. We focused comparison of non-White races against White races in a top-down approach examining the nature of any between-race effects.

Results: In general, family use of Medicaid was associated with lower adaptive skills in children compared to private insurance (e.g. GAC scores, p<.001). GAC scores were only lower in Black children relative to White children (p=.008). This was driven by differences in both Conceptual Composites (p=.004) and Practical Composites (p=.004), but not Social Composites (p=.149). In turn these composite differences were driven by Communication (p=.023) and Functional Academic (p=.001), but not Self-Direction (p=.052) or Functional Pre-Academics (p=.250) Conceptual sub-domain scaled scores; and by Community Use (p=.004), Home Living (p=.017), Health & Safety (p<.001), but not Self Care (p=.271) Practical sub-domain scaled scores. Interestingly, though GAC score differences were not observed,
Background: A growing body of literature suggests that exposure to early life air pollution is associated with increased risk for autism spectrum disorder (ASD). Recent studies have shown that community level socioeconomic status (SES) may modify the association between air pollution and child health outcomes. Few studies have examined the potential synergistic effects of neighborhood characteristics and air pollution exposure on ASD or associated traits.

Objectives: To examine the modifying role of neighborhood deprivation for the association between prenatal and postnatal ambient air pollution and ASD risk and ASD-related quantitative traits in children.

Methods: Data came from two prospective pregnancy cohorts enriched for a family history of ASD (n=409), Early Autism Risk Longitudinal Investigation (EARLI), Markers of Autism Risk in Babies – Learning Early Signs (MARABLES). Weekly air pollution exposures were estimated based on maternal residential address during pregnancy and the first year of life using inverse-distance squared spatial interpolation. Community socio-economic deprivation was derived from indicators in the American Community Survey data and categorized into tertiles: low, moderate, and high deprivation. Multivariable logistic and linear regression models were completed to evaluate the association between pregnancy and first year of life air pollution exposures and ASD diagnosis and ASD-related traits (Social Responsiveness Scale [SRS]) stratified by neighborhood deprivation. Distributed lag models examined sensitive windows of exposure between air pollutants and SRS by neighborhood deprivation.

Results: We observed an increased risk of having a child with ASD for each 1-unit increase in NO\(_2\) exposure during pregnancy (aOR=1.25 95% CI: 0.99-1.64, P=0.07) and the 1st year of life (aOR=1.51, 95% CI: 1.15, 2.10, P<0.01) in the low deprivation group. Inverse associations between air pollution during the 1st year of life and risk of ASD were observed for O\(_3\) (aOR=0.81, 95% CI: 0.64, 0.99, P=0.05), PM\(_{2.5}\) (aOR=0.62, 95% CI: 0.35, 1.03, P=0.08), and PM\(_{10}\) (aOR=0.79, 95% CI: 0.61, 0.97, P=0.04) in the low deprivation group. Increasing PM\(_{2.5}\) during preconception period was associated with lower SRS raw scores (less autistic traits) in the low deprivation group (weeks 1-5) and with higher SRS raw scores (more autistic traits) in the moderate deprivation group (weeks 1-12).

Conclusions: Our results suggest that air pollution impacts on ASD risk and ASD-related traits are present among children with higher SES (low or moderate neighborhood deprivation). Such results should be studied in the context of access to care indicators to better identify vulnerable populations or assess the role of diagnostic bias in ASD.

422.119 (Poster) Air Pollution Exposure, Autism Diagnosis, and Autism-Related Quantitative Traits By Neighborhood Deprivation

Asian children differed from White on the Social Composite (p=.006). This was driven by both Leisure (p=.039) and Social (p<.001) Social composite sub-domain scaled scores.

Conclusions: Even when controlling for age and insurance type, we see significant differences in conceptual, social and practical domains of adaptive behaviors between children of White to Black and Asian families. This exploratory study leads to larger questions of why Asian caregivers identify more social impairments, which includes both social and leisure skills, in their children compared with White caregivers’ rating of their children. Even starker differences were noted when comparing Black and White children in their community use, home living, health and safety, but not in their self-care skills. One may consider the impact race has on how a caregiver perceives the safety of their child in their community, as well as differences in access to developmental opportunities. Standardized measures are not able to account for such effects, yet they may impact who ultimately qualifies for benefits and services within their state. Limitations: families completing an ABAS may not be representative of the general population, e.g. cancellation rates in this sample were 19.8%, whereas for n=4855 comparison children referred for diagnostic evaluation average cancellation rates per individual were 29.1% (p<0.001). Replication as well as controls for multiple comparisons are needed.
Objectives: We are using whole genome sequencing-based variant analysis to assess the carrier genome influence on ASD. The experimental setup uses a meta-cohort of parents, siblings, and affected infants and will search for single markers as polygenic components.

Methods: Whole genome sequencing (WGS) was performed on 300 members including infants of families where ASD has already been observed in one child (sibling). Single nucleotide variants (SNV), small insertions and deletions (Indels up to ca 100bp), and copy number variants (CNV) were called by comparison to the genome build 38 and pools of (assumed) normals. Three analysis strategies were implemented. Firstly already identified genes potentially affecting ASD were analyzed for variants. Secondly variants segregating with propensity for ASD in the family or enriched in affected children across families were identified. Thirdly polygenic risk scores for ASD were calculated using different computational approaches. All analysis strategies implied the usage of multiple combined or alternative filtering strategies.

Results: On average ca 5 million variants were analyzed for each individual. Different filtering strategies were applied depending on the analytical pipeline. By setting a polymorphism filter at 5% population frequency in a similar context as that of the project, ca 90% of the variants could be set aside as normal polymorphism, leaving ca ½ million variants to analyze per genome. The variants or genotypes that were new to the affected persons (de novo / not inherited) were identified. The analysis for polygenic risk scores was performed on the complete set of variants subsampled from the cohort(s). Results of the different analysis strategies is presented.

Conclusions: Overall, our findings so far strengthens the vision of the not very strong influence of the carrier genome on the development of ASD. The identified polygenic risk scores might in specific populations contribute to the early identification of ASD. Further information will be provided due to ongoing sample collection.

422.121 (Poster) Antiseizure Medication Prescribing and Its Indications during Pregnancy and Offspring Neuro-Developmental Outcomes: A Study of Two Cohorts from the UK and Sweden
P. Madley-Dowd, H. Forbes, V. Ahlqvist, J. E. Rast, C. Zhong, F. Z. Martin, J. Campbell, K. Lyall, C. J. Newschaffer, T. Tomson, N. Davies, C. Magnusson, B. K. Lee, and D. Rai; (1)University of Bristol, Bristol, United Kingdom, (2)Department of Non-communicable Disease Epidemiology, London School of Hygiene & Tropical Medicine, London, United Kingdom, (3)Global Public Health, Karolinska Institutet, Stockholm, Sweden, (4)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (5)Department of Epidemiology and Biostatistics, Dornsife School of Public Health at Drexel University, Philadelphia, PA, (6)Fielding Graduate University, San Antonio, TX, (7)College of Health and Human Development, The Pennsylvania State University, State college, PA, (8)Department of Clinical Neuroscience, Karolinska University Hospital, Karolinska, Sweden, (9)Population Health Sciences, Bristol Medical School, MRC Integrative Epidemiology Unit, Bristol, United Kingdom, (10)Karolinska Institutet, Stockholm, SWEDEN, (11)Department of Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (12)Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, UNITED KINGDOM

Background: The teratogenic potential of valproate especially in relation to adverse neurodevelopmental outcomes is well documented. However, the safety of other anti-seizure medications (ASMs) during pregnancy is not well understood. Recent work has suggested that use of Topiramate during pregnancy may be a risk factor for neurodevelopmental outcomes including autism, intellectual disability (ID), and global developmental delay.

Objectives: To examine whether ASM prescribing in pregnancy and its indications are associated with adverse neurodevelopmental outcomes in exposed children.

Methods: This is an intergenerational study with prospectively collected data from the UK Clinical Practice Research Datalink (CPRD) GOLD (birth years 1995-2018) and the Swedish Developmental Origins of Health and Disease (DOHaD) dataset built from the national registers (birth years 1995-2020). CPRD GOLD holds primary care data from around 9% of the UK population and is approximately representative in terms of age and sex, while DOHaD contain information for nearly all births in the country. We identified maternal prescriptions for ASMs (carbamazepine, gabapentin, lamotrigine, levetiracetam, valproate, pregabalin, topiramate, or other) recorded during the pre-conceptional and pregnancy periods and their likely indications (including epilepsy, psychiatric conditions, and somatic conditions). Child neurodevelopmental outcomes included autism, attention deficit hyperactivity disorder (ADHD) and ID identified using Read codes and ICD-10 codes in the UK and ICD-10 codes in Sweden. We examined associations for prescribing any time in pregnancy, in each trimester, initiation during the first trimester and discontinuation early and late into pregnancy using log-binomial regression adjusted for confounders and year of birth (to account for differing lengths of follow up). Results in each cohort were pooled using fixed effects meta-analysis. We will implement exposure discordant sibling analyses, negative control analyses with a latent variable and other methods to aid with causal interpretation of findings.

Results: We have identified cohorts of 518,050 children in the UK and 2,666,272 children in Sweden. Prescription at any time in pregnancy was most common in lamotrigine in both countries (exposure prevalence for UK and Swedish cohorts found in Table 1). Associations with autism were found for carbamazepine (adjusted RR = 1.37; 95% CI = 1.18-1.59), topiramate (adjusted RR = 1.61; 95% CI = 1.14-2.27) and valproate (adjusted RR = 1.89; 95% CI = 1.62-2.20) but not lamotrigine (adjusted RR = 0.98; 95% CI = 0.86-1.13) in pooled analyses across the two cohorts (results from each cohort and from meta-analyses presented in Table 2). Analyses are ongoing and the results of causal inference methods will be used to investigate whether the reported associations are likely to reflect causal effects.
Conclusions: The results will help provide pregnant women and their clinicians with useful information to make informed choices about ASM use in pregnancy.

422.122 (Poster) Association between Parental Concerns about Their Child's Development during the First Year of Life and Subsequent Autism Spectrum Disorder Diagnosis

O. Kerub¹, M. Sapitsky Goshen¹, R. Frenkel¹ and I. Menashe³, (1)Ben-Gurion University of the Negev, Ministry of health, Be’er Sheva, Israel, (2)Ben-Gurion University of the Negev, Be’er Sheva, Israel, (3)Azrieli National Centre for Autism and Neurodevelopment Research, Ben-Gurion University of the Negev, Beer-Sheva, Israel

Background:
Eliciting parents’ concerns about their child’s development is a key component of developmental surveillance. About 50% of parents of children with autism spectrum disorder (ASD) report having had concerns about their child’s development during the first year of life.

Objectives:
To assess whether parental concern about their child’s development during the first 12 months of age, is associated with later diagnosis of ASD, and to identify the child’s developmental characteristics associated with such parental concerns.

Methods:
In this retrospective matched case-control study, data about developmental milestones and parental concerns from the first 12 months of life was compared between 280 children with ASD and 560 children with typical development that were matched to cases based on their age, sex, and ethnicity. Data about the participants’ developmental milestones and parental concerns at ages of 2, 4, 6, 9 and 12 months of age were obtained from the computerized database of the Ministry of Health Maternal and Child Health Centers (MCHCs) in southern Israel. Differences between groups and the association between parental concerns, ASD and child’s developmental characteristics were assessed using standard univariate statistics.

Results:
At 2, 4, 6, 9 and 12 months, 0.6%, 0.3%, 1.4%, 4% and 4.9% of the parents in the sample raised concerns about their child development. Notably, over half of the children whom their parents raised concern about their development were subsequently diagnosed with ASD. This association between parental concern and ASD was the most striking at age 12 months with 34 of the 39 children (87%) whom their parents raised concern were subsequently diagnosed with ASD (p<0.001). Parental concerns were significantly associated with failure in mastering developmental milestones during the first year of life (OR=13.489; 95%CI = 3.276-55.545). This association was the most prominent at age 4 months (OR=3.029; 95%CI =1.687-5.440). Notably, parental concerns were most strongly associated with failure in language developmental milestones (OR=5.274; 95%CI = 2.811-9.913).

Conclusions:
Our findings suggest that parental concerns for their child development during the first year of life are important factor in screening for early signs of ASD at this age.

422.123 (Poster) Association between the Financial Impact of COVID-19 Pandemic and Mental Health of 5 Years Old Children with Neurodevelopmental Traits in Japan

Y. Sakamoto¹, M. Saito¹, A. Osato¹, A. Terui¹, T. Mikami¹ and K. Nakamura¹, (1)Neuropsychiatry, Hirosaki University, Hirosaki, Japan, (2)Graduate School of Comprehensive Rehabilitation Science, Hirosaki University, Hirosaki, Japan, (3)Neuropsychiatry, Hirosaki University, Hirosaki, Japan

Background: COVID-19 pandemic has affected not only our physical health but also our mental health and worldwide economy. The impact of financial problem caused by the pandemic on mental health of children with neurodevelopmental traits is not well known.

Objectives: This study aimed to investigate the association between the financial impact of COVID-19 pandemic and mental health of 5-year-old children with neurodevelopmental traits.

Methods: The subjects were recruited from participants in the 5-year-old developmental checkup in Hirosaki city, Japan. In fiscal year 2021, 1130 children and their caregivers participated in it. The caregivers of 919 children consented to this study (participation rate was 81.3%, boys: girls =506:413). The Japanese versions of following measures were used: CRISIS AFAR, a questionnaire about COVID-19;
the Autism Spectrum Screening Questionnaire (ASSQ); the parent-rated Strength and Difficulties Questionnaire (SDQ). The CRISIS AFAR includes questions about children’s daily behaviors and Emotions/worries. The SDQ subscales are “Emotional Symptoms” (SDQ-ES), “Conduct Problems” (SDQ-CP) et al, these subscales and total score are classified as “Low need”, “Some Need” and “High Need”, according to the previous report. Statistical analysis was performed using Spearman correlation coefficient (p<0.05).

**Results:** 5.3% of caregivers had an annual household income of less than $1,400. In particular, 33.7% of single-parent family had an annual income of less than $1,400. Spearman correlation coefficient showed that negative correlation between annual incomes and financial problem by COVID-19 pandemic (p=-0.313, p<0.001). When analyzed as a whole, there wasn’t much correlation between children’s worries about infection and ASSQ, SDQ, and financial problem. When analyzed for children with ASSQ>19, spearman correlation coefficient showed that positive correlations between financial problem and “Worries about their family/friend’s infection” (p=0.476, p>0.019), “Talk about infections” (p=0.440, p=0.028). When analyzed for children with Some/High Need in SDQ-ES, spearman correlation coefficient showed that positive correlations between financial problem and “Worries about own infection” (p=0.246, p=0.015), “Worries about physical health” (p=0.202, p=0.048) and “Worries about mental health” (p=0.209, p=0.041). When analyzed for children with Some/High Need in SDQ-CP, spearman correlation coefficient showed that positive correlations between financial problem and “Worries about infection” (p=0.237, p>0.004), “Worries about their family/friend’s infection” (p=0.273, p>0.001), “Worries about physical health” (p=0.276, p>0.001) and “Worries about mental health” (p=0.245, p>0.003). When analyzed for children with Some/High Need in SDQ-total, spearman correlation coefficient showed that positive correlation between financial problem and “Worries about own infection” (p=0.238, p>0.005), “Worries about their family/friend’s infection” (p=0.301, p>0.001), “Worries about physical health” (p=0.247, p>0.004), and “Talk about infections”(p=0.235, p>0.006). From the above; 1) Families with lower incomes, especially single-parent families, are more affected by COVID-19 pandemic. 2) As for children with ASSQ>19 or Some/High Need in SDQ-ES, SDQ-CP, SDQ-total, the greater the financial problem, the more they worry about own/family/friend’s infections, physical/mental health, and talk about infections.

**Conclusions:** This study showed the correlations between the economic impact of COVID-19 pandemic and mental health of 5 year old children with neurodevelopmental traits. We should take each financial problem into account when we assess the impact of COVID-19 pandemic on children’s mental health.

422.124 (Poster) Autism Spectrum Disorder Prevalence in Somali Children in Minnesota: Data from the MN-ADDM Study
A. N. Esler, J. A. Hall-Lande, R. Nguyen and L. Hallas, (1)University of Minnesota, Minneapolis, MN, (2)UCEEED, University of MN, Minneapolis, MN

Background: Minnesota has the largest Somali cultural community in the U.S., an estimated 82,890 people (Minnesota Compass, 2020; https://www.mncompass.org/topics/demographics/cultural-communities/somali). Our surveillance projects have tracked autism prevalence in Somali children in Minnesota since 2010. This work arose from community concerns that Somali children had higher rates of autism, and a form of autism with greater support needs, than other children. To date, prevalence estimates in the Twin Cities metro area have not yet detected higher prevalence of autism for Somali children. However, rates of co-occurring intellectual disability (ID) varied, with some study years showing significantly higher rates of autism with ID in Somali children (Hewitt et al., 2016; Esler, Hall-Lande, & Hewitt, 2017) and some study years showing no differences. Small sample sizes have limited interpretability of these results.

**Objectives:** We will compare autism prevalence in 4- and 8-year-olds across racial/ethnic groups using data from the Minnesota site of the CDC Autism and Developmental Disabilities Monitoring Network (ADDM), surveillance years 2018 and 2020, including Somali children. We will also compare co-occurrence of ID in autistic children across racial/ethnic groups.

**Methods:** We will combine data from 2018 and 2020 surveillance years to obtain adequate sample sizes to compare prevalence across our populations of interest. Data analysis from 2018 is complete, and analysis of 2020 data is in progress. Prevalence calculations utilize standardized ADDM methods (Maenner et al., 2021) involving systematic review of health and special education records of 4- and 8-year-old children within our surveillance area. The area includes three large urban counties that house four of the five largest school districts in Minnesota. Population denominators were from the National Center for Health Statistics’ bridged-race postcensal population estimates using the most recent vintage available at the conclusion of each study year and adjusted to include only children living in the surveillance area. A child is classified as Somali based on reported home language in education and health records.

**Results:** In surveillance year 2018, prevalence estimates for 8-year-olds revealed lower autism prevalence for Hispanic children compared to Somali and non-Somali Black children. Sample sizes were too small to compare rates of co-occurring ID for Somali children. Among 4-year-olds in 2018, higher autism prevalence was found for Somali children compared to White, non-Somali Black, and Hispanic children. Sample sizes were small, but 95% of autistic Somali 4-year-olds had ID compared to an overall ID rate of 57%. Prevalence estimates and rates of co-occurring ID from combined surveillance years 2018 and 2020 will be compared across racial/ethnic groups assuming a Poisson distribution. Chi squared and Fisher’s exact tests will be used to identify differences between populations.

**Conclusions:** Because early identification and intervention can improve outcomes, identifying subgroups of children with a higher prevalence of autism or with greater support needs can inform public health policy and improve developmental growth for autistic
Background:

There is significant interest in understanding reasons for the rapid increase in measured ASD prevalence over the last few decades. In the U.S., the Centers for Disease Control and Prevention’s Autism and Developmental Disabilities Monitoring (ADDM) Network is the primary source for ASD prevalence estimates. These estimates are critical to assess and plan for needed care, funding, and community resources. While ASD prevalence was previously thought to peak at age 8, previous research demonstrates only two-thirds of people with ASD are identified by this age. Monitoring change in ASD overtime within multiple birth cohorts (BC) through early adulthood may provide more accurate estimates of ASD prevalence than estimates based cross-sectionally on 8-year-olds.

Objectives:

Methods:

ASD identification in the 1994 and 2002 birth cohorts was based on International Classification of Diseases, ninth or tenth revision codes for autism and/or an autism special education eligibility. ASD ascertainment was conducted statewide from birth through 2018; age at earliest identification was identified. The population size from birth through 2018 was identified by age and sex from the National Center for Health Statistics' bridged-race postcensal population estimates using the latest vintages. The cumulative incidence was measured as the number of children identified with ASD at or before each year of age divided by the total population at or before each year of age. Prevalence, risk ratios (RR) and associated 95% confidence intervals were estimated.

Results:

The cumulative incidence of ASD was significantly lower in the 1994 versus the 2002 BC in 2018 (20.0 vs 31.3; RR = 0.50, 95% confidence intervals (CI): 0.46-0.55; Figure 1). In both cohorts, the cumulative incidence of ASD was significantly higher in 2018 than at age 8 (1994 BC: 20.0 vs 7.4, RR: 1.90, 95% CI: 1.66-2.17); 2002 BC: 31.3 vs. 22.2, RR: 1.64, 95% CI: 1.27-1.48). ASD prevalence in 2018 in the 1994 BC was significantly lower than in the 2002 BC (14.8/1000 versus 29.5/1000; RR= 0.49, 95% CI: 0.45-0.54; Figure 2). A plateau in ASD cumulative incidence appears to begin at age 16 in the 1994 BC; whether a similar plateau is occurring in the 2002 BC by age 16 is yet unclear but is suggested.

Conclusions:

Utah’s ASD identification at health and school settings continues into adolescence for both the 1994 and 2002 birth cohorts. The cumulative incidence appears to plateau after 16 years old, which may suggest that Utah’s peak incidence occurs at 16 instead of 8. The significant increase in ASD prevalence between 1994 and 2002 birth cohorts suggests a corresponding two fold increase in diagnostic and intervention service needs, funding, and community resources over the past 20 years. ASD service planning in Utah, however, is currently informed by single age, single birth cohort studies and may not correspond with population need.
Background: Prior work has demonstrated differences in autism prevalence by demographic factors. Whether observed differences are due to differential access to care, traits at presentation, or true differences in rates has been debated.

Objectives: Our goals were to compare 1) associations of demographic factors with both autism diagnosis and quantitatively-assessed autism-related traits according to the Social Responsiveness Scale (SRS), and 2) the ability of the SRS to predict autism diagnosis across categories of maternal race/ethnicity and education, key demographic factors previously associated with diagnosis.

Methods: Participants (n=8,224; 4,279 boys, 3,945 girls) were drawn from 46 cohorts with children born from 1999-2019 from the Environmental influences on Child Health Outcomes (ECHO) program. Information on demographic factors, parent report of an autism diagnosis by a doctor or clinician, and SRS scores from children aged 2.5-18 years was obtained. Relationships between demographic factors and autism diagnosis, and separately, demographic factors and SRS scores above a threshold typically consistent with autism diagnosis (SRS T score >65) were compared based on estimated odds ratios (OR) and 95% confidence intervals (CI) from generalized linear mixed models with random effects for individual cohorts. Adjusted analyses were mutually accounted for race/ethnicity and education, as well as maternal age, BMI, and cohort; we also tested for effect modification by sex in stratified models. Differences in predictive ability across demographic groups were determined using receiver operating characteristic (ROC) analyses of SRS scores predicting autism diagnosis, and area under the curve (AUC) values across racial and ethnic groups as well as education level were compared from these models.

Results: Approximately 60% of participants identified as non-Hispanic White, nearly 20% as non-Hispanic Black, and 15% as Hispanic; approximately 25% of parents fell in each of 4 education levels. In adjusted regression models, the odds of autism diagnosis were lower for Non-Hispanic Black children (OR=0.72, 95%CI 0.53, 0.98), but similar for Asian and Hispanic children, relative to Non-Hispanic White children. In sex-stratified analyses, this association appeared to be driven by reduced odds of reported diagnosis in Black females. In comparison, no significant associations of race/ethnicity with odds of SRS scores>65 were seen. Higher maternal education was significantly associated with reduced odds of autism diagnosis (OR=0.57, 95% CI 0.41, 0.79 for graduate vs. high school degree) and, even more strongly, with SRS T-score>65 (OR=0.35, 95%CI 0.26, 0.47). In ROC analyses, prediction of autism diagnosis by SRS scores was strong for all groups (AUC>0.8), but lowest for Non-Hispanic Black (AUC=0.84, p=0.007 compared to the non-Hispanic white children, AUC=0.93), and for those with the lowest education (AUC=0.81, p<0.001 compared to all other education groups).

Conclusions: Results from this large nationwide sample suggest lower diagnostic recognition of autism in non-Hispanic Black children from cohorts born 1999-2019, particularly in girls, despite a similar degree of reported autism-related traits falling in the clinically elevated range. Further work is needed to address this disparity, reduce barriers to diagnosis in underserved groups, and understand sex differences in ASD recognition.

422.127 (Poster) Differential Relationship between Low Birthweight and Risk across ASD and ID Outcomes By Maternal Race and Ethnicity

D. A. Bilder1, M. J. Maenner1, J. A. Hall-Lande1, A. Adesomo1, A. V. Bakian1, (1)Psychiatry, University of Utah, Salt Lake City, UT, (2)Centers for Disease Control and Prevention, Atlanta, GA, (3)UCEDD, University of MN, Minneapolis, MN, (4)Obstetrics and Gynecology, University of Utah, Salt Lake City, UT

Background: Fetal growth is influenced by several maternal and obstetrical factors and is an important indicator of fetal health. Low birthweight, which is known to vary by race/ethnicity, is an established risk factor for autism spectrum disorder (ASD) and intellectual disability (ID). Prevalence rates across ASD/ID disability category (i.e., ASD only, ASD+ID, ID only) differ substantially between White (NHW) and Black (NHB) children of non-Hispanic origin. Race/ethnic disparities in birthweight and disability prevalence are only partially attributable to differences in maternal socioeconomic factors. Further exploration of the relationship between birthweight and risk for ASD and ID by race/ethnicity is warranted in a racially and geographically diverse population.

Objectives: Using a case-cohort design, this study evaluates the relationships between ASD/ID risk and birthweight by race/ethnicity for children ascertained with ASD/ID across sites participating in the U.S. Centers for Disease Control and Prevention’s Autism and Developmental Disabilities Monitoring Network (ADDN).

Methods: In even-numbered years 2000-2016, 8-year-old children were ascertained with ASD only, ASD+ID, and ID only (N=8643, N=3455, N=6174, respectively) using ADDN methodology, and linked to birth certificate records. The comparison cohort (N=1,464,932) was composed of all births ascertained through the National Center for Health Statistics corresponding to each birth year and ascertainment
Ascertainment areas were communities within Arizona, Arkansas, Utah, Maryland, Minnesota, Georgia, North Carolina, South Carolina, and New Jersey. Birthweight, maternal race/ethnicity, and covariates (i.e., sex, birth year, gestational age, maternal age, maternal education, gestational weight gain, maternal smoking) were obtained from birth records. ANCOVA using the Sidak correction for multiple comparisons was performed to measure least square mean (LSM) differences in birthweight across a 4-level variable of exposure: (1) other race/ethnicity (ORE) comparison group, (2) NHB comparison group, (3) ORE affected group, and (4) NHB affected group. ANCOVAs were formulated separately for each affected groups (i.e., ASD only, ASD+ID, ID only). The ORE cohort was composed of 66.6% NHW, 27.2% Hispanic, 6.1% non-Hispanic other. See Figure 1.

Results: The overall F statistics were significant for all ANCOVA models (p-values < 0.01). LSM birthweight in comparison groups was significantly lower for NHB (3220 grams, SE=1.08) than ORE children (3358 grams, SE=0.57, p<0.001). The comparison NHB group had a lower LSM birthweight than three of the four ORE groups: comparison, ASD only, and ASD+ID. While ASD only status was associated with significantly lower LSM birthweight for ORE children (versus comparison ORE, LSM difference=-28.47 grams, p=0.034), LSM birthweight did not differ between comparison NHB children and ASD only NHB children (LSM difference=0.82 grams, p=1.00). ID only NHB children had the lowest LSM birthweight across all groups.

Conclusions: Birthweight differed across disability categories: ASD only and ID only were associated with the highest and lowest LSM birthweights among affected groups within race/ethnicity category strata, respectively. While birthweight was significantly and consistently lower for NHB than ORE children across comparison and disability groups, birthweight was not associated with ASD only risk among NHB children. Mediation of health disparities adversely affecting neurodevelopment in NHB children should include optimizing maternal health and wellbeing during pregnancy.

**422.128 (Poster) Does Autism Manifest Differently in Girls and Boys?**

N. Jindal1 and M. Juneja2, (1)Maulana Azad Medical College, New Delhi, India, (2)Maulana Azad Medical College New Delhi India, New Delhi, India

Background:

Epidemiological studies suggest that prevalence of Autism Spectrum Disorder varies with gender, with males having 4-6 times higher chance of being diagnosed as having ASD. The difference in prevalence has been attributed to multiple factors like better coping mechanisms in females, genetic/epigenetic factors and hormonal influences. However, existing diagnostic criteria are mostly based on male symptomatology and have a higher chance of misdiagnosing female patients. There is a need to understand female symptomatology of ASD so that female oriented ASD assessment tools can be devised.

Objectives:

To identify the difference in clinical phenotypes between female and male children with Autism Spectrum Disorder.

Methods:

31 girls with ASD (median age-58 months) age-matched with 31 boys with ASD (median age-60 months) were enrolled for the study. Developmental assessment/ Intellectual Quotient of the enrolled subjects was done using Developmental Profile-3 for children upto 12 years of age and Binet Kamat Test for children older than 12 years. The median IQ/DQ of girls was 54 (44-69.5) and that of boys was 60 (43.75-71.5). Childhood Autism Rating Scale-2 (CARS-2), Child Behaviour Checklist (CBCL), Social Responsiveness Scale-2 (SRS-2), Vineland Adaptive Behavioural Scale-2(VABS-2) and Repetitive Behaviour Questionnaire-2 (RBQ 2) were used for comprehensive assessment of symptoms.

Results:

The mean CARS-2 score, though higher in females, was statistically not significant (Mean 37.4 ;SD 4.79 in females vs mean 36.60; SD 6.75 in males). The SRS-2 total score was also found to be higher in females (Females: 76.29 ± 10.66 ; Males: 75.03 ± 11.34). The SRS-2 Social Communication Index score was 74.87 ± 11.30 in females and 75.48 ± 12.34 in males. However, the SRS-2 RRB score was significantly higher in females (Females: 75.52 ± 9.48; Males: 70.13 ± 9.95; p=0.033), which probably contributed to higher SRS-2 total scores in females. The RBQ-2 also showed significantly higher RRBs in females [32 (29.5-35)] versus males [ 29 (27-32)], p=0.041. There was significant difference between female and male ASD patients in terms of CBCL Internalising score (p=0.002) and Total score (p=0.022) with females scoring higher in each domain. The VABS-2 showed a significant difference between the 2 groups in Daily Living Skills Domain standard score (p 0.049), with the mean being higher in males suggesting better daily living skills in males.

Conclusions:
This study affirms that girls with ASD have different symptom expression as compared to boys. No significant difference was found between the two groups in severity of ASD even though the scores were higher in females. The females were also found to have significantly higher RRBs than males. Our findings of higher CARS-2 scores and higher RRBs in girls are contrary to existing literature. As the study was conducted immediately post-COVID, females exhibiting severe symptoms may have attended the hospital. Further studies with significant sample size are required for comprehensive understanding of female ASD symptoms.

422.129 (Poster) Early Screening for Autism Spectrum Disorder in Tunisian Toddlers

T. Brahimm, R. Manaaa, A. Guedriaa, M. Ben Fredjb, A. H. Srib and N. Gadddour, (1)PSYCHIATRY, UNIVERSITY OF MONASTIR, MONASTIR, Tunisia, (2)child psychiatry, University hospital of Monastir, Monastir, Tunisia, (3)University of Monastir, Monastir, Tunisia, (4)preventive medicine, university hospital of Monastir, Monastir, Tunisia, (5)preventive medicine, University hospital of Monastir, Monastir, Tunisia, (6)University Hospital Fattouma Bourguiba, Monastir, Monastir, Tunisia

Background:

In Tunisia, the last prevalence study of ASD was in 2009 and did found a prevalence of 0.3%. However, in our daily practice we observe a rise in the number of children diagnosed with the disorder. Is it an awareness of the diagnosis or a real increase in prevalence?

Objectives:

Early screening of Tunisian infants for ASD.

Determine the prevalence of ASD in a general population sample.

Methods:

A cross-sectional community-based study, conducted during the first semester of 2022. We included the first 1000 toddlers coming for the 18 months’ obligatory vaccines. The final number of participants was 918 with 82 questionnaires not interpretable. We enrolled the study population in the different primary care structures in the East central region of Tunisia. We used an Arabic validated version of the Modified Checklist for Autism in Toddlers (M–CHAT) for first screening, then the M–CHAT Follow-Up Interview for the positive ones. Children with pathological scores were referred for evaluation using the Autism Diagnostic Interview revised (ADI-R).

Results:

In 177 (19.3%) of cases, the M-CHAT was positive. In the second screening using the M-CHAT Follow-up, only twenty was positive for possible ASD. From this 20: nine had a confirmed diagnosis of ASD using the ADI-R, one had a global developmental delay, one had hearing impairment, Reactive attachment disorder was confirmed for one child, one had language disorder, three had no developmental problems and three were absent for their schedules. This screening led us to a prevalence of ASD reaching 1% with a confidence interval at 95% of [0.35-1.65]

Conclusions:

The prevalence of ASD in Tunisia meets international estimates. Using a double screening tools could be a cost-effective strategy of detection. The mandatory vaccine system in Tunisia is a helpful way to be the most exhaustive in screening campaigns.

422.130 (Poster) Effects of Insurance Status and Child Sex on Clinical Characteristics of Autism Spectrum Disorder

C. Gilchrest, J. M. Campbell and L. Gardner, (1)Johns Hopkins All Children's Hospital, St. Petersburg, FL, (2)Psychology, Western Carolina University, Cullowhee, NC

Background: The global mean age for autism spectrum disorder (ASD) diagnosis in young children is 43.18 months (Hof et al., 2020), and research supports autism is more commonly diagnosed in males than females with a 3:1 ratio (Loomes et al., 2017). Although a strong male bias has been consistently observed, diagnosis of ASD is impacted by many factors (e.g., symptom severity, provider shortage, physician knowledge, insurance coverage, family awareness, language, and stigma; Malik-Soni et al., 2021). To determine barriers that limit access to diagnostic evaluations and best meet patient and family needs, it is imperative to continue analyzing factors that facilitate and impede diagnosing autism in young children.

Objectives: Examining the effects of socioeconomic status (SES), sex, and SES by sex interaction on ASD diagnosis in a clinical sample of young children.
Evaluating Causal Associations between Maternal Health Conditions and Autism in Offspring Using a Two-Sample Mendelian Randomization Approach

(1)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Department of Psychiatry and Institute for Human Genetics, University of California San Francisco, San Francisco, CA, (4)Division of Research, Kaiser Permanente Northern California, Oakland, CA, (5)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)Emory University School of Public Health, Atlanta, GA

Background:

Several case-control and cohort studies have reported associations between health conditions experienced by mothers during pregnancy and increased odds of autism in children. Despite consistent findings from observational studies, these associations may still be explained in part by unmeasured or residual confounders. For example, few studies included sibling controls to account for familial confounding. Mendelian randomization is a tool for estimating causal effects of potentially modifiable environmental exposures from observational data by using genetic risks as instrumental variables to account for potential confounding.

Objectives:

Estimate causal effects of maternal body mass index (BMI), type 2 diabetes (T2D), and asthma on autism in offspring using two-sample Mendelian randomization (2SMR) approaches.

Methods:

Summary statistics for independent single nucleotide polymorphisms (SNPs) were used from genome-wide association studies (GWAS) of BMI (N=322,154 individuals; GIANT Consortium), T2D (N= 9,978 cases/13,348 controls; EPIC-InteractAct Cohort) and asthma (N=10,549 cases/47,146 controls; UK Biobank Cohort). Effect alleles and directions were harmonized with autism GWAS summary statistics (N= 18,381 cases/27,969 controls; iPSYCH-PGC), and overlapping SNPs used as multiple genetic instruments for 2SMR. Instrument strength was evaluated using F-statistics for individual SNPs and averaged across all SNPs for each condition. Causal effects of maternal conditions on autism were estimated using the inverse-variance weighted (IVW) method and sensitivity analyses were performed for outlying SNPs and pleiotropic effects using weighted median and MR-Egger, respectively.

Results:

A total of 95 SNP instruments were used in 2SMR for BMI, 200 SNPs for T2D and 58 SNPs for asthma. The mean instrument strengths (F-statistics) for BMI, T2D and asthma were 57, 55 and 31, respectively and for all SNPs were above the empirical cut-off of 10 (minimum= 16). Estimates from IVW analyses did not support causal effects of any of the three exposures on autism (BMI: OR (per 1 SD

Conclusions: In young children diagnosed with ASD, insurance status (i.e., Medicaid eligibility) had a main effect on the severity of clinical characteristics and levels of support assigned at diagnosis. Outcomes did not support sex impacting severity of symptoms or diagnosis in a tertiary care setting. Findings do support insurance status facilitated access to diagnosis at an early age given the clinic prioritized providing evaluations for young patients with Medicaid.
Background: Electronic healthcare record (EHR) data presents a unique opportunity for autism researchers to look at large, diverse samples of autistic individuals across an entire healthcare system. For example, EHR data allows us to test whether reported proportions about the presentation of autism are reflected in real-world clinical practice. One commonly reported statistic is that the rate of girls diagnosed with autism is approximately 20% (or a 4 to 1 ratio of boys to girls). A variety of factors, such as male bias in interpreting clinical presentation and core symptom variability, have been cited as contributing to missed or delayed diagnosis in girls. Sex differences in diagnoses are not exclusive to autism, as research shows a similar sex ratio of 3 to 1 for boys to girls diagnosed with Attention-Deficit/Hyperactivity Disorder (ADHD). Given the high co-occurrence rate (30-50%) of ADHD among individuals on the autism spectrum, additional analysis is needed to understand the interplay of sex ratios and autism/ADHD co-occurrence at different ages. Leveraging the advantages of EHR datasets, we can begin to look at these sex proportions from childhood to early adulthood in autistic individuals with and without ADHD.

Objectives: Aim 1: Determine if the proportion of girls identified as having autism changes over different ages. Aim 2: Test whether a subset group of children with co-occurring autism and ADHD follows a similar prevalence rate to the general population rates of ADHD and if the sex differences within the group also change over time.

Methods: Participants included de-identified data of 9,162 autistic children and young adults ages 2-21 years that were pulled from the Children’s Hospital of Philadelphia Electronic Healthcare Database up to 2019. After grouping participants by age in years, we examined the proportion of autistic girls relative to the total of children at each age. Our two largest races represented were white (49.5%) and Black/African American (31.2%) participants.

Results: The proportion of autistic girls within our system was exactly as expected – 20%. The number of participants within each age group ranged from 159 (at age 2) to 579 (at age 8). Contrary to our predictions, the proportion of girls diagnosed with autism remained stable over age (Figure 1) with the highest proportion of girls diagnosed at 2 years of age (25.6%) and the lowest proportion is at 7 years (18%—a difference of 7%).

Conclusions: These results show that despite literature indicating that girls are diagnosed with Autism Spectrum Disorder later in life than boys, the proportion of girls identified as autistic does not change over age in a large pediatric sample. Ongoing analysis will reveal whether the proportion of autistic girls with co-occurring ADHD is different from the reported 3 to 1 ratio in the ADHD population as well as if the subsample of individuals diagnosed with autism and ADHD follows similar sex ratios over age. Analyzing large population samples, made possible through novel EHR research, can help illuminate population trends that might not be apparent in smaller cohort studies.
Background:

The SPARK study was launched in 2016 to recruit and retain a cohort of individuals with autism and their family members across the United States. In order to recruit the now over 300,000 participants, SPARK has adopted a multimodal approach that includes the use of traditional and social media, partnerships with community organizations and support of a network of clinical sites throughout the US. Participants who affiliate with a clinical site may be provided additional support to complete enrollment and core study tasks.

Objectives:

To describe the major recruitment strategies for SPARK and to evaluate their relative effectiveness with respect to enrollment and core task completion.

Methods:

This study includes “primary account holders,” defined as the individuals who first join SPARK on behalf of their families and are assigned the majority of study tasks, who joined between January 31, 2018 to May 29, 2019. Data collected and utilized in the analyses include self-reported sociodemographic characteristics, clinical site affiliation (Y/N), how the participant heard about SPARK, the website URL used to join, enrollment completion (online registration and returning saliva kit; Y/N) and core task completion (completion of initial participant dashboard questionnaires; Y/N). Bivariate and multivariable logistic regression analyses were performed to evaluate the odds of enrollment and core task completion by recruitment method.

Results:

33,855 individuals joined SPARK during the study period. Forty one percent were recruited through or affiliated with a clinical site. A clinical site (40%) or online (38%) were the most common ways a participant heard about SPARK. Of participants with available URL data (77%), the top websites used to join the study were Facebook or Instagram (48%), the SPARK website (17%), Google or other search engines (15%), and SPARK clinical site URLs (14%). A total of 87% completed online registration (i.e., consented to both data and genetic portions of SPARK), and 45% completed enrollment including (online registration and returning saliva kit). Participants affiliated with a clinical site had ~3 fold higher odds of completing enrollment compared to those not affiliated with a clinical site (unadjusted OR: 2.79, 95% CI 2.67 - 2.92; adjusted OR: 2.98, 2.98 OR, 95% CI 2.69 - 3.31). With respect to how participants heard about SPARK, compared to clinical sites, participants referred through online and media announcements were significantly less likely to complete enrollment. In terms of the distinct URL used to join, participants were almost 7.5 times more likely to complete enrollment if it was directly through directly the SPARK website (i.e. www.SPARKforAutism.org/UCLA) as compared to coming from a Facebook or Instagram post or advertisement. The same relationships were observed for core task completion.

Conclusions:

For many SPARK participants, their increased likelihood of completing enrollment and study tasks may be attributable to the “personal” connection provided through affiliation with a clinical site and/or support provided by the study coordinators. Findings from this study underscore the value of adopting a multimodal recruitment approach that combines widespread national social media advertising and focused recruitment strategies through clinical sites.

422.134 (Poster) Factors Related to Earlier Autism Spectrum Disorder Diagnosis in New Jersey
M. J. Conlan1, V. Vought1, C. Molletta1, K. Sidwell2, J. Shenouda and W. Zahorodny2, (1)Department of Pediatrics, Rutgers--New Jersey Medical School, Newark, NJ, (2)Department of Pediatrics, Rutgers University, Newark, NJ

Background: Early diagnosis and intervention of Autism Spectrum Disorder (ASD) has been identified as a public health priority [1]. Yet, the median age of ASD diagnosis has hovered around 52 months from 2000-2016 in the United States and New Jersey [2,3]. Since ASD can be reliably diagnosed by 24 months, there is significant room for improvement in early identification [4]. To promote equal access to beneficial early intervention programs, it is critical to investigate how sociodemographic and clinical factors may affect ASD diagnosis age.

Objectives: The objective of this study is to describe how birth year, sociodemographic and clinical factors are related to age of ASD diagnosis in New Jersey.

Methods: Seven consecutive New Jersey Autism Study surveillance cycles from 2000-2016 contributed data. Each cycle reflected a cohort of 8-year-old children residing in Hudson, Ocean, Union and Essex counties. Data regarding sex, race, socioeconomic status (SES), birth year, intellectual ability, developmental delay status and ASD severity were all obtained from the children’s health and educational records. The outcomes were community provider ASD diagnosis by 36 and 48-months. Pearson Chi-square evaluated differences between children diagnosed by 36 and 48-months. Crude and adjusted models were estimated to examine sociodemographic and clinical factors associated with ASD diagnosis by 36 and 48 months.
Results: Of the 4,661 ASD cases identified through active surveillance from 2000 to 2016, analysis was restricted to 3,450 (82% male) children with an existing ASD diagnosis from a community provider by 8-years of age. The sample was racially diverse, comprised of mainly minority children. There were no differences in proportion of males and females diagnosed by 36 (p=0.42) or 48 months (p=0.74). County differences in diagnosis by 36 (p=0.05) and 48 months (p=0.001) were observed. Differences by race and birth year were observed at 36 months (p<0.05), but not at 48 months. After adjusting for birth year, sociodemographic, and clinical factors, non-Hispanic Black (NHB) children had lower odds of diagnosis by 36 months than non-Hispanic White (NHW) children (AOR = 0.8; 95% CI: 0.6-1.0). Children residing in high-income areas had higher odds of diagnosis by 36 months (AOR = 2.1; 95% CI: 1.7-2.6) and 48 months (AOR: 1.8; 95%CI: 1.5-2.2) than children from low-income areas. Across all models, the odds of diagnosis by 36 months were greater in more recent study years. Finally, presence of a co-occurring intellectual disability, presence of developmental delays and more severe ASD each independently increased the odds of ASD diagnosis by 36 and 48 months.

Conclusions: The greater proportion of children diagnosed with ASD by 36 months represents improvement of the ASD diagnostic system in our region. This demonstrates progress, since the first few years of life are particularly important for the development of children with ASD [5]. We observed NHB children and children from low-SES were vulnerable to delayed ASD diagnosis. We recommend the usage of a universal ASD screener to promote earlier identification and reduce disparities in ASD diagnosis age.

422.135 (Poster) Fecal Microbiota Transplantation from Autistic Children Modulates Behavior, Intestinal Parameters and Inflammation in BALB/c Mice
A. D. Kraneveld, N. Prince and L. Peralta Marzal, Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands

Background: Increasing evidence highlights the involvement of the microbiota-gut-brain axis in autism spectrum disorder (ASD). Gastrointestinal (GI) deficits and gut microbiota dysbiosis have been suggested to contribute to the development or severity of ASD.

Objectives: To validate the role of the gut microbiota in autism and investigate mechanisms though which they interact with the gut and brain, we transplanted BALBc mice with stools of children diagnosed with ASD without and with gastrointestinal (GI) symptoms or their siblings as controls.

Methods: Stool samples of n=4 children diagnosed with ASD (A, all male 6-8 yrs.), sibling controls (S-A, 3 male, 1 female 3-14 yrs), ASD with GI problems (AG, all male 7-10 yrs) and sibling controls (S-AG, 2 male and 2 females 3-13 yrs) were collected and pooled for transplantation into mice. Conventional colonized male BALB/c (3-4 wks, n=6 per group), that were depleted by bowel cleansing using polyethylene glycol (PEG), were transplanted with AG or S-AG stools for three consecutive days by gavage (200μl, hFMT). Germ free male BALB/c (GF, 3-4 wks, n=9-13 per group) were transplanted with A, S-A, AG or S-AG stools in a similar way. Behavioral and cognitive tests were performed (9-11 wks). In addition, microbiota composition & activity, intestinal phenotype, systemic inflammation and neuroinflammation in the brain after sacrificing at wk 12.

Results:

In PEG-microbiota depleted BALB/c mice, hFMT with AG stools decreased exploratory behavior compared to S-AG. AG hFMT induced low-grade intestinal inflammation with a reduction in enteric glial cells, low-grade systemic inflammation and neuroinflammation in the brain in recipient mice when compared to control transplanted mice. Metabolomics showed altered tryptophan metabolism in hFMT AG transplanted mice. Moreover, hFMT with AG, but not sibling control stools, resulted in increased intestinal barrier permeability, which was associated with lower soluble IgA response. Fecal short chain fatty acids (SCFA, acetate) and branched & long chain fatty acid levels were significantly enhanced in stool samples of hFMT AG compared to S-AG transplanted mice.

In GF BALB/c mice, hFMT with A or AG stools did not induced difference in behavior or neuroinflammation in the brain compared to respective sibling control transplanted mice. In both A and AG hFMT GF mice decreased number of serotonergic neurons in the ileum and raphe nuclei was observed. 6 Wks after hFMT, a significant increase in fecal alpha diversity was found in AG, but not in A, compared to sibling control stool transplanted GF mice. hFMT with A and AG stools induced significant differences of beta diversity when compared to respective sibling controls, which was associated with different SCFA profiles.

Conclusions: Overall, our findings enlighten the alterations in the intestinal microbiota and physiology, the immune system and behavior of mice transplanted with A or AG stools and provide evidence for hFMT as a promising tool to study ASD pathophysiology, specifically the microbiota-gut-immune system-brain axis, or the potential effects of treatments.

422.136 (Poster) Frequency of Fruits and Vegetables Consumption and Their Possible Interactions with Genotypes of Glutathione S-Transferase Genes in Relation to ASD and ASD Severity in Jamaican Children
S. Saroukhani1, M. E. Samms-Vaughan1, J. Bressler1, M. Lee1, C. E. Byrd-Williams1, M. Hessabi1, M. L. Grove1, S. Shakespeare-Pellington1, K. A. Loveland1 and M. H. Rahbar1,2, (1)Biostatistics/Epidemiology/Research Design (BERD) core, Center for Clinical and Translational Sciences (CCTS), The University of Texas Health Science Center at Houston, Houston, TX, (2)Division of Clinical and Translational Sciences, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, USA

Aims: To explore the frequency of Fruits and Vegetables Consumption and their possible interactions with genotypes of Glutathione S-transferase (GST) genes in Jamaican children with ASD.

Methods: A total of 538 Jamaican children (312 ASD and 226 Control) aged 4-17 years were included in this study. The frequency of Fruits and Vegetables Consumption was measured using a structured food frequency questionnaire. The genotypes of GST genes were determined using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). The associations between Fruits and Vegetables Consumption and genotypes of GST genes were assessed using logistic regression analysis.

Results: The frequency of Fruits and Vegetables Consumption was significantly lower in children with ASD compared to controls (p<0.05). Moreover, certain genotypes of GST genes were associated with reduced Fruits and Vegetables Consumption in children with ASD.

Conclusions: The lower frequency of Fruits and Vegetables Consumption in children with ASD may be attributed to their genotype. Further studies are needed to confirm these findings and to explore the possible role of GST genes in the development of ASD.
Background: Atypical selective eating, with reduced preference for fruits and vegetables (FVs), is common in children with Autism Spectrum Disorder (ASD). These children are prone to deficiency of phytonutrients with antioxidant effects. Polymorphisms in glutathione S-transferase (GST) genes can also influence susceptibility to increased oxidative stress, a possible underlying mechanism for ASD.

Objectives: To investigate associations of the frequency of FV consumption, and its interactions with GST genes, in relation to ASD and ASD severity in Jamaican children.

Methods: Using Exploratory Factor Analysis, we identified seven groups of FVs. Factor scores were calculated by summing reported weekly basis intakes of the factor food items and analyzed as scores: ≥ 3rd quartile vs. < 3rd quartile representing high vs. low consumption. Using data from 242 pairs of age-(± 6 months) and sex-matched ASD cases and typically developing (TD) controls (n=484), we assessed additive and interactive associations of the frequency of FV consumption with polymorphisms in three GST genes (GSTM1, GSTP1 and GSTT1) in relation to ASD, using conditional logistic regression models. With data from (n=242) ASD cases, we used General Linear Models to assess the association of the frequency of FV consumption, and its possible interaction with the GST genes in relation to ASD severity as measured by the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) standardized total, as well as the Social Affect (SA) and Restricted and Repetitive Behaviors (RRB) domains specific comparison scores (CSs).

Results: After adjusting for child’s age and socioeconomic status, ASD cases consumed significantly fewer servings of all groups of FV than TD controls (all matched odds ratios ranging from 0.14 to 0.64, and all P ≤ 0.02). Among ASD cases, high consumption of fruits high in unsaturated fatty acids, legumes and unpeeled fruits was associated with less severe social and/or behavioral signs of ASD (all P ≤ 0.03). Additionally, the presence of at least one Val allele for GSTP1 was associated with consuming fewer servings of fruits high in unsaturated fatty acids, vitamin C and beta-carotene, antioxidants, and fruits and/or vegetable juice by ASD cases than TD controls (all P ≤ 0.01, and P for interaction ≤ 0.02). GSTT1 and GSTM1 1/1 or 1/D genotypes were also associated with consuming fewer servings of legumes and any types of unpeeled fruits by ASD cases than TD controls (P for interaction = 0.02 and 0.03, respectively). Furthermore, high versus low frequency of legumes and juices was associated with significantly lower ADOS-2 SA CS only among ASD cases homozygous for GSTP1 Ile105 (P = 0.01 and 0.03, respectively; P for interaction ≤ 0.04). Similarly, high consumption of fruits high in antioxidants had an inverse association with ADOS-2 RRB CS only among ASD cases with GSTP1 Ile/Ile genotype (P ≤ 0.01; P for interaction ≤ 0.03).

Conclusions: Our findings suggest the frequency of fruits and vegetables consumption is associated with ASD and ASD severity, and the genotype for GST genes may have a modifying role on these associations in Jamaican children, though they require replication in other populations.

422.137 (Poster) Genome, Environment, Microbiome and Metabolome in Autism (GEMMA) Study Design: Biomarkers Identification for Precision Treatment and Primary Intervention of Autism Spectrum Disorders By an Integrated Multi-Omics Systems Biological Approach

A. Mezzelani1, A. Zahrah1, G. Leader2, S. Kadzielski1, A. Fasano1 and C. Vecchi1, (1)Institute of Biomedical Technologies, Milan, Italy, (2)Harvard Medical School/Massachusetts General Hospital, Cambridge, MA, (3)University of Galway, Galway, Ireland, (4)Harvard Medical School/Massachusetts General Hospital, Boston, MA, (5)Harvard Medical School/Massachusetts General Hospital, Boston, MA, (6)CISO Fondazione Ehris, Salerno, Italy

Background: Increasing evidence is highlighting that the intestinal microbiota participates in the gut-brain axis playing a key role in Autism Spectrum Disorder (ASD). The GEMMA project (Genome, Environment, Microbiome and Metabolome in Autism) is a study that focuses on the role of the gut-brain axis in ASD by in-depth evaluation and observation of newborns who have a family history of ASD (i.e. siblings of children with ASD). The consortium consists of 16 partners from leading research institutions across Europe and the US.

Objectives: GEMMA aims to identify potential biomarkers which may pave the way for early diagnosis and personalized therapeutic support of ASD, followed by validation on large multi-omics datasets. The study will provide mechanistic evidence of the condition onset and progression in relation to dynamic changes in abnormal gut microorganisms causing epigenetic modifications controlling gut barrier and immune function.

Methods: Italy, Ireland, and the US are enrolling 600 infants for an in-depth evaluation through sample collection (stool, blood, saliva, and urine) and ASD evaluations. For the observational trial, Biospecimens are being collected from birth and every 6 months from infants up until 36 months of age. Enrolled infants are observed from birth and followed over time for early interception of clinical manifestation of ASD and associated microbial and molecular biomarkers detected by omics analyses. The project also includes an interventional arm (to
Germline Aging in Sperm Is Associated with Quantitative Autistic Traits in an Autism-Enriched Cohort

(1) Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2) Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3) College of Health and Human Development, Pennsylvania State University, University Park, PA, (4) University of California at Davis, Davis, CA, (5) Division of Research, Kaiser Permanente Northern California, Oakland, CA, (6) Johns Hopkins University, Baltimore, MD

Background: Advanced paternal age is among the prevailing hypotheses for paternal contributions to autism in children. This is due in part to increased rates of DNA mutations and fragmentation in sperm, and decreased efficacy of DNA proofreading and repair enzymes. However, how other biological indicators of aging that are detectable in sperm — such as epigenetic germline age — are associated with autism or autistic traits has not been assessed. This is important, given that the faithful transfer of gametic genetic and epigenetic information to the developing fetus is essential for neurodevelopment. Recently, a model was developed that uses the sperm DNA methylome to predict an individual’s germline age. This can serve as a biomarker for germline aging and allow for the investigation of how deviations from one’s chronological age might be associated with autistic traits in children.

Objectives: Given that advanced paternal age is associated with autism likelihood in children, we hypothesized that accelerated germline age, relative to chronological age, is associated with quantitative autistic traits in three-year-old children from an autism-enriched cohort.

Methods: This work was conducted in the Early Autism Risk Longitudinal Investigation (EARLI) – a prospective pregnancy cohort that enrolled pregnant people with a child diagnosed with autism. Autistic traits were measured by 1) the Social Responsiveness Scale (SRS), a 65-item questionnaire measuring social communication deficits; 2) the Vineland Adaptive Behavior Scale (VABS), a semi-structured interview that assesses adaptive functioning across multiple domains; and 3) the Mullens Scale for Early Learning (MSEL) that measures cognitive functioning. Sperm was collected from fathers around the time of conception and DNA methylation was analyzed on the Infinium HumanMethylation450 BeadChip platform. We computed estimated germline age (years) using the Jenkins clock, and accelerated epigenetic age was defined as the positive residual obtained from regressing chronologic age on germline age. Generalized linear models adjusting for child sex, paternal education, and genetic ancestry principal components were run to determine how germline age associated with composite and subscale scores for SRS (n=29), VABS (n=33), and MSEL (n=32).

Results: After adjusting for confounders, we demonstrated that accelerated germline age was associated with deficits in social communication for SRS composite scores (β=3.88, p = 0.04, for a one-unit increase) as well as deficits in the cognition (β=0.93, p = 0.01) and communication (β=1.42, p = 0.04) subscales. Decelerated germline age was associated with increased adaptive functioning for VABS composite (β=−2.42, p = 0.007, for a one-unit decrease) and subscale scores across the communication (β=−1.43 p = 0.03), daily living (β=−1.11, p = 0.02), and socialization (β=−1.23, p = 0.01) domains. We did not observe any significant associations between germline age and MSEL composite or subscale scores, though the direction of the relationship between germline aging and trait-outcomes was consistent with observations for SRS and VABS.
Conclusions: We demonstrate that accelerated paternal germline aging is associated with deficits in social communication and adaptive functioning in children from an autism-enriched cohort. These findings provide further support for the role of non-genetic paternal contributions to autism liability.

422.139 (Poster) Head Circumference Trajectories in Autism and Psychotic Experiences
S. Ashley, K. Merritt, P. Laguna, F. Solmi, A. Reichenberg and A. David, (1)UCL, London, United Kingdom, (2)Cardiff University, Cardiff, United Kingdom, (3)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Autism spectrum disorder (ASD) and schizophrenia are both considered to be neurodevelopmental disorders, and research indicates several similarities between the two conditions including negative symptomatology, genetics, and brain structure alterations (Patel et al., 2020; Stone & Iguchi, 2011) However, early brain overgrowth is frequently cited in ASD, while psychotic disorders, which have a later onset, are more commonly associated with attenuated volumes. Head circumference, which can be used as a proxy measure for brain development, may offer insights into the neurobiological trajectories in these two disorders.

Objectives: To compare head circumference trajectories in those with 1) ASD, 2) psychotic experiences (PE), to 3) neurotypical controls, in the Avon Longitudinal Study of Parents and Children (ALSPAC).

Methods: Head circumference measurements were collected in the ALSPAC birth cohort at birth, 7 years and 15.5 years in over 3000 participants. Parents confirmed their child’s ASD status using a questionnaire at age 9 years. Psychotic experiences were assessed using the Psychosis Like Experiences Semi-Structured Interview (PLIKSi) at age 18 years. Participants with PE’s were subdivided into the following groups: suspected PE, definite PE, and psychotic disorder. Analyses of variance were conducted for each timepoint cross-sectionally, with multi-level modelling of repeated measures currently underway to assess longitudinal trajectories (additional timepoints to be included).

Results: Autism was associated with significantly larger head circumference compared to controls at birth (F(1:5927) = 4.6, p = 0.03) with a similar trend at age 7 years (F(1:6275) = 3.45, p = 0.06). There was no difference between the ASD and control groups at age 15.5 (p = 0.26). In contrast, psychotic experiences were associated with a trend towards reduced head circumference at birth (F(3:3572) = 2.55, p = 0.054) and a significant reduction at age 7 compared to controls (F(3:4020) = 3.99, p = 0.008). Post-hoc tests revealed smaller head circumferences in the psychotic disorder group compared to controls (p <0.01). There was no difference between PE and control groups at age 15.5. Preliminary longitudinal analyses suggest that head circumference is increased in ASD (p = 0.006) with no difference over time (no interaction between diagnosis and age (p = 0.91)).

Conclusions: Differences in childhood head circumference in both ASD and PE compared to neurotypical controls indicates the presence of atypical neurodevelopment. The finding of divergent trajectories across the two disorders suggests that head circumference may act as an early biomarker to distinguish autism from psychotic experiences.

422.140 (Poster) Hospitalizations of Autistic Individuals in the United Kingdom during the Covid-19 Pandemic
B. S. Kennedy, S. Baron-Coheir, C. Allison, E. M. Weir and A. Tsompanidis, (1)Department of Psychiatry, University of Cambridge, Autism Research Centre, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, Autism Research Centre - University of Cambridge, Cambridge, United Kingdom, (4)Psychiatry Department, University of Cambridge, Autism Research Centre, Cambridge, United Kingdom

Background: Autistic people have increased rates of physical and mental health conditions compared to non-autistic people. Prior research indicates significant overlap between those conditions which pose increased risk for a serious illness due to Covid-19 and conditions that frequently co-occur with autism (National Health Service, 2021; Croen et al., 2015; Davignon et al., 2018; Hand et al., 2020; Weir et al., 2021; Weir et al., 2022). Specifically, autistic individuals have elevated likelihood for immune disorders, diabetes, obesity, and respiratory, cardiovascular, mental health, and neurological conditions as compared to non-autistic individuals (Croen et al., 2015; Davignon et al., 2018; Hand et al., 2020; Weir et al., 2021; Weir et al., 2022). Data on substance misuse and immune dysregulation were less consistent (Croen et al., 2015; Vohra et al., 2017; Butwicka et al., 2017; Davignon et al., 2018). Overall, these co-occurring health conditions could result in more severe Covid-19 outcomes for autistic people compared to non-autistic people.

Objectives:

This study investigated whether autistic people were overrepresented in the population of individuals hospitalized during the Covid-19 pandemic. The two specific outcomes that were investigated were risk of all-cause hospitalizations and risk of Covid-19 associated hospitalizations.

Methods:
Data were drawn from the clinical practice research database. All-cause and Covid-19 associated hospitalization hazards ratios were calculated using Cox regression for 46,194 patients (N = 15,398 autistic patients) and 46,956 patients (N = 15,652 autistic patients) respectively. Patients were matched on age (± 2 years), sex, and GP practice. Sex, indices of multiple deprivation (a measure of SES in which lower levels indicate greater deprivation), age, GP practice, obesity, smoking, and alcohol misuse were entered into the models as covariates.

Results:

Table 1 shows elevated risk for all-cause hospitalization during the Covid-19 pandemic among autistic individuals who did not misuse alcohol as compared to controls of similar demographics (AHR: 1.33, 95% CI: 1.24–1.42, p < 0.001 with FDR adjustment). Males had significantly less risk of all-cause hospitalizations than females (AHR: 0.52, 95% CI: 0.49–0.56, p < 0.001 with FDR adjustment). Alcohol misusers were excluded in order to satisfy proportional hazard assumptions.

Table 2 shows that autistic people had significantly greater risk for Covid-19 related hospitalizations compared to controls (AHR: 1.90, 95% CI: 1.25–2.89, p < 0.01 with FDR adjustment). Males again had significantly less risk than females (AHR = 0.49, 95% CI: 0.32–0.75, p < 0.001 with FDR adjustment). Individuals in the lowest deprivation level had greater risk than individuals in the second lowest quartile, shown by the AHR less than one for IMD level 2 (AHR: 0.41, 95% CI: 0.20–0.83, p = 0.01).

Conclusions:

These results indicate that autistic people have increased risk for hospitalizations, and especially heightened risk for Covid-19 associated hospitalizations. For all-cause hospitalization risk specifically, alcohol misusers were excluded from the all-cause hospitalization cox analysis to satisfy cox proportional hazards assumptions, so no conclusions can be drawn about smokers. These data indicate that autistic individuals may have heightened risk for serious illness as a result of Covid-19.

422.141 (Poster) Sex Differences in Autism Symptom Severity Change across Childhood

E. Waizbard-Bartov1, E. Ferrer1, B. Heath1, D. S. Andrews1, S. J. Rogers1, C. W. Nordahl2, M. Solomon3 and D. G. Amaral4, (1)UC Davis M.I.N.D. Institute, Davis, CA, (2)UC Davis, Davis, CA, (3)Department of Psychiatry and Behavioral Sciences, University of California Davis, MIND Institute, Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, MIND Institute, UC Davis Medical Center, Sacramento, CA, American Samoa, (5)Department of Psychiatry and Behavioral Sciences, UC Davis The M.I.N.D. Institute, Sacramento, CA

Background: Autism symptoms are comprised of social-communication deficits and restricted/repetitive behaviors (RRB). The severity of these symptoms can change during childhood, with differences between boys and girls. We have previously found that young autistic girls show a stronger tendency to decrease and a weaker tendency to increase in their overall autism symptom severity levels compared to young autistic boys (Waizbard-Bartov et al., 2020; 2022). It is not clear, however, which symptoms are driving these sex differences across childhood.

Objectives: In the current study we evaluated the trajectories of independent autism symptoms across childhood and compared patterns of change (increase or decrease in severity) and stability in such symptoms between boys and girls.

Methods: The study included 183 children diagnosed with autism (55 girls) evaluated three times across childhood, at ages 3, 6 and 11. We analyzed 24 independent items from the Autism Diagnostic Observation Schedule-2 (ADOS-2), the gold-standard assessment tool for autism symptoms, each item representing a specific autism symptom. We used latent growth curve (LGC) models to estimate the trajectories for the 24 ADOS-2 items across childhood, for boys and girls separately. We characterized these trajectories in terms of an initial symptom severity level (i.e., intercept), change across childhood (i.e., slope) and the association between the two (i.e., covariance of intercept and slope) for boys and girls.

Results: Fifteen of 24 items evaluated showed significantly changing trajectories across childhood, 13 of these decreasing-severity trajectories, for boys, girls or both. Both sexes had decreasing trajectories for several social-communication symptoms including “overall level of language”, “conversation”, “response to name”, “unusual eye contact”, “facial expressions” and “gestures”. Only girls had a decreasing trajectory for the “response to joint attention” item and only boys had a decreasing trajectory for the “quality of social o Ivets” item. For RRB, both boys and girls had a decreasing trajectory for “echolalia”. Boys also had decreasing trajectories for the “mannerisms” and “speech abnormalities” items, whereas the slopes of these items for the girls did not reach significance (i.e., considered stable). While only decreasing and stable trajectories were identified for girls, boys had two significantly increasing-severity trajectories, for the “shared enjoyment” and “stereotypic, idiosyncratic speech” items. Both boys and girls showed decreasing trajectories for “creative, imaginative play”. Boys also had a decreasing trajectory for “functional play”, whereas for girls, this did not reach significance. For all other items, the estimated slopes were not statistically significant and, thus, deemed to indicate stable severity levels across childhood.
Conclusions: Girls and boys showed similarities and differences in the in the changes of autism symptom severity across childhood. Both sexes tended to decrease in the severity of several social-communication symptoms, while other symptoms remained stable. Boys had a stronger tendency to decrease in severity of RRB than girls. But, while girls showed only decreasing-severity and stable trajectories, boys also had increasing-severity trajectories for some of the symptoms.

422.142 (Poster) Evaluating Sex Differences in Change Patterns of Autism Symptom Severity across Childhood

E. Waizbard-Bartov, E. Ferrer¹, B. Health², D. S. Andrews³, S. J. Rogers³, C. W. Nordahl⁴, M. Solomon⁵ and D. G. Amaral⁶. (1)UC Davis M.I.N.D. Institute, Davis, CA, (2)UC Davis, Davis, CA, (3)Department of Psychiatry and Behavioral Sciences, University of California Davis, MIND Institute., Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, MIND Institute, UC Davis Medical Center, Sacramento, CA, American Samoa, (5)Department of Psychiatry and Behavioral Sciences, UC Davis The M.I.N.D. Institute, Sacramento, CA

Background: Autism symptoms are comprised of social-communication deficits and restricted/repetitive behaviors (RRB). The severity of these symptoms can change during childhood, with differences between boys and girls. We have previously found that young autistic girls show a stronger tendency to decrease and a weaker tendency to increase in their overall autism symptom severity levels compared to young autistic boys (Waizbard-Bartov et al., 2020, 2022). It is not clear, however, which symptoms are driving these sex differences across childhood.

Objectives: In the current study we evaluated the trajectories of independent autism symptoms across childhood and compared the patterns of change in such symptoms between boys and girls.

Methods: The study included 183 children diagnosed with autism (55 girls) evaluated three times across childhood, at ages 3, 6 and 11. We analyzed 22 independent items from the Autism Diagnostic Observation Schedule-2 (ADOS-2), the gold-standard assessment tool for autism symptoms, each item representing a specific autism symptom. First, we used latent growth curve models to estimate the trajectories for the 22 ADOS-2 items for each child in the study. Second, we extracted the factor scores representing the individual slopes for each ADOS-2 item (i.e., slope representing that child’s change in that specific item). Third, we used factor analysis to identify common patterns of change among the ADOS-2 items, separately for boys and girls, i.e., which autism symptoms tend to change together and which change independently across childhood.

Results: The best emerging patterns for both boys and girls identified four common factors: three factors representative of changes in social-communication symptoms and one factor describing changes in RRB. Boys and girls showed the same pattern of change in RRB, with four items (e.g., speech abnormalities) changing together across childhood and three items (e.g., mannerisms) changing independently of other items. For social-communication deficits in boys, three factors were identified: the first factor included six items representing initiating and engaging in social-communication (e.g., quality of social otures, conversation), the second factor included five items describing responsive social-communication (e.g., response to name) and the third factor included three items related to different aspects of social-communication (e.g., level of language). Girls’ social-communication deficits also loaded onto three factors: the first factor included five items (e.g., unusual eye contact), the second factor included six items (e.g., quality of social response) and the third factor included four items (e.g., showing). Some items showed similar patterns of change for both sexes (e.g., responsive joint attention), while other items showed differences (e.g., shared enjoyment).

Conclusions: Girls and boys had different patterns of change in autism symptom severity across childhood. For RRB, both sexes showed similar patterns. For social-communication symptoms, however, there were both similarities and differences between boys and girls in the way symptoms changed over time. The strongest patterns of change were identified for initiating and engaging in social-communication for girls.

422.143 (Poster) Prenatal Exposures to Endocrine-Disrupting Chemicals and Autism-Related Outcomes in Childhood

Background: Many endocrine-disrupting chemicals (EDCs) have neurotoxic potential, but their influence on autism spectrum disorder (ASD) remains to be elucidated. Per- and polyfluoroalkyl substances (PFAS) and organophosphate esters (OPEs) are two classes of EDCs that are widely detected in the U.S. population, including pregnant people, due to their ubiquitous use in industry, manufacturing, and consumer products. To date, the epidemiological evidence linking prenatal exposure to these EDCs with altered neurodevelopment is inconclusive, and few large studies have focused on autism-related outcomes.

Objectives: This study investigates whether concentrations of PFAS and OPEs in biospecimens collected during mid-pregnancy are associated with child autism-related outcomes.

Methods: Twenty cohorts from the National Institutes of Health (NIH)-funded Environmental influences on Child Health Outcomes (ECHO) Program were included. Fourteen PFAS were measured in maternal serum/plasma samples from 10 cohorts (n=1,429) and nine OPE analytes were measured in maternal urine samples from 19 cohorts (n~7,000). We assessed dimensional autism-related behaviors in children via parent report on the 65-item Social Responsiveness Scale (SRS). We also obtained information on clinical diagnosis of ASD from either parental report or abstraction of medical records. We examined relations of individual PFAS and OPE analytes with SRS scores in multivariable linear models and with child ASD diagnosis in multivariable logistic models. All models were adjusted for potential confounders including maternal age at delivery, maternal educational attainment, maternal race/ethnicity, parity, and child sex. EDC levels were modeled continuously, categorically, or as detect/non-detect depending on the proportion of participants with values above the limit of detection. We further modeled each EDC class as a mixture using Bayesian methods in order to evaluate the aggregate and relative contributions of each EDC within each class. We examined modification of these relations by child sex.

Results: Concentrations of most PFAS were not associated with child SRS T-scores. Perfluorononanoic acid (PFNA) showed the strongest and most consistent association: each ln-unit increase in PFNA was associated with greater autism-related traits (adj-β:1.5, 95% CI: -0.1, 3.0). PFNA showed a stronger association with scores on the SRS subscale of social communication and interaction (adj-β:1.8, 95% CI: 0.2, 3.4) relative to the subscale of restricted interests and repetitive behaviors (adj-β: 1.1, 95% CI: -0.6, 2.8). The summed mixture, which included 6 PFAS detected in >70% of participants, was not associated with SRS T-scores (adj-β: 0.7, 95% Highest Posterior Density Interval: -1.4, 3.0). We did not observe a clear pattern of associations between PFAS and ASD diagnosis and the estimates were imprecise. We did not observe consistent evidence of sex differences with respect to PFAS. We will also discuss analyses of the association between prenatal OPEs and autism-related outcomes, which are currently underway.

Conclusions: We found limited evidence that prenatal PFAS blood concentrations are associated with autism-related outcomes in children. Future work should continue to examine the relationship between exposures to both legacy and emerging PFAS, other EDCs, and additional dimensional, quantitative measures of child neurodevelopment and neurobehavior.

---

**POSTER SESSION — EPIDEMIOLOGY**

**433 - Epidemiology II**

**433.167 (Poster) How Socioeconomic Status and Urban-Rural Environment Can Influence Time of Late Suspicion of Autism: Results from a Pilot Study**

E. Grossi and E. Castagna,(1)Autism Research Unit, Villa Santa Maria SCS, Taverno, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy

Background:

There has been recent interest in the relationship between socioeconomic status, urbanicity level and the diagnosis of autism in children. Studies in the United States have found lower rates of autism diagnosis associated with lower socioeconomic status, while studies in other countries report no association, or the opposite. In a large Danish register-based cohort the urbanicity level was critical, with an earlier age of ASD diagnosis in urban areas. No specific studies on the socioeconomic factors and urban context associated with the age at ASD diagnosis have been conducted in Italy. Since a diagnostic delay may depend on a heterogeneous functioning of the local health care systems in term of waiting times, a more specific connection for our targets of interest is the age at first medical contact for diagnostic suspicion rather than age at diagnosis.

Objectives:
The focus of this pilot study is the association between age at first medical contact for diagnostic suspicion and socioeconomic status and urbanicity level in Lombardy Region, the most populous and rich Region in Italy.

Methods:

Twenty ASD cases referred to our Institute for rehabilitation from 2020 to 2021 coming from 16 municipalities were entered in the study. The age at first medical contact for parental concern was determined from parents reports. Family socioeconomic status was calculated from four factor index of social status (mother and father education achievement level and occupation level). Age and place of birth of parents (North, Centre, South Italy) and city size where the family lived, and child gender were other variables used for input data.

Results:

The study group was composed by 12 males and 8 females (mean age 7.19 yrs; range 2-11 yrs) diagnosed with autism according to DSM V criteria. The age at first medical contact for parental concern ranged between 13 and 79 months (mean= 32.8 months) while the age at diagnosis ranged between 23 and 91 months (mean= 43 months). The delta time between these two ages was in mean 10 months with a peak of 42 months. Family socioeconomic status index ranged from 4 to 15 (mean= 10.25). Correlations between age at first access and study variables are shown in table 1. Mother education years, family SES and father education years being the variables with the highest inverse correlation(R= -45; - 0.43; -0.41 respectively) resulted the most important factors for an early diagnostic suspicion.

Conclusions:

Higher mother and father education years and higher family socioeconomic status, play a substantial role in influencing positively the decision to seek medical help for ASD suspicion and consequently the age at diagnosis, while city size has a minor role.

433.168 (Poster) Investigating Sex Differences in AQ and BAPQ Factor Structures Among University Students

C. Marceau-Linhares, K. E. Hannah, E. J. Choi and R. A. Stevenson; (1)University of Western Ontario, London, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

Background:

Autistic girls and women are often underdiagnosed, and symptom presentation may differ between males and females. Consequently, measures used to quantify autism-related traits in autistic and non-autistic samples, such as the Autism-spectrum Quotient (AQ) and Broad Autism Phenotype Questionnaire (BAPQ), may measure traits differently across the sexes. Investigating questionnaire factor structures in a large sample of men and women from the general population would allow for a clearer picture of autistic traits in both sexes. Additionally, this investigation may inform later considerations of measurement techniques of autistic traits in both non-clinical and autistic samples.

Objectives:

1) Establish factor structures of the AQ and BAPQ in a large sample of university students;
2) Determine if these factor structures are invariant across sex assigned at birth.

Methods:

1773 participants (1044 female) completed the AQ, and 1742 participants (1024 female) completed the BAPQ. Exploratory structural equation modelling was used to explore factor loadings for each questionnaire, followed by invariance testing to determine if questionnaire models differed between sexes. Group differences in total and subscale scores of the AQ and BAPQ were compared using Mann-Whitney U-tests.

Results:

Overall, items did not cluster well onto the AQ’s original five-factor model. Configural, metric, and scalar model tests were significant (ps<.001), indicating different factor structures for men and women. More items loaded onto intended existing factors in the female model than the male model. Females scored significantly lower on total AQ, and Communication and Imagination subscales; but scored higher on Attention Switching compared to males (Figure 1).

Despite both male and female models clustering relatively well onto the BAPQ’s three-factor model, certain items loaded onto different factors for men and women. Relatedly, configural, metric, and scalar model tests were significant (ps<.001), indicating different factor structures for men and women. Females scored significantly lower than males on total BAPQ and all subscales (Figure 2).

Conclusions:

Both the AQ and BAPQ measures showed sex differences in autistic trait constructs. Specifically, multiple items on each questionnaire had high loadings for only males or only females. For the BAPQ, some items loaded onto completely different factors for men and women. These findings suggest that sex should be considered when using these measures to assess autistic traits.

Broadly speaking, females scored lower on both questionnaires, in line with previous literature. While this is generally interpreted as
resulting from autism being male-dominant, this could also be related to a lack of sensitivity to autism presentation in females. Interestingly, females also scored higher on AQ Attention Switching than males, potentially supporting the idea that autistic traits present differently in females.

Lastly, BAPQ latent factors found in the current study are better aligned with the original theoretical model in contrast to those of the AQ. This may be due to our non-clinical sample, as the AQ was originally tailored to clinical autistic populations while the BAPQ was intended to measure a broader phenotype. Despite the AQ’s popularity in non-clinical samples, current research suggests using the BAPQ to yield accurate results when studying non-clinical samples.

433.169 (Poster) Males and Females Are Markedly Similar across Domains in the Autism Inpatient Collection: Implications for Conceptualization of Profound Autism
E. Touchette, K. A. Pedersen, S. L. Santangelo and M. S. Siegel, Center for Clinical and Translational Science, MaineHealth, Portland, ME

Background: Many studies have examined differences between male and female children with autism spectrum disorder (ASD). However, there is little research from large samples examining differences between male and female children with profound autism and severe challenging behavior, such as those who are hospitalized in specialized inpatient units.

Objectives: To describe patient demographics enrolled in the Autism Inpatient Collection (n=1354 sample). To examine for potential differences between males and females on clinical and behavioral assessments in this sample of profound ASD.

Methods: Data from 1354 hospitalized children and adolescents with an Autism Diagnostic Observation Schedule-2 confirmed ASD diagnosis from the Autism Inpatient Collection (AIC), and parent-reported data, were analyzed. The AIC is a multi-site study of patients hospitalized in inpatient units specialized for the psychiatric treatment of children with ASD and other neurodevelopmental disorders. At admission, parents completed demographic measures and the Aberrant Behavior Checklist (ABC), the Child Behavior Checklist (CBCL), Vineland-3, and Emotional Dysregulation Inventory (EDI). Descriptive statistics, including means and standard deviations for continuous variables and proportions for categorical variables, were computed. Independent samples t-tests were conducted to examine for differences between males’ and females’ for continuous variables and chi-square tests for categorical variables.

Results: The majority of patients in the sample were male (80%), White (84%), non-Hispanic (93%), mean age 12.6 years, Leiter non-verbal IQ score of 74.2, and 48.3% minimally verbal. There were no significant differences between males and females on race, ethnicity, age, length of hospital stay, IQ, or verbal ability (see Table 1). Males in our sample had significantly higher Vineland-3 externalizing problem behavior scores (20.9±1.7, vs 20.0±2.0, p=.01), and ABC-hyperactivity scores (28.4±10.8, vs 26.7±11, p=.04), compared to females. Females in our sample had significantly higher CBCL attention deficit/hyperactivity problems (68.7±7.5, vs 67.3±7.7, p<.001), dysphoria scores on the EDI (57.1±8.2, vs 55.7±8.9, p=.03), and ABC-irritability subscale scores (challenging behavior) (28.9±9.2, vs 26.6±9.5, p=.002), (see Figure 1).

Conclusions: Female children with ASD from our sample have significantly higher ADHD, dysphoria, and challenging behavior scores compared to males. Females displaying greater levels of challenging behavior is a finding that has not been well represented in the literature and should be further explored to identify related factors in this sample. While markedly similar to males on most measures, female ASD inpatients exhibit even more challenging behaviors. Given that the overwhelming majority of study participants in our sample were male, there is a need to collect additional data describing the characteristics of female children with ASD. Further exploration is warranted into the sex and gender-specific phenotypic manifestation of these differences, which could inform gender-specific interventions.

433.170 (Poster) Maternal Gestational Weight Gain and Offspring’s Neurodevelopmental Outcomes: A Systematic Review and Meta-Analysis
D. Wu, Y. Li, L. Chen, M. Klein, B. Franke, J. Chen and J. K. Buitelaar, (1)Department of Cognitive Neuroscience, Radboud University, Nijmegen, Netherlands, (2)Department of Child Health Care, Shanghai Children’s Hospital, School of medicine, Shanghai Jiao Tong University, shanghai, China, (3)Department of Occupational Therapy Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, (4)Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, (5)Department of Human Genetics and Psychiatry, Radboud University Medical Center, Nijmegen, Netherlands, (6)Department of Cognitive Neuroscience, Radboud University, Nijmegen, NETHERLANDS, (7)Karakter Child and Adolescent Psychiatry University Center, Nijmegen, Netherlands

Background:

Since the Institute of Medicine (IOM) released updated recommendations for appropriate and abnormal gestational weight gain (GWG) in 2009, found that GWG was increasing globally, above guidelines in 47% of pregnancies. Meanwhile, a multitude of studies have focused on the association between weight gain during pregnancy and adverse neurodevelopmental outcomes in the offspring. However, there are inconsistencies in the results of existing studies and incompleteness in the previous published meta-analysis.
Objectives:

To perform a systematic review and meta-analysis to evaluate associations between excessive or insufficient gestational weight gain and offspring’s neurodevelopmental outcomes.

Methods:

This systematic review and meta-analysis was conducted according to the criteria of Preferred Reporting Items for Systematic Reviews and Meta Analyses (PRISMA). The review protocol was registered in PROSPERO (Registration number: CRD42022338227). We searched publications in PubMed, Embase, Cochran databases and China National Knowledge Infrastructure (CNKI) databases, published before July 19, 2022, for observational studies stratified by total gestational weight gain. Inclusion and exclusion criteria were discussed and approved by all authors. A modified Newcastle-Ottawa Scale (NOS) was used to assess the quality of the included studies. Data were extracted by two independent reviewers. Effect size (ES) and 95% confidence intervals (95% CI) were calculated with a random-effects model to accommodate the expected heterogeneity of the observational studies. Primary outcomes were offspring with autism spectrum disorder (ASD), intellectual disability (ID), and/or attention-deficit/hyperactivity disorder (ADHD). Secondary outcome was ASD combined with ID.

Results:

Of 2075 identified studies, 20 met the inclusion criteria. Excessive gestational weight gain was associated with higher risk for neurodevelopmental disorders (NDDs; ASD & ID & ADHD: OR= 1.11 [95% CI 1.06-1.16]), ASD (OR=1.14 [95% CI 1.07-1.21]), ADHD (OR=1.08 [95% CI 1.01-1.15]), ASD with ID (OR=1.20 [95% CI, 1.04-1.39]), and ASD without ID (OR=1.12 [95% CI 1.06-1.19]). Risk for ID showed no association with weight gain (OR=1.10 [95% CI 0.97-1.24]). Insufficient gestational weight gain was associated with higher risk for ID (OR=1.19 [95% CI 1.11-1.29]); no significant association was observed with NDDs (OR=1.08 [95% CI 0.98-1.18]), ASD (OR=1.04 [95% CI 0.91-1.19]), ASD with ID (OR=1.08 [95% CI, 0.91-1.29]), ASD without ID (OR=1.10 [95% CI 0.95-1.26]), or ADHD (OR=1.08 [95% CI 0.90-1.28]).

Conclusions:

Gestational weight gain greater than or less than IOM guideline recommendations, compared with weight gain within the recommended range, was associated with higher risk for offspring’s neurodevelopmental outcomes. While interesting, this finding does not allow causal inferences given potential confounding by genetic factors, gene-environment interactions, and confounding by (pre-)pregnancy diabetes. More consideration should be given to genetically sensitive designs in future studies to enable investigation of the role of GWG in offspring neurodevelopmental disorders.

433.171 (Poster) Maternal Sars-Cov-2 Infection during Pregnancy and Child Neurodevelopmental Outcomes at 18 Months of Age

L. A. Croen, Y. Qian, J. L. Ames, S. Alexeeff, R. Yolken and J. Van de Water; (1)Division of Research, Kaiser Permanente Northern California, Oakland, CA, (2)Division of Research, Kaiser Permanente Division of Research, Autism Research Program, Oakland, CA, (3)Johns Hopkins University, Baltimore, MD, (4)MIND Institute, University of California, Davis, Davis, CA

Background: Little is known about the impact of COVID-19 during pregnancy on child neurodevelopment. Maternal inflammation during pregnancy can result from immune dysregulation due to infections or stress. COVID-19 illness may therefore result in increased maternal inflammation during pregnancy. Several lines of evidence suggest that in utero exposure to inflammation can have deleterious effects on fetal neurodevelopment and increase risk for autism spectrum disorders.

Objectives: To investigate maternal COVID-19 during pregnancy and risk of autism spectrum disorders and other neurodevelopmental outcomes in a large and diverse population receiving medical care in the same integrated healthcare delivery system.

Methods: We conducted a longitudinal cohort study of women who were members of Kaiser Permanente in Northern California (KPNC), pregnant during the COVID-19 pandemic from March to December 2020 and delivered a liveborn baby (N=35,754). We ascertained maternal COVID-19 infection status and child neurodevelopmental outcomes from information prospectively recorded in the KPNC electronic health records. Maternal COVID-19 infection was defined by a positive SARS-CoV-2 PCR test result during pregnancy. We identified all children diagnosed with any neurodevelopmental disorder (NDD) or an autism spectrum disorder (ASD) in the first 18 months of life. We fit crude and adjusted logistic regression models to estimate the association between maternal COVID-19 during pregnancy and NDD diagnosed by 18 months of age. Covariates included maternal age at delivery, maternal race/ethnicity (Asian, Black, Hispanic, White, Other), maternal insurance type (commercial, government), child sex, and the child’s length of KPNC membership after birth (months).

Results: Of the 626 (1.75%) women who had a positive SARS-CoV-2 PCR test during pregnancy, 1.9% were in the first trimester, 21.2% in the second trimester, and 76.8% in the third trimester. Women with a positive test were more likely to be younger, Hispanic, have less
Background: The human microbiota can be looked at as the interface between genes and an individual’s history of environmental exposures, thus providing new insights into the neurodevelopment and behavioral phenotypes. Recent studies demonstrated that children with ASD and gastrointestinal symptoms show major fecal microbiota alterations. The interventional arm of this study seeks to study the changes of the micro-environment of the gastrointestinal tract (and associated inflammatory consequences) at an early age through dietary intervention. This interventional study will help to understand and identify potential biomarkers of dysbiosis in infants with ASD through the use of the probiotic called Visbiome. It has been reported that the usage of Visbiome in children with ASD showed a decrease in gastrointestinal symptoms (GI) and an increase in adaptive functioning (Santocchi et al, 2020). In conjunction with Visbiome, the infants enrolled in the study will have ASD evaluations that includes the Brief Observation of Symptoms of Autism (BOSA), the Vineland Adaptive Behavior Scale, Developmental-Profile-3 and 4, and the Social Responsiveness Scale-2. The symptoms of ASD will be evaluated through these scales to measure ASD symptom changes before and after a 6-month Visbiome treatment.

Objectives:

- To observe the development of ASD symptoms in 600 at-risk infants for ASD in Ireland, Italy, and the United States.
- To enroll participants from the Observational study who have undergone comprehensive ASD evaluation into the Interventional arm of the study.
- To evaluate the effects of Visbiome on ASD symptoms and Gastrointestinal Symptoms

Methods: The BOSA Scale is designed to measure ASD behavioral symptoms including communication, social interaction, restricted and repetitive behaviors. For the BOSA assessment, checklists can be used to view symptom presence across each diagnostic domain. These children will be categorized into the following groups: Little-to-no concern, mild-to-moderate concern, and moderate-to-severe concern. Mild-to-moderate concern and moderate-to-severe concern will be eligible to participate in the interventional arm of the study. The Vineland Adaptive Behavior Scale, DP-3/4, and the SRS-2 scale will be used in conjunction with the BOSA to further evaluate the child’s functioning in physical skills, adaptive behavior, social-emotional scale, cognitive scale, and communication. In order to evaluate gastrointestinal symptoms, the Gastrointestinal Symptom Rating Scale (GSRS) and food diaries will be administered on a monthly basis.

Results: While analysis is ongoing, currently, 33% of children in the Observational Study are currently showing mild-to-moderate and moderate-to-severe concern as measured by the BOSA. Results from Vineland Adaptive Behavior Scale, Developmental Profile-4, and Social Responsiveness Scale-2 will also be reported. In May 2023 we will present the results of the Visbiome interventional arm of the study.

Conclusions: Overall, our findings are on-going and so far show a high-risk of developing ASD from having a sibling already diagnosed. The treatment arm of Visbiome may contribute to reducing ASD and GI symptoms.

433.172 (Poster) Multi-Centered Early Developmental Evaluations and Probiotic Treatment of Infants at-Risk of Autism Spectrum Disorder from Ireland, Italy, and the United States

A. Zahrah1, G. Leader2 and S. Kadzielski3, (1)Harvard Medical School/Massachusetts General Hospital, Cambridge, MA, (2)University of Galway, Galway, Ireland, (3)Harvard Medical School/ Massachusetts General Hospital, Boston, MA

433.173 (Poster) Prematurity and Autism Spectrum Disorder: A Look at the Interpretation of Screening and Diagnostic Tools in Patients at a Brazilian Children's Hospital

L. N. Yamada1, W. A. Gonçalves2, M. A. Pinhel3, L. Chaves3 and D. C. Aragon3, (1)Department of Pediatrics, University of São Paulo, Ribeirão Preto, Brazil, (2)University of São Paulo, Ribeirão Preto, Brazil, (3)University of São Paulo, Ribeirão Preto, Brazil
Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental delay characterized by difficulties in social communication and the presence of repetitive, restricted behaviors and/or interests. This disorder appears in early childhood and affects the autonomy of the individual in a heterogeneous, direct, and chronic way. There is a genetic basis and environmental factors that can act as "triggers", such as prematurity and maternal age. This population needs a follow-up to avoid further damage.

Objectives: To evaluate the incidence of ASD and related risk factors in children who were born at less than 34 weeks of gestational age at a 12-month follow-up, using screening and diagnostic tools.

Methods: Sixty-one subjects born in a Children's Hospital of a Brazilian Medical School were evaluated at two different times: Time 0 (T0); subjects with corrected age between 18 and 24 months and Time 1 (T1); these same participants 12 months later. In T0, the Modified Checklist for Autism in Children - MCHAT was applied to all participants and, in T1, the Autism Behavior Checklist - ABC. After these assessments, patients were assigned with ASD (ASD+) and without ASD (ASD-). With the ABC, it was possible to identify the permanence, loss or emergence of signs for autism when comparing T0 with T1.

Results: The mean age and the standard deviation of the 61 participants was 21.2±3.3 months at T0 and 33.5±2.1 months at T1 (p<0.0001). The total maternal age was 29.4±5.7 years. At T0 for MCHAT, it was observed that 44 (72%) patients were MCHAT- and the remain 17 (28%) had suspicious signs of ASD (MCHAT+), of these, 5 (29%) supported ASD criteria at T0 (MCHAT+ and ABC+). Of the total MCHAT- in T0 (n=44) only 1 (2%) was ABC+ in T1. Therefore, 10% (n=6) of patients were diagnosed with ASD, furthermore, maternal age did not differ between ASD+ (29.1±5.3 years) and ASD- (29.4±5.8 years; p =0.903). Individuals with ABC+ (n=6) had positive responses to critical questions 7, 9 and 14 of the MCHAT (100%, 67% and 83%, respectively) compared to those with ABC- (n=55) (9%, 27% and 18%, respectively) (p<0.001). A higher total ABC score was observed for ASD+ (88.3±19.9 points) compared to ASD- (27.3±12.8 points; p<0.0001), these data reflect the increased mean values of all ABCs in patients with ASD+ compared to ASD- (p<0.05 for all).

Conclusions: In this context, prematurity appears to be a risk factor for ASD, unlike maternal age. In addition, it is important to note that all individuals with ASD+ responded positively to 3 out of 6 critical MCHAT questions, in addition to having an overall ABC score above average. These data serve as a potential warning score for ASD in the follow up this at-risk population.

433.174 (Poster) Prenatal Mood and Anxiety Disorders and Risk of Neurodevelopmental Disorders in Children

A. Kepinska, L. E. Cohen, J. D. Busbaum, D. Grice and B. Mahjani, (1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Mount Sinai School of Medicine, New York, NY, (3)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (4)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

Background: One in five women suffer from mood and anxiety disorders during pregnancy. These disorders are associated with an increased risk of neurodevelopmental disorders (NDDs) in children. Interpreting this association is complicated: (a) most studies only focus on depression despite a substantial morbidity of other disorders. Anxiety disorders and obsessive-compulsive disorder (OCD) are equally as prevalent; (b) there is a gap in our understanding of the pathways by which prenatal mood and anxiety disorders (PMADs) are associated with risk of NDDs in offspring; and (c) paternal PMADs also contribute to the offspring’s risk of NDD, but research on it is scarce. The aim of this project is to measure the extent to which maternal and paternal PMADs increase the risk of NDDs: autism spectrum disorder (ASD), intellectual disability (ID), and attention-deficit/hyperactivity disorder (ADHD) in offspring.

Objectives: To determine the association between active maternal and paternal PMADs and an increased risk of NDDs in offspring.

Methods: We systematically searched all English-language articles in the databases PubMed, Cochrane Central Register of Controlled Trials (CENTRAL), and OVID from January 1, 1988 to September 16, 2022. Two authors independently screened all articles for inclusion. Data were extracted independently by two authors. We included all articles referencing prenatal anxiety-related disorders, depression, OCD, and offspring ADHD, ASD, and ID. For each included manuscript, we checked the quality of the study design, the power of the study, the appropriate statistical techniques, and other related criteria. We performed random-effect meta-analyses for the impact of each PMADs on the risk offspring NDDs.

Results: We identified 1,971 relevant articles in the literature, and 150 articles fulfilled the inclusion criteria for the systematic review. First results from our study are already implicating maternal prenatal anxiety-related disorders and depression are associated with increased risk of ADHD, ASD, and ID in offspring. Our analyses also highlight that there are very significant gaps in the literature. While some PMADs, such as prenatal OCD, have been reported among fathers, research on prenatal paternal mental health during pregnancy has lagged behind that of prenatal maternal mental health. In particular, the association between paternal PMADs and risk of NDDs in offspring is mostly unknown and bears mixed results. Some studies have shown that paternal anxiety and depressive symptoms are positively associated with externalizing behaviors in offspring, including oppositional-defiant behavior and conduct problems. In contrast, other studies either did not find any association, or demonstrated a weak or negative association between paternal PMADs and offspring NDDs.

Conclusions: While still preliminary, our results indicate that PMADs contribute to the risk of NDDs in offspring. This research is crucial as it addresses critical gaps in understanding associations between PMADs and the risk of NDDs in children. This will help guide future
research by pinpointing probable mechanisms of this association which in turn can influence early interventions for PMAD management and/or NDD prevention.

433.175 (Poster) Prevalence of Self-Reported Medication Use during Early Pregnancy in the Early Autism Risk Longitudinal Investigation (EARLI)

Background: Medication use during pregnancy presents considerations for both the mother and child. Previous work has described commonly used medications among pregnant women in the general population, and their relationships to child outcomes like autism, but medication use during early pregnancy among women who have a prior child with a developmental disorder, which may alter medication use patterns and prevalence, is less well characterized.

Objectives: To characterize common maternal medication use during early pregnancy in families with at least one child with autism.

Methods: Participants were drawn from the Early Autism Risk Longitudinal Investigation (EARLI) study, a cohort enrolling pregnant mothers who already had a child with autism and followed the subsequent child to 36 months of age. Data on self-reported maternal medication use during first or second-trimester pregnancy was used to estimate the prevalence of medication use during early pregnancy and to ascertain the most commonly reported medications. Descriptive statistics were used to assess potential differences in medication use by maternal characteristics. In addition, the prevalence of medication use by category of indications was compared to external reference samples.

Results: A total of 234 pregnant mothers were included in the analyses. Use of any reported medications during early pregnancy was reported by 76% (n=177) of mothers, with most reporting common over-the-counter (OTC) medications, including pain medication (48%) and GI-related medications (33%). In addition, 32% of those reporting any medication use reported medications (OTC or prescription drugs) for allergy/asthma-related illness, while 19% reported the use of antibiotics, and 10% reported psychotropic medications. The five most commonly reported medications were acetaminophen (n=82, 34%), followed by ibuprofen (n=32, 13%), calcium carbonate (n=31, 13% antacid), pseudoephedrine (n=26, 10%, nasal decongestants), and dextromethorphan guaifenesin (n=13, 5%, cough suppressants). The most reported prescription-only drug was azithromycin (n=12, 5%, antibiotics). Despite overall high prevalence of any medication use, use of prescription drugs and categories of drugs like psychotropics were similar in this population to reference comparison groups including NHANES. Comparing mothers who reported any medication use to those with no reported use, the majority of the former group reported White race, while mothers who reported no medication use were more likely to report non-White race. Mothers in the medication-use group also had a higher average BMI (mean=28.3, SD=7.21) relative to mothers in the non-use group (mean=25.6, SD=4.89). Those in the non-use group were more likely to have a lower income than the medication-use group (17.5% vs 29.4%).

Conclusions: In this autism family cohort, medication use during pregnancy across categories of medications was common, with pain-related medication being the most common category. Approximately 1 in 3 mothers reported the use of acetaminophen during the first half of the pregnancy. Differences in medication use by maternal BMI and race support the need to account for these factors in analyses of associations with child outcomes. Further analyses will examine these maternal medication use categories in association with child autism-related outcomes in this population.

433.176 (Poster) Proportional over-Representation of Gender-Diverse Identities in Two US-Based Autistic Adult Samples Recruited through the SPARK Database

Background: Previous literature indicates proportional over-representation of autism and, more broadly, autistic traits, within gender diverse populations (i.e., those with gender identity/identities incongruent with their sex assigned at birth). Studies of gender diversity and autism, as well as a recent study suggesting developmental and mental health phenotypes differentially related to gender identity vs. assigned sex at birth, emphasize the importance of studying gender as it relates to autism presentation and diagnosis (Strang et al., 2020, Strang et al, 2021, Kallitsounaki & Williams, 2022; Warrier et al., 2022). Several recent studies report a proportional over-representation of gender identity diversity in autism. A study of a large sample of autistic adolescents and adults (n = 675) from the Netherlands Autism...
Register showed a rate of trans and nonbinary identities at 15% (Walsh et al. 2018; see also Dewinter De Graag, & Begeer, 2017). In comparison, just 3.9% of the general population in the Netherlands had a trans or nonbinary identity (Kuyper & Wijsen, 2014). A subsequent study found that 6.5% of the autistic adolescent sample (n = 573) and 11.4% of the autistic adult sample (n=807) self-reported a desire to be a gender other than what they had been assigned at birth, compared with 3.1% of a standardization sample of adolescents aged 11-18 years old (van der Meisen et al., 2018). Research documenting the prevalence and experience of gender diversity within autistic adults is still limited in US-based samples.

Objectives: This study examined rates of gender diversity and mental health conditions in autistic adults who enrolled in an online study unrelated to the topic of gender identity.

Methods: We examined rates of gender diversity and co-occurring mental health conditions in two independent moderately sized, US-based autistic adult samples (total n=448) enrolled in two separate online studies investigating predictive processing.

Results: In this study, 16% of autistic adults in Dataset 1 and 20% of autistic adults in Dataset 2 reported being gender diverse (having a gender identity or identities different from their sex assigned at birth). Additionally, participants who reported being gender diverse, compared to those who did not, were up to 6 times more likely to report an anxiety and/or mood disorder.

Conclusions: The finding of a proportional over-representation of gender diversity in autistic adults is consistent with previous reports, though somewhat higher than prior estimates (Walsh et al. 2018; see also Dewinter De Graag, & Begeer, 2017). This study highlights the need for improved characterization of gender diversity in autism, including future research with larger sample sizes, to investigate the intersection between gender diversity, autism presentation, and mental health and resilience.

433.177 (Poster) Revisiting Smoking and Autism Spectrum Disorder from a Multigenerational Perspective: Findings from a Nation-Wide Prospective Cohort Study

Background: Animal studies have shown that exposure to cigarette smoke during pregnancy can induce neurobehavioral anomalies in multiple subsequent generations, possibly through effects on the germline. However, little work has examined such effects in humans.

Objectives: To explore the potential multigenerational association between smoking during pregnancy and risk of autism spectrum disorder (ASD) among grandchildren using three-generation data.

Methods: We studied 66,240 mothers (G1) and grandmothers (G0), and 149,000 grandchildren (G2) in the Nurses’ Health Study II. In 1999 and 2001, mothers (G1) and grandmothers (G0) reported the grandmothers’ (G0) or their own smoking during pregnancy, respectively. Grandchildren’s (G2) ASD diagnoses were reported in 2005 and 2009. Odds ratios (OR) were estimated for G2 ASD associated with grandmaternal (G0) smoking during pregnancy, adjusting for key confounding factors such as socioeconomic status. Potential effect modification by different factors was also explored.

Results: Among grandmothers, 15,508 (23.4%) smoked during pregnancy, and 840 (0.6%) grandchildren were diagnosed with ASD. We found no association of grandmother smoking during pregnancy with grandchild ASD (adjusted OR [aOR] = 1.05; 95% CI: 0.88, 1.26). While this association did not differ by G2 birth year, grandmaternal smoking during pregnancy was weakly associated with grandchild ASD (aOR = 1.25; 95% CI: 0.94, 1.66) among mothers who gave birth at advanced age (≥35 years; 17,246 G0/G1 and 22,065 G2). Using G0 report of their own smoking during pregnancy, we observed a dose-response relation with cigarettes smoked per day by the grandmother (1–14 cigarettes: aOR = 1.22; 95% CI = 0.71, 2.08; 15+: aOR = 2.14; 95% CI = 1.15, 3.97) among the grandchildren born at advanced maternal age (≥35 years; 7,159 G0/G1 and 9,227 G2). Results were similar when both maternal (G1) and grandmaternal (G0) smoking were modeled together.

Conclusions: Grandmaternal smoking during pregnancy was associated with higher grandchild odds of ASD among grandchildren delivered at advanced maternal age. Our results suggest potential persistent impact of gestational exposure to environmental insults across three generations and combined effects of factors affecting ASD risk.

433.178 (Poster) Social and Economic Factors Associated with Geographic Variation in Children Receiving Educational Services for Autism

S. Greer, A. James, A. R. Guhlincozzi, M. H. Palmer, A. Brown and K. Sohl, (1)Medicine, University of Missouri, Columbia, MO, (2)MU Peds, 65212, MO, (3)Geography, University of Missouri, Columbia, MO, (4)University of Missouri School of Medicine, Columbia, MO, (5)ECHO Autism Communities, Child Health, Columbia, MO

Background:
Autism spectrum disorder (ASD) prevalence has been increasing in the state of Missouri in recent years. This increase is partially attributed to better diagnostic tools and early identification. Previous studies suggest that there may be geographical differences in access to diagnostic services and early treatment, but this has not been explored in the state of Missouri. Early intervention for children with ASD is crucial for successful outcomes and geographical analyses can help identify communities at risk.

Objectives:

The goal of this study is to assess the geographic variation in children receiving educational services for ASD and to assess if school district-level variability is associated with social and economic characteristics such as poverty, education, or employment characteristics.

Methods:

Data were obtained from Missouri Department of Elementary and Secondary Education for 2020. Percentage of enrolled students who were receiving special educational services for ASD (hereafter referred to as ASD prevalence) were calculated by school district. Prevalence data were merged with U.S. Census data that includes school district-level percentage of individuals and families living below national poverty level, percentage of adults age 25 and older who graduated from high school, and rate of unemployment among people aged 16 and older in the civilian work force. Mean ASD prevalence was compared across districts in the 75th percentile compared with districts in the 25th percentile of poverty, educational attainment, and unemployment rates using t-tests.

Results:

A total of 502 school districts in the state of Missouri were used for this analysis. Mean (SD) ASD prevalence by school district was 15.1 (8.4) per 1,000 enrolled students. ASD prevalence by school district ranged from 1.8 to 71.4 per 1,000 enrolled students. Mean (SD) ASD prevalence by poverty level was 12.6 (6.1) per 1,000 in high poverty districts (≥12% of families lived below the national poverty level) compared to ASD prevalence of 15.8 (7.4) per 1,000 in low poverty districts (≤5.5% of individuals and families lived below poverty) (p<.001). Mean ASD prevalence by unemployment rate was 13.9 (7.1) per 1,000 in districts with low (≤3.2%) unemployment rates and 13.9 (7.1) per 1,000 in districts with high (>5.3%) unemployment rates (p=.991). Mean ASD prevalence by percentage of people age 25 and older who were high school graduates was 17.0 (7.5) per 1,000 in districts with low percentage of high school graduates (<36.9%) compared to ASD prevalence of 13.4 (6.7) per 1,000 in districts with a relatively higher (≥43%) percentage of high school graduates (p<.001).

Conclusions:

There are substantial differences in the rates of children receiving special education services for ASD by Missouri school district. These rates also differ by percentage of families in the school district-level living below national poverty level and the percentage of people in the district age 25 and older who are high school graduates. This may reflect differential access to diagnostic services and resources for children with ASD. These results characterize the potential for GIS analysis in identifying at risk communities and can help providers and policymakers allot resources to higher risk areas.

433.179 (Poster) Trait Trends: Distribution of Autistic Traits across Time in Echo Birth Cohorts

Background: Autism Spectrum Disorder (ASD) diagnosis has become more common in the last two decades. It is unknown whether this increase reflects true increases in the presence of the condition, or is due to increased recognition and diagnosis. Dimensional approaches in understanding childhood psychopathology are growing as they better capture the full range of phenotypic differences among those who do and do not meet diagnostic thresholds, and may help to address questions surrounding prevalence increases.

Objectives: Our goal was to determine whether ASD traits have become more common over time by examining whether ASD traits are higher in children born in later years.

Methods: Participants were drawn from cohorts in the Environmental influences on Child Health Outcomes (ECHO) program. Information on demographic factors including the child’s year of birth, age at assessment, sex, and Social Responsiveness Scale (SRS) scores were obtained for children by parent report. For children with multiple SRS assessments, we selected the SRS conducted closest to when the
Background: Emotional wellbeing is a priority for the autism community. Emotional wellbeing incorporates not only the absence of mental disorder symptoms, but also positive developmental outcomes such as emotion regulation. A life course perspective in autism research holds promise for improving emotional wellbeing outcomes. Life course epidemiology (LCE) is a growing theoretical framework that has contributed to key developments in several public health domains, such as cardiovascular health. Key LCE concepts include the accumulation and interaction of risk/protective factors over time; critical or sensitive periods during development, maturation, and senescence; and how environmental exposures during earlier stages of life impact later stages of life. Central to a LCE is integration across varying domains of development and quality-of-life outcomes, including physical wellbeing, emotional wellbeing, and participation.

Objectives: We conducted a scoping review of prior reviews of emotional development and wellbeing in autism research, to synthesize and map review findings from a LCE perspective.

Methods: We followed PRISMA guidelines for scoping reviews. We searched Medline, ERIC, and CINAHL for reviews using the following inclusion criteria: 1) autism as the population; 2) included an affect-related developmental or wellbeing outcome; 3) related to a life course epidemiology concept; 4) available in English; and 5) peer reviewed. Emotional development and wellbeing outcomes were: affective experience (emotion, stress, mood), affective psychiatric disorders/symptoms, harm to self or others, and affect-related development (e.g., emotion regulation, neurophysiology, transdiagnostic constructs). LCE concepts included accumulated risk/protection, critical or sensitive periods for development and intervention, cohort effects, age differences/effects, period effects, intergenerational effects, developmental trajectories, exposure-outcome relationships across life stages, and long-term outcomes of services or intervention. Extracted data included but were not limited to outcome(s), LCE construct(s), and findings.

Results: From 4,196 abstracts we identified 59 reviews that met all inclusion criteria. Reviews of affect-related developmental outcomes were most common (K=25), followed by comorbid psychiatric disorders/symptoms (K=17), neurophysiology (K=9), and suicide, self-injury, or aggression (K=6). Regarding LCE concepts, reviews either synthesized evidence for age group differences (K=28) or provided perspectives on developmental trajectories across childhood and adolescence (K=27). Three reviews synthesized findings on risk factors for negative emotional wellbeing outcomes (K=3). Nearly all included reviews emphasized deficits or negative outcomes in relation to typically developing peers. The majority of central LCE concepts were not present in the included reviews. None of the reviews of interventions identified by our database searches addressed long-term effects on emotional wellbeing.

Conclusions: There is growing emphasis on emotion-related outcomes “across the lifespan” for the autism population. In the extant body of reviews this perspective is limited in its operationalization to comparisons of outcomes across age groups, from a deficits perspective. LCE can help expand this important field of research by providing a rich set of theoretical constructs for identifying gaps in current knowledge, as well as guidance on methods and analyses to address novel research questions. Such knowledge can provide a basis for improving environments, interventions, policies, and services with a positive impact on emotional wellbeing for the autism spectrum population.

433.181 (Poster) Use of Adductomics to Identify Environmental Exposures and Biological Pathways Associated with Autism Risk Using Newborn Dried Blood Spot Samples
Background: Increasing evidence suggests that early life exposures to environmental toxins, including air pollution, are associated with autism spectrum disorder (ASD). However, biomarkers associated with environmental exposures are widely lacking and often transient. In addition, ascertaining biospecimens during pregnancy and early periods of development to assess the prenatal environment remains largely infeasible as ASD is diagnosed clinically based on developmental features that emerge in childhood, without the benefit of reliable or easily identifiable prenatal diagnostic risk indices.

Objectives: To address these challenges, we previously identified relationships between air pollution exposure during pregnancy and human serum albumin Cys\(^{\alpha}\) (HSA-Cys\(^{\alpha}\)) adducts in newborn dried blood spots (DBS) samples in a cohort of 120 infants, selected to maximize the range of residential air pollution exposure during the entire pregnancy to PM\(_{2.5}\), PM\(_{10}\), NO\(_2\), O\(_3\). This study builds on these findings by characterizing identified adducts associated with air pollution in a cohort of 150 with ASD and 150 controls, along with an expanded panel of 54 annotated adducts in newborn DBS samples.

Methods: Newborn DBS were obtained from a state archived cohort of 150 infants with ASD and 150 control infants without any developmental disability, born at Kaiser Permanente Southern California (KPSC) hospitals. Blood was extracted from 4.7mm DBS punches and HSA was isolated using methanol to precipitate interfering proteins. After trypsin digestion, samples were analyzed using an Agilent 6490 QqQ mass spectrometer in dMRM mode, and adduct concentrations were normalized using a housekeeping peptide.

Results: Results indicate successful measurement of the initial six adducts associated with PM\(_{2.5}\) and O\(_3\) during pregnancy (including direct oxidation products, adducts formed with small thiol compounds, and adducts formed with reactive aldehydes), as well as for an expanded panel of 48 additional adducts. Additional analysis currently underway will report findings from linear regression models to explore discordant adduct features associated with ASD status.

Conclusions: Environmental exposure occurring during pregnancy can alter biology and leave measurable impacts on the developing infant captured in the newborn DBS adductome. Here, we successfully characterized the prenatal HSA-Cys\(^{\alpha}\) adductome in a cohort of 150 infants who were later diagnosed with ASD and 150 controls. Adducts associated with ASD will be reported, with a focus on oxidative stress related adducts that might inform oxidative stress pathways that were previously associated with air pollution exposures.

Objectives: To address these challenges, we previously identified relationships between air pollution exposure during pregnancy and human serum albumin Cys\(^{\alpha}\) (HSA-Cys\(^{\alpha}\)) adducts in newborn dried blood spots (DBS) samples in a cohort of 120 infants, selected to maximize the range of residential air pollution exposure during the entire pregnancy to PM\(_{2.5}\), PM\(_{10}\), NO\(_2\), O\(_3\). This study builds on these findings by characterizing identified adducts associated with air pollution in a cohort of 150 with ASD and 150 controls, along with an expanded panel of 54 annotated adducts in newborn DBS samples.

Methods: Newborn DBS were obtained from a state archived cohort of 150 infants with ASD and 150 control infants without any developmental disability, born at Kaiser Permanente Southern California (KPSC) hospitals. Blood was extracted from 4.7mm DBS punches and HSA was isolated using methanol to precipitate interfering proteins. After trypsin digestion, samples were analyzed using an Agilent 6490 QqQ mass spectrometer in dMRM mode, and adduct concentrations were normalized using a housekeeping peptide.

Results: Results indicate successful measurement of the initial six adducts associated with PM\(_{2.5}\) and O\(_3\) during pregnancy (including direct oxidation products, adducts formed with small thiol compounds, and adducts formed with reactive aldehydes), as well as for an expanded panel of 48 additional adducts. Additional anlaysis currently underway will report findings from linear regression models to explore discordant adduct features associated with ASD status.

Conclusions: Environmental exposure occurring during pregnancy can alter biology and leave measurable impacts on the developing infant captured in the newborn DBS adductome. Here, we successfully characterized the prenatal HSA-Cys\(^{\alpha}\) adductome in a cohort of 150 infants who were later diagnosed with ASD and 150 controls. Adducts associated with ASD will be reported, with a focus on oxidative stress related adducts that might inform oxidative stress pathways that were previously associated with air pollution exposures.
adjusted Cox regressions to assess the associations between standardised autism PRS and incidence of dementia, MI and stroke over ~10 years of follow-up. Lastly, we performed two-sample Mendelian randomisation (MR) using the PGC + iPSYCH autism GWAS summary statistics dataset and outcome GWAS summary statistics datasets with the largest sample sizes. We assessed any causal effects between genetic liability to autism and cardiometabolic phenotypes using inverse variance weighting, MR Egger and weighted median MR methods.

Results:

Up to 462,652 participants were included in PRS analyses. There was good evidence for associations between standardised autism PRS and T2DM (OR=1.02; 95% CI 1.01, 1.04), and HDL (b=-0.003 95% CI -0.004, -0.002), SBP (b=-0.16; 95% CI -0.22, -0.11) and BMI (b=0.03; 95% CI 0.02, 0.05). Out of the adverse health outcomes, we found that a SD increase in autism PRS was associated with a 2% increase in risk of incident MI (HR=1.02; 95% CI 1.00, 1.05). From the MR analyses, we observed that genetic liability to autism had a causal effect on diabetes (IVW estimate=1.20; 95% 1.05, 1.37, p 0.006). All other results were null findings.

Conclusions:

Cardiometabolic health in autistic adults may, in small part, be influenced by shared genetics between autism and some cardiometabolic outcomes. There was good evidence for the causal effect of genetic liability to autism on risk of T2DM, which should be investigated further. We also observed good evidence for an association between standardised autism PRS and a small increase in risk of incident MI.

433.183  (Poster) Describing Multidomain Positive Health Outcomes in Autistic Children in the Echo Program

Background: Positive health outcomes are not well characterized in children on the autism spectrum. While a significant work in autism research has focused on developing interventions to improve outcomes in autistic individuals, epidemiologic analyses have focused to large extent on predicting the diagnosis itself, rather than variability within it. Existing work has not sufficiently characterized multidimensional health outcomes, such as wellness, life satisfaction, and positive affect among individuals on the autism spectrum, particularly in large population samples. Furthermore, existing work focuses on positive health outcomes within a single domain, such as sleep health. A more comprehensive understanding of well-being in autism, capturing multidimensional aspects of health, is therefore needed.

Objectives: To describe and characterize positive health outcomes across three core domains – overall well-being, emotional health, and physical health – in a large sample of autistic and non-autistic children within the Environmental influences on Child Health Outcomes (ECHO) program.

Methods: Participants were 4511 individuals (286 autistic individuals) ages 5-20, from 29 cohorts in the ECHO Program. Descriptive statistics were used to characterize positive health outcomes across three primary domains: overall well-being (PROMIS Global Health, PROMIS Life Satisfaction, PROMIS Peer Relationships), emotional health (CBCL Emotional Dysregulation, PROMIS Positive Affect, PROMIS Depressive Symptoms), and physical health (body mass index, PROMIS Sleep Disturbance, PROMIS Sleep Impairment, PROMIS Physical Activity). In ongoing work, latent class analyses will be conducted to define clusters of positive health outcomes for children on the autism spectrum. Demographic factors, including age, assigned sex, and race/ethnicity, will be examined in relation to positive health outcome clusters.

Results: The autistic sample had a higher proportion of male participants than the non-autistic sample (Table 1). Groups had approximately equal proportions regarding race, ethnicity, household income, and maternal education. Participants on the autism spectrum were more likely than non-autistic participants to be born pre-term, have co-occurring intellectual disability and/or Attention-Deficit/Hyperactivity Disorder, and have a sibling on the autism spectrum. A higher proportion of autistic participants were recruited from ECHO cohorts that recruited individuals with a familial history of autism and infants born pre-term (indicating a higher likelihood of being diagnosed with autism). Outcome measures were administered at similar ages across the two groups (7-13 years across measures). Within the domain of well-being, autistic participants scored lower on measures of global health, life satisfaction, and peer relationships (Table 2). Within the
The emergence of tele-mentoring programs designed to build the competence of medical providers, such as Project Extension for Community Healthcare Outcomes when adapted and targeted to caregivers, may be able to support families in developing the requisite knowledge, skills, and confidence needed to effectively manage and coordinate their child’s care. This panel will present four unique family targeted applications of the ECHO model to meet a common goal: Supporting families of children with autism. Nevill will demonstrate how ECHO can be used to build behavior management knowledge, self-efficacy, and empowerment among caregivers of children who lost services during COVID-19. Brewer-Curran will discuss ECHO Autism: Family Advocates as a feasible and acceptable model to equip family and self-advocates with skills to navigate complex systems of care and education. Moody will describe the application of the ECHO model in an extremely rural/frontier state that has very limited services for children with autism. Hess will discuss Family ECHO: Autism as an effective model to build knowledge and confidence for parents caring for children with autism. Through these applications, we will explore how ECHO can be used to build community, empower families, equip them with knowledge and resources, and build their self-efficacy.

223.001 (Panel Discussion) Using the Echo Model to Deliver Virtual Behavior Management to Families
R. E. Nevill, M. O. Mazurek, G. E. Lovette, K. Bateman and N. Badgett, (1)Curry School of Education and Human Development, University of Virginia, Charlottesville, VA, (2)University of Virginia, Charlottesville, VA, (3)College of Education, University of Washington, Seattle, WA

Background: Children with autism and related developmental concerns experience significant wait times to accessing behavior support services, despite challenging behavior being consistently reported as a high contributor to parenting stress. During the COVID-19 pandemic, this issue was further compounded by the closure of schools and clinic-based services, and the increased anxiety and adjustment difficulties many children with autism and related developmental concerns experienced due to reduced community access.

Objectives: The present study investigated the effectiveness of the ECHO model for delivering interdisciplinary education and support to parents of children with autism and related developmental concerns demonstrating challenging behavior during the COVID-19 pandemic. ECHO is a telehealth-based consultation model that, in this application, connects a multidisciplinary “hub” team of experts with a community-based network of parents for problem solving and educational workshops around challenging behavior. While ECHO is traditionally applied with community-based practitioners, using this model with parents and families has the potential to accelerate the rate at which key knowledge and resources are connected directly to families.

Methods: Participants (n = 30) were parents from across the United States, representing households within rural (53%), urban (27%), and suburban (20%) communities and from a broad range of socioeconomic backgrounds. A pre-post intervention design was used to evaluate the effect of ECHO on participants’ knowledge of behavior modification strategies, self-efficacy in behavior management, empowerment as caregivers, negative emotional reactions to challenging behavior, and understanding of the function of behavior. Participants’ children were primarily diagnosed with autism (38%), ADHD (43%), and anxiety disorders (24%) and were demonstrating a broad range of challenging behavior at home, most frequently defiance, verbal aggression, hyperactivity, and inattention at rates of multiple times per day.

Results: The intervention resulted in significantly increased knowledge \( t(1) = 8.30, p < .001, g = 1.50 \), self-efficacy in managing challenging behavior \( t(1) = 4.39, p < .001, g = 0.79 \), and caregiver empowerment \( t(1) = 4.48, p < .001, g = 0.81 \), as well as significant reductions in depressed/angry \( t(1) = -3.50, p < .001, g = 0.64 \) and fearful/anxious \( t(1) = -2.79, p < .001, g = 0.51 \) reactions to challenging behavior. Satisfaction ratings showed that ECHO was highly acceptable to families (M = 4.77/5). Parents reported really
valuing ECHO, and particularly that participating in ECHO provided them with access to a network of peers experiencing similar difficulties at home, as well as consultation from an interdisciplinary team around their child’s behavioral support needs.

**Conclusions:** ECHO allows flexibility in its ability to be offered on free teleconferencing platforms, making it easier for families in rural and underserved areas to access support. This novel adaptation of ECHO has promising implications for supporting children and their families beyond the COVID-19 pandemic as an approach for building knowledge, empowerment, and self-efficacy, as well as peer connectedness and reduced sense of isolation.

A. Brewer Curran, K. Sohl, V. Nanclares-Nogues, M. Mahurin and K. Boles; (1)Department of Child Health, Thompson Center for Autism, Columbia, MO, (2)ECHO Autism Communities, Child Health, Columbia, MO, (3)Child Health, ECHO Autism Communities, University of Missouri, Columbia, MO, (4)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (5)Child Health, University of Missouri, Columbia, MO

**Background:**

The prevalence of autism spectrum disorder (ASD) continues to rise, with 1 in 44 children diagnosed across the United States (CDC, 2020). For families to access best-practice autism screening, assessment, and treatment to address the core symptoms of autism and co-occurring conditions, they must interact with a wide variety of systems and professionals within those systems to address the multifaceted needs of an autistic person and their family. However, these systems remain complex and fragmented; navigating them can be overwhelming and challenging to coordinate necessary services, supports, and resources (Brewer, 2018).

The ECHO Autism: Family Advocates program was developed to increase access to self- and family advocates with increased self-efficacy in systems navigation and best practice autism resources. This program utilizes the ECHO model®, where an interdisciplinary team of content experts share best-practices with family and self-advocates through ongoing guided practice and case-based learning.

**Objectives:**

- Increase self-efficacy in navigating complex systems of care
- Increase self-efficacy in connecting others in underserved communities to best-practice information/resources, services and supports
- Increase self-efficacy in advocacy and leadership skills

**Methods:**

University of Missouri ECHO Autism Communities developed the Family Advocates program in 2020. The hub of content experts includes representatives from core systems involved in autism and disabilities broadly including disability law, healthcare, education, employment, policy, and community resources across the life span. Participants are engaged self- and caregiver advocates eager to advance their professional skills to serve as a resource to others in their community. This program consists of 12-18, 90 minute, twice monthly sessions consisting of short didactic learning and deidentified case discussion related to systems navigation. Pre-training and program satisfaction, as well as pre- and post-program surveys, were collected to measure participant outcomes utilizing the ECHO Model®. The program also implemented changes throughout each of the series by using quality improvement methodology.

**Results:**

One hundred-twenty unique advocates have participated, and 100% of participants report that participation in ECHO Autism: Family Advocates program was a good use of their time and that they respected the expertise of the content experts. Eighty-eight percent of attendees who presented a case rated the case-based discussions and recommendations as “very helpful,” or “helpful” on a four-point scale. Additionally, 89% of attendees reported that participating in the program enhanced their ability to navigate systems of care and education for their own children, as well as their ability to mentor and coach other families. Overall self-efficacy improved in six of seven domains from pre- to post-program test, with the greatest rates of growth in the domains of employment and state eligibility services. Results from the third cycle of the program will be available prior to INSAR.

**Conclusions:**

The ECHO Autism: Family Advocates program is a feasible and acceptable model demonstrating increased self-efficacy in systems navigation and autism best practices among autistic and caregiver advocates. Replicating this program in additional states/regions is necessary to generalize program findings.
**223.003 (Panel Discussion)** Echo for Families: Improving Family Outcomes in Frontier Areas through a 5-Year Virtual Community of Practice

**Background:** Systems of care are often difficult for families of children with ASD to navigate, which can lead to significant declines in family functioning, wellbeing and parent mental health. Rural residents face additional challenges due to lack of providers, long distances to access providers, and must often manage their children’s care needs on their own. Due to these challenges, programs that provide families with supports and information are needed that are uniquely tailored to rural communities.

To address these challenges, we adapted The Extension for Community Health Outcomes (ECHO) model (Arora, et. al, 2014, Hardesty, et. al 2020) for use with family members of children with ASD (Moody, et al, 2020). The initial implementation delivered a series of sessions on family mediated applied behavior analysis. Later implementations deliver content on navigating systems of care, resiliency and other family selected topics that align with the unique needs of families in rural communities (Singh, et al, 2018). This allows for the development of a virtual community of support that the families can rely on to combat social isolation and use to develop new skills to support their children. This network has been translated into Spanish and is being adapted to implement best practices in the RUBI model with their families.

**Objectives:** To evaluate the impact of the adaptation of ECHO on family’s ability to support their children, further adapt the network to meet unique needs of other underserved groups (e.g., Spanish speaking families) and address the evolving needs of families in a large, underserved, frontier state.

**Methods:** The ECHO for Families has been implemented yearly since 2018. For each implementation year, pre and post network self-report evaluations was collected, along with post-session evaluations. We measured satisfaction and usefulness of the network/session, knowledge change using retrospective pre/post measures, and self-reported implementation of new skills. Administrative data were used to compute impact and reach.

**Results:** 378 family members joined 52 sessions over four years; 80 families completed the evaluations. 16 of 23 counties were represented; all but two are rural/frontier communities. 90% of respondents were highly satisfied with the training. 82.6% of respondents reported increased connection to other families and professionals. 95.8% founds the sessions useful. Parents’ knowledge significantly increased, t(371)=18.22, p<.001. 92.8% of respondents reported they will be able to use skills at least monthly and 67.4% plan to use skills weekly or daily. Moreover, 91.3% were moderately confident in abilities to use these new skills.

**Conclusions:** The ECHO model was successfully modified to be used with families. While some considerations must be made to manage confidentiality issues, fidelity to the model was maintained. Families who participated were significantly more knowledgeable about basic interventions for ASD, able to implement some tools independently and adapt practices to meet the current and evolving needs. ECHO for Families can be quickly adapted to meet the changing needs of families, including to the COVID-19 pandemic. ECHO for Families is an important tool to improve family outcomes in extremely remote communities with limited access to other services.

**223.004 (Panel Discussion)** Family Echo: Autism - Adapting the Project Echo Model for Families

A. Hess, E. M. Butter, K. G. Stephenson, N. Long, A. Neuweyer, L. Bartram, J. Perlman and C. Hostutler, (1)Nationwide Childrens Hospital, columbus, OH, (2)Nationwide Children's Hospital, Columbus, OH, (3)Nationwide Childrens Hospital/Ohio State University, Columbus, OH, (4)Developmental and Behavioral Pediatrics, Nationwide Children's Hospital, Columbus, OH, (5)Autism Speaks, new york, NY, (6)Nationwide Children's Hospital, columbus, OH

**Background:** Families of children with autism are key members of care teams and often the primary coordinators for their child’s treatment. Despite calls for interdisciplinary training and collaboration across medical, education, and community systems families typically receive very little education and training in autism, care coordination or team-based care.

Family ECHO: Autism adapted the Project Extension for Community Healthcare Outcomes (Project ECHO) model to build the knowledge and confidence of families raising children and adolescents with autism. The series provides access to interdisciplinary subject matter experts from a learning health network, autism resources, resource coordinators, and community connectedness to build care and treatment knowledge of families.

**Objectives:**

- Increase self-efficacy in knowledge and confidence to care for children with autism and other developmental disabilities
• Understanding of care and treatment best practices
• Increase capacity in connecting families to resources and regional autism care networks

Methods:

Our adaptation maintained the core tenants of the Project ECHO model: case-based learning (termed case vignettes), didactic presentations, interdisciplinary hub team of subject matter experts, and building a community of learners.

Series delivered 9 topic sessions from fall 2021 through spring 2022. Series provided an open format that allowed participants to self-select Family ECHO: Autism sessions that best fit their family’s needs and modified the time of sessions to later in the day to accommodate busy life schedules of families.

Participants of the series completed registration and satisfaction surveys and were provided the opportunity to provide input to series offerings to ensure reflection of current care and treatment needs. The hub was a balance of psychology, neuropsychologists, social work, developmental and behavioral pediatrics, marriage and family therapist, parent partner, sibling advocate, self-advocate and leadership from the Autism Care Network.

Results:

Family ECHO: Autism series topics included anxiety, irritability and challenging behavior, ADHD, family support and more. Series results show 5357 total registrations, yielding 2287 total attendances across 9 sessions. Average number of participants per session equaled 254. Participants attended from 47 US States and 22 countries such as Canada, Argentina, Ethiopia, Japan and many others.

Survey data collected from over 850 participants demonstrates high satisfaction in knowledge gains, acquiring best practices, idea generation and meaningful discussion from case vignettes.

Conclusions:

The mission of Project ECHO to democratize implementation of best practices for healthcare and education is a promising approach to address caregiver knowledge, skills, and confidence.

Preliminary evaluations suggested that families found the information useful, reliable, and relevant. They also reported learning best practices related to team-based autism care and felt their knowledge and ability to care for their child with autism benefited from participation in this adaptation of Project ECHO.

The series is not only maintaining but is growing, with future topics chosen based on participant input. We anticipate continuing to expand the national and international reach of Family ECHO: Autism to support families in the journey toward building optimal quality of life and improving care for children with autism.

ORAL SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

301 - Ethical, Social & Legal Implications of Autism Genetics & Neuroscience

Moderator: Paul Wang, Simons Foundation

301.001 (Oral) Parent Attitudes Towards Data Sharing in Developmental Science

Background: The power of data sharing in developmental research is receiving increasing recognition. Data sharing can accelerate the pace of discovery, link researchers with high quality analytic expertise to researchers with large datasets and democratise the research landscape. However, there are significant privacy and security concerns as well as conceptual and ethical considerations. These are particularly acute for developmental science, since infants cannot consent for themselves. It is essential that as we move forward into an era of data openness that we adequately incorporate the views of stakeholder communities, such as those of parents, in our decision-making processes.
Objectives: To establish parent attitudes towards data sharing in developmental science.

Methods: We conducted a comprehensive survey of the opinions of 195 parents on data sharing in developmental science. The sample comprised 122 parents of typically developing children (henceforth TD group) and 73 parents of a child with one or more neurodevelopmental condition (henceforth NDC group). Participants were recruited from Birkbeck Babylab database and Birkbeck Babylab social media. The survey was hosted on the Gorilla platform. Statistical analysis was conducted using SPSS (IMB version 26.0.0.0). Non-parametric tests were used due to the ordinal and categorical nature of the data. Answers to open questions were explored using Leximancer Desktop 5.0.

Results:

Who to share data with? 96.4% of the sample would be happy to share their child’s data with universities and research centres, while only 16.9% of participants would be happy to share their child's data with private companies and industry. The NDC group were more willing than the TD group to share their child’s data with GP's and hospitals, private companies and industry, and charities (p ≤ 0.000).

How is the data shared? Whole-group results showed that parents were generally supportive of curated (66.7%) but not open (33.3%) data sharing. Parents overwhelmingly supported nuanced consenting models in which preferences for particular types of sharing could be changed over time.

What data is shared? A significant difference was found between the type of biological data and parents' willingness to donate and share this as per Friedman’s χ²(6) = 265.149, (p ≤ .000). Parents were significantly less comfortable to share DNA than other biological measures e.g., hormone levels, non-invasive brain imaging and eye-tracking. In every case, the NDC group were more willing to share each type of data than the TD group (p ≤ .00).

Why is the data shared? Parents across groups frequently used terms like “better”, “faster” and “peer review”, suggesting that they hoped data sharing would improve research speed and quality. Parents from the NDC group frequently used terms like “helps” and “others”, suggesting a sense of altruism towards others in their community.

Conclusions: The field should create repositories that implement dynamic consent and mechanisms for curated sharing that allow consideration of the scientific questions addressed. Better communication and outreach are required to build trust in data sharing. Advanced analytic methods will be required to understand the impact of selective sharing on reproducibility and representativeness of datasets.

Background: Genetic research and clinical genetic testing (CGT) in autism spectrum disorder (ASD) concern families with autistic children and autistic adults. However, there is still limited information about the opinions and attitudes toward research and CGT in ASD, especially from autistic adolescents and adults. Expanding the research to include the whole community is important, as autistic adults can serve as a proxy for autistic children, who are typically too young to consent to genetic testing/research.

Objectives: We aimed to survey and compare attitudes and perceptions toward the etiology, CGT, and genetic research specific to ASD and general health conditions, among parents of autistic children and autistic adolescents and adults through a community survey.

Methods: Two online questionnaires, one targeted at parents with at least one autistic child and one targeted at autistic adolescents (from 15 years) and adults, were conducted with over 50 questions on the issues. We performed both quantitative and qualitative analyses on the received answers from 868 parents of autistic children (parent group, 94.7% women) and 213 autistic adolescents or adults (ASD group, 74.6% women) to analyze the overall opinions, similarities, and differences between the two respondent groups.

Results: Approximately 85% of the respondents in both groups indicated that inherited factors contribute to a very high degree or a high degree to ASD. Although more than 50% were positive about undergoing CGT after ASD diagnosis in both respondent groups, the ASD group had significantly fewer positive responses (p = 0.03). In both groups, the respondents were most positive about CGT if it could lead to personalized interventions, but the parents were significantly more positive (p < 0.001). Similarly, most of the respondents were positive about genetic research in ASD. However, autistic adults and adolescents were concerned either to a very high or high extent (61.1%, n=130) that genetic research results could be used for the wrong purposes. Based on our thematic analyses of the open-ended answers, the concerns clustered within six themes, including eradicating autism from society, increased discrimination, and exclusion from society.
Conclusions: We show support and interest in genetic research and CGT in autism from parent and autistic respondent groups; however, there are significant differences between the groups, with autistic adults being more negative to both. It is important to highlight the opinions of autistic adults on the issues and work together to address the concerns raised.

301.003 (Oral) Ethics Along the Path to Translation of Neuroscience Findings in Autism

Background:

Each step in the translation of clinical neuroscience findings into therapies that benefit children with autism raises pressing ethical questions, ranging from optimizing informed consent for biospecimen donation to helping families evaluate risks and benefits prior to enrolling in a clinical trial. Active engagement between ethicists, scientists, clinicians, and communities is critical to address these questions. This presentation will discuss conceptual and empirical ethics work that has been developed alongside basic and clinical neuroscience efforts to understand mechanism, prediction, and treatment for autism spectrum disorder.

Objectives:

To outline ethical challenges related to biospecimen donation, presymptomatic prediction, and clinical trial design and propose solutions that incorporate the perspectives of impacted stakeholders, including individuals with autism and their families.

Methods:

Empirical data collection included (A) semi-structured qualitative interviews with parents (n = 30) of autistic children and autistic adults (n = 2) who donated biospecimens for brain organoid research; and (B) interviews with parents of infants at high likelihood of developing autism (n = 30) and parents of infants at low likelihood (n = 25) to understand attitudes towards prediction of autism in infancy and potential designs of presymptomatic intervention trials. Conceptual methods included applying ethical frameworks developed in the context of pediatric genetics to the autism research context.

Results:

Major themes emerging from qualitative interviews will be discussed alongside implications for future research and translation. (A) In interviews related to biospecimen donation for brain organoid research, participants emphasized the importance of transparency during initial informed consent, obtaining additional consent for continued use of samples when children reach age of majority, and desire to receive ongoing updates on progress from the research team. (B) In interviews related to presymptomatic prediction and intervention, most participants stated an interest in obtaining a predictive diagnosis for their infant, described their anticipated reactions to learning a predictive result was wrong, and stated a willingness to participate in a presymptomatic intervention trial if they had no safety concerns and were able to simultaneously pursue services in their communities.

Conclusions:

Real-time ethics engagement can enable elicitation and incorporation of the perspectives of those most likely to be impacted by the process of neuroscience translation. Anticipating the ethical and social impacts of new advances in neuroscience can maximize the benefits of resulting therapies and avoid inadvertent harm to families and communities.

301.004 (Oral) Return of Genetic Results in the Largest Recontactable Cohort of Individuals with Autism

Background: SPARK (SPARKforAutism.org) is the largest recontactable cohort of people with autism. As part of SPARK’s partnership with participants, SPARK returns results, including genetic results that significantly contributed to autism.
Objectives: To characterize individuals who have received genetic results in SPARK and analyze differences between those with and without genetic results.

Methods: Returnable results are likely pathogenic (LP) and pathogenic (P) (ACMG criteria) variants from a predefined list of genes and copy number variants that meet ClinGen or DDGP standards of “definitive” and “strong” for autism, intellectual disability and neurodevelopmental conditions. All returned variants are confirmed in a clinical laboratory.

Results: We have identified 1,616 returnable results in 21,264 people with autism (7.6%). Of results with known inheritance, 78% occurred de novo and 22% were inherited. 61% of genetic results are single nucleotide variants (SNVs)/indels with the remainder being chromosomal abnormalities or copy number variants (CNVs). There was no significant difference in the odds of a CNV or SNV/indel being inherited.

The results show significant heterogeneity, with 437 unique loci and 18% seen only once or twice. The most common CNV is the 16p11.2 deletion in 4.0% of results, and the most frequent gene is SHANK3 in 2.0%.

For 40% of participants with autism, SPARK has DNA from both parents. Diagnostic yield in these offspring is 9%. The odds of identifying a result for return is 1.4-fold higher if both parents submitted samples (p=3.1E-10).

105 participants inherited a P/LP SNV and 88 inherited a CNV from 178 parents. Of the 145 transmitting parents with phenotypic data, 4.8 percent reported an autism diagnosis and approximately one third reported a neuropsychiatric symptom. This is significantly higher (OR 1.9, p=0.003) than the remaining parents in SPARK. The neuropsychiatric condition most correlated with the odds of transmitting an autism variant is ADHD.

The strongest predictors of a genetic result in people with autism are motor delay (OR 3.1, p=6.8E-76), congenital anomalies (OR 2.8, p=2.7E-23), cognitive impairment (2.7 E7.9E-73) and seizures (OR 2.6, p=2.2E-25). The odds of having an autism-related genetic result in participants with all of these features are 5 times higher than in participants without all of these features (p=5.6E-8). However, 21% of participants with results reported none of the above features.

Being a female with autism increases the odds of having an autism-related genetic result by 1.6-fold (p=2.1E-17). By contrast, ADHD was not predictive and endorsing depression slightly lowered (OR 0.72, p=0.0006) the likelihood of having an autism-related genetic result.

The study showed that participants who had received some form of genetic testing were more likely to have a result in SPARK (OR 2.63, p=2.21 E-65). However, participants who suspected there was a genetic cause were no more likely to receive a result than those who did not.

Conclusions: Our results demonstrate that it is possible to return genetic results to hundreds of individuals at scale. Although syndromic features increase the probability of finding a genetic result, the findings are not restricted to individuals with these features.
The LEANS project resources are designed to facilitate whole-class teaching about neurodiversity as an “umbrella” concept to children age 8-11 years, in order to increase pupil and teacher understanding of differences in learning, interaction, and sensory experiences, and to promote inclusive actions and attitudes. Unlike psychoeducation programmes focusing on autistic/neurodivergent children only, or teacher training about specific diagnoses, LEANS is not an intervention for perceived problems or deficits. It upskills all pupils and staff members through teacher-delivered, whole-class work focused on understanding and acceptance.

**Objectives:** To assess whether LEANS programme was feasible, acceptable, and safe when teacher-delivered in real mainstream primary classrooms. Assess impacts on pupils’ neurodiversity knowledge, and their self-reported attitudes and intended actions at school.

**Methods:** Seven classroom across four mainstream Scottish primaries volunteered to deliver the LEANS programme (~140 children exposed to programme, Aug-Dec 2021). Using opt-in family recruitment, 62 children’s LEANS measures and demographics were then shared with researchers (female=36, mean age 9.84 years). 17.74% of participants had reported additional support needs (e.g. formal diagnoses such as autism, undiagnosed challenges).

Teachers administered two bespoke measures to their classes before and after delivering LEANS: attitudes/actions, and neurodiversity vocabulary and knowledge. We collected additional qualitative data from free-response questions, follow-up interviews (child participant subset) and written “teacher diaries” about the experience of delivering LEANS.

**Results:** Post-test multiple-choice measure scores illustrated that participating pupils could successfully demonstrate knowledge of the neurodiversity concepts contained in LEANS, and expressed more inclusive and accepting attitudes and intended actions following LEANS participation (both p <.001). Quantitative analyses were pre-registered: https://osf.io/38jrh

Analyses of teacher diaries and child qualitative data consistently supported these quantitative findings, providing specific, personal examples of changed knowledge and actions. They provided actionable feedback on resource revision (e.g. issues with length of some items). No data or school communications reported harms resulting from LEANS.

**Conclusions:** These results are highly encouraging, especially given Covid-19 disruption during the evaluation period. Based on child knowledge at post-test and significant changes in attitudes and intended actions, LEANS appears to be a successful tool for introducing neurodiversity concepts in primary schools. It offers a basis for ongoing classroom discussion and potentially facilitating longer-term change, though follow-up data is needed. Post-evaluation, the LEANS resources were revised to incorporate teacher and pupil feedback, and were released as a free download in June 2022, with delivery commencing in some schools for the 2022-2023 school year.
Autistic participants \(n = 5\) were interviewed as a mock-suspect implicated in a fictional crime by a real-life police investigator \(n = 5\), whilst accompanied by a forensic support worker \(n = 5\) in a police custody interviewing suite. Investigators were provided with an overview of the mock-offence and ‘incriminating evidence’ against the mock-suspect and were instructed to conduct the interview as if part of a genuine police investigation. All participants were subsequently interviewed by the lead researcher about their experience of the mock-suspect interview and their perspectives on police interviewing practice more broadly. Police officers and support workers also drew upon their real-life experiences of interviews with autistic suspects. All interviews were analysed using qualitative thematic analysis to identify thematic patterns in the data address relevant to the study research questions. We then used a socio-ecological framework to examine interrelated individual, interpersonal and environmental factors that influence an autistic persons’ experience during a police suspect interview.

Results:

We identified three main themes across participants’ interviews: (1) Psychological, emotional, and socio-cognitive needs of autistic suspects; (2) Supporting an interview account with an autistic suspect; and (3) Perceptions of credibility, behaviour, and power. Using these themes and associated sub-themes, we produced a conceptual socio-ecological framework to demonstrate how an autistic person’s experience of a police suspect interview is influenced by a range of interconnected factors at individual (e.g., sensory experience); interpersonal (e.g., neurotypical perceptions of behaviour) and environmental (e.g., custody security) levels.

Conclusions:

Autistic adults, investigators, and support staff are presented with individual, interpersonal, and environmental barriers to engaging effectively in police suspect interviews. Greater attention should therefore be paid to providing appropriate support to autistic adults whilst in custody prior to, during, and following a police suspect interview. We provide a number of practical adaptations that can be made to better support an autistic person when interviewed as a police suspect.

307.003 (Oral) “It’s Really Complicated”: Engaging Key Stakeholders to Inform a Novel Parent-Led Sexual Health Education Program for Autistic Youth

K. T. Cosgrove\(^2\), C. Middleton\(^1\), T. Thompson\(^3\), B. Bernard\(^4\) and L. DeVries\(^5\), (1)Psychology, The University of Tulsa, Tulsa, OK, (2)Children’s Hospital Colorado, Aurora, CO, (3)University of Colorado School of Medicine, Aurora, CO, (4)JFK Partners/University of Colorado Anschutz School of Medicine, Aurora, CO

Background: There is a paucity of research on sexual health education for autistic individuals, despite a clear need for such work. Youth with autism spectrum disorder (ASD) often experience challenges navigating puberty, sexuality, and relationship changes that take place during adolescence. This can result in less perceived and actual knowledge of sexual health topics (Hannah & Stagg, 2016) and an increased risk of problematic sexual behaviors in adulthood (Stokes et al., 2007). Parents may be a useful source of sexual health information for their children with ASD. However, few evidence-based programs exist to support parents in navigating this role. Thus, there is a need for the development of such programs, particularly those incorporating the lived experiences of key stakeholders.

Objectives: The present qualitative investigation aimed to determine the sexual health education needs of autistic youth and to inform a novel, parent-led sexual health education program using data gathered through focus groups with parents and self-advocates.

Methods: Autistic self-advocates \((N=4; \text{ages } 28-57)\) and parents \((N=4)\) of 11- to 18-year-old autistic youth were recruited through local advocacy groups to participate in two rounds of focus groups (4 total groups). Licensed clinical psychologists facilitated all groups via teleconferencing with co-facilitation from an autistic self-advocate for the self-advocate groups. Groups were audio recorded and transcribed verbatim. The first round of focus groups (120-minutes each) was held prior to the start of a pilot cohort of a novel, parent-led sexual health education program. Stakeholders were asked to share their subjective experiences with sexual health education and provide feedback on an overview of proposed program content. Preliminary findings were used to tailor program implementation. The second round of focus groups (90-minutes each) was held after completion of the eight-week program. Programmatic changes based on stakeholder feedback were discussed and member checking confirmed themes derived from initial focus groups. The research team conducted rapid qualitative analysis on all four group transcripts. Focus group summaries were consolidated into structured matrices by participant type to identify common barriers, facilitators, and implementation recommendations.

Results: Synthesized data across both rounds of self-advocate and caregiver focus groups revealed four overarching themes regarding the sexual health education needs of youth with ASD: “Empower parents as educators,” “Individualize supports and education,” “Prioritize safety,” and “Consider cultural and intersecting identities.” See Table 1 for subthemes and illustrative quotes.

Conclusions: General sexual health education is insufficient for youth with ASD, and resources specific to this population are needed. Parents are a primary mechanism for providing this education and would likely benefit from participating in a program that considers the unique needs of autistic youth, the importance of safety, and the influence of other aspects of identity. Future research on the implementation of such a program is needed.
Racial and Ethnic Group Differences in Service Utilization in Children with Autism Spectrum Disorder: The Role of Parental Stigma

Background: Racial and ethnic disparities in service utilization among children with autism spectrum disorders (ASD) have been widely documented (e.g., Broder-Fingert et al., 2013); however, the factors driving these disparities are less well understood. ASD-related parental stigma may play a role (Rivera-Figueroa, Marfo & Eigsti, 2022). Parents from racial/ethnic minoritized (REM) and other marginalized backgrounds may experience more stigma, due to their child’s ASD, and their membership in a marginalized group themselves; both factors may impede their access to needed resources.

Objectives: The present study quantifies stigma among a large, diverse sample of US-based parents of children with ASD and measures the impact of stigma on service utilization. Stigma was defined multidimensionally as community stigma (negative attitudes of community members), affiliate stigma (internalization of negative views), stigma salience (intensity and automaticity of negative thoughts), and stigma as a treatment barrier (stigma’s impact on treatment engagement).

Methods: A sample of 826 English-proficient parents were recruited via the Simons Foundation Autism Research Initiative (SPARK Consortium, 2018) and completed an online survey. Parents received $25 for study participation. In addition to measures of stigma, parents responded to questions about discriminatory experiences, satisfaction with their ASD provider, and sociocultural values. Across racial/ethnic groups, participants differed in socioeconomic status (SES), the number of children with ASD in the household, and target child’s age (Table 1); as such, analyses controlled for parental education, financial stability, child age, and number of children with ASD.

Results: Findings revealed significant REM group differences in reported family stigma, service utilization (number of recommended services that were unavailable or only partially used), and perception of unmet needs (i.e., receipt of necessary treatments). Asian and White parents reported significantly more affiliate stigma than other groups; White parents reported more stigma salience than Latinx and Multiracial parents. Asian and Latinx parents were less likely to fully engage in recommended services, and Asian parents endorsed less service availability. Less financial stability predicted service underutilization, unavailability of services, perceptions of unmet needs, and more stigma. Higher parental education predicted more stigma. Parental stigma was related to reduced treatment engagement across the sample, although associations were small; this relationship significantly differed across REM groups and was stronger for Asian, Black, and Multiracial compared to Latinx and White parents. These results suggest greater susceptibility to the adverse effects of stigma on service utilization for Asian, Black, and Multiracial families.

Conclusions: Families from diverse backgrounds have disparate treatment needs. Results suggest that adverse effects of ASD-related stigma are contingent on sociodemographic factors, including race/ethnicity, and that parents from marginalized backgrounds may be more susceptible to the negative impacts of stigma on healthcare utilization. Intersectional methods recognizing the diverse impacts of race/ethnicity, SES, and their combination, illuminate the interacting dimensions that exacerbate ASD healthcare disparities. Study limitations include reduced representation from parents of certain marginalized backgrounds (e.g., less English proficiency and SES), who may be more likely to experience stigma and barriers to services. Overall, results indicate that racial and ethnic disparities are pervasive and impact even well-resourced parents.
Background:

Autism is represented in every racial, ethnic, cultural, and linguistic group; however historically marginalized and minoritized children experience unequal access to timely identification, diagnosis, and services (Magaña et al. 2017; Mandell et al. 2007; Stahmer et al. 2019). Delays in early intervention access narrow this important window of opportunity for intervention and skill development. Disparities in autism identification and access to services are pervasive equity issues affecting historically marginalized and minoritized families (Stahmer et al. 2019); these patterns may be strongly influenced by a lack of culturally responsive and patient-centered care within service systems. While the majority of caregiver engagement research focuses on barriers and facilitators to caregiver empowerment, few studies systematically measure the ecosystem of knowledge and resources embedded in the social networks of caregivers of autistic children that can help them locate autism providers and successfully navigate the autism service system. We used a Community Partnered Participatory Research (CPPR) approach (Jones et al. 2009) to develop a program, called Mind the Gap (MTG) that engages peer navigators to connect caregivers with service providers and help them grow their services network for the child on the autism spectrum, post-diagnosis.

Objectives: The current study utilized a randomized control trial (RCT) to compare two conditions: 1) MTG Program with peer navigation and accompanying resources and activities (called MTG Program) to 2) a MTG resource only group (called MTG Resources-only) to examine program impact on time to first service (primary outcome) and caregiver support and family empowerment (secondary outcomes).

Methods: We compared MTG Program (n=53) to MTG Resources-only (n=59) in a four-site randomized controlled trial in racially and ethnically diverse, under-resourced communities. Our primary outcome was caregiver service access over time and our secondary outcomes were caregiver reported family and professional support networks and family, community, and services empowerment.

Results: In our intent-to-treat analysis, there were no treatment differences in the time to first new service (Z=-1.019, p=0.308, cox PH). There were also no treatment differences in uptake of new services ($\chi^2 = 0.03$, p=0.87). There was a significant change in professional network size for caregivers in the full MTG program group, as compared with those in the comparison group (see Figure 1). The MTG Program group increased their professional network size more than the comparison group ($F(1.91)=3.71$, p=0.05) from baseline to exit. For caregivers in the MTG Program group, there was a significant overall improvement in average service empowerment from pre to post (p=0.001).

Conclusions: While results suggest that MTG Program with peer navigator support did not significantly impact the time to service access, the MTG Program did improve caregiver connections to professional supporters and caregiver service empowerment: key factors likely to impact the quality and quantity of service provisions for children on the autism spectrum. More research is needed to determine the potentially cascading effects of increased connections and empowerment with service professionals on later management and support of children on the autism spectrum, as they progress through schooling and later the transition to adulthood.

317.002  (Oral) The Effectiveness of Acceptance and Commitment Training (ACT) for Family Caregivers of Autistic People or People with Other Neurodevelopmental Disabilities

A. Porthukaran, J. Lake, K. Fung, L. Steel, B. Redquest, J. A. Weiss and Y. Lansky, (1)Psychology, Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)Psychiatry, University of Toronto, Toronto, ON, Canada, (3)UHN - Toronto Western Hospital, Toronto, ON, Canada, (4)Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)University of Calgary, Calgary, AB, Canada, (6)Psychology, York University, Toronto, ON, Canada, (7)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada

Background: Family caregivers (hereafter referred to as caregivers) of autistic people and people with other neurodevelopmental disabilities often experience high levels of distress (Marquis et al., 2020). Interventions targeting parenting skills or providing strategies for caregivers to implement with their family members are increasingly available, but psychological interventions directly targeting caregiver mental health are less common. One intervention that directly targets the mental health of the caregiver is Acceptance and Commitment Training (ACT). ACT is a therapeutic approach incorporating cognitive behavioural strategies with an emphasis on acceptance, value-driven action and psychological flexibility. Our ACT model for caregivers of people with neurodevelopmental disabilities is not only co-designed by caregivers and clinicians, but also delivered in partnership with them (Fung et al., 2021)

Objectives: We sought to examine predictors of psychological wellbeing among caregivers of children, youth and adults with neurodevelopmental conditions, including autism, intellectual disability, and fetal alcohol spectrum disorders, who participated in our group-based ACT intervention. Findings provide insight into levels of caregiver depression and stress, as well as the change over time while attending the group.

Methods: We report on data from 96 caregiver participants, including 65 caregivers of autistic people. We examined the relationship between caregiver demographic variables (e.g., age, marital status), child demographic variables (age, diagnostic group), and depression and stress, as measured by the Depression, Anxiety and Stress Scale (DASS; Lovibond & Lovibond, 1995). We also examined psychological variables, including cognitive flexibility using the Cognitive Fusion Questionnaire (CFQ; Gillanders et al., 2014). Caregiver
workshop participants completed a survey with these measures before the workshop (time 1), immediately after the workshop (time 2) and at 3 month follow-up (time 3).

**Results:** Depression scores across the different child diagnostic groups showed a significant decrease from time 1 to time 2 on paired sample t-tests ($p < 0.001$) and remained lower at time 3 ($p < 0.001$). Stress scores also showed significant decreases at both time points (both $p < 0.001$). At times 1, 2 and 3, no differences were observed between the diagnostic groups on depression or stress scores. Improvements in depression and stress occurred regardless of child or caregiver age, or marital status. K-means cluster analyses specifying 3 groups revealed that there was a group of caregivers that experienced significant improvement ($n = 5$), a group with moderate improvement ($n = 41$) and a group with little improvement ($n = 41$). Cognitive fusion scores at time 1 were a significant predictor of group membership (i.e., more fusion was associated with the poorer outcome group on the DASS; $p = 0.029$).

**Conclusions:** Results of this study demonstrate the effectiveness of ACT for caregivers of people with neurodevelopmental disabilities. These effects are present for caregivers of autistic people, as well as those with other neurodevelopmental conditions. In addition, the lack of significant differences among specific caregiver demographic variables suggest that psychological variables (e.g., cognitive fusion) rather than demographic variables (e.g., age of caregiver or child) predict success in the group. Implications of the predictors of success will be discussed.

**317.003 (Oral) Family-Centered Care and Quality of Life in Caregivers of Toddlers with Confirmed or Likely Autism**

**Background:**

Caregivers of autistic children face unique demands at many social-ecological levels (individual, family, and within the healthcare system). These demands may differentially impact quality of life (QoL) for caregivers of toddlers with likely or confirmed autism, compared to caregivers of children with other developmental concerns or parents of children with no current concerns (Russa et al., 2015). Further, having a supportive experience at the system level (e.g., perceiving the care a primary care provider (PCP) provides to be family-centered; Boncinelli et al., 2015), may ameliorate individual- or family-level stressors that caregivers experience.

**Objectives:**

The objectives of the current study were to: (1) Examine the extent to which three contextual levels of determinants (demographic, family, and system) predict caregiver QoL; and 2) Investigate whether receiving more family-centered care improves the relation between parenting stress and QoL, for caregivers of children with autism/autism concerns, developmental delay (DD) concerns, and no concerns.

**Methods:**

Our sample ($n=484$) comprised three groups: caregivers of children with autism/autism concerns ($n=119$), caregivers of children with other developmental concerns ($n=101$), and caregivers of children with no concerns ($n=264$). Children were 17 to 42 months old ($M=23.35$; $SD=5.01$) when their caregivers filled out a demographic questionnaire, the Parenting Stress Index (PSI-SF), the Measure of Processes of Care (MPOC-20)—which assesses the degree of family-centered care they perceive from their primary care provider (PCP)—and finally, the WHO Quality of Life (QoL) measure (WHOQOL-BREF). A hierarchical linear regression assessed the additive effect of demographic (child age, caregiver employment status, income, and number of other children), caregiver (parenting stress), and system (family-centered care) level factors on QoL, and whether there were interactions with concerns group.

**Results:**

Having a younger child ($b=-.16$), higher income ($b=.30$), lower parenting stress ($b=-.59$, $R^2$ change=$.04$, $p<.001$), and more experiences of family-centered care ($b=.23$, $R^2$ change=$.36$, $p<.001$) all predicted greater caregiver QoL regardless of concerns group, $p<.001$. Negative effects of parenting stress on QoL were stronger for caregivers of children with autism/autism concerns ($b=-.80$, $r=-.80$) than for parents of children with developmental ($b=-.16$, $r=-.64$) or no concerns ($b=.15$, $r=.65$), $R^2$ change=$.02$, $p<.001$ (Figure 1). This effect was not ameliorated by receiving family-centered care ($b=.05$, $p=.15$). However, higher reported levels of family-centered care predicted improved QoL equally well for all groups ($b=-.23$) (Figure 2).

**Conclusions:**

Caregivers of children with autism or autism concerns perceive their PCP to be providing family-centered care at similar levels to other caregivers, which is encouraging. Receiving family-centered care does not seem to reduce parenting stress. Future research is needed to determine how to provide additional support to caregivers with lower QoL, particularly caregivers who are experiencing income or...
parenting related stress and low levels of family-centered care. The role of parenting burnout (Aktan et al., 2020) on family-centered care and QoL should be explored. Caregiver QoL is especially important to support across service settings (e.g., medical, early intervention) during the birth-to-three period, when the identification of autism and the process of accessing services are new experiences for caregivers.

317.004  (Oral) Best FACES Forward: Outcomes of an Advocacy Intervention for African American Parents Raising Autistic Youth

J. Pearson1, K. M. Malone and D. Mason Martin2, (1)Teacher Education and Learning Sciences, North Carolina State University, Raleigh, NC, (2)Applied Developmental Science and Special Education, University of North Carolina at Chapel Hill, Chapel Hill, NC. (3) 2310 Stinson Drive, North Carolina State University, Raleigh, NC

Background:

The autism diagnosis disparity between Black and non-Black children has recently narrowed, reducing chronic underrepresentation (e.g., Maenner et al., 2020; Nevison & Zahorodny, 2019). However, Black children are still diagnosed later than their white peers and are often presumed to have other disabilities first (e.g., intellectual disability; Constantino et al., 2020). Given these disparities, Black autistic youth and their families experience unique barriers to accessing autism-related services and supports compared to their non-Black peers, such as lack of social support and communal stigma. One way to increase access to and use of autism-related services is by improving parents' capacity to advocate for their children (e.g., Dababnah et al., 2018; 2021; Pearson, et al. 2021). While parents raising children with disabilities have historically been the strongest advocates for the strengths and needs of their children, advocacy groups typically comprised middle-class White parents (Turnbull et al., 2010). Simultaneously, Black parents raising autistic youth conveyed they did not possess adequate capacity to advocate for autism-related services (e.g., Dababnah et al., 2021; Jamison et al., 2017; Pearson, Meadan et al., 2020).

Objectives:

This study measured the outcomes of the FACES training on the advocacy capacity among a larger sample of Black parents raising autistic youth, using a quasi-experimental design. Our research questions were: (1) Does the FACES program increase empowerment and perceptions of advocacy ability in Black parents raising autistic youth? (2) Does the FACES program increase parents’ understanding of autism, social communication, and behavior strategies? (3) Does the FACES program affect parent-professional communication?

Methods:

We used a quasi-experimental research design that compared pretest and posttest measures for 16 Black parents raising autistic youth. Intervention participants demonstrated increases in family empowerment, school communication, and perceptions of advocacy ability. Our small sample size and the missing data dictated the use of nonparametric statistics in analyses. We conducted a Wilcoxon Signed-Rank Test to evaluate the effective difference between pretest and posttest median scores for both groups for each of the six measures.

Results:

Findings offer emergent evidence of advocacy programs for Black families raising autistic youth. Following FACES, intervention participants had statistically significantly greater scores on family empowerment, and parent-professional communication, but not on autism knowledge. In addition, social validity data conveyed high satisfaction with the intervention.

Conclusions:

We draw four conclusions from these results. First, the study offers further evidence for the FACES training. Second, parents’ perceived advocacy capacity and overall empowerment increased despite no changes in their knowledge of autism characteristics and social communication/behavior strategies. Third, implementation fidelity was negatively impacted by participants’ desire to continue discussing religion and coping in Session Three. Religion (and the Black Church specifically) continues to hold a prominent role in the Black community (Avent Harris, 2019). Fourth, experimental group participants showed tenable gains in school communication, but not on family-professional partnership. Our findings extend the pilot study (Authors, 2021), and contribute exploratory evidence suggesting the positive effects of FACES on parental advocacy capacity.

POSTER SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

402 - Family Issues and Stakeholder Experiences I

402.075  (Poster) "A System That Wasn’t Really Optimized for Me": Autistic University Students’ Access to Information

Background: Autistic people are increasingly pursuing higher education (Cox, 2017), though lower graduation rates suggest they are experiencing difficulty. Potentially contributing to this difficulty is that universities expect students to enter with and acquire both explicit and implicit institution-related knowledge (Lessky et al., 2021). This institution-related knowledge allows students to benefit from resources and support. But accessing this knowledge requires a combination of formal and informal information behavior: searching and seeking behaviors used to resolve one’s need for information (Bates, 2010). Both individual and interactional (i.e., the combination of two interactants’) characteristics may influence autistic university students’ information behavior and, subsequently, their opportunities to acquire information about resources and support. However, institutional policies and practices also likely influence these opportunities.

Objectives: Our aim was to gain insight into the factors that influence autistic university students’ access to information about resources and opportunities. Despite calls across disciplines to investigate autistic people’s access to information (e.g., Byrne, 2020; Gibson & Hanson-Baldauf, 2019), we currently have an insufficient understanding of the individual, interactional, and institutional factors that impede autistic students’ full access to higher education.

Methods: We interviewed 14 autistic students (mean age = 20.86, 35.71% male, 35.71% female, 28.57% non-binary, 71.43% White) about their experiences at a large, public university. Twelve participants spoke with us in individual or group interviews and two completed text-based interviews. We used Reflexive Thematic Analysis (Braun & Clarke, 2006; 2022) to deductively and inductively develop themes that were informed by the literature and by the knowledge of our neurodiverse research team.

Results: We constructed two themes relating to autistic students’ ability to access information about opportunities and resources. The first, "Navigating the interactions required to acquire information is challenging," focuses on participants’ accounts of difficulty acquiring information from other people. Participants often identified individual autistic characteristics as barriers to accessing information about resources and opportunities, particularly when this information access was socially mediated. We considered their experiences through a reciprocal framework (Milton, 2012), as the characteristics they identified as causing difficulty exist in inherently interactive contexts. The second theme, "Access to Information is Limited by University Expectations," examines how the university structures information access and what these policies and practices imply about the university’s expected student. We extended the first theme’s focus on misalignment by situating participants’ experiences in the context of institutional-level expectations. Identifying how universities conceptualize the “expected” university student (Koutsouris et al., 2021) as neurotypical and non-disabled provides insight into the barriers enacted by the policies and practices stemming from these expectations.

Conclusions: When their informational needs go unmet, autistic students are unlikely to be able to access resources and support that could facilitate their success (Cage & Howes, 2020). The experiences participants shared with us spanned multiple domains of university life, indicating that the need for change extends beyond the academic space. Only through understanding how higher education systems fail to support autistic university students can we move towards reshaping the systems that further marginalize this historically excluded population.

Background: The Developmental Disabilities Assistance and Bill of Rights Act of 2000 (DD Act; Public Law 106-402, 106th Congress) ensures that individuals with developmental disabilities (IWDD), including autistic individuals, and their families participate in the design of and have access to needed community services, individualized supports, and assistance that promote self-determination, independence, productivity, and integration and inclusion in all facets of community life. State Councils on Developmental Disabilities (SCDD) work to support autistic university students can we move towards reshaping the systems that further marginalize this historically excluded population.

Objectives: Given the call for increased partnership between IWDD and stakeholders, researchers, and service systems (Crimmins et al., 2019; Poulsen et al., 2022), this study aims to leverage data collected by the California SCDD to summarize and quantify stakeholder priorities for state policies.

Methods: Participants (n = 99) included family members (48.5%), community members (23.2%), IWDD (i.e., self-advocates; 14.1%), and professionals (14.1%) across California. As part of the Bill Idea Contest, participants completed a survey and responded to the question “What problem do you hope to solve?” in Fall 2021. Using an inductive analysis approach, responses were tabulated and coded under problem domains and subdomains that emerged (Wertz, 2011). To ensure consistency across coders, 20% of responses were double coded.
and indicated acceptable reliability (domain: 90%; subdomain 75%); disagreements were discussed to achieve consensus across all coders. Frequencies were run to determine top priorities.

**Results:** A total of 99 submissions were received. The following problem domains were identified (Figure 1): Priorities under the Health & Human Services domain included service access issues (e.g., barriers, lack of services) and billing practices or insurance coverage issues, and priorities under Education included legal issues and parent support issues (Table 1).

**Conclusions:** The SCDD is committed to advancing research priorities, public policy, and systems change that support IWDD, including autistic people. The present study not only supports policymakers and care systems to best align policy and practice with the priorities of IWDD and their families, but also summarizes results of a needs assessment from stakeholders’ perspectives to support future research priorities. The survey aimed to capture views from people throughout California, the state with the largest number of IWDD, and one of the highest rates of autism across the U.S. (CDC, 2021). Findings indicate top priorities to be Health & Human Services and Education. Identified priority domains and subdomains, potential solutions, and relevance to research, public policy, and practice changes that may impact autistic people and their families will be discussed.

402.077 *(Poster)* A Comparison of Autistic and Non-Autistic Adults’ Mental Health and Therapy Experiences
**S. M. Brunt, J. E. Pappagianopoulos, E. Sadikova and M. O. Mazurek, (1)University of Virginia School of Education and Human Development, Charlottesville, VA, (2)Clinical and School Psychology, School of Education and Human Development, University of Virginia, Charlottesville, VA, (3)University of Virginia, Charlottesville, VA**

**Background:**
Autistic adults are significantly more likely than non-autistic adults to have co-occurring mental health conditions such as anxiety and depression. Although best-practice guidelines for treating many mental health conditions have been established for neurotypical individuals, less research has focused on adapting these strategies for individuals with autism. Previous research has not directly compared autistic adults’ perceptions of therapy experiences to non-autistic individuals’ experiences, especially regarding specific therapeutic strategies.

**Objectives:**
The aim of the current study was to compare autistic and non-autistic adults’ symptoms of anxiety and depression, the presence of mental health conditions, and ratings of perceived helpfulness and ease of use of therapeutic strategies.

**Methods:**
The sample consisted of 296 autistic and 157 non-autistic individuals aged 21-78 (M=38.4, SD=12.4). The autistic sample was recruited online through the Simons Foundation Powering Autism Research for Knowledge (SPARK) Research Match process. The non-autistic sample was recruited through Amazon’s Mechanical Turk. Participants completed an online demographic survey, the AQ-Short, PHQ, and questions about their mental health and therapy experiences. Participants rated therapeutic strategies they had used on their perceived helpfulness (1=not at all helpful to 5=very helpful) and ease of use (1=very difficult to 5=very easy). T-tests were conducted to compare mean AQ scores and PHQ Depression and Anxiety subscale scores. Chi-square goodness of fit tests were used to compare the groups on mental health diagnoses. Wilcoxon rank-sum tests were conducted to compare ratings of therapeutic strategies.

**Results:**
Autistic participants had significantly higher scores than non-autistic participants on the AQ-Short (t=-26.10, p<.001), PHQ Anxiety (t=-10.67, p<.001) and PHQ Depression (t=-10.54, p<.001). Autistic adults were more likely to have been diagnosed with anxiety (X^2=135.02, p<.001), depression (X^2=129.83, p<.001), bipolar (X^2=28.61, p<.001), OCD (X^2=27.01, p<.001), PTSD (X^2=64.67, p<.001), and ADHD (X^2=99.96, p<.001). Thirty non-autistic (19.1%) and 263 autistic (88.9%) participants had previous therapy experiences. The groups did not differ in ratings of perceived helpfulness of exposure, breathing, progressive muscle relaxation, or behavioral activation strategies. The autism group rated cognitive (z=2.99, p=.003), mindfulness (z=2.57, p=.01), and guided imagery (z=1.99, p<.05) as less helpful than the non-autistic group. Breathing was the only strategy that the autism group rated as less easy to use (z=2.06, p=.04).

**Conclusions:**
Results highlight the significant co-occurring mental health challenges that autistic adults face in comparison to non-autistic adults. Moreover, some common strategies used in therapy may not be as helpful or as easy to use for autistic clients. Our study was limited by an imbalanced sample size, since fewer non-autistic adults had received therapy. Future research should investigate factors related to autistic adults’ differences in therapy experiences. For example, autistic adults may have unique life challenges for which cognitive strategies are
Background: Caregiving challenges often persist and evolve across the life course for families of autistic youth, with unique needs in the years immediately preceding and following the transition to adulthood. Most research on support for caregivers of autistic individuals is cross-sectional, quantitative, and focuses on caregivers of children with ASD. Further, not all family support may be equally helpful or important to caregivers as they and their loved ones on the spectrum age. An in-depth, qualitative investigation can provide rich insight into aspects of family support that are most valued by families raising an autistic youth across their transition to adulthood.

Objectives: Use a qualitative approach to 1) examine change and stability in the sources and characteristics of support most valued by caregivers of youth with autism during the transition to adulthood, 2) examine differences in valued sources and characteristics of support between caregivers of individuals of different cognitive ability (i.e., more able (MA; IQ ≥70) and less able (LA; IQ<70)).

Methods: Caregivers of 127 autistic individuals (20% female; 82% White) from an ongoing longitudinal study completed a modified version of the Family Support Scale (FSS; Bromley et al., 2004; Dunst et al., 1988) at five time points from adolescence into young adulthood (Table 1), as part of which caregivers answered the open-ended question: “Which of the above sources of social support is the most important to you? Why?”. Thematic analysis was utilized to identify themes, subthemes, and codes. Reliability (80% agreement on 20% of data) was established. All data was double-coded and discrepancies were resolved through consensus discussions.

Results: Caregivers’ partners were the most frequently valued source of support (approximately 40%) at all time points for both MA and LA groups (Table 1). The pattern of support sources over time differed between MA and LA groups. For example, only among caregivers of LA individuals, siblings showed increasing value into early adulthood.

Regarding characteristics of valued support sources, similar themes, subthemes, and codes emerged across all five time points. However, response frequencies varied across time and group (Table 2). Within the Type of Support theme, a subtheme, Instrumental Support (e.g., helping with daily tasks), was more valued than emotional support in adolescence. In contrast, Emotional Support became more highly valued than Instrumental Support during young adulthood; this pattern was particularly pronounced in the LA group. The top-rated characteristics of valued sources of support included being dependable, understanding, and providing partnership. These characteristics were relatively consistent across time and group (Table 2).

Conclusions: Using qualitative coding of open-ended responses, family support, especially from partners, emerged as a valued source of support for caregivers of autistic youth across the transition to adulthood. Factors contributing to the value of support changed over time, shifting from valuing instrumental support to emotional support, especially for caregivers of LA adults. Additionally, fine-grained analyses revealed that providing a sense of partnership and dependability throughout adolescence and young adulthood were highly important to caregivers.

Objectives: To understand the parent experience of participating in the Door 2 program and to compare/contrast it with supports received previously or currently to help manage their child’s co-occurring conditions.

Methods: Semi-structured interviews were conducted with nine mothers of daughters with an ED and autistic traits asking about their experience participating in the Door 2 program. Interpretative phenomenological analysis was used along with member checks to derive themes from the participants’ narratives.
Results: Two superordinate themes emerged from the interviews. “Taking a step back” consisted of narratives around the parent-child relationship and “We needed to do something different” consisted of narratives around support parents have received both in the past and at the present time. The recognition of both conditions (ED and autism) was emphasised as being an important component in their child’s recovery, as was the inclusion of and access to lived experience mentors.

Conclusions: While further research is needed to evaluate the effectiveness of the Door 2 program, the findings of this study suggest that it shows promise in helping families of young people with an eating disorder and autistic symptoms.

402.080 (Poster) A Scoping Review of Evidence-Based Supports on College and University Campuses for Autistic Post-Secondary Students
(1)School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, (2)University of Calgary, Calgary, AB, Canada, (3)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (4)Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada, (5)University of Western Ontario, London, ON, Canada, (6)SKIP Lab, Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (7)Ryerson University, London, ON, Canada, (8)First Nations Technical Institute, Elphin, ON, Canada, (9)Alberta Health Services, Edmonton, AB, Canada, (10)Department of Psychology, Center for Mind and Brain, UC-Davis, Davis, CA, (11)Carleton University, Ottawa, ON, Canada, (12)University of Calgary, Edmonton, AB, Canada

Background: Navigating campus life and attaining credentials is often difficult for autistic adults, despite their considerable contributions to postsecondary campuses (Nachman et al., 2021). It has been reported that up to 80% of autistic postsecondary students do not graduate (Vanbergeijk et al., 2008); other research has reported limited implementation of autism-specific supports (Ames et al., 2022). Given a demand to better address the principles of equity, diversity, inclusion, and accessibility in higher education (Smith et al., 2021; Craig et al., 2010), research into both barriers and promising practices to support autistic students on postsecondary campuses has advanced, with an emerging trend of exploring autism-specific supports. Recognition of the need for equitable access to postsecondary education for autistic students has been coupled with a growing understanding that autistics require support in a variety of non-academic domains.

Objectives: The objective of this scoping review is to identify, map, and characterize literature that enumerates and describes supports for autistic postsecondary students.

Methods: Our scoping review was limited to peer-reviewed research published between 2012 and 2022, in these databases: Web of Science, PsycINFO, Medline, EMBASE, ERIC, Social Work Abstracts, Social Services Abstracts, and EMCARE. Aligned to Joanna Briggs Institute methodology for scoping reviews (Peters et al., 2022), we mapped existing approaches to creating accessible campuses across eight key domains of the PASS Taxonomy (Duke et al., 2017; Table 1) and a systematic review by Widman and Lopez-Reyna (2020; Table 2), in consultation with Autistic Community Partners (ACP). Four ACPs made up an expert panel of autistic individuals with postsecondary experience who acted as co-researchers, guiding the development of the review. Data extraction was completed by three independent graduate students using the data extraction tool developed by the authors (DS, HN, JC, BDR).

Results: The review included 154 articles from the US, Australia, Canada, Netherlands, Israel, Sweden, Ireland, Norway, Nigeria, Slovenia, and Belgium. Table 1 presents frequency counts for studies describing supports for autistic students as either successes or barriers in eight domains seen previously (Duke et al., 2017; Widman & Lopez-Reyna, 2020). Support and barrier categories with the three highest frequency counts were, Academic, Social, and Emotional. Success counts outnumbered barriers only in the Academic category, consistent with evidence that autistic PS students are academically well-prepared (Flegenheimer & Scherf, 2022). Social was almost evenly split, and Emotional, including counseling, generated higher counts for barriers than successes. Other categories emerged and were inductively grouped (Table 2) and from these, only Interpersonal and Participatory Action Process had predominantly success counts. Areas where barriers were predominant occurred within Sensory environments, Individualized supports, Attitude, Diagnosis, Disclosure, Intersectionality, Finance, Sexual Health/Education, and Service Navigation.

Conclusions: This review is the first to summarize both areas that have been researched and under-studied domains in the literature that contributes to successes and barriers for autistic students on postsecondary campuses. Mapping the literature in known and emerging categories indicated that broad categories of support are experienced variably by autistic students. Findings provide multiple avenues for future research.

402.081 (Poster) A Systematic Review of Assent Practices in Research That Establish Evidence-Based Practice for Autistic Individuals
(1)May Institute, Randolph, MA, (2)Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)University of South Florida, Tampa, FL, (5)Mosaic Therapy, Charlotte, NC, (6)College of Saint Rose, Albany, NY, (7)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (8)Advocacy Without Borders, Houston, TX, (9)Oregon Health & Science University, Binghamton, NY, (10)Department of Psychology, Center for Mind and Brain, UC-Davis, Davis, CA

Background:
When an individual is unable to consent to participate in research (e.g., a minor), they should be given an opportunity to assent. An Institutional Review Board may waive the need for assent based on the age, maturity, and capability of the individual (FPPHS, 2018). This can introduce uncertainty for when and how researchers obtain assent for certain populations, such as autistic individuals. Autistic individuals present with differences in communication and behavior. For example, autistic individuals may not vocally communicate in ways consistent with social mores of non-autistic individuals. Autistic self-advocates have questioned the degree to which differences are dismissed as presumed incapability rather than accommodated by non-autistic people (Milton, 2012; Oliver, 2017). It is critically important that researchers document consent and assent procedures with autistic people to ensure appropriate processes are being utilized and refined over time. This is especially true considering growing concerns that interventions may differ in acceptability (Schuck et al., 2021). Instances of consent/assent, or lack thereof, may be one proxy metric of acceptability from participants’ perspectives.

Objectives:

We sought to identify how researchers report consent and assent procedures in autism intervention research used to establish evidence-based practice. We aimed to identify (a) the percentage of studies that document consent/assent procedures, (b) how assent was obtained, and (c) when assent was obtained.

Methods:

The NCAEP review is the most recent large-scale synthesis of research that establishes evidence-based practices for autistic individuals (Steinbrenner et al., 2020). We extracted intervention articles from their review to code consent and assent procedures. We coded study characteristics (publication year, design type, intervention type) and basic participant demographics. Next, we coded whether the authors explicitly documented consent/assent. In studies documenting assent, we also coded how and when assent was obtained.

Results:

We included 616 articles that utilized single-subject designs (SSD; n=1681 participants) and 178 articles that utilized group designs (n=9049). SSDs included younger participants on average ($M=2.75$) relative to group designs ($M=8.57$). While consent procedures were mentioned more frequently in group design studies, both group designs and SSDs rarely documented assent (7-17%; Table 1). Assent procedures were largely not described even when referenced (~75% not described). For studies documenting when assent occurred, it primarily was obtained prior to study onset only. There has been a small increase in the percentage of studies reporting assent in recent years concomitant with a larger number of studies being published (Figure 1).

Conclusions:

The current body of literature that establishes evidence-based practices for autistic individuals largely does not report consent and assent practices within the published manuscript. There may be several reasons for limited reporting practices, including lack of motivation to report such, journal restrictions (e.g., page limits), waiving assent due to actual or perceived incapability, and/or using retrospective data from clinical practice. In this presentation, we argue the importance of carefully selecting and reporting assent practices and outcomes in the context of autism research and practice. We also discuss challenges and implications of selecting different assent procedures and timeframes.

402.082 (Poster) A Systematic Review of Community-Academic Partnership Quality in Autism Intervention Research

J. E. Tschida, A. Pomales-Ramos and J. D. Lee, (1)Department of Psychology, Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI, (3)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

Background:

There is minimal research on the quality of community-academic partnerships in studies of interventions for autistic children. However, both community members and researchers have emphasized the importance of building high quality community engagement in autism intervention research to improve implementation outcomes (Carrington et al., 2016; den Houting et al., 2020; Fletcher-Watson et al., 2019). We are completing the first systematic review of reported community-academic partnership quality in research on psychosocial and educational interventions for autistic children and their families. We will explore associations between reported partnership quality and reported implementation outcomes.

Objectives:

1) Systematically evaluate the quality of reported community-academic partnerships in research on psychosocial and educational interventions for autistic children and their families.
2) Explore associations between quality of reported community-academic partnerships in research on psychosocial and educational interventions for autistic children and their families and implementation outcomes.

Methods:

Search and Inclusion:

We searched eight databases (APA PsycArticles, APA PsycExtra, APA PsycInfo, Embase, ERIC, ProQuest, PubMed, and Web of Science) with keywords related to community-academic partnerships and autism intervention. Articles were screened by title and abstract and with full text. We included studies that report community-academic partnership, empirical data on psychosocial or educational interventions, and inclusion of autistic children and their families.

Data Extraction:

We are extracting data on participant demographics, partnership, and implementation outcomes. For extraction of community-academic partnership data, we are using the conceptual framework for assessing research-practice partnerships (Henrick et al., 2017). For extraction of implementation outcomes data, we are using the taxonomy of distinct implementation outcomes (Proctor et al., 2011). We are appraising the quality of each study using JBI critical appraisal tools (Munn et al., 2020). Inter-rater reliability will be examined for 28.57% of included articles.

Data Analytic Approach:

To evaluate community-academic partnership quality, we will complete a narrative synthesis using the dimensional indicators from the conceptual framework for assessing research-practice partnerships. To explore associations between reported partnership quality and reported implementation outcomes, we will conduct exploratory correlations.

Results:

We identified 135 articles from our literature search and 9 articles from researcher knowledge. Title and abstract screening and full text review resulted in a total of 14 included articles. Preliminary data extraction (n=6 articles) has indicated varied reporting of community-academic partnership quality (Table 1) and implementation outcomes (Table 2). In terms of community-academic partnership quality indicators, conducting rigorous research to inform action appears to be one of the most common indicators assessed whereas building capacity seems to be one of the least common indicators assessed. For implementation outcomes, acceptability seems to be most commonly assessed and sustainability least commonly assessed.

Conclusions:

Our systematic review will provide the first examination of reported community-academic partnership quality in research on interventions for autistic children. This examination will also have potential to suggest broader relationships between community-academic partnership quality and implementation outcomes. Preliminary results highlight the potential need for greater focus on assessing capacity building and sustainability within community-academic partnerships.

402.083 (Poster) Accommodating the Neurodivergent Needs of Children in an Educational Concert Setting

C. Sim¹, M. Moura¹ and E. M. Quintin¹,², (¹)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (²)Transforming Autism Care Consortium, McGill University, Montreal, QC, Canada, (³)Orchestre Symphonique de Montréal, Montreal, QC, Canada

Background: As there is growing evidence for the benefits of inclusive education, many neurodiverse students, including autistic students, are integrated into mainstream classrooms. These students participate in functions and fieldtrips with their school groups regardless of the accommodations provided in locations outside of their educational institution. Given the evidence that autistic children have an interest and ability for music, functions and fieldtrips to attend musical concerts could be of particular interest for neurodiverse students, although the overall experience may not be adapted to their needs.

Objectives: We aimed to assess whether neurodiverse students attend music concerts as part of school fieldtrips and whether they appreciate the musical repertoire and overall concert experience.

Methods: The Montreal Symphony Orchestra (Orchestre Symphonique de Montreal [OSM]) and McGill University’s Behaviour, Autism, and NeuroDevelopment (BAND) Research Group, including an autistic researcher, collaborated to assess the audience’s appreciation of the
Results: Preliminary results showed that 63% of school groups attending OSM educational concerts included neurodivergent students, and approximately 70% of the neurodivergent students that attended struggled with some aspect of the concert experience. Nevertheless, 70% of educators of neurodivergent students deemed the content of the concerts to be suitable for their students. This has an important implication as it suggests that students are not struggling with the content of the concerts but the experiences surrounding it (i.e., volume (sensory sensitivities), concert dynamic, wait times, etc.). Indeed, most school groups (67%) reported that the dynamic between the theatrical and musical components of the concerts affected their concert experience, 20% reported that the volume of certain parts of the experience significantly impacted the experience.

Conclusions: A large proportion of school groups attending classical music concerts include neurodiverse students. Most of them struggle with some aspects of the concert experience although they enjoy the musical repertoire. Our results thus support existing evidence suggesting that neurodiverse students have an affinity for music and that efforts should be made to increase accessibility to musical activities. Our findings hold the potential to demonstrate that making accessibility a universal experience can benefit everyone, especially neurodivergent individuals.

402.084 (Poster) Amplifying Autistic Perspectives: Learning from and with Autistic Adults to Understand and Enhance Self-Determination
S. Thompson-Hodgets; J. Ryan; A. Xavier; E. Coombs; and H. M. Brown; (1)Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (2)Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada, (3)SKIP Lab, Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (4)Educational Psychology, University of Alberta, Edmonton, AB, Canada

Background: Self-determination has been conceptualized as making choices and decisions regarding one’s quality of life free from undue external influences or interference (Wehmeyer, 1999). Self-determination is a fundamental human right and is positively related to quality of life. However, autistic people often have less opportunities to be self-determined than non-autistic people.

Objectives: To (1) understand what self-determination means to autistic people; and (2) learn from autistic people how they would like to be supported to be self-determined.

Methods: This study is part of a larger study addressing our research objectives specific to autistic adults who do and do not experience co-occurring intellectual disability. These data were gathered from autistic adults who do not experience intellectual disability. Semi-structured interviews, 30-60 minutes, were done using Zoom. Interviews were recorded, transcribed and analyzed by three autistic and two non-autistic researchers through an iterative process of data familiarization, coding, and theme development. Coding and initial theme development were informed by the basic psychological needs put forth in self-determination theory: autonomy (self-directed freedom), competence (confidence in one’s ability) and relatedness (trusting and respectful relationships; Ryan & Deci, 2017).

Results: Participants included 19 autistic adults (mean age = 34.8 years, range 18-62 years) who represented diversity across many demographic variables (e.g., identified gender, educational attainment, income/financial resources, relationship status, employment status). Addressing objective #1, self-determination held the same meaning for autistic people as others, including non-autistic people. More specifically, participants discussed meaning related to making choices and decisions in life free from undue external influences or interference. However, most participant’s experiences of self-determination were centered around a lack of control, assimilation and conformity to neuro-typical and ableist social expectations, and forced choices. Preliminary analysis related to objective #2 revealed that participants desired guidance and support across all three psychological needs outlined in Deci and Ryan’s (2017) self-determination theory. Desired areas of support were noted in four themes: (1) opportunities to feel in control of one’s immediate and longer-term choices, and of one’s supports, including by whom, in what areas, and to what extent; (2) support with executive functioning and self-regulation, including options, consequences of those options, being given time to evaluate options, and identifying modifiable choices. The term ‘overwhelm’ was frequently used to describe emotional responses to choices that influence immediate and longer-term outcomes; (3) feeling supported to ‘unmask’ and be valued for one’s authentic autistic self, including the choices one makes; and (4) being recognized and respected as competent by others, even if one makes choices differently than they, or the majority of others, might have done.

Conclusions: Existing research suggests that autistic people live less self-determined lives than others, often due to ableist expectations. Our findings suggest that autistic adults desire to be self-determined and can flourish with support, as they determine to be appropriate, which might look different from supports commonly offered or sought by non-autistic people.

402.085 (Poster) An Examination of Mychart for Recruitment into a U.S.-Based Autism Research Cohort
R. P. Goin-Kochel; I. Lozano; G. Marzano; R. Sanchez; M. L. Law; and L. N. Berry; (1)Baylor College of Medicine, Houston, TX, (2)Meyer Center for Developmental Pediatrics & Autism, Texas Children’s Hospital, Houston, TX, (3)University of Houston, Houston, TX,
Background: We previously demonstrated that a research Best Practice Advisory (BPA) can successfully engage providers in the recruitment of autism patients for the national SPARK study (Simons Foundation Powering Autism Research for Knowledge; Simon et al., 2022; Duhon et al., 2022). However, provider dismissal of the BPA without action is common and tends to increase over time as a function of alert fatigue, which means that many potentially eligible and interested families may not learn about SPARK via their provider. MyChart is a secure web-platform that allows patients to view their medical information, communicate with their providers, and actively manage their healthcare—essentially, the patient-facing side of the electronic health record (EHR). Exploring MyChart as a research recruitment tool is valuable for assessing its efficacy in capturing families for research opportunities via a familiar EHR platform.

Objectives: To examine the utility of MyChart in recruiting pediatric patients with autism for the SPARK study at the Texas Children's Hospital site.

Methods: Between November 2021 and October 2022, 2,086 families of children with ASD who triggered the SPARK BPA but had no provider response recorded were sent a SPARK recruitment message via MyChart. The message included a description of the study, eligibility criteria, and incentive information. Families could respond to the message as either Interested or Declined; if Interested, the research team emailed them additional study information, including the registration link. 297 Interested caregivers who had not enrolled after ~3 months were sent a reminder email. 223 families who never responded to the MyChart message triggered the SPARK BPA a second time during a subsequent clinical visit. Participant MyChart responses and SPARK enrollment status were tracked and analyzed descriptively.

Results: During the year-long surveillance, 400 (19%) caregivers responded Interested to the MyChart message; 58 (14.5%) of this group enrolled after receiving the initial recruitment email and 16 (5%) enrolled after the reminder email. 136 (7%) responded Declined to the MyChart message; 3 (2%) of them enrolled in the study. 1550 (74%) did not respond to the MyChart message; 3 (0.2%) enrolled in SPARK. Of the 223 who triggered the BPA again, 101 (45%) responded Interested; 14 (14%) among this Interested group enrolled. Overall, 94 (4.5%) families who received a MyChart message about SPARK enrolled in the study (see Figure 1). Analyses examining rates of study completion and factors that predict enrollment following receipt of the MyChart message are currently underway.

Conclusions: Nearly 1 in 5 families indicated interest in the SPARK study following receipt of the MyChart message, and ~20% of this group enrolled in the study after receiving emailed information. Although these numbers are lower than those seen with the SPARK BPA, they nevertheless demonstrate the viability of MyChart to engage families in the study. That some families ultimately enrolled in SPARK who declined or ignored the MyChart message suggests that they may have learned about it via another compelling channel (e.g., social media, friend/family member). Further research should explore functionality within the EHR to support clinical-research recruitment and retention efforts.

402.086 (Poster) An Examination of Parent’s Perspective of Paraprofessionals Delivering Direct Applied Behavior Analysis
D. A. Samelson and L. Sneed, (1)Clinical Excellence, Catalight Foundation, Walnut Creek, CA, (2)Research Institute, Catalight, Walnut Creek, CA

Background: Applied behavior analysis (ABA) is an effective and commonly used intervention supporting the skill development of autistic children and youth. In the US the most common ABA model for autistic children is practitioner-mediated ABA. While parent training is often included, most direct treatment in the practitioner-mediated model is provided by a paraprofessional usually working under the supervision of Board Certified Behavior Analyst® (BCBA®). Despite the frequent use of paraprofessionals in ABA there is a paucity of research investigating parent’s perspectives of paraprofessionals. Understanding parent’s perspectives of the paraprofessional working with their autistic child is an important step in improving the practitioner-mediated model.

Objectives: Examine parent’s perceptions of paraprofessional competency in practitioner-mediated ABA provided in the home or community settings.

Methods: A thematic analysis of 130 parent’s comments about paraprofessionals working with their child was conducted. Comments were taken from a satisfaction survey asking parents questions about their experience in ABA. Only comments about paraprofessionals were used for this study.

Results: Thematic coding resulted in 69 positive and 61 negative parent perceptions of paraprofessionals. Five themes emerged from the thematic analysis of parent’s comments about the paraprofessional working with their child; experience/knowledge, consistency, caring behavior, professionalism and match between the child and paraprofessional. For both positive and negative comments “knowledge and experience” was the most common theme. As one parent put it, “Give more training to the new ABA [paraprofessional] updated them in the different behavior trained them on autism behaviors.” An example of a positive comment with the knowledge and experience theme was, “My child’s [paraprofessional] is highly experienced ... and she's always giving me tips on how to work with my child throughout the day and outside of sessions.” The second most common theme for negative comments was “consistency,” but this theme was mentioned much less often than knowledge and experience. For positive comments the second most common theme was “caring behavior” but as with the negative comments this secondary theme appeared much less often than knowledge and experience. Even when secondary themes were
mentioned these themes were often combined with the knowledge and experience theme. For example, one parent who had a negative perception of the paraprofessionals working with their child said, “We had frequent [paraprofessional] change[s] and some of them weren’t equipped to do their job.”

Conclusions: For both positive and negative perceptions of paraprofessionals, parents mentioned knowledge and experience of the paraprofessional working with their child most often. Fidelity in ABA treatment implementation is an important factor in achieving good outcomes and researchers and others in the field of ABA have expressed concerns about paraprofessional training pointing out paraprofessionals working in ABA have less training than practitioners participating in university studies (Leaf et al, 2017). While no parent mentioned the term fidelity directly for either negative or positive perceptions the theme of knowledge and experience speaks to fidelity of paraprofessional performance as well as training of paraprofessionals.

402.087 (Poster) An Exploration of the Experiences of Neurodiversity-Affirming Families
T. O’Donnell-Killen and N. Zadurian, (1)Thriving Autistic, Dublin, Ireland, (2)Department of Psychology, University of Derby, Derby, United Kingdom

Background: There has been an increased interest in a human-rights based approach to parenting Autistic children by stakeholders. Research literature to date has primarily focused on suggestions for researchers and practitioners.

Objectives: To explore the experiences of families who take a human-rights based, neurodiversity-affirmative approach to parenting Autistic child(ren) with and without co-occurring conditions.

Methods: Twenty-nine self-identified neurodiversity-affirming parents participated in a semi-structured, synchronous online interview. An inductive reflexive thematic analysis was employed to analyse the data.

Results: Initial analysis shows two primary themes and three sub-themes: In theme 1 "My child is a complete person", participant's explore their perspective of seeing their child as a whole human being, different, but not less-than neurotypical people. Sub-themes include (a) how parents are "seeing the world through a different, more positive lens", since adopting a human-rights based approach to autistic people, and how (b) professionals and other people in children's lives "don't see the psychological harm" of neuro-normative, conforming approaches. Theme 2 describes how parents work to create a psychologically safe environment where their children are free to be themselves in "home as haven", sub-theme (a) "managing conflicting needs" explores participant's experiences of woking to create a home environment that meets the various needs of different family members. Further analysis is ongoing and results will be finalised and available prior to the presentation.

Conclusions: The current study represents the first exploration into the experiences of families who take a human-rights based Neurodiversity-Affirmative approach to parenting autistic child/ren. This study adds to the literature in understanding the experiences of families who apply the neurodiversity paradigm which represents a fundamental shift in attitude from "autistic people as deficit" to "autistic people as valid, natural variation".

402.088 (Poster) Applying Communication Privacy Management Theory to the Use of Social Technologies for Adults with Autism and Allies
S. S. Buford, X. Page and T. P. Gabrielsen, (1)Computer Science, Brigham Young University, Provo, UT, (2)Computer Science, Brigham Young University, PROVO, UT, (3)Counseling Psychology and Special Education, Brigham Young University, Provo, UT

Background: In 2021, over 4.48 billion people used social media worldwide. Much research focuses on understanding privacy needs for the general population of social media users, yet privacy for Autistic users is under-explored. Traditional privacy frameworks, such as Communication Privacy Management theory (CPM) have been useful in understanding privacy expectations and behaviors for the general population when multiple people are involved in managing whether to share a given piece of personal information. It can serve as a useful tool for understanding privacy attitudes and behaviors of autistic users and their allies (e.g., parents, case workers) who are often involved with privacy management.

Objectives: CPM asserts that individuals create “rules” regarding how their private information is shared. We aim to understand what privacy rules autistic users and their allies are creating to dictate online social behavior.
Methods:

We partnered with two community organizations located in the Northeastern United States that provide day services for Autistic adults. We interviewed eight clients (who are formally diagnosed with Autism, “participants”) and fourteen allies (case workers, parents). We extracted all instances of ally-participant mediation and engaged in theoretically-driven coding using CPM, supplemented by open-coding.

Results:

Interviewees verbalized many of their privacy rules, while others we observed based on behavior. Explicit rules vocalized by participants included “I don’t accept Facebook requests from men” (participant 2) or “I don’t share any money online” (participant 4). In other instances, rules were not explicitly stated, but rather implicitly revealed by behavior. Many participants shared personal information with potential romantic partners, revealing an implicit rule of behavior between partners, even if they had just connected online. Other participants had much more accepting rules regarding sharing strong negative emotions or nude photos online than their allies did. We found that ally rules often did not match the rules participants created for themselves. For example, if a participant felt it was appropriate to share their exact location on their Facebook wall, but an ally did not, this would create a mismatch of rules. The ally’s rules were more concrete and verbalized more frequently than rules created by other participants. Some examples of ally rules included: don’t accept every friend’s request, filter content based on context, don’t express strong negative emotions online, don’t trust “romantic interests”, never share location and many more. In our presentation we will share more about common privacy rule mismatches.

Conclusions:

Through this study we found that many participants shared personal information at a more intimate level than most allies felt comfortable with. This mis-match of “rules” led to conflict. We discuss how CPM can be utilized as a lens by which to mediate conflicts. By analyzing both user and ally rules, one can then identify the extent to which privacy risks exist due to the mismatch. It may also help allies and Autistic individuals better express their desires and explain the situations where they feel sharing private information is and is not appropriate. Engaging in such dialog can allow them to develop mutually agreeable rules around sharing.

402.089 (Poster) Association between Parent Stress and Family/Child Quality of Life Is Mediated By Mental Health in Parents of Autistic Youth
E. A. DeLucia, C. G. McDonnell and A. Scarpa, (1)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Department of Psychology, University of Wyoming, Laramie, WY, (3)Department of Psychology, Virginia Tech, Blacksburg, VA

Background: Quality of life (QOL) is increasingly considered an important outcome measure in autism research. As such, it is important to consider factors which may affect QOL for autistic individuals and their families. Parental characteristics are likely to have a significant impact on QOL in families of autistic youth; literature suggests that parents of autistic youth often have higher levels of stress and more internalizing symptoms than parents of non-autistic peers due to multiple familial and systemic factors (Clauser et al., 2021; Cohrs & Leslie, 2017). Given these differences in parental characteristics and recent interest in QOL, it is critical to understand associations between parent wellbeing factors and QOL for autistic children and their families.

Objectives: The current study aimed to evaluate whether parent internalizing symptoms mediated the association between parent stress/family QOL and parent stress/child QOL in autistic and non-autistic youth.

Methods: 117 parents of autistic youth and 125 parents of non-autistic youth ages 2-17 completed the Perceived Stress Scale (PSS) which measured parent stress; the Beach Family Quality of Life questionnaire (FQOL) which measured parent perception of family functioning and cohesion; the Pediatric Quality of Life Inventory (PedsQL), which measured physical, emotional, social, and school functioning of youth; and the Dysphoria subscale of the Inventory of Depression and Anxiety Symptoms, Second Edition (IDAS-II), which measured parent depression/anxiety symptoms. Mediation analyses were conducted using the SPSS PROCESS macro (Hayes, 2018) to determine whether parent anxiety/depression symptoms mediated the following associations: 1) parent stress and family QOL in autistic youth; 2) parent stress and family QOL in non-autistic youth; 3) parent stress and child QOL in autistic youth; and 4) parent stress and child QOL in non-autistic youth.

Results: Results of our mediation models suggested that parent internalizing symptoms partially mediated the association between parent stress and FQOL (indirect effect estimate = -.17, CI=-.27 -.08, see Figure 1) and completely mediated the association between parent stress and child QOL in autistic youth (indirect effect estimate = -.10, CI =-.1.57 -.51, see Figure 1). In non-autistic youth, parent internalizing symptoms did not mediate either the stress-family QOL association or the stress-child QOL association.

Conclusions: The current study finds that for autistic youth, the association between stress and family QOL is partially mediated by parental mental health symptoms, while the association between parental stress and child QOL is entirely mediated by parent mental health symptoms.
Past studies have identified several barriers to autism screening in Ecuadorian paediatric settings, which mainly concern the availability of indicated mental health treatment for parents has the potential to benefit the family unit as well as autistic youth specifically. Previous work has found positive effects of psychotherapy for parents of autistic youth (Lunsky et al., 2018); future research should endeavor to prospectively consider the impact of parental individual therapy on the overall wellbeing of the family and the autistic child.

402.090 (Poster) Attitudes of Early Childcare Professionals Toward Inclusive Education and the Inclusion of Children with ASD
C. Mejia Cardenas1, M. Rivard2 and Z. Mestari3, (1)Université du Québec à Montréal, Montréal, QC, Canada, (2)Psychology, Université du Québec à Montréal, Montréal, QC, Canada, (3)Psychology, UQAM, Montreal, QC, Canada

Background: The prevalence of autism spectrum disorder (ASD) continues to increase (1 in 44 children USA; CDC; 2021). With new initiatives and policy for integration into educational settings at an early age (Yu, 2019), this increase is also observed in early childhood daycares (D'Agostino & Douglas, 2021). Several studies show that school inclusion quality depends on several factors, including attitudes of teachers and administrators towards inclusive education (Jury et al., 2021). Although early childhood daycares are often the first place of integration for these children, few studies have focused on the attitudes of staff in these settings (Lee et al., 2015). Yet, the experience of inclusion in early childhood, including staff’s attitudes and practices, has important repercussions on social integration and inclusion in schools (Lee et al., 2015).

Objectives: To document the three dimensions of attitudes (affective, cognitive, behavioral) of 211 mainstream daycares professionals (159 early childhood educators and 52 administrators), toward inclusive education and the inclusion of children with ASD.

Methods: This study is a mixed-method research design using standardized questionnaires (descriptive quantitative analyzes and independent sample t-test) and clinical vignettes (qualitative analyses; L'Ecuyer, 1990), to measure the concept of attitudes according to several perspectives. The sample consisted of 190 women and 21 men. Among these, 87.2% of participants had experience working in ASD, 23.2% were certified in Special Education, and 30.8% had training in ASD. The Multidimensional Attitudes Toward Preschool Inclusive Education Scale (MATPIES; Lohmann et al., 2016) was first translated and validated in French and English for this study (Mejia-Cardenas et al., 2022) and comprise 15 items using a 6-level Likert scale (1 = most negative, 6 = most positive) and 4 subscales (positive and negative believes, affective, behavioral). The MATPIES and clinical vignettes describing three profiles of ASD were administered in an online survey.

Results: Overall, participants expressed positive attitudes towards inclusive education on all subscales (range: 3.05 to 5.34). Educators reported higher scores on all subscales compared to administrators (p <0.001) except on the affective subscale (p = 0.129). Several individual factors related to the participants (e.g., type of job), to the profiles of the children (e.g., symptoms severity), and to the context (e.g., resources) were significantly associated with attitudes towards inclusive education and ASD. The behaviors perceived as the most perturbing for inclusion were difficulties with emotional and behavioral regulation. The characteristics belonging to the second domain of the diagnostic criteria of the DSM-5 were most identified by the respondents. Having had a positive integration experience with similar children, as well as adequate training were factors commonly mentioned by participants for feeling able to welcome these children into their groups.

Conclusions: Given the importance of early childhood environments as one the first for inclusion, studying educators' attitudes towards inclusion is a priority, because it allows for a better understanding of the issues related to inclusion and children with ASD. In addition, it allows for the identification of staff training needs, both in general knowledge about ASD and in evidence-based interventions that promote inclusion.

402.091 (Poster) Autism Diagnostic Experiences of Parents in Ecuador
P. Boffle1, T. Cavadin2, E. Gentaz and L. Crane1, (1)Faculty of Psychology, University of Geneva, Ge, Ecuador, (2)Faculty of Psychology, University of Geneva, Geneva, Switzerland, (3)Institute of Education, Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, UNITED KINGDOM

Background:

Timely identification of autism in children could ease access to diagnostic and support services that may be beneficial to families and their children. Many children show the first signs of autism between the ages of twelve to eighteen months or earlier (Zwaigenbaum & Penner, 2018), and parents are often the first to notice that their child may be developing differently from other children. Parents’ responses can contribute to timely access to a diagnostic evaluation and subsequent support. However, a bias affecting low-income and non-English-speaking families has been noted in high resources countries (Nowell et al., 2015). In Ecuador, the latest official estimates in 2017 indicated the prevalence of autism at 0.28% in children under five years old, and 1266 people were registered with a diagnosis of autism. Past studies have identified several barriers to autism screening in Ecuadorian paediatric settings, which mainly concern the availability of...
time, knowledge, and resources to refer children (Buffle et al., 2022). A greater understanding of the earliest signs of autism and parents' reaction to these early signs have significant potential to support early identification and diagnosis of autism in Ecuador.

Objectives:

We aimed to collect data from an Ecuadorian sample of parents of children who had received a formal diagnosis of autism, focusing on: (i) the child's age at initial developmental concerns, (ii) the nature of initial concerns, (iii) the time from first concerns until the first consultation, (iv) whether the parents consulted with private or public networks, (v) the number of professionals consulted through the process, and (vi) feelings and thoughts when receiving the diagnosis.

Methods:

Six hundred fifty caregivers (567 women, 84 men) of children with a formal diagnosis of autism (ages 2 to 15) from diverse socio-economic backgrounds and geographic areas participated in an online survey (adapted from Crane et al., 2016, who examined autism diagnostic experiences in the United Kingdom). Participants were recruited via the Ecuadorian Parent Association (APADA) and the Ecuadorian National Council on Disability and Equality, the former of whom provided their telephone number for parents aiming to include participants with no internet access.

Results:

Most caregivers identified initial signs of autism by the age of two, and a smaller proportion between three and four years. The most common first concerns were delays in language and social development. Most caregivers sought professional help immediately or in the six months following the first concerns, mainly in the private health sector. In most cases, four or more professionals were encountered to obtain a diagnosis. Parents reported feelings of fear, worry, helplessness, frustration and uncertainty at the point of diagnosis.

Conclusions:

Some of these results are consistent with previous findings in high- and low-to-middle-income countries, on the importance of proactive professional responses to parental concerns. These findings can inform Ecuadorian health policies on the need for standardized screening and assessment in private and public networks. They also reiterate the importance of continuous professional training to build the capacity to deliver timely and accurate autism diagnoses and post-diagnostic support.

402.092 (Poster) Autism Spectrum Conditions in Peru: First Descriptions and Current Overview
M. Baquerizo1,2 and J. Lucero1,3, (1)Turing: science, technology and neurodiversity, Lima, Peru, (2)Universidad Continental, Lima, Peru, (3)Universidad Peruana Cayetano Heredia, Lima, Peru

Background: Autism spectrum conditions - ASCs are characterized by a particular cognitive phenotype that underlies (A) persistent difficulties in communication and social interaction and (B) the presence of restrictive and repetitive patterns of behavior, interests, or activities. The global prevalence of ASCs is about 1%, but in many low-and middle-income countries (LMICs) there are no prevalence estimates.

Objectives: This review aims to present the first descriptions of ASCs in Peru, to understand from a historical perspective the current challenges regarding diagnosis and treatments.

Methods: MEDLINE, Embase, and PsycINFO databases were searched. The search combined keywords and MeSH terms: "autism" or "autism spectrum disorder" and "Peru", also considering their translations into Spanish. A manual search of reference lists for review articles, reports, editorials, and resource texts was also performed; and an online search of government, university, and non-government websites to identify other non-peer-reviewed data sources.

Results: The scientific study of nervous and mental diseases began to be cultivated in Peru shortly before 1920. Perhaps the first article that refers to a case of "Childhood Schizophrenia", in terms of Eugen Bleuler, was published in 1944. There is evidence that in 1959 the diagnosis of "Early Childhood Autism" was raised in one case. Currently, there is a significant lack of ASCs diagnoses in Peru and there are significant problems of access to specialized, timely and quality services, especially in health and education.

Conclusions: The ASCs in Peru represent a great challenge that must be addressed as a priority. The need to implement effective public policies to improve access to early diagnosis is evident. More research is needed to identify the short-, medium-, and long-term needs of people with ASCs in Peru.

402.093 (Poster) Autism Voices: Toward Better Methods to Capture First-Person Perspectives of Autistic Individuals
Background: According to the United Nations Convention on the Rights of the Child, all children have a right to be included in decisions concerning them, regardless of their abilities. Participatory research is lacking in the autism field and very few studies include the first-person perspectives of autistic individuals (DePape & Lindsay, 2016). Further, when autistic individuals are included in research it is rarely those with intellectual disabilities or communication challenges.

Objectives: The Autism Voices project aimed to develop methods to capture the first-person perspectives of autistic youth with various intellectual and language abilities and to apply the methods to inquire about their daily experiences and hope for the future.

Methods: We first conducted a synthesis of methods previously used to obtain the first-person perspectives of youth with various disabilities. The identified methods were then presented and discussed in a parent focus group to determine their suitability for autistic youth. The synthesis, as well as strength-based methods and universal design, then informed the development of a protocol, which included a pre-interview survey and a semi-structured interview. The protocol was piloted with 31 autistic youth with various language and intellectual abilities communicative acts used by participants and the mitigation strategies to enhance communication used by interviewers were coded. Finally, a thematic analysis of the responses provided by the participants was carried out.

Results: Six methods (questionnaires, interviews, group discussion, narratives, diaries and art) and four communication output modalities (language, sign language and gestures, writing, and images) were identified in the synthesis. Potential barriers and facilitators to the use of these methods with autistic youth were discussed in the focus group and led to the creation of the Autism Voices interview protocol. Participants interviewed used both conventional and alternative communication methods, such as echolalia for example to engage with interviewers. Mitigation strategies used by interviewers, such as reformulating questions to avoid response patterns, efficiently enhanced communication, especially with minimally verbal participants. Finally, six themes emerged from the interviews: 1) autistic identities, 2) thinking about the future, 3) seeking social connection on their own terms, 4) seeking autonomy, 5) school as both a stressor and social facilitator and 6) experiences of stress and anxiety.

Conclusions: The contribution and continuous collaboration of autistic youth, families and experts is key when developing novel inclusive methods. Our experience using the Autism Voices protocol highlights that communication goes beyond verbally answering questions and shows that alternative communication acts can provide unique insight into autistic youth’s perspectives. The themes raised by youth during the interviews parallel what many typically developing teenagers experience, but are influenced by their experience of autism. Overall, Autism Voices provides a promising novel method to facilitate the active involvement of autistic youth of all intellectual and language levels. The current talk will highlight the lessons learned through the project and how Autism Voices can be applied in multiple settings.

Background: The COVID-19 pandemic thrust families of school-aged children into an era of social distancing and remote learning that changed the family dynamic in a myriad of ways. Transitioning to online education was especially hard on families of children with autism around the globe, finding that families found challenges guiding their children and needed supports to help with their stress (Althiabi, 2021), which was difficult as these parents felt that they were poorly supported by their children's schools (Heyworth et. al, 2021) and their mental health and that of their children was being severely impacted by the pandemic (Bozkus-Genc & Sani-Bozkurt, 2022).

Objectives: This study aims to examine what resources and support parents of children with autism desire compared to parents of typically developing children and those with other special education needs, to better illustrate the areas of need for both groups during this unprecedented time.

Methods: Participants were part of the Parent Experience of Remote Learning Study (PERLS), a longitudinal study that surveyed parents of school-aged children (Kindergarten - 12th grade) monthly over six months, starting in March 2021. At timepoint one, respondents were asked an open-ended survey question, “In your own words, what resources or supports do you wish you had right now?” Researchers conducted a thematic analysis, leaving the substantive parent responses (n = 529) almost evenly split between remote and hybrid instruction, with only 4% fully in-person. For the purposes of this study, results were grouped into parents who had a child with ASD (n = 60; 51.7% fathers and 48.3% mothers) and those who had a child that was typically developing and all other SEN (n = 469; 45.3% fathers and 54.7% mothers).
Results: Fifteen themes emerged from the qualitative data. The top five endorsed categories for parents of children with ASD are general (e.g., “hope to get more help and support” and “face-to-face communication opportunities”); 20.00%, health and wellness (13.33%), educational resources and services (11.67%), financial support (10.00%), and return to normalcy before the pandemic (8.33%). For parents of typically developing children or those with other SEN, the top five themes were financial support (20.90%), health and wellness (20.26%), satisfaction (9.17%), school support (8.32%), and day-to-day help and support (7.89%). None of the parents of children with ASD were unsure or endorsed religious and spiritual support.

Conclusions: The current analysis showed that a year into the pandemic, the resource and support needs for parents of school-aged children differed between those with children with autism and those without. The autism group valued educational resources and services, such as professional support and services, while other parents valued school support with the day-to-day. The group of children with ASD had a desire to return to normalcy before the pandemic that was far stronger than the other group, and while satisfaction was third highest endorsed by the "TD and all else" group, it was the lowest for those with autistic children.

**402.095 (Poster) Autistic Mothers - Perspectives on Parenthood**

**J. Stošić, M. Matos, K. Petek and A. Wagner Jakab**, (1)Faculty of Education and Rehabilitation Sciences, University of Zagreb, Zagreb, Croatia, (2)Centar za upbringing, education and rehabilitation "Križevci", Križevci, Croatia, (3)Wisdom Tree School, Zagreb, Croatia

Background: There is a large body of research on the experiences, quality of life, well-being and mental health of parents of autistic children. However, there is a small number of studies that include the experience of autistic parents and an even smaller number of those with an active participation of autistic people. In this small participatory study autistic people were included in defining aims, formulating interview questions and final analysis of data.

Objectives: The aim of this study was to gain insight into the autistic mothers' experience of parenthood. Specifically, we wanted to explore the relationship with children, characteristics of parenting and support needs of autistic mothers.

Methods: Participants were 7 autistic mothers with at least one autistic child. Data was collected through semi-structured interviews that were conducted online or in person depending on the preferences of each participant. Data was analysed using thematic analysis.

Results: Key findings were organized in three themes, Perception of parent-child relationship, Autistic parenting, and Support. Although some mothers consider their relationship with a child overwhelming, demanding and stressful, all participants consider it a fulfilling and valuable experience that inspired their personal growth. Advantages of being autistic parents include learning from own experiences, understanding of autistic child’s needs, acceptance, and better communication with the child. The sources of support in parenting included only informal support and the lack of formal support for both mothers and children was recognized.

Conclusions: This study provides an insight into experiences and support needs of autistic mothers. Further research that includes perspectives and active participation of autistic parents is needed to provide a foundation for the development of the support that will be tailored to the needs of the family.

**402.096 (Poster) It's More Than a Score: Describing Participation Profiles in Autistic Children and Adolescents**

**K. Simpson, M. Stainer and D. Adams**, (1)Education and Professional Studies, Autism Centre of Excellence, Griffith University, Brisbane, QLD, Australia, (2)School of Applied Psychology, Griffith University, Gold Coast, QLD, Australia, (3)Autism Centre of Excellence, Griffith University, Brisbane, Australia

Background: Participating in activities is viewed as supporting an individual’s quality of life and influencing family functioning. To date, the research on participation in autistic individuals has tended to describe scores, with the implied (neurotypically-driven) assumption that more is better and little consideration of what that score reflects. A different approach is to identify and describe profiles of participation scores within autistic young people and explore factors that differ between those. This would not only further our understanding of participation in autism, but also identify avenues of support for those who may wish to adjust their profile.

Objectives: The aim of this exploratory study was to investigate the participation profiles of autistic children, and to identify if child and/or family factors differed between the participation profiles.

Methods: Data for two cohorts of autistic children were extracted from a longitudinal study; the younger cohort were aged 6-8 years (n = 98) and the older cohort aged 10-13 years (n = 95). Caregivers reported on their child’s participation across home, school and community using the Participation and Environment Measure Child Youth (PEM-CY). In addition, caregivers completed the Social Communication Questionnaire (SCQ), Short Sensory Profile -2 (SSP-2), Anxiety Scale for Children with Autism Spectrum Disorder: Parent Version (ASC-ASD-P) and provided their family income to identify which child and family factors differed between profiles. Profile development was determined by an analytic hierarchy process with the final model selected based on the profile number that was identified as best fit.
Results: In the younger cohort, five participation profiles were identified compared to four participation profiles in the older group. Profiles in the younger cohort showed differing participation patterns across contexts. Profiles in the older cohort showed a more stable pattern of low, med, and high participation across all domains. Autism characteristics and anxiety differed between profiles for the younger cohort. Sensory, anxiety and family income differed between profiles for the older cohort.

Conclusions:

To the authors’ knowledge this is the first study to investigate participation profiles in autistic children, highlighting participation varies within this population. Consideration of what is desired participation for autistic children is an important area for future research. Some child and family factors were associated with different participation profiles, and these appeared to differ with age. Barriers to participation is an important area of consideration for future research to support autistic individuals to live a life they find meaningful.

402.097 (Poster) Autistic Perspectives on the Acceptability of Pediatric Autism Therapies
I. Caven1, Y. Hamdani1 and M. Fenner1, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Institute of Medical Science, University of Toronto, Toronto, ON, Canada, (3)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada

Background: Autistic children and their families may access different services, such as occupational therapy (OT), speech language pathology (SLP) services, applied behaviour analysis (ABA)-based therapies and physiotherapy (PT). There are varying levels of evidence supporting the efficacy of these therapies, and some autistic-led advocacy is critical of the methods and aims of certain services. There are a few academic articles exploring autistic perspectives on these therapies; however, the sample sizes are relatively small. Exploring stakeholder perspectives is critical to ensure services are appropriate and informed by lived experiences. This work is part of a larger survey that explored the perspectives of autistic individuals, parents of autistic children, and clinicians on these services.

Objectives: This study explored how autistic people perceive the acceptability of pediatric autism therapies (OT, SLP services, ABA-based therapies, PT).

Methods: Using the Theoretical Framework of Acceptability (TFA), a mixed methods survey was built with input from autistic people, parents of autistic children and clinicians. The survey was shared online through social media and autism organizations. Autistic respondents’ demographic data and perspectives on the therapies were captured. An acceptability sub-score was produced for each therapy, ranging from 0 (least accepting) to 64 (most accepting). The sub-scores were combined into an overall acceptability score. Open-ended questions were qualitatively analyzed using deductive content analysis following the TFA, and categories within constructs of ethicality and intervention coherence are presented.

Results: 21 autistic people completed the survey. Their median (range) sub-scores were OT 40 (16 – 56), SLP 43.5 (28 – 57), ABA 19.5 (8 – 48), PT 39.5 (28 – 57). Qualitative categories within the TFA construct of ethicality included: 1) concerns about harms and negative experiences that can potentially occur because of therapies; 2) a lack of support for what respondents identified as behavioural techniques or methods. Intervention coherence reflects an individual’s understanding of a therapy, and respondents viewed the goals and methods of therapies as acceptable or unacceptable. With respect to intervention coherence, unacceptable goals were identified by respondents as those that aim to promote neurotypical behaviour or hide autistic identities. Acceptable goals included those that were affirming of neurodiversity, provide strategies to navigate challenges, and are inclusive of all forms of communication.

Conclusions: Our findings are similar to existing perspectives that some autistic people have towards ABA-based therapies. However, these findings also highlight that some autistic people may view any therapy as unacceptable if it promotes neurotypical behaviour or incorporates behavioural methods. Autistic people, regardless of if they have engaged in a therapy, bring important insights into how therapies can help autistic children thrive. Further work is needed to gain a better understanding of specific aspects of behavioral methods that are viewed as unacceptable, particularly given that some strategies, such as positive reinforcement, are widely used in different therapies and with the general population. Future work should explore perspectives from larger samples of autistic people, with focus on individuals who do not engage with social media and compare findings to parents of autistic children and clinicians.

402.098 (Poster) Autistic Women, Nonbinary, and Transgender Autistic Stakeholders’ Perceptions of the Intersection between Autism and Policing

Background:
Individuals with disabilities, such as autism, face an elevated risk of negative outcomes during police interactions, including increased risk of injury and death (Bronson, Maruschak, & Berzofsky, 2015; Perry & Carter-Long, 2016; Swaine et al., 2016). In the United States, evidence demonstrates inequitable treatment from police officers towards marginalized communities, especially individuals with multiple intersecting marginalized identities, including gender diverse autistic individuals, which only increases their risk of negative outcomes (Lipperman-Kreda et al., 2020). However, it is not known whether the perception of autism and policing differ among self-identified female, gender diverse, and male adult autistic stakeholders.

Objectives: Compare perceptions of policing among autistic adults who self-identify as female, gender diverse (e.g., non-binary, transgender), or male.

Methods: One hundred and seven adult autistic stakeholders (Table 1) responded to a 10- to 15-minute online survey (Table 2). Fisher’s exact test compared patterns of responding among different gender groups.

Results:

A majority of participants (91%) reported interacting with police. Approximately half the sample reported that their diagnosis influenced their interactions with police (51%) and the majority felt that police lack the skills necessary to interact safely with autistic individuals (79%; no significant effects of gender identity). However, when asked whether they think gender has influenced their interactions with police, 51% of female autistic stakeholders and 50% of gender diverse autistic stakeholders responded “Yes”, in contrast to only 9.5% of male autistic stakeholders ($p<0.0001$). There was an effect of gender identity on participants’ level of comfort in telling police officers about their diagnosis ($p<0.0001$), with male-identified autistic stakeholders more likely to report feeling comfortable disclosing their autism (67%) compared to 33% of female-identified autistic stakeholders and only 21% of gender-diverse stakeholders. Significantly more male autistic stakeholders thought telling police officers about their diagnosis would be helpful to the situation (62%), in contrast to 42% of female autistic stakeholders and 14% of gender diverse autistic stakeholders ($p=0.0011$). Overall, 89% of stakeholders worried that their autistic traits would be perceived as dangerous or suspicious by police officers, and this concern was amplified for female (93%) and gender diverse (96%) stakeholders relative to male autistic stakeholders (74%; $p=0.0179$). Finally, 60% of male autistic stakeholders, 40% of female autistic stakeholders, and only 5% of gender diverse autistic stakeholders reported that they believe police departments provide justice equally to all people ($p<0.0001$).

Conclusions:

Autistic stakeholders are concerned about safety during police interactions, with strikingly amplified concerns among female-identified and gender diverse individuals. These findings suggest that individuals with multiple marginalized identities, (i.e., autistic female-identified and gender-diverse individuals) experience persistent fear for their safety when interacting with police officers. These findings underscore an increased need to incorporate diverse perspectives from civilians, particularly those at the critical intersection of gender diversity and autism, when developing police policies and best practices in order to help ensure safe interactions. This may motivate further support and training to lower the risk of injury, death, or other negative outcomes from interactions between police and civilians with disabilities.

402.099 (Poster) Barriers and Facilitators to Coping with the COVID-19 Pandemic: Contextualizing Perceptions of Canadian Caregivers of Youth with Developmental Delays and Disabilities

(1)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (2)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada, (3)Department of Psychology, Manchester Metropolitan University, Manchester, United Kingdom, (4)Montreal Neurological Institute-Hospital, Montreal, QC, Canada, (5)Autism Speaks, New York, NY

Background: The UNICEF-World Health Organization Global Report on Developmental Delays, Disorders, and Disabilities, is an ongoing initiative with the aim of increasing awareness, compiling data, proving guidance on strengthening health systems, and engaging international and country-level partners. Previous data from a caregiver survey assessing impact of the COVID-19 pandemic showed that half of youths with developmental delays and disabilities (DDDs) and their caregivers struggled to cope during the pandemic, with a significant portion reporting a lack of supports and difficulty managing the worsening of the child’s symptoms in isolation (Yusuf et al., 2022). Governments created service strategies supporting vulnerable groups. However, little is known about the alignment between COVID-19 policies for persons with disabilities and their lived experiences. Contextualizing caregivers’ experiences can promote the development of tailored public supports for these families as we emerge from the pandemic.

Objectives: To contextualize experiences of youth with DDDs and their caregivers during the pandemic in relation to Canadian COVID-19 policies for persons with disabilities.

Methods: Online survey data were collected from June-July 2020, leading to a convenience sample of caregivers of youth with DDDs (N=883) across Canada. Data for this project were responses to two open-ended questions: a) “Write down anything that has made it hard to keep safe and cope during the pandemic. Think about yourself and everyone in your home when answering.” and b) “Write down
anything that has made it easier to keep safe and cope during the pandemic. Think about yourself and everyone in your home when answering”. We conducted a thematic analysis of responses using inductive and deductive coding on NVivo software. Overarching codes derived from the dataset were mapped onto federal and provincial policies published during the pandemic. Parallels with these policies supported the exploration of families’ and youths’ experiences during the same period.

Results: Five hundred and thirty-one (N=531) participants answered open-ended questions. Barriers to coping at the individual level were family mental health complications, concerns about regression of the child’s condition, along with challenges involving the child’s online schooling, insufficient play spaces, and managing physical health in quarantine. Environmental barriers included the worsening of families’ finances, loss of public services, and experiencing stigma. In contrast, caregivers reported several facilitators to coping, including media entertainment, time spent with family, outdoor spaces, and their child’s resilience. Other environmental facilitators were receiving community support, information from government, and access to telehealth services. Few COVID-19 policies aligned practical services to caregiver-identified barriers. Facilitators aligned with pre-existing policies (e.g., leisure access and physical activities) but some COVID-19 restrictions were deterrents to accessing these facilitators during the pandemic.

Conclusions: Prioritizing needs of families of youths with DDDs during a public health emergency can significantly impact their experiences and mental health. Increasing financial benefits for these families, offering telehealth services, and creating inclusive public spaces for play are priority areas exiting the pandemic.

402.100 (Poster) Be-Longing: Experiences of Autistic Girls in English Schools
G. Pavlopoulou, N. Brennan De Vine, C. Clarke and R. Moyse, (1)Department of Psychology and Human Development, Institute of Education, Group for Research in Relationships in Neurodiversity, London, UNITED KINGDOM, (2)UCL, IONDON, United Kingdom, (3)AT-AUTISM, IONDON, United Kingdom

Background: Autistic girls’ social motivation and associated desire to fit in, suggests that feeling a sense of belonging is important for the girls. This may be particularly relevant during adolescence, as this period is marked by uncertainty and loneliness due to increasing independence and development of identity. There is evidence that feeling a sense of belonging provides pupils social acceptance and is a protective factor against harmful psychological outcomes. Despite this, limited research has considered autistic girls belonging experiences in mainstream schools and what needs to change to facilitate belonging. Further, the historical underdiagnoses of autistic girls has entailed that their personal stories are mostly absent from autism research.

Objectives: This research prioritises autistic girls’ voices by exploring the girls’ constructs of belonging, including the facilitators of and barriers to feeling a sense of belonging, and the impact on wellbeing.

Methods: This study included the autistic community in the research process in various ways. An autism advisory group provided consultation on pre-study considerations, data collection and data analysis. Personal constructs and lived experiences of school belonging were explored using semi-structured interviews and personalised activities (e.g. drawings and poetry) with eighteen adolescent autistic girls. Participants were involved in the data analysis process as they commented on emerging codes and themes.

Results: Data were analysed using thematic analysis and five themes were identified: (I) autistic girl’s want to be seen and heard, (II) the joys and pains of mutuality, (III) losing myself under the mask, (IV) marginalisation links with invalidation, (V) sensory fatigue.

Conclusions: The autistic girls defined belonging from a relational perspective, as they want to be externally valued, heard, and involved in the school community. However, aspects of masking, stigma and sensory experiences limit the girls belonging in school. Implications for schools and Educational Psychologists are discussed using an experience sensitive framework of wellbeing.

402.101 (Poster) Caregiver Attendance Pattern in a Caregiver-Focused Intervention for Families of Children with Autism
Y. Yu, A. C. Stahmer, E. McGhee Hassrick, S. Iadarola, C. Kasari, D. S. Mandell and M. Pellecchia, (1)Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (3)A.J. Drexel Autism Institute, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (4)University of Rochester Medical
Background: Retention is a significant issue in caregiver-focused interventions (Axford et al., 2012; Kasari et al., 2014) with attrition ranging from 35% to 60%. Missed visits reduce treatment effectiveness (Haine-Schlagel & Walsh, 2015). We explored caregiver attendance patterns in a caregiver service navigation intervention, Mind the Gap (MTG), using latent class analysis (LCA), as a first step towards identifying strategies to improve retention.

Objectives: Identify patterns of caregiver attendance, and child and caregiver characteristics associated with them.

Methods: MTG comprises strategies to support caregiver engagement in minoritized families (Stahmer et al., 2019), such as culturally-matched peer parents as navigators, flexible meeting methods (e.g., in person, zoom) or location (e.g., home, community center), and extended timeline for intervention completion (Iadarola et al., 2020). MTG provides education about autism, service navigation, and other relevant topics. Participants were primary caregivers of children (2-7 years) with an autism diagnosis (n = 52). Navigators who were trained parents of autistic children implemented MTG. Race, ethnicity, gender, age, age of diagnosis, and employment status were tested as variables associated with latent class membership. Attendance was coded dichotomously for each session (1 = attended, 2 = no show/cancelled). Models were estimated using SAS 9.3 via Proc LCA using maximum likelihood estimation.

Results: Participants were mostly female (85%); about a third were Hispanic (35%) or White (35%), and 21% spoke Spanish or Korean. Average child age was 4.46 years, and average age of diagnosis was 3.14 years. On average, caregivers attended 7.71 sessions. We retained a 3-class model: High Attendance, Low Attendance, Intermittent Attendance (BIC = 724.75, AIC = 621.34, Entropy = .90). 49% were in the High Attendance Class, 19% in the Low Attendance Class, and 32% in the Intermittent Attendance Class. Members of the Low Attendance Class had lower likelihood (29%) of joining the first session after intake (i.e., Week 2), and attendance was consistently low throughout the sessions. The probability of attending sessions stayed relatively high across the 18-weeks in the High Attendance Class. Members of the Intermittent Attendance Class were more likely to attend the first session after intake (56%), compared to the Low Attendance Class, and their probabilities of attending sessions dropped after Week 6, with periodic increases every two or more weeks (See Figure 1). Participants who were employed had a higher probability to be in the Low Attendance Class, whereas those who were stay-at-home caregivers were more likely to be in the High Attendance and Intermittent Attendance Classes. No child and caregiver characteristics were associated with attendance.

Conclusions: Findings can inform strategies for retaining caregivers in interventions for families of autistic children. Caregivers who are less likely to participate the initial intervention session after the intake have poorer “prognosis” for attending any sessions and are more likely to no show/cancel. Supports may be needed for buy in at initial sessions (e.g., intake). For caregivers in the Intermittent Attendance group, whose probability of attendance dropped after first five weeks of intervention, critical materials may need to be addressed earlier in the intervention.
and child public health insurance on parent outcomes. The study relied on this nationally representative dataset to construct point estimates and conduct a series of multivariate regression analyses to quantify these differential and interactive effects.

Results: Question 1 - Parents of children with ASD and ASD/ID who used public insurance, were found to have 3.9- and 7.4-times higher odds of poorer health, respectively. These findings were significant and denote medium to large effects. Question 2 - Parents of children with ASD and ASD/ID using public health insurance experienced significantly higher odds of workforce exclusion, with odds ratios of 1.6 and 2.5, respectively, denoting small effects. Additionally, parents of children with ASD experienced 4.3 times higher odds of unemployment, denoting significant, medium effects.

Conclusions: Parents of children with ASD and ASD/ID face inequities. These findings have direct policy and programmatic implications, suggesting parents whose children access public health insurance programs may have additional family support needs that are important to consider. Future research is needed to further understand these parental experiences and how they effect the family unit.

402.103 (Poster) Investigation of Internalized Stigma Perception, Social Support, and Family Functioning in Parents of Children with Neurodevelopmental Disorders

G. Antilir and M. Eyuboglu, (1) Child and Adolescent Psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey, (2) Child and Adolescent Psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey

Background: Neurodevelopmental disorders such as Autism Spectrum Disorder (ASD), Attention Deficit Hyperactivity Disorder (ADHD), and Intellectual Disability (ID) are conditions that create significant challenges not only for children but also for parents. Stigma is among the crucial difficulties experienced by the parents of these children. In addition, it is known that experienced stress and psychosocial difficulties have the potential to impair family functionality. In addition to the difficulties that mental disorder brings to the individual, all these difficulties experienced by families show the importance of family-based approaches in treatment and direct intervention to the individuals.

Objectives: In this study, we aimed to evaluate the internalized stigma perception, social support level, and family functionality of the parents of children with ASD, ADHD, and ID and to compare the results with those of children with typically developing (TD). It was also among our aims to examine the relationship of our findings with the psychosocial difficulties experienced by children.

Methods: This study was carried out in the Child and Adolescent Psychiatry outpatient clinic after obtaining approval from the Eskişehir Osmangazi University Faculty of Medicine Clinical Research Ethics Committee. A total of 163 cases diagnosed with Attention Deficit and Hyperactivity Disorder, Autism Spectrum Disorder, and Intellectual Disability according to DSM-5 diagnostic criteria were included in the study (ADHD:41, ASD:44, ID:40, TD:38). Parents were asked to fill out Sociodemographic data form, Parents' Internalized Stigma of Mental Illness Scale, Multidimensional Scale of Perceived Social Support, Family Evaluation Scale and Strengths and Difficulties Questionnaire.

Results: The perception of internalized stigma was significantly higher in the parents in the ASD group compared to the ADHD and ID (p<0.05). It was found that parents in the ASD and ID groups had a lower perception of social support compared to the other groups. While the family functionality level was higher in families with children with TD, there was no significant difference between Neurodevelopmental Disorders. The psychosocial difficulties experienced by the child were only significantly related to the internalized stigma perception in the parents in the ID group. Finally, a significant negative relationship was found between the psychosocial difficulties experienced by children with ASD and parents' perception of social support.

Conclusions: The result of this study that families in the ASD diagnosis group have a higher level of stigma perception compared to other neurodevelopmental disorders indicates the negative impact of this disorder on the family. Low perception of social support and family functionality also show the importance of parent-oriented intervention programs in children with neurodevelopmental disorders. Future research should focus on developing interventions that will help remove the stigma and increase social cohesion and functioning among the parents of these children.

402.104 (Poster) Caregiver Perspectives on Participating in Pediatric MRI Research

B. Demetri, C. Reineri, B. Sholar and S. Shultz, (1) Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2) Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3) Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA

Background: Given its potential to relate structural and temporal patterns of activation in the brain to behavior, neuroimaging methods have been increasingly utilized to investigate typical and atypical brain development. In fact, longitudinal studies of brain development have the potential to provide insight into neural mechanisms underlying various developmental disabilities, such as autism spectrum disorder (ASD). However, in contrast to studies of adults and school-aged children, neuroimaging studies of infants face additional challenges acquiring high-quality usable data, which often requires infants to be scanned during natural sleep. Although MRI is a safe and non-invasive imaging technique, the prospect of caregivers enrolling their infants in clinically unnecessary MRI can be overwhelming. Additionally, since the
commitment to participate in longitudinal MRI research can be demanding, there is often participant attrition which poses additional challenges to longitudinal work. Given the challenging nature of pediatric neuroimaging research, efforts aimed at minimizing participant attrition while maximizing useful MRI data collection are crucial.

Objectives: The objective of this study is to elicit caregiver feedback through the use of focus group interviews about their experience participating in our longitudinal infant MRI study at the Marcus Autism Center. Our goal is to better understand how we can revise our current protocols for infant neuroimaging studies to improve enrollment, data acquisition and lower participant attrition rates.

Methods: 13 caregivers were recruited from a group of caregivers who completed a longitudinal infant MRI study at the Marcus Autism Center. The infants enrolled in the MRI study were either at low or elevated likelihood for ASD. Three focus groups were conducted (3-5 caregivers per group) where a semi-structured interview was used to elicit caregiver feedback about their experience participating in MRI research, suggestions for infant MRI protocol improvement, and why they chose to participate in the research. Focus group interviews were transcribed and hand-coded to identify emerging themes from the focus group responses.

Results: Overall, caregivers recalled a positive experience in participating in our longitudinal infant MRI study and, if given the opportunity, would participate again. Caregivers also provided feedback that will allow for improving recruitment strategy, study materials, and study protocols. Caregivers reported experiencing anxiety around whether or not their infant would be able to successfully complete the entire MRI protocol and provide usable data. Contributing to science was the most common motivation for the caregivers to participate in research.

Conclusions: Our findings provide critical insight into the experience of participating in infant MRI research from the caregiver point of view, which will allow researchers to improve participant experience in the field of infant neuroimaging.

**S. Vanegas and S. Magana,** (1)Texas Center for Disability Studies, University of Texas at Austin, Austin, TX, (2)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX

Background: Substantial research finds that racially/ethnically diverse children are less likely to receive evidence-based treatments (Baio et al., 2018; West et al., 2016). Limited access to healthcare, insurance, providers, interpreters, and transportation contributes to these disparities (Dababnah et al., 2018; Windham et al., 2014). Low socioeconomic resources may further exacerbate these challenges for families of children with autism (Park et al., 2002). Training parents on naturalistic, developmental, and behavioral intervention (NDBI) strategies can be a cost-effective method to address the needs of children with autism, especially among low-resource communities (Gerow et al., 2018). However, to date, there is limited research on caregivers’ use of NDBI strategies, particularly from racially/ethnically diverse and low-resource communities.

Objectives: The aim of this study is to assess and compare caregiver use of NDBI strategies as measured through self-report and observation.

Methods: Caregivers were recruited to participate as part of a larger, ongoing study examining the efficacy of a parent-mediated intervention. In this study, we present data from the baseline assessment. Caregivers were eligible to participate if they had a child between 18 months and 6 years of age, the child had an autism diagnosis or screened at elevated likelihood for autism, and the family met low-resource criteria (i.e., Medicaid, the primary caregiver had a high school or lower education, household income <=200% federal poverty level). Caregiver use of NDBI strategies was measured via self-report and through the Measure of NDBI Strategy Implementation: Caregiver Change (MONSI-CC; Vibert et al., 2020). The MONSI-CC captures caregiver use of NDBI strategies through behavioral coding from a caregiver-child interaction. Additional measures included child challenging behavior, child autism symptoms, parenting stress, and family quality of life. All measures were available in English and Spanish.

Results: Preliminary analyses were conducted with data from 61 families of children with DD. Most parents/caregivers were reported to be Hispanic/Latino (85.2%), were foreign-born (77.0%) and were primarily Spanish-speakers (67.2%). Children were, on average, 3.89 (1.22) years of age, primarily male (75.4%), and mostly born in the United States (91.8%). Most children had an autism diagnosis (88.5%), followed by speech delay/speech-language impairment (18.0%) and developmental delay (8.2%). Pearson correlation analyses showed that caregiver confidence in using NDBI strategies (setting the stage, turn-taking, communication temptations) was associated with greater family quality of life, all p’s < .05. Increased confidence in setting the stage for child learning and following the child’s lead were associated with lower autism symptoms (Social Communication Questionnaire – Current; p’s < .05). Additional analyses will compare the frequency of NDBI strategy use across self-report and observation (MONSI-CC) and identify child, caregiver, and family-level factors associated with NDBI strategy use.

Conclusions: This study evaluates caregiver use of NDBI strategies in a sample of racially/ethnically diverse caregivers who reside in low-resource households. We find that caregiver confidence in using NDBI strategies is associated with family quality of life and autism.
symptoms. The results of this study will help inform caregiver training approaches to ensure more equitable access to evidence-based support for children with autism.

402.106 (Poster) Caregiver-Reported Profiles of Child Functioning for Children with Developmental Delays and Disabilities Twenty Months after the Onset of the COVID-19 Pandemic

A. Yusuf1, N. Wright, M. Steinman, M. Gonzalez, A. Shih, K. Shikako-Thomas and M. Elsabbagh2. (1)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (2)Montreal Neurological Institute-Hospital, Montreal, QC, Canada, (3)Department of Psychology, Manchester Metropolitan University, Manchester, United Kingdom, (4)Autism Speaks, New York, NY, (5)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada

Background: There has been ongoing concern about the effect of the COVID-19 pandemic on children and youth. We previously identified heterogenous profiles among children and youth with developmental delays and disabilities (DDDs), including autism, three months after the pandemic began (Yusuf et al. 2022). Among those was a resilient profile where there were consistent improvements or stability across functioning domains. This resilient profile was more likely with greater parenting self-efficacy and ease in accessing schooling. As the COVID-19 pandemic continues into its third year, individuals’ functioning may fluctuate. Emerging evidence among adults suggests heterogenous profiles one year after the start of the COVID-19 pandemic (Liang et al. 2022). The course of functioning throughout the COVID-19 pandemic and its predictors among children and youth with DDDs is unknown.

Objectives: To identify patterns of functioning 20 months post-pandemic onset and examine prospective associations with child age, gender, baseline parenting self-efficacy, and access to schooling among children with DDDs.

Methods: As part of the UNICEF-WHO Global Report’s initiative to document experiences of caregivers of children with DDDs globally, we administered an online survey across Canada twice: at baseline (June-July 2020) and follow-up 20 months post-pandemic onset (November-December 2021). To identify classes of functioning 20 months post-pandemic onset, we subjected caregiver-reported changes on 12 domains of functioning at follow-up to latent class analysis. We assessed prospective associations between patterns of functioning at follow-up with candidate predictors measured at baseline: child age and gender, parenting self-efficacy and access to schooling, using multinomial logistic regression.

Results: We identified four classes of functioning 20 months post-pandemic onset (n=305). The first was a class exhibiting zero probability of improving across domains (n=81), named ‘Worsening’. The second class showed zero probability of either improving or worsening (n=42), named ‘Stable’, and a third ‘Mixed’ class showed a 20-30% chance of worsening or improving (n=108). Finally, we identified a class showing moderate chance of worsening or not changing on all domains except for mental health, sleep, and sensory issues, which showed high probability of improvement, (n=73), named ‘Domain-Specific Resilient’ (DSR). Older children were more likely to belong to the DSR than the Worsening class (OR=3.09, p=.001). Females were more likely than males to belong to the DSR, Stable, and Mixed classes (ORs≥2.25, ps≤ .012). Higher parenting self-efficacy at baseline was associated with greater likelihood of belonging to the DSR, Stable, or Mixed classes (ORs≥1.74, ps<.001). Membership in the DSR class was more likely for those reporting easy access to school at baseline, (OR=3.67, p=.016), and less likely when there was difficulty accessing school at baseline (OR=0.27, p=.001), compared with those whose school access was neither easy nor hard at baseline.

Conclusions: Our findings indicate that older age, female gender, greater parenting self-efficacy and easier access to school early in the COVID-19 pandemic are associated with potential long-term resilience in children with DDDs. We highlight the importance of parenting self-efficacy and access to schooling as modifiable factors that could promote long-term resilience in the context of adversities such as the COVID-19 pandemic.

402.107 (Poster) Co-Production of a Research Training Protocol for Autistic Community Partners

Background:

Patient-centered initiatives and approaches call for the inclusion of individuals with lived experience as partners in all phases of the research process. Most Autistic individuals who have participated in research, even in an advisory capacity, are rarely included in all aspects of a project as equal partners. Providing community partners with more research knowledge and skills will enhance their engagement throughout the research process.
Objectives:

Develop and pilot an adapted multi-modal, training curriculum on the basics of research to increase research skills and knowledge among Autistic adults with different support needs.

Methods:

Through a Community Based Participatory Research (CBPR) approach, a team of 7 Autistic and 4 non-autistic research partners collaborated in the co-production and piloting of the training course which focused on 1. What is Research, 2. Ethics in Research, and 3. How to be a Community Partner. All team members were involved in every step of the curriculum development through an iterative editing process until a final version was created. Accommodations were provided to ensure optimal participation. A local service agency that supports adults with developmental disabilities hosted the training and their staff were consulted during the course development. Training course participants were recruited among their clients and agency staff provided support. An Autistic instructor from the research team delivered the training and non-autistic members served as logistical and breakout group support during training exercises. All research team members, training participants, and agency staff were compensated for their time.

Results:

Autistic collaborators contributed the original idea, concepts, appropriate language, examples, scenarios, and instruction. After 6 months of development and refinement, a 3-unit virtual course was completed. Consisting of 2 hours of group instruction and in-class exercises, each unit was delivered online during 3 consecutive weeks to 12 Autistic participants of varying ages and support needs. Accommodations were provided such as individual classes when group instruction was unsuitable, make-up classes, text reminders before instruction, and class materials sent in advance with notes from the previous class. All participants completed the course and provided positive feedback; agency staff highlighted the culturally appropriate content and presence of an Autistic instructor as key elements for its success. Research team members are continuing to work together to create a final version of the research basics training for wide distribution.

Conclusions:

A team of Autistic and non-autistic researchers collaborated in the production of a 3-unit training aiming to build research knowledge and skills among Autistic adults in the community. Starting from a topic of importance to the Autistic community, an inclusive team in which all collaborators worked as equal partners, developed a culturally appropriate curriculum that was piloted successfully in a community setting. The voices of Autistic adults are vital in deciding research topics that represent their interests and should receive priority attention. Expansion of the training will facilitate Autistic people having a greater voice in the research process and shaping research priorities.

**402.108 (Poster) Collaborative Development of Culturally Appropriate Resources for Parents of Individuals with Autism**

*M. Melgarejo, J. Suhrheinrich and P. Schetter; (1)San Diego State University, San Diego, CA, (2)UC Davis, Sacramento, CA*

Background: Research indicates that disparities in access to services and quality of resources is not new for minority ethnic groups. Latinx parents report higher unmet needs and worry about receiving resources in their native language (Magaña et al., 2013; Zuckerman et al., 2014; Blanche et al., 2015). Ethnic minority families are also less likely to receive high quality, evidence-based services and interventions. Importantly, these quality indicators have been found to mediate the utilization of services (Parish et al., 2012). Researchers have found that minority families in particular have difficulty understanding the autism diagnosis and appropriate services and interventions. Blanch et al. (2015) interviewed Latinx parents who had a child diagnosed with autism and discovered they identified different stressors than non-Latino parents including understanding autism, having to independently research autism, and having to explain the diagnosis to family members. By educating parents and other stakeholders about evidence-based practices, they can better advocate for their children and appropriate services.

Objectives: The purpose of this study was to identify the needs of parents and caregivers of individuals with autism from underserved, linguistically diverse communities to inform the adaptation and development of autism resources.

Methods: Informed by county data on the primary languages spoken by consumers served by the developmental disabilities system, parents and caregivers who spoke Spanish (n=7), Vietnamese (n=4), and Tagalog (n=3) were targeted to participate in focus groups. Three focus groups were conducted, one for each language group. Focus group questions asked about 1) the types of resources for autism they access, 2) barriers and facilitators to accessing resources, 3) whether resources considered their linguistic and cultural needs, and 4) additional resources needed Thematic coding was utilized to identify main themes.

Results: The main themes that emerged from the focus group data indicated that parents and caregivers needed more guidance about service systems and information about autism. Participants also discussed accessibility of resources, indicating videos are a preferred mode of dissemination. Given the information gathered from the focus groups, a series of videos on navigating different service systems (e.g., early intervention, school, developmental services) were adapted and translated into each target language. These videos include an
overview of the service system, eligibility criteria, role definitions, review of important terms such as “IEP”, and steps on how to get started with services.

Conclusions: This project allowed for the development of accessible resources tailored for linguistically diverse populations through informed feedback from stakeholders. Materials are free to access on the California Autism Professional Training and Information Network (CAPTAIN) website. Partnering with CAPTAIN has allowed for the dissemination of these resources through their network of family resource centers, maximizing the reach of resources.

402.109 (Poster) Committing to Collaboration: Participatory Approach to Developing Game Design and Employment Workshops for Autistic Youth

Background: Autistic people often face barriers obtaining meaningful employment (Burgess & Cimera, 2014; Shattuck et al., 2012). Although not all autistic people are interested in STEM fields (Cheriyan et al., 2021), some have STEM interests and strengths that are well aligned with workforce needs (Bureau of Labor Statistics, 2015; Krzeminska, & Hawse, 2020; Murray & Lesser, 1999). Through collaboration with a participatory team of neurodivergent students and a technology education not-for-profit, we have been iteratively developing a game design and employment skills workshop for autistic youth.

Objectives:

1. Describe a participatory approach to developing workshop learning objectives (LOs).
2. Outline challenges honoring participatory directives.
3. Identify instructional strategies that engage autistic youth.
4. Assess outcomes of workshop participation.

Methods: 22 of 23 participants (M = 16.82, SD = 2.24) completed a screener, pre-, and post-workshop assessments. Participants were screened for interest in workshop topics and basic tech skills (e.g., navigating Zoom). In the screener and pre-assessment survey, participants rated interest in potential LOs. For post-assessment, students rated workshop gains with regard to LOs. Pre- and post-workshop, participants completed surveys measuring self-determination, video game design and career decision-making self-efficacy (See Table 2). Students also rated their engagement during select workshop activities (See Table 1). A pre-registered alpha level of .01 was used for all analyses.

Results:

LOs the participatory team rated as important often aligned with participants interest ratings. However, the participatory team critiqued a LO rated highly by incoming students, “appropriate workplace behaviors”. This LO was revised to “workplace dynamics” to avoid encouraging normalization. Nevertheless, normalizing language and goals (e.g., pushing students to adapt to “norms”) emerged in the workshop. Although an autistic researcher and others coached staff to use neurodiversity-aligned approaches, the recurrence of these approaches demonstrates a need for additional training next year.

At the midpoint and end of the workshop, participants collectively reviewed and gave feedback on their engagement ratings, leading to curriculum adjustments (e.g., adding more games). On the final day, many students reflected that their feedback led to improvements in the workshop.

Pre-workshop interest in learning specific topics was sometimes associated with student-reported engagement in workshop activities. For example, pretest interest in learning to create websites and troubleshooting were positively associated with engagement in working on a personal website/development log (ps<.006).
Results showed a trend toward structured collaborative activities being rated more engaging than unstructured collaborative activities (ps≤.04). There was no evidence that combined game design and employment activities were more engaging than game design or employment only activities (ps>.21).

Participation in the workshop was associated with improvements in game design self-efficacy (p=.004) but no improvements in career self-efficacy and self-determination (ps>.07; See Table 2).

Conclusions: Findings reflect how workshops relating to employment and STEM fields can address barriers to meaningful employment for autistic people. Future workshops should incorporate engaging, collaborative, and neurodiversity-aligned activities for participants to hone their individual and employment skills. We hope autistic people’s employment outcomes in STEM and other settings would thereby improve.

402.110 (Poster) Communication Skills and Executive Functioning in Children with Autism without Intellectual Disability. Relationship with Parenting Stress

Background: Research evidence that parents of children with autism without intellectual disability report significantly higher levels of stress and report negative experiences compared to parents of typically developing children (Davis & Carter, 2008). Parenting stress depends on a set of risk factors including individual characteristics of children with ASD, such as autism symptoms severity, behavioral problems, communication deficits or problems with daily life executive functioning (EF). Difficulties on communication skills, specifically pragmatic language in children with high functioning autism and executive dysfunction are important parents’ concerns. EF deficits have been found in children with ASD, and executive impairments are suggested to be associated with their language difficulties (Apperly et al., 2009). Little is known about the relationship between these child domains and parenting stress in ASD.

Objectives: this study aims to examine the relation between parental stress and children ‘domains such as communication abilities and daily live executive functioning in autism spectrum disorder without intellectual disability.

Methods: The participants of this study were thirty-six families (N = 36) of children with an autism diagnosis, aged 7 to 11 years (M = 8.8; SD = 1.4). Thirty-three of the children were boys (91.6%) and their intellectual functioning was within the normal range according to the scores of the Kaufman Brief Intelligence Test (K-BIT). Families were recruited through specialized centres from Spain. Children had received a clinical diagnosis of ASD in neuropsychiatric services based on Diagnostic and Statistical Manual of Mental Disorder criteria (DSM-IV-TR; or DSM-V); the Autistic Diagnostic Interview— Revised (ADI-R) and the Autism Diagnostic Observation Schedule-WPS (ADOS-WPS; Lord et al., 2000). The vocabulary subtest from the WISC-IV had an average of 13.3 (SD = 4.1). Parents, mostly mothers completed the Parental Stress Index (PSI), the Children's Communication Checklist (CCC-2) and the Behavior Rating Inventory of Executive Function, Second Edition (BRIEF-II).

Results: The results of Pearson correlation analyses evidenced statistically significant associations between parent child interaction stress domain and pragmatic communication abilities, emotional regulation index and behavioural regulation index from BRIEF-II. Additionally, the multiple regression analysis conducted revealed that the emotional regulation index was the only significant predictor of parental stress, and specifically of the child-parent dysfunctional interaction.

Conclusions: The findings suggest that executive dysfunctions in daily life in children with autism are an important factor to consider in addressing parental stress. In addition, the results could support the possible mediating role of communication deficits in executive functions suggested by some studies (Joseph et al., 2005). Therefore, there is a need for further research about the impact of deficits in cognitive flexibility and emotional control, in parental stress to improve the parent-child interactions.

Results showed a trend toward structured collaborative activities being rated more engaging than unstructured collaborative activities (ps≤.04). There was no evidence that combined game design and employment activities were more engaging than game design or employment only activities (ps>.21).

Participation in the workshop was associated with improvements in game design self-efficacy (p=.004) but no improvements in career self-efficacy and self-determination (ps>.07; See Table 2).

Conclusions: Findings reflect how workshops relating to employment and STEM fields can address barriers to meaningful employment for autistic people. Future workshops should incorporate engaging, collaborative, and neurodiversity-aligned activities for participants to hone their individual and employment skills. We hope autistic people’s employment outcomes in STEM and other settings would thereby improve.

402.110 (Poster) Communication Skills and Executive Functioning in Children with Autism without Intellectual Disability. Relationship with Parenting Stress

Background: Research evidence that parents of children with autism without intellectual disability report significantly higher levels of stress and report negative experiences compared to parents of typically developing children (Davis & Carter, 2008). Parenting stress depends on a set of risk factors including individual characteristics of children with ASD, such as autism symptoms severity, behavioral problems, communication deficits or problems with daily life executive functioning (EF). Difficulties on communication skills, specifically pragmatic language in children with high functioning autism and executive dysfunction are important parents’ concerns. EF deficits have been found in children with ASD, and executive impairments are suggested to be associated with their language difficulties (Apperly et al., 2009). Little is known about the relationship between these child domains and parenting stress in ASD.

Objectives: this study aims to examine the relation between parental stress and children ‘domains such as communication abilities and daily live executive functioning in autism spectrum disorder without intellectual disability.

Methods: The participants of this study were thirty-six families (N = 36) of children with an autism diagnosis, aged 7 to 11 years (M = 8.8; SD = 1.4). Thirty-three of the children were boys (91.6%) and their intellectual functioning was within the normal range according to the scores of the Kaufman Brief Intelligence Test (K-BIT). Families were recruited through specialized centres from Spain. Children had received a clinical diagnosis of ASD in neuropsychiatric services based on Diagnostic and Statistical Manual of Mental Disorder criteria (DSM-IV-TR; or DSM-V); the Autistic Diagnostic Interview— Revised (ADI-R) and the Autism Diagnostic Observation Schedule-WPS (ADOS-WPS; Lord et al., 2000). The vocabulary subtest from the WISC-IV had an average of 13.3 (SD = 4.1). Parents, mostly mothers completed the Parental Stress Index (PSI), the Children's Communication Checklist (CCC-2) and the Behavior Rating Inventory of Executive Function, Second Edition (BRIEF-II).

Results: The results of Pearson correlation analyses evidenced statistically significant associations between parent child interaction stress domain and pragmatic communication abilities, emotional regulation index and behavioural regulation index from BRIEF-II. Additionally, the multiple regression analysis conducted revealed that the emotional regulation index was the only significant predictor of parental stress, and specifically of the child-parent dysfunctional interaction.

Conclusions: The findings suggest that executive dysfunctions in daily life in children with autism are an important factor to consider in addressing parental stress. In addition, the results could support the possible mediating role of communication deficits in executive functions suggested by some studies (Joseph et al., 2005). Therefore, there is a need for further research about the impact of deficits in cognitive flexibility and emotional control, in parental stress to improve the parent-child interactions.
Background: Most children with autism and other developmental disabilities live in low- or middle-income countries. With the focus shifting from mere survival to being able to thrive there is an impetus to study the quality of life of children with developmental disabilities and their families.

Objectives: To explore the relationship between caregiver-reported quality of life and disability weights associated with their child’s condition in families with children with a developmental disability or a physical health condition in Ethiopia.

Methods: Participants were recruited in two outpatient paediatric and child mental health clinics in Addis Ababa. Complete data was available for 241 caregiver-child dyads (mean age child = 4.8y, 35% girls; mean age caregiver = 34.4y, 82% female). Diagnostic information was derived from the child’s medical records, supplemented by information received from the caregiver based on responses to questionnaires assessing the child’s developmental level (Autism Treatment Evaluation Checklist, ATEC; Borissov et al., 2021) and communication (the Communication Profile-Adapted; Ceccharelli et al., 2021). A total of 139 children had a developmental disability diagnosis including autism, intellectual disability, attention deficit hyperactivity disorder and developmental language disorder. 102 children had a physical health condition, including amongst others diagnoses of respiratory tract infections, malnutrition and Human Immunodeficiency Virus (HIV). Based on the available medical and caregiver-reported information, disability weight scores (a measure of health loss developed by the Global Burden of Disease study team) were estimated for each participating child. Caregiver quality of life was assessed using the Pediatric Quality of Life Inventory™ (PedQL™), Family Impact Module, validated for use in Ethiopia (Borissov et al., 2021).

Results: The quality of life of caregivers of children with developmental disabilities was significantly lower compared to caregivers of children with a physical health condition (p < 0.001; see Table 1). Group differences remained significant after controlling for caregiver education, caregiver age and gender, and child age and gender. Mean disability Weight Scores in the developmental disability group were higher than for the physical health condition group (p < 0.001), indicating greater health loss. Disability weight scores correlated negatively with quality of life in the total group (β = -0.17, p = 0.007; see Figure 1). However, this association was no longer significant when explored within the developmental disability or physical health condition groups separately.

Conclusions: Caring for a child with a developmental disability in Ethiopia has a pronounced effect on family functioning and is associated with substantial reduction in quality of life compared to families caring for children with physical health problems. Support for children with developmental disabilities is often underfunded compared to care for physical health conditions, especially in resource-constrained contexts. Development and scale-up of this support should be prioritised.

402.112 (Poster) Comparing Stress and Coping in Mothers and Fathers of Children with Autism Spectrum Disorder
T. Kuan, A. Perry and R. Shine; (1)Psychology, York University, Toronto, ON, Canada, (2)Surrey Place, Toronto, ON, Canada

Background: Parents of children with autism spectrum disorder (ASD) experience major impacts in the family and it is commonly reported that mothers experience greater stress and more difficulty coping in comparison to fathers, although fathers are often underrepresented through small sample sizes in research. The Parenting Stress Index – Short Form (PSI-SF) and the Family Crisis Oriented Personal Evaluation Scales (F-COPES) are widely used measures in the literature. However, a recent factor analysis suggested that the subscales of these measures may not be as psychometrically sensitive for parents of children with ASD and proposed a new set of subscales (Shine, 2021), but research has yet to utilize these factor structures.

Objectives: The current study investigated differences in parenting stress and coping experiences between mothers and fathers of children with ASD using a large community-based sample, and compared results using factor structures of the PSI-SF and F-COPES as published by their authors and as suggested by Shine (2021).

Methods: The current study is a secondary analysis of archival survey data collected from mother-father dyads (n = 810 dyads for the PSI-SF, n = 692 dyads for the F-COPES) of children with ASD who received clinical assessments at a public agency in Toronto, Ontario, Canada. Children (84% male) ranged in age from 18-83 months (M = 43.83, SD = 13.39). The PSI-SF and F-COPES scores for mothers and fathers were compared using the original subscales and Shine’s (2021) factor models.

Results: Paired samples t-tests were conducted to compare mothers and fathers across PSI-SF and F-COPES subscales. Scores were generally similar between mothers and fathers as well as between factor structures, with significant differences indicating less favourable scores for mothers. More specifically, mothers reported experiencing greater general distress than fathers in both Shine’s (2021) factor model (t(799) = 4.58, p = .001, d = .16) and the original model (t(801) = 4.58, p = .001, d = .18). Mothers also reported greater difficulty managing their child than fathers (t(787) = 4.63, p = .001, d = .17). Additionally, mothers reported a greater use of general social supports than fathers with the original model (t(673) = 2.95, p = .003, d = .11). Shine’s (2021) model found similar gender differences for mothers’ greater use of friends/family supports (t(675) = 3.21, p = .001, d = .12), but no gender differences were found for social support from neighbours (t(669) = .95, p = .34, d = .04).
Background: Understanding consumer satisfaction with interventions for children with autism spectrum disorder (ASD) is critical. Acceptability influences uptake and engagement, and is central in delivering client-centered care. Qualitative methodology assesses satisfaction and usability of ASD-focused programs, but it is susceptible to investigator biases, which can present challenges when analyzing data that emerge from diverse families. Sentiment analysis is an alternative, used to identify patterns among marketing and customer service initiatives, such as analysis of customer reviews and social media posts. There are few applications among clinical medicine, and those published in the scientific literature have not addressed satisfaction after participating in clinical trials. Opportunity is ripe to explore how data analysis findings may differ across these two well-established analytic techniques.

Objectives: Use qualitative and sentiment analysis to identify themes among satisfaction survey data from caregivers who participated in a family-navigation program post ASD diagnosis. Compare themes gleaned from each of these approaches.

Methods:

Program satisfaction data (N=76) were collected as part of an exit satisfaction survey to a program (Mind the Gap; MTG) for caregivers following a developmental disability diagnosis. Qualitative researchers conducted latent content analysis using NVivo software. Upon completion of latent coding and consensus coding, a researcher created higher-level categories of the basic codes. Categories were reviewed and agreed upon with a second researcher.

Machine learning (ML) approaches analyzed caregiver responses in R. A term document matrix provided visualization, as well as term frequency and lower correlation limits, and in order to calculate sentiment (overall positivity/negativity in responses). A coder reviewed the most frequently used terms and which words were most highly correlated with them in order to identify themes.

Results:

Caregivers identified positive aspects of the MTG intervention: coach characteristics, provision of specific and relevant information, program organization and characteristics, and creation of a community. While the majority of caregivers stated they did not have any additional suggestions for the program, several provided ideas: provision of additional types of information, changes in coach assistance or coach-parent contact, and changes in the organization and requirements of the intervention.

Qualitative responses were calculated as generally positive through sentiment analysis, even among the area of suggestions. Caregivers shared that the best parts of the program included the availability of information, the partnership with their peer coach, and the help to their family. The main suggestion of the program was to customize the number of meetings and amount of time in the program to fit individual family needs.

Conclusions: ML approaches can enhance traditional qualitative coding methods, as they may help quickly identify commonly occurring terms and correlations to other words that help identify themes. These approaches may allow for a more nuanced exploration of terms and themes among participant qualitative responses. Traditional qualitative analyses still serve as an important step in interpreting high-context communication that requires deep cultural or technical understanding. A combination of both methodologies (beginning with a ML approach, followed by modified, traditional approach that elucidates unclear data) will result in a more robust understanding of qualitative data.
Background:

Parents of infants at elevated likelihood of autism (EL-A) demonstrate more parenting stress than parents with typically developing children, especially due to sensory hyperresponsiveness (Ben-Sasson et al., 2013; DesChamps et al., 2020; Kirby et al., 2015). Because parenting stress is associated with reduced response to parent-mediated interventions and elevated child externalizing behavior problems (Moreland et al., 2016; Osborne et al., 2008), it is important to effectively measure parenting stress to intervene with families demonstrating clinically significant stress. There are several parent-report questionnaires used to examine parenting stress, including the Parental Stress Scale (PSS). The PSS is written at a 7th grade level, making items easily accessible. Additionally, this scale includes only 18 items, requiring 5-10 minutes to complete. These attributes of the PSS make it attractive for use in research; however, the underlying factor structure is unclear due to several analyses demonstrating differing results. The original factor analysis identified four factors (Berry & Jones, 1995); however, a two-factor model was a better fit for these data in a community sample of infants at EL-A (data collected from 2010-2014; Watson et al., 2017). The two-factor structure is useful due to its parsimonious nature and ease of interpretation for clinical and research purposes.

The prevalence of high parenting stress has changed over time, primarily due to an increase in technology use, which may yield differences in the psychometric properties of the PSS in a later birth cohort. Technology use in everyday life has increased (Statista and The Next Web, 2019), and interference of technology in family interactions is associated with more child externalizing behaviors and later higher parenting stress (McDaniel & Radesky, 2018).

Objectives: To explore whether the two-factor structure of the PSS demonstrates invariance across two birth cohorts approximately 5 years apart.

Methods: The new sample of infants are similar to the Watson et al. (2017) sample in geographic location, identification, and recruitment processes, allowing for comparative analyses across birth cohorts. Data on the PSS was collected in both samples at baseline of larger longitudinal intervention studies. The new participants are a community sample of parents (n=39) of 11-16-month-olds at elevated likelihood of autism based on a screening questionnaire at baseline of a longitudinal intervention study. We conducted a differential item functioning (DIF) analysis to examine the invariance of the two-factor model across cohorts.

Results: Results of invariance testing at the metric, configural, and scalar levels were non-significant (p = 0.65, 0.40, and 0.17, respectively). Chi-squared test of model fit ($\chi^2 = 348.4, p<.001, df = 228$), RMSEA (0.087), and CFI (0.81) indicate adequate model fit for an invariance testing model.

Conclusions: The two-factor structure of the PSS was invariant across birth cohorts, suggesting that this parsimonious scoring of the PSS may still be useful, even in the face of changing sources and types of parenting stress across time.

402.115 (Poster) Contributors to Family Life Impairment for Families of Young Autistic Children

K. T. MacKenzie, M. J. Crown, J. B. Northrup, A. G. Hartman and C. A. Mazefsky, (1)Department of Psychiatry, University of Pittsburgh Department of Medicine, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)University of Pittsburgh, Pittsburgh, PA

Background: Families of young autistic children tend to report greater impairment on broad measures of family outcomes than those without family members with autism spectrum disorder (ASD). However, the mechanisms underlying family life impairment in this population are not well known. Identifying contributors to family life impairment above and beyond having an autistic family member can help researchers and clinicians develop appropriate, supportive interventions across a range of domains to more holistically enhance family life.

Objectives: The purpose of this project was to investigate potential correlates of family life impairment above and beyond ASD characteristics in families of young autistic children in an effort to identify practical targets for family interventions.

Methods: Cross-sectional data were collected from 564 parents of autistic children aged 2 to 5 years ($M = 4.23$), who participated in an online study. All participants provided basic demographic information in addition to completing all study measures (See Table 1). A series of stepwise multiple linear regression models were generated to examine whether child emotional reactivity, child dysphoria, child verbal ability, child flexibility, child sleep problems, and parent depression were associated with family life impairment across five domains: total
impairment, family impairment, parent impairment, childcare impairment, and positive growth. All models controlled for child age, sex, race, and ethnicity as well as family income and whether parents had a parenting partner.

Results: Table 2 shows the results of multiple linear regression analyses. ASD characteristics were significantly associated with total impairment and childcare impairment but not with family or parent impairment. Higher emotional reactivity, more sleep problems, less flexibility, lower verbal ability, and greater parent depression were associated with greater total family life impairment. Lower verbal ability, higher reactivity and dysphoria, and less flexibility were associated with family impairment. More sleep problems and parent depression were associated with parent impairment. Lower verbal ability and less flexibility were associated with greater childcare impairment. None of the variables were significantly associated with positive growth.

Conclusions: Families of autistic children generally report greater impairment, but it is not necessarily the characteristics of ASD that drive this phenomenon. Rather, the findings of this study point to other predictors of family life impairment and suggest new avenues through which families might be supported. Associations identified between child verbal ability and flexibility and various aspects of family life impairment suggest that providing additional support in assistive or augmented communication and establishing family routines may be beneficial. Development of interventions targeting child emotion regulation, child sleep issues, and parent depression may also be practical mechanisms through which to reduce family life impairment. Finally, more attention should be paid to childcare policies and providing parents with childcare options that embrace and are sensitive to the unique needs of autistic children. The findings of this study offer further insight into the experiences of families of autistic children and offer researchers and clinicians more nuanced ways to address impairment across different domains of family life.

402.116 (Poster) Conversations with Researchers: Practices Promoting Increased Inclusivity Among Research Participants
M. S. McManus and A. Fettig, (1)Special Education, University of Washington, Seattle, WA, (2)University of Washington, Seattle, WA

Background: Recruitment practices tied to traditional systems result in traditional participants - members of the dominant culture (e.g., White, upper-middle class, college-educated). Parent-Implemented Intervention (PII) studies with traditional participants report significant measurable outcomes for children with Autism Spectrum Disorder (ASD) and their caregivers. Such outcomes reinforce continued adherence to traditional systems. This qualitative interview study sought to understand how these systems increase or decrease participant inclusivity and focused on 1) understanding systems influencing researchers’ engagement recruitment, 2) how these systems directly/indirectly impact participant inclusivity, and 3) highlighting practices supportive of increased participant inclusivity.

This study is rooted in the idea that, globally, marginalized populations who have historically experienced systemic racism in the form of micro- and macro-aggressions based on their ethnic, socioeconomic or linguistic identities stand to benefit from researchers implementing inclusive recruitment practices.

Objectives: include 1) highlighting recruitment practices systematically offering support for diverse families, 2) encouraging researchers to reflect upon specific practices making recruitment of diverse families a priority when designing future studies, and 3) discussing strategies to foster communication between diverse families and researchers with the intent to develop culturally-responsive practices promoting increased participant inclusivity.

Methods: were designed intentionally to support PII research becoming more accessible and responsive to diverse families’ unique concerns and needs. A literature review was conducted to situate the research questions, an interview protocol was designed to support consistency and thematic analysis, deductive coding was used to identify commonalities among responses, and inductive coding was completed to create a set of culturally responsive recruitment practices intended to meet the needs of marginalized communities who have been systematically excluded from previous research.

Nineteen researchers (principal investigators) self-identified as 15 White females, three White males, and one Asian female, with experience conducting research ranging from 12-35 years at institutions across the United States, Ireland, and Australia were interviewed via Zoom.

Results: include 1) giving researchers space and structure to reflect on previous experiences with recruitment resulted in considering how to alter future recruitment to focus more intentionally on increasing inclusivity, 2) identifying how researchers who conduct studies with traditional participants are rewarded by traditional systems (i.e., funding, publication, and recognition), and 3) challenging traditional systems by constructing a set of culturally-responsive practices (see Table 1).

It is recommended that researchers 1) engage in consistent reflection within the larger research process (i.e., impact of exclusion criteria, creation/distribution of inclusive recruitment materials, 2) work with diverse families to update traditional systems based on identified concerns and supports, and 3) empower families to be active collaborators when designing future studies.
Conclusions: Caregivers from diverse backgrounds face unique barriers to participation in studies with the potential to positively impact their child’s development. Engaging in recruitment practices intended to support diverse families gain access to the benefits of intervention studies is a necessary step toward promoting equity in research. Implementing inclusive recruitment practices leads to old standards shifting toward targeted integration of diverse participants. Only then will all families have the opportunity to experience success.

402.117 (Poster) Cross-Cultural Comparison of Knowledge and Attitudes Towards Autism Among University Students in Hong Kong, the United Kingdom and the United States: A Mixed-Methods Online Study

Y. Cheng, C. T. Keating and P. Dwyer, (1)The University of Hong Kong, Hong Kong, Hong Kong, (2)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (3)Department of Psychology, Center for Mind and Brain, UC-Davis, Davis, CA

Background: The rise of the neurodiversity movement, advocating for equal rights for neurodivergent people, has brought about positive shifts in attitudes towards autism (den Houting, 2019; Kapp et al., 2013). However, research on autism and neurodiversity is largely based on Western samples. While prior studies comparing attitudes towards autism across cultures reported higher levels of autism stigma among university students in non-Western countries such as Lebanon, Japan and Malaysia (Obeid et al., 2015; Gillespie-Lynch et al., 2019; Someki et al., 2018; de Vries et al., 2020), there remains limited understanding of how cultural differences and values may influence knowledge and attitudes towards autism and neurodiversity in a predominantly Chinese society such as Hong Kong. Greater understanding of the intersections between autism and culture is needed to better inform interested parties’ discussions on neurodiversity and lead to more neurodiversity-affirmative and culturally-sensitive anti-stigma interventions.

Objectives: To compare, and determine predictors of, knowledge and attitudes towards autism and neurodiversity among university students in Hong Kong, the UK and the USA.

Methods:

361 university students were recruited online via university email lists and Prolific (119 from Hong Kong, 120 from the UK, and 122 from the USA).

On Qualtrics, participants completed three questionnaires measuring explicit stigma towards autism (as measured by the Social Distance Scale; Gillespie-Lynch et al., 2019), knowledge about autism (as measured by the Participatory Autism Knowledge Measure; Kim et al., 2021), and cultural orientation (as measured by the Cultural Orientation Scale; Triandis & Gelfhand, 1998). Following this, participants answered four open-ended questions on autism and neurodiversity. They were then directed to the Gorilla.sc platform to complete an Implicit Association Test (IAT; Jones et al., 2021), which measured implicit stigma towards autism.

To compare knowledge and stigma across countries, a Multivariate Kruskal-Wallis test was conducted with Bonferroni-corrected Dunn’s post-hocs. Multiple linear regressions were run to identify factors contributing to knowledge and stigma.

Results:

1. While participants reported positive explicit attitudes towards autism, their implicit attitudes were negative.
2. There were significant main effects of country, p’s<.001, on knowledge and explicit stigma. Hong Kong participants reported less knowledge than in the UK and USA, p’s<.001, and more explicit stigma, p’s<.001. There was no effect of country on implicit stigma.
3. Greater autism knowledge was predicted by lower acceptance of inequality, p<.001, and postgraduate (vs. undergraduate) status, p<.05. Greater explicit stigma was predicted by more implicit stigma, p<.01, less knowledge, more acceptance of inequality, and more individualism, p’s<.05. No factors predicted implicit stigma.

Conclusions: Implicit attitudes towards autism were more negative and less cross-culturally variable than explicit attitudes. Cultural differences may influence knowledge about autism, and cultural values such as collectivism and acceptance of inequality may then contribute to explicit stigma towards autism. Further research is needed to identify factors influencing implicit stigma in order to better inform anti-stigma interventions.

402.118 (Poster) Decision-Making By Parents of Children with Autism Regarding Treatment

O. E. Hetzroni, Special Education, University of Haifa, Haifa, Israel

Background: The diagnosis of autism in children can elicit a sense of a crisis among their parents as it can encompass complex feelings including contradicting emotions such as relief and grief along with a need for critical decision-making. From the moment autism is diagnosed, parents find themselves at a crossroads of making decisions concerning appropriate treatments for their child. This crossroad involves decisions resulting from the need to understand the consequences of the child's condition, selecting professionals to work with
their child, and choosing treatments. The preliminary search is accompanied by a sense of stress, grief, and emergency due to the understanding that early treatment is of critical urgency. Previous studies have focused on the moment of the diagnosis or the early years of the children, with limited research identifying the critical decision-making junctions that involve crisis and complex emotions. However, range of differences and complexity among individuals with autism, and the variability among treatments, as well as the evolving needs along the life span, create a complex and unique path for parents of children with autism. This path encompasses uncertainty that evolves around changes that shift along the life -long trajectory.

Objectives: The purpose of this study was to analyze critical decision-making junctions with an emphasis on the first junction immediately after diagnosis, followed by other critical moments in their parenting life, especially with reference to decisions made regarding treatment for their child across the trajectory.

Methods: Sixteen parents of children ages 2-20 were interviewed using naturalistic decision-making paradigm (NDM) interview qualitative method. This qualitative study was conducted based on critical-decision-making (CDM) theory. CDM is based on the understanding that real-life decision-making incorporates uncertainty and stress; and is complex and dynamic, thus dependent on the processes taken during decision making. Data analysis was based on theory and evidence-based research to establish categories and themes and create a critical decision-making model.

Results: Parental decision-making was influenced by many factors, arranged into several categories including problem identification, uncertainty and use of uncertainty reduction strategies, search, and use of resources, incorporating emotional and logical processes, and insights. Grief was incorporated into all levels of decision-making junctions with different levels and stages evolving over the trajectory.

Conclusions: Critical decision-making junctions appear at critical times over the trajectory portrayed in a spiral format that is influenced by many factors, incorporating various strategies over time. Recurring feelings of grief are experienced by parents demonstrating the spiral nature of the trajectory. Decision-making evolved over time, as parents shift and transition to become experts in making decisions for their child. Results of this study provide an insight into parental decision-making, and the spiral nature of the processes. Examples will be presented and discussed.

**402.119 (Poster) Design and Usability of mHealth Autism Screening Tools for Families Underserved in Autism Care: Parent Perspectives**

L. Rivas Vazquez, P. Fuchu, S. Bataclan, V. Chamberlain, B. W. Sanders, S. Broder-Fingert, S. Bedrick, E. Fombonne, J. K. Dolata and K. Zuckerman, (1)Department of Pediatrics (Division of General Pediatrics), Oregon Health & Science University, Portland, OR, (2)University of Massachusetts Medical School, Worcester, MA, (3)Oregon Health & Science University, Portland, OR, (4)Department of Medical Informatics and Clinical Epidemiology, Oregon Health & Science University, Portland, OR, (5)UMASS Medical School, Boston, MA, (6)Department of Psychiatry, Oregon Health & Science University, Portland, OR, (7)Department of Pediatrics, Oregon Health & Science University, Portland, OR, (8)Division of General Pediatrics, Oregon Health & Science University, Portland, OR

Background: Families of color and/or low-income families experience autism inequities, including delayed diagnosis of ASD. Mobile health (mHealth; mobile or tablet-based device-based) autism spectrum disorder (ASD) screening apps have the potential to improve these inequities. Use of mHealth tools for screening and identification of ASD is gaining prevalence, bringing clear benefits such as video content, connections to community resources, and instant interpretation of results. However, it is unclear whether current mHealth ASD screeners will actually reduce disparities or help those already advantaged in autism care. Understanding the perspectives of parents is imperative in ensuring mHealth screeners meet needs of diverse families and thereby reduce autism diagnostic disparities.

Objectives: To conduct qualitative interviews and user testing of mHealth ASD screening tools in parents of children of color and/or of low-income children, in order to assess usability and acceptability of mHealth ASD screening tools in this population.

Methods: 16 parents were recruited to participate in the study. To be included, parents had to (1) be English and/or Spanish speaking, (2) be low income and/or a parent of a child of color, and (3) have a child with high or low risk of ASD. High-risk children were recruited from a university autism clinic wait list. Low-risk children were recruited from a general pediatrics clinic. We conducted brief telephone interviews to gauge parents’ general technology knowledge. We then conducted semi-structured qualitative interviews and in-person user testing, in which parents tested 1-2 mHealth ASD screening tools on their own mobile phone or tablet. Screening tools were selected based on a previous study assessing tools' scientific/clinical basis, functionality, usability, accountability, and accessibility (Sanders, 2022). Interviews and user testing were video-recorded, transcribed in the original language, and each transcript was coded by two study team members using QSR NVivo. Spanish transcripts were coded by bilingual team members. A phenomenological approach was used to develop key themes.

Results: Parents identified 4 themes and 11 subthemes describing benefits and challenges in using mHealth tools (Table). Tool Content included tool question wording, use of numbers/statistics, and general ease/difficulty understanding content. Tool design and function included user interface features, ease/difficulty navigating the tool, and time burden experienced by parents using the tool. Tool purpose and appropriateness included the relevance of the tool to the family’s context, and resources or next steps the tool provided. Tool acceptability included the parent’s first impression of the tool, perceived legitimacy of the tool, parents’ trust in the tool, and tool framing
of ASD. Parents suggested improvements such as reducing the reading level of text (making it easier to read), improved question wording to clarify response options, and making tools shorter to fit in parents’ daily lives.

Conclusions: Parent perceptions of ASD screening tools varied, and reflected challenges with content, design/function, purpose/appropriateness, and acceptability. Parents’ lack of familiarity with mHealth applications and ASD, lack of familiarity with the use of mobile technology, and lower literacy may undergird these challenges. Designing mHealth tools based on the needs of diverse parents may make improve equity and impact.

402.120  (Poster) Designing Autism Evidence-Based Practice Modules for Caregivers: Focus Group Analysis
A. D. Duenas, M. Y. S. Bak, A. M. Reilly, Q. Pan, S. D’Agostino, M. Kunze and L. Bell, (1)Special Education, San Diego State University, San Diego, CA, (2)Educational Psychology, University of Minnesota - Twin Cities, Minneapolis, MN, (3)Educational Psychology, University Of Minnesota - Minneapolis, MN, Minneapolis, MN, (4)Educational Psychology, University of Minnesota, Minneapolis, MN, (5)Special Education and Rehabilitation Counseling, Utah State University, Logan, UT, (6)Center on Brain Injury Research & Training, University of Oregon, Eugene, OR

Background:

Research points to several known benefits of caregiver education. Caregivers spend the most time with their children and when taught to use evidence-based strategies during natural child and family routines, they can help increase exposure to these strategies to meet intensity of service needs. To date, an extensive body of research, as well as national and international policy initiatives, have highlighted the utility, practicality, and efficiency of parent education to address the developmental and behavioral difficulties of autistic children. However, despite the research-support for caregiver training, there is not yet a consensual tailoring framework in the field to evaluate appropriate, effective, and efficient caregiver training.

Objectives:

The current study aimed to ask caregivers of autistic children their perspectives on caregiver training. Specifically, we invited caregivers as a focus group to answer the following research question: what are the necessary components of caregiver training to help caregivers understand and advocate for effective autism interventions?

Methods:

Seven caregivers of autistic children were recruited and divided into two focus groups (group of four and three) according to their availability. A topic guide adapted from training modules for behavior technicians was used to guide the discussion. Each group spent two hours discussing needs, benefits and limitations of caregiver training led by a facilitator. Focus group discussions were recorded and transcribed verbatim. Participants also completed a demographic survey, the Maternal Autism Knowledge Questionnaire, and the Family Empowerment Scale.

Results:

Transcriptions from the two focus groups were analyzed using thematic analysis based on focus group methodology. Several broad themes emerged from the analysis: concerns for caregivers of newly diagnosed children, negative and positive experiences as caregivers of autistic children, advocacy, and suggestions for caregiver training. Specifically for caregiver training, participants expressed the need for parsed information (e.g., shorter durations and chunked information); caregiver-led choices (e.g., option to choose those related specifically to their child); specific video examples pertaining to the home setting; and a feedback loop (e.g., time for caregivers to digest the information and check-in with their service provider).

Conclusions:

By using focus group methodology, we were able to yield honest and often critical feedback from the caregivers on current caregiver training practices. Participants provided insights into practical solutions for enhancing the long-term effectiveness of caregiver training such as accessible and digestible segments (i.e., 10-minute videos); time in between sessions for caregivers to reflect on and test out learned content; and interactive options to select topics specific to their child. Caregivers also voiced concerns about the intensity of some interventions and the fear that their child will be missing out on their childhood. Although caregiver-implemented interventions are considered an evidence-based practice, very little caregiver training is initiated and created alongside caregivers. Future caregiver training should leverage the knowledge of parents and the community to determine the modality of intervention and whether it is appropriate to the population intended. The need to bridge the gap between research and caregiver educational practice is critical to intervention development.
Background: Autistic girls, women and gender diverse* people experience physical and mental health challenges, are at increased risk of sexual violence, and have additional needs related to sexual and reproductive health. However, there is a lack of specific research that addresses these areas of need. In addition, the research agenda has predominantly been set by researchers rather than the autistic community. It is important to develop priorities with autistic girls, women and gender diverse people to provide research that it meaningful for their lives.

Objectives: This project aimed to develop an autistic-led research agenda for autistic girls, women and gender diverse people in Australia.

Methods: A group of autistic women and non-binary people led the project. Semi-structured interviews were conducted with 47 autistic people aged 7 and above. Reflexive thematic analysis was conducted to determine a draft research agenda. A follow up survey was then conducted in which we obtained feedback from 411 autistic girls, women and gender diverse people on our draft research agenda. Following this, consensus was reached, and the research priority areas were finalised.

Results: Research priorities were developed separately for young people and adults, to ensure that their differing needs and voices were recognised. Six research priorities were developed for autistic young people, covering a range of topics including school, the importance of understanding strengths and challenges, mental health support, friendships and relationships, experiences of gender diversity and providing accommodations to make life easier. Eight priority areas were identified for autistic adults, including understanding and supporting needs in adulthood, experiences of trauma, abuse and sexual violence, supporting mental health and wellbeing, physical health needs, addressing barriers in healthcare, education and employment, understanding the role of society, embracing neurodiversity and the importance of autistic identity, and the importance of co-designing research and supports with autistic people, including those with intersecting identities and from harder to reach groups.

Conclusions: This is the first project to develop research priorities that are led and informed by, and only includes autistic people. The research priorities identified will result in outcomes that are directly relevant for autistic girls, women and gender diverse people in Australia.

*This includes cis women and girls, transgender, non-binary, and gender diverse people, and anyone who was socialised, or identifies as a woman or girl.

**Poster** Developing an Autistic-Led Research Agenda for Autistic Women, Girls and Gender Diverse People in Australia

R. Grove, H. Clapham, T. Moodie, G. Hall and S. Garrin, (1)University of Technology Sydney, Sydney, NSW, Australia, (2)University of Technology Sydney Autistic Advisory Board, Sydney, NSW, Australia

**Poster** Differing Conditions for Research Participation of Adults and Children on the Autism Spectrum and Non-Autistic Participants

S. Lipinski, K. T. Boegl, R. Hartmann, I. Heuer, W. Lassleben, O. Speer, U. Suenkel, A. Zickert and I. Dziobek, (1)Humboldt-Universität zu Berlin, Berlin, Germany, (2)Autism-Research-Collaboration (AFK), Berlin, Germany, (3)Eberhard Karls Universität, Tuebingen, Germany

Background: To date, research studies involving people with autism have hardly taken into account the specific needs and characteristics of those living with the diagnosis as study participants (e.g. sensory issues, social behavior). In order to realize a more autism-friendly and safe study environment, it is necessary to create ethically relevant standards for autism-specific research.

Objectives: A participatory autism research collaborative explores such standards for adult study participants on the autism spectrum. Since many scientific studies on autism primarily identify children as the target population, furthermore, a framework that supports adherence to ethically relevant and autism-specific standards for under-age study participants on the autism spectrum is explored.

Methods: For the study, relevant aspects from the literature (e.g., developmental psychological and sensory characteristics of children with autism), focus group work of the participatory research group, and expert interviews, 55 needs from the categories planning, process, sensory, communication, format (e.g. duration) and general conditions (e.g. payment) for participation in research studies were evaluated and integrated as approximately 47 items in an online questionnaire. These were rated for personal relevance in two nationwide surveys by 273 adult participants (autistic: N=185 (68%); age: M=39, SD=11; 67% female, non-autistic controls: 88 (32%); age: M=32, SD=9; 71% women) and 179 children (autistic: N=87 (49%); age: M=13, SD=3; 8% female, non-autistic controls: 92 (51%); age: M=12, SD=3; 53% women). Answers were rated according to mean scores and factor analysis was performed. Subsequently, linear discriminant analysis was used to identify those items that differentiate most strongly between the groups with and without an autism spectrum diagnosis.

Results: Group comparisons revealed statistically significant differences in the strength of importance ratings of adults and children with autism spectrum condition and respective controls: The choice of the type of contact, attention to sensory needs, announcement of touch, understanding of the benefits of the study, and later information about the study results were rated as more relevant by autistic adults than by the control group. In contrast, limitation of duration and compensation for expenses were rated as most important by the control group. For the group of autistic children adherence to previous study information given, avoidance of parallel tasks, and sensory needs among
others were rated more relevant than for non-autistic controls. The results of both surveys will be presented. Guidelines derived for researchers will be shared. Comparison between children’s and adults’ needs with autism will be discussed.

Conclusions: Results obtained in the study can illustrate possible special needs and preferences of autistic adults and children for study participation. Adaptation of study participation conditions for autistic participants of all ages, as a consequence, may reduce stress for autistic participants and increase internal validity of research studies as a result.

402.123 (Poster) Distraxaty: Disability, Stress, Sport and Relax. Meditation and Relaxation Techniques for Parents of Children with Neurodevelopmental Disorders, a Pilot Project.

M. Siracusano, E. Cardoni, M. Ferrara, L. Arturi, A. Riccioni, J. Calsolaro, L. Mazzone, (1)Biomedicine and Prevention, POLICLINICO TOR VERGATA, University of Rome Tor Vergata, Rome, Italy, (2)Child and Adolescence Psychiatry Unit, Policlinico Tor Vergata Hospital, Rome, Italy, (3)Child and Adolescence Psychiatry Unit, University of Rome Tor Vergata, Rome, Italy, (4)System Medicine, Division of Child Psychiatry, University of Catania, Italy, Rome, ITALY

Background:

Parenting a child with a disability including neurodevelopmental disorders (NDDs) implies a high level of stress with an impact on the caregivers’ quality of life. Most of parental supportive interventions are focused on handling child difficulties. Meditation and relaxation training seems to be efficacious in the management of pervasive emotions, tension and stress within general population. Therefore, we developed the Distraxaty project, addressed to parents of children with a disability.

Objectives: To evaluate the efficacy of meditation and relaxation techniques in the reduction of Parental Stress within a group of parents of children with NDDs.

Methods: The Distraxaty project consists in sessions of meditation-relaxation techniques (1/week) addressed to all parents with a child affected by NDDs. 63 parents of children with NDDs including Autism Spectrum Disorder and Intellectual Disability, were considered for enrollment. 38 accepted to participate; 13 dropped out. 25 were enrolled as controls (did not practice meditative and relaxation techniques). At baseline and after 4 months of sessions, all participants underwent an evaluation of Parental Stress (Parental Stress Index), depressive symptoms (Beck Depression Inventory Scale-BDI) and sleep (minisleep questionnaire). Children of both groups were clinically characterized in terms of Intellectual Quotient (IQ), adaptive functioning (Adaptive Behavior Assessment System 2nd ed. ABAS-II), autism symptoms (Autism Diagnostic Observation Schedule 2nd Ed Calibrated Severity Score-ADOS-2 CSS), socio-relational skills (Social Responsiveness Scale-SRS), and behavioral problems (Child Behavior Checklist-CBCL).

Results: Final sample: meditation-relaxation Group (MRG) 25 parents (3 M; 22 F; mean age 47.6 yrs) vs Control Group (CTRL) 25 parents (3 M; 22 F; mean age 43.9 yrs) (Figure). Offspring of MRG parents were statistically significant older in comparison to children of control parents (11.2 vs 7.48; p = 0.0009). The two child-groups did not differ in terms of clinical features including IQ, adaptive functioning, ADOS-2 CSS, SRS total, CBCL total (Figure). Noteworthy, at T0, MRG parents were characterized by a major level of stress in most of the domains investigated (Total score p = 0.005, parental distress p = 0.006, parents-child interaction p = 0.0003) except for the subscale Difficult Child, whose score is influenced by the child disorder and clinical profile (homogeneous within this study). At T1, this difference among groups in level of parental stress did not persist. In the comparison T0-T1, no significant difference emerged within MRG group and within CTRL (PSI subscales, BDI, minisleep questionnaire).

Conclusions: Results obtained in the study can illustrate possible special needs and preferences of autistic adults and children for study participation. Adaptation of study participation conditions for autistic participants of all ages, as a consequence, may reduce stress for autistic participants and increase internal validity of research studies as a result.

402.124 (Poster) Employer Perspectives on Working with Individuals with Autism Spectrum Disorder

L. S. Athamanah and K. White, (1)Educator Preparation & Leadership, University of Missouri - St. Louis, Saint Louis, MO, (2)Mary Immaculate College, Limerick, Ireland

Background: Employment is a socially normative activity critical to an individual’s autonomy and quality of life (Saleh & Bruyere, 2018; Walsh et al., 2014). Employers with previous experience feel that individuals with autism spectrum disorders (ASD) positively affect the workplace and are more likely to hire those with ASD (Author et al., 2022; Huang & Chen, 2015). Furthermore, workplace accommodations and inclusive practices implemented for all employees within a positive organizational culture result in better employee attitudes and support toward those with disabilities (Erickson et al., 2014; Schur et al., 2014). Thus, understanding employers’ perspectives...
and experiences are vital to creating positive organizational and cultural practices to ensure the employment success of individuals with ASD.

Objectives: Despite efforts to increase the employment of individuals with ASD, opportunities for competitive integrated employment have remained limited (Lysaght et al., 2012; 2017). Decreased revenue, adverse interactions between employees, and increased assistance for several employees are just a few of employers’ negative perceptions of individuals with ASD in the workplace (Scott et al., 2017). Therefore, when employers have these negative perceptions, it may deprive individuals with ASD of the opportunity to improve their financial stability, quality of life, and social opportunities through competitive integrated employment (Jahoda et al., 2009). This study aims to identify employers’ perceptions of individuals with ASD in competitive integrated employment. The following research questions are addressed: (1) What are employers’ perceptions and experiences with individuals with ASD in competitive integrated employment; and (2) What are the supports and needs employers require to work with individuals with ASD?

Methods: For this study, we are conducting a cross-sectional online survey (Creswell, 2012) of state-wide employers to collect their knowledge, experiences, and perceptions of working with individuals with ASD. We are using a 52-item survey on Qualtrics to assess challenges to hiring, advantages and disadvantages of employing individuals with ASD, and ease of implementing specific supports. The data will be analyzed using a range of statistical analyses, including descriptive analyses, \( t \)-tests, ANOVA, and multiple regression.

Results: Preliminary results show the sample \( (n = 36) \) is 55% female, 67% white, and 44% have earned their bachelor’s degree. Their ages range from 18-65 years old, with most companies employing 1-9 employees (75%). The participants’ knowledge of ASD is average (3.5; 1 = Very Poor, 5 = Excellent), and they are somewhat confident working with someone with ASD (3.9; 1 = not at all confident, 5 = very confident). While 94% \( (n = 34) \) of employers know someone with ASD (e.g., family member, friend, coworker), only 28% \( (n = 9) \) currently have an employee with ASD.

Conclusions: While these are only preliminary results, employers seem to have an average knowledge of ASD and are somewhat confident working with someone with ASD. The vast majority know someone with ASD, yet only a quarter employ an individual with ASD. Additional analysis with a larger sample will hopefully shed light on employers’ perspectives, experiences, and what employers need to hire additional individuals with ASD.

402.125 (Poster) Interns’, Employers’ and Parents’ Qualitative Experiences and Views of Employ Autism Network Internships.

M. C. Ashworth1, L. Crane2, B. Heasman3 and A. Remington4, \( ^1 \)Centre for Research in Autism and Education, IOE, UCL’s Faculty of Education and Society, London, United Kingdom, \( ^2 \)Institute of Education, Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, UNITED KINGDOM, \( ^3 \)York St John University, York, United Kingdom, \( ^4 \)UCL Centre for Research in Autism and Education, London, UNITED KINGDOM

Background: Autistic people experience poor outcomes when progressing from education to employment, but supported employment initiatives have been shown to increase employment rates for autistic young people. Despite their success, little is known about the few employment initiatives that are designed to support this transition. A UK employment and Education charity, Ambitious about Autism, developed a unique supported and paid internship programme for autistic young people between the ages of 18 -25: the Employ Autism network. The Employ Autism network provides training and support for both the autistic interns and employers throughout the entire employment process, from applications to post-internship. In determining the success of such a programme, it is essential to examine the first-hand experiences and views of those involved the scheme. Specifically, autistic young people and their employers can offer valuable insight about the experience, and parents can offer insights about their important role in supporting their children’s transition into employment. Taken together, these insights can offer valuable, holistic information that advances evidence about best practice; both for this internship, and other similar schemes.

Objectives: The current study aimed to examine autistic young people’s (‘interns’), employers’ and parents’ experiences and views of a previously unevaluated paid internship scheme, the Employ Autism network.

Methods: This was a qualitative, multi-informant study, and data were collected using semi-structured interviews. A total of 51 participants across 8 internships participated: 19 interns, 22 employers, and ten parents. Each participant group’s interview schedules followed a similar structure and content, including questions about (1) previous experience of employment and autism, (2) experience/views of the internship, and (3) outlook after the internship. The interview transcripts were analysed following the phases of reflexive thematic analysis outlined by Braun and Clarke (2006, 2019), and the authors used a semantic, inductive approach to identify patterns and themes in the data through an iterative through discussion. The participant groups were analysed separately to reflect the different types of involvement in the Employ Autism network.

Results: Interns’ results yielded three themes: the Employ Autism network offered an opportunity to (1) break down barriers to provide “a foot in the door”; (2) a window for self-development; and they felt they experienced (3) effective and reciprocal communication during the Employ Autism internship. Employers’ results also yielded three themes: (1) partnerships were complimentary between employers and interns, however key to the success was (2) parking preconceptions and challenging stereotypes. Further, for this to be organisationally
relevant, the employers started to (3) rethink their current systems and practice. Parents corroborated the interns’ reports, and one further theme identified was that the Employ Autism network was perceived as (1) a path to independence for their young people.

Conclusions: These findings offer the first qualitative three-way informant data about one of the few supported employment schemes available to autistic young people. Such evaluations can be used to identify best practice for supported employment schemes, which has important implications for the development of further schemes.

**402.126 (Poster) Engaging Communities during Development of a Web-Based Tool for Communication about Environmental Health Research in Autism**

A. E. Garton, A. C. Haugen, C. P. Lawler, A. Rooney, and K. Pelch, (1)National Institute of Mental Health (NIMH), Durham, NC, (2)Division of Extramural Research and Training, National Institute of Environmental Health Sciences, Research Triangle Park, NC, (3)Division of Translational Toxicology, National Institute of Environmental Health Sciences, Durham, NC, (4)Natural Resources Defense Council, San Francisco, CA

**Background:** Both heritable (genetic) and non-heritable (environmental) factors contribute to the alterations in biological processes that lead to autism and its co-occurring conditions. One subset of non-heritable factors that have been increasingly studied are environmental chemicals, such as air pollution or pesticides. Communication about this rapidly growing body of research is important for a broad range of stakeholders. Scoping reviews and evidence maps are tools for researchers to summarize the current state of the peer-reviewed literature. However, these tools have limitations, including that they are static one-time assessments and are primarily written and developed for use by other researchers and may not be accessible to a wider audience. To address these challenges and provide a resource to communicate about the state of environmental health research in autism for both researchers and the broader autism community, the National Institute of Environmental Health Sciences (NIEHS) is developing a Web-based tool for Autism Research and the Environment (aWARE). For such a tool to be successful, it must incorporate features and functionality that make it useful for the multiple and complex intended audiences. To understand exactly what those features are, input from those audiences is needed.

**Objectives:** To engage with and collect feedback from an inclusive set of stakeholders that would inform the development of aWARE.

**Methods:** Four listening sessions and a meeting of the Environmental Epidemiology of Autism Research Network (EEARN) were held in the summer and autumn of 2022 to gather feedback and input regarding aWARE. Participants representing autistic individuals and families, advocacy and funding organizations, physicians and clinicians, and researchers were included in the listening sessions. During both the EEARN meeting and listening sessions, the aWARE project was briefly described before a longer guided discussion where participants were asked open-ended questions about how communities could use this tool and what features would make it more useful. Following these meetings, comments from participants were analyzed and themes identified.

**Results:** Participants in the series of listening sessions spoke to various themes that reflected their lived experiences and how they and their communities interact with scientific literature. Different stakeholder groups emphasized distinct features (e.g., accessibility, lay language) and metrics (details extracted from publications) that would make this tool most useful for their community. Participants provided information about various resources for web-tool and science communication development that can be incorporated in aWARE. A common theme across discussions was the scope of environmental health research, which indicates the need for clear definitions when describing the tool. Multiple sessions highlighted the opportunity that this tool presents to help educate a large range of stakeholders about environmental health research and reading scientific literature as a body rather than as individual papers. Integrating this feedback from the community as the development of the tool continues will be a major consideration.

**Conclusions:** Engagement with a broad range of stakeholders and communities has already provided valuable information and identified key opportunities for aWARE. Continuing this engagement throughout development and deployment of this web-based evidence map will be critical for its success.

**402.127 (Poster) Environmental Contributors to Autism Spectrum Disorder in Federal-Funded Research**

A. C. Haugen, A. E. Garton and C. P. Lawler, Division of Extramural Research and Training, National Institute of Environmental Health Sciences, Research Triangle Park, NC

**Background:** The National Institutes of Health (NIH) of the U.S. Department of Health and Human Services (DHHS) is the primary government agency whose mission is to conduct and support biomedical research in the interest of impacting public health. The NIH includes 27 institutes and centers, each responsible for defined, mission-relevant biomedical and scientific disciplines. The National Institute of Environmental Health Sciences (NIEHS) is an NIH institute focused on environmental exposures and human health. Environmental factors pertaining to the NIEHS mission are man-made or natural chemical substances, whereas others (e.g., nutrition or infection) are within the primary mission responsibility of other NIH institutes. All NIH institutes depend on portfolio analyses to better understand gaps and trends in funding and science, including in autism spectrum disorder (ASD) and environment research. This project uses a comprehensive definition of environment.
Objectives: NIEHS presents findings from a portfolio analysis of ASD and environment, comprising FYs 2008-2019, and its relationship to similarly supported research across NIH institutes and other federal agencies.

Methods: Federal grant data were collected, coded, and analyzed for trends in funding, environmental health factors, study types, impacts, and growth. Global networks and thematic components were extracted and visualized with software tools like Gephi and IN-SPiRE.

Results: Five federal agencies funded ASD-environment projects with the NIH funding the majority (87.8%). Most NIH projects were awarded by the National Institute of Mental Health (NIMH) (33.9%), NIEHS (32.1%), and the National Institute of Child Health and Disease (NICHD) (18.2%). The most researched environmental factors were maternal immune, psychosocial, pharmaceutical drugs, air pollutants, and nutrition. NIEHS supported nearly all research involving industrial chemicals and environmental pollutants. These frequently co-occurred with other in-mission and out-of-mission exposures (e.g., maternal infection), partly due to more cohort and observational studies. NIMH and NICHD primarily focused on single environmental factors with NIMH supporting more mechanistic projects with model systems. Temporal analysis of the NIEHS portfolio revealed a few metals (e.g., mercury), brominated (e.g., PBDEs) and chlorinated compounds (e.g., PCBs) before 2006. The portfolio evolved (through 2019) to include more variety of metal exposures, endocrine disrupters, and new categories like air pollutants. Immune-related genes appeared central in a co-occurrence network when we looked for biological and mechanistic themes. We visualized the genes in a bipartite network, finding associations with various environmental factors. Sixty-four percent were not in the SFARI database of autism susceptibility genes and probably considered for mechanistic or toxicological roles in exposure-related research. They may eventually merit future inclusion in the SFARI database of autism susceptibility genes.

Conclusions: Evaluating federal support of research in nongenetic factors and ASD provides a birds-eye view of the influential role government has on the state of the science and its evolution. This work provides context to help interested parties see gaps and opportunities for future research, including underlying biological associations with symptoms and co-occurring conditions. Innovation and new knowledge may accelerate their transition to interventions and services that help minimize the negative aspects of ASD-related symptoms and conditions for autistic individuals and their families.

402.128  (Poster) Evaluation of a Community-Academic Research Partnership with Racially and Ethnically Diverse Young Adults on the Autism Spectrum  
J. S. Ellenberg1, S. Suswaram1, E. Gabovitch1, K. Martin1, M. Gordillo1 and K. Long1; (1)Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA, (3)Boston, MA

Background: The autism community has expressed growing concerns about research not reflecting the priorities of autistic people. In response to these concerns, the Academic Autism Spectrum Partnership in Research and Education (AASPIRE) recently published practice-based guidelines for including autistic adults as co-researchers. Despite the presence of these guidelines, community-engaged research rarely includes autistic individuals from racially or ethnically marginalized groups.

Objectives: This study (1) evaluates our process of engaging racially and ethnically diverse autistic young adults in a community advisory board (CAB) according to AASPIRE guidelines and (2) describes the resulting improvements to the research process based on this partnership.

Methods: Our university-based research group studies the transition to adulthood among culturally-diverse autistic youth. Community-engaged research methods were used to ensure that culturally diverse autistic voices shaped our research process. Existing partnerships with community organizations were leveraged to recruit 6 autistic young adults (3 Black, 2 Latinx, 1 White; ages 18-24). Young adults attended virtual CAB meetings every 3-4 months. The AASPIRE guidelines were used to evaluate the resulting community-academic partnership and inform areas for improvement.

Results: Our process of engaging culturally diverse autistic young adults in the CAB was consistent with many aspects of the AASPIRE guidelines (Table 1). To ensure transparency about community partner roles, researchers discussed involvement details, communication preferences, and accommodation needs with each potential CAB member. We practiced effective communication and power-sharing by collaboratively developing group rules, providing flexible communication options, and sending materials in advance of the meetings. In order to build and maintain trust, researchers explicitly acknowledged their own privilege and biases, and young adults were encouraged to share their own lived experiences. Toward the aim of collaborative dissemination, young adults were invited to co-author conference presentations and manuscripts. Finally, grant funding was used to compensate CAB members for their work.

Reviewing our community-engaged research process according to AASPIRE guidelines also highlighted areas for improvement, such as increasing transparency in reporting how the researchers incorporated CAB feedback, offering CAB members opportunities to advance their own goals, and regularly engaging in visioning exercises to define shared goals.

This partnership led to important revisions to the research strategy and materials. For example, young adults gave us helpful feedback about the format for a transition-planning program, which was subsequently revised to better center the preferences of autistic youth. Their input
also informed hypothesized mechanisms of disparities to be studied quantitatively. Finally, CAB members were instrumental in revising questions about complex ideas, such as culture and identity, for qualitative interview guides.

Conclusions: Community-academic partnerships with culturally diverse autistic young adults have the potential to increase the relevance of research findings to the autism community. Given the history of mistrust between researchers and racially minoritized and disability communities, community-engaged research approaches may be especially important for those with multiple marginalized identities. Maintaining flexibility regarding communication preferences, facilitating open conversations about power and privilege, and ensuring that CAB member feedback is thoughtfully incorporated throughout the research process are key to successfully including diverse autistic voices in research partnerships.

402.129  (Poster) Evaluation of an Online Autism Experience Session: Improved Autism Knowledge and Reduced Stigma
J. Maljaars, S. Van der Paelt, I. Roeyers and I. Noens, (1)Child Psychiatry, KU Leuven, Leuven, BELGIUM, (2)Department of Experimental-Clinical and Health Psychology, Ghent University, Departement of Experimental, Clinical and Health Psychology, Ghent, BELGIUM, (3)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (4)Parenting and Special Education Research Unit, Faculty of Educational Sciences, KU Leuven, Leuven, Belgium

Background: Autistic individuals and their families report that they are often subject to stigma, which can have a negative impact on participation and wellbeing. Previous studies already indicated a link between autism knowledge and stigma. To reduce stigma and improve attitudes towards autistic individuals, combining information with personalized interactions has been proven to be effective.

Objectives: This study aims to evaluate the effect of an online autism experience session on autism knowledge and stigma.

Methods: An online autism experience session is an interactive meeting via Zoom for neurotypical individuals to experience the world from the perspective of autistic individuals. The online autism experience session is built around several activities regarding sensory sensitivities, communication and social interaction. The session is guided by two persons from the autism community (i.e., an autistic individual and/or a family member). In a pre- and post-test design, 48 participants (age: M = 44y, SD = 10.6; sex: men = 13%, women = 87%) filled out an online survey in the month before and in the week after the online experience session. The survey consisted of translated and adapted questionnaires on autism knowledge (Autism Awareness Survey; Gillespie-Lynch et al., 2017) and stigma towards autistic individuals (Social Distance Scale; Gillespie-Lynch et al., 2017). Our survey was developed in collaboration with the Flemish Association for Autism and a group of autistic adults involved in the organization of the online experience sessions.

Results: Although participants already had a relatively high level of autism knowledge before the session, their scores on the Autism Awareness Survey were significantly higher at post-test compared to pre-test (t = 2.41, p = .02). A significant decrease in stigma was found when we compared pre- and post-test scores on the Social Distance Scale (t = -3.13, p = .003). Autism knowledge was significantly negatively correlated with stigma at post-test (r = -.51, p < .001).

Conclusions: This study shows the potential of an one-off session with experience activities and testimonials of autistic individuals to improve autism knowledge and reduce stigma. However, additional research with a larger sample and a control group is needed to exclude alternative explanations.

402.130  (Poster) Examining Child Characteristics Associated with Parenting Daily Hassles in Parents of Individuals with Autism Spectrum Disorder and Other Developmental Disabilities
N. Bahri, L. L. McIntyre and C. L. Neece, (1)Loma Linda University, Loma Linda, CA, (2)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (3)Psychology, Loma Linda University, Loma Linda, CA

Background:

Parenting daily hassles (PDH) are the day-to-day parenting tasks of caring for a child (Crnic & Low, 2002). Reports of PDH are often used as an indicator of parenting stress (PS). As the frequency and intensity of PDH accumulate consistently, parents are more likely to see their hassles as more distressing than what they can handle (Crnic & Low, 2002). Moreover, PS is associated with negative parenting and child outcomes (Crnic & Low, 2002). As stress is a multidimensional concept, examining different dimensions of PS is necessary. Parents of individuals with autism spectrum disorder (ASD) often report higher PS and DH compared to neurotypical children (Quintero & McIntyre, 2010). Given that research has suggested child characteristics are associated with PS in parents raising individuals with autism (Emily & Grace, 2015; Green & Carter, 2015), understanding child characteristics impact on PDH is a logical start. However, little research has focused on child characteristics associated with PDH in parents raising children with ASD.

Objectives:
In this study, we utilized a sample of children aged 3-5 diagnosed with either ASD or other developmental disabilities to understand child characteristics associated with PDH.

Methods:

Participants included 256 children (65.2% male, M age = 3.84 years (SD = .832), Hispanic/Latino = 66.4%). Close to half of the children had an autism diagnosis (N=121, 47.3%). PDH were measured through the Parenting Daily Hassles Scale (PDH; Crnic & Greenberg, 1990), and we used three subscales (See Table 1). Adaptive skills were measured through the Vineland Adaptive Behavior Scales – Third Edition – Interview Form (Vineland-3; Sparrow, Cicchetti, & Saulnier, 2016). IQ was measured through the Stanford-Binet Intelligence Scales – Fifth Edition (SB-5; Roid & Poplun, 2012).

Results:

Pearson’s correlations between child characteristics (Child age, gender, IQ, Vineland-3 subscale scores, and ASD diagnosis status) and PDH subscales were conducted (see Table 1). Variables that were significantly associated with PDH subscales were included in the final model. A series of hierarchical multiple regression analyses were used to determine the influence of significant child characteristics on the three PDH subscales. Together, child communication and externalizing behaviors accounted for 11.3% of the variance in total daily parenting hassles, F (2,140) = 8.94, p < .001, and were unique predictors of total daily parenting hassles. Together, communication, externalizing, IQ, and ASD diagnosis accounted for 14.4% of the variance in challenging parenting, F (4,116) = 4.90, p = .001. In the final model, communication (p = .014) and externalizing (p = .002) were significant predictors, but IQ and diagnosis were not. Predicting parenting tasks, together, communication, internalizing, externalizing, and IQ accounted for 11.3% of the variance, F (4,117) = 3.72, p = .007. In the final model, communication (p = .041) and externalizing (p = .011) were significant predictors but internalizing and IQ were not.

Conclusions:

These findings point towards two significant factors, child communication and externalizing behaviors, playing a role in PDH across the domains. The results are promising as communication and externalizing behavior problems are domains where we have highly effective interventions that may ameliorate PS.

Background: Positive caregiver responsiveness supports children’s age-appropriate development, especially in the domains of emotional self-regulation, compliance, social skills, and cognition (Ayar et al., 2021). However, for caregivers of children with social communication challenges such as autism, caregivers may struggle with responsiveness due to differences in how children respond to and interact with the environment (Stahmer et al., 2019). In addition, caregivers self-perception of their caregiving skills may be impacting caregiver behavior during caregiver-child interactions. In this study, caregivers self-report of caregiver self-efficacy and responsiveness during caregiver-child interactions were examined. These data may provide insight to improve support provided to caregivers within the context of early intervention settings.

Objectives: This project examines caregiver report of self-efficacy and direct observation of caregiver behavior to inform supports caregivers may benefit from in the context of early intervention services for young children with autism.

Methods: Data for this project were drawn from a community-based early intervention (EI) study involving 68 caregiver-child dyads receiving Part C EI services in California. Children averaged 25 months of age (SD = 5 months), were 75% Male (n = 51), and 57% Hispanic/Latinx (n = 39). Participating caregivers were 85% biological mothers (n = 58), and 54% identified as Hispanic/Latinx (n = 37). Caregiver behavior was assessed using the Parent Interactions with Children: Checklist of Observations Linked to Outcomes (PICCOLO; Roggman et al., 2013). Video-recordings of caregiver-child interactions were evaluated by trained coders across PICCOLO domains: Affection, Responsiveness, Encouragement, and Teaching. Caregiver self-efficacy was self reported using a 29-item measure called the Self-Efficacy for Parenting Tasks Index - Toddler Scale (SEPTI-TS), with domains: Nurturance, Discipline, Play, and Routine (van Rijen et al., 2014). Subscales of each measure were explored to examine potential relationships among constructs and reporting methods.

Results: On average, caregivers scored within the normal ranges for all domains of the SEPTI-TS: Nurturance (M = 38.12, SD = 2.95), Discipline (M = 25.00, SD = 4.99), Play (M = 35.19, SD = 5.14), and Routine (M = 29.08, SD = 8.88). Comparisons among subscale means revealed the Discipline score was significantly lower than the three other subscales (ps < .05). During direct observation, caregivers
displayed high levels of Affection ($M = 12.30$, $SD = 1.90$), Responsiveness ($M = 11.74$, $SD = 2.13$), and Encouragement ($M = 11.11$, $SD = 2.39$) on the PICCOLO, and scored significantly lower in the Teaching domain ($M = 9.66$, $SD = 3.13$, $p < .05$). There were no significant correlations among the subscales of the PICCOLO and SEPTI-TF measures ($ps > .05$).

Conclusions: Caregivers of young children with autism receiving early intervention services report adequate feelings of self-efficacy and are successfully responsive during interactions with their children. Self-reported caregiver feelings of parental self-efficacy were not related to observed interactions with their children during play. Lower scores in the Discipline and Teaching PICCOLO domains highlights these two areas as targets for possible support to caregivers within the context of early intervention services. Strategies to address this gap will be discussed.

**402.132** (Poster) Examining the Identities of Autistic Students through an Intersectionality-Informed Lens: A Pilot Study

**S. Shevchuk-Hill** and K. Gillespie-Lynch, (1)College of Staten Island, Staten Island, NY, (2)Department of Psychology, CUNY Graduate Center, Staten Island, NY

**Background:**

Autistic people who are diverse in multiple ways, such as people with co-occurring disabilities and/or racial, ethnic, sexual, and/or gender minorities, may face unique barriers to full societal inclusion (Jones et al., 2020; Mallipeddi & VanDaalen, 2021; Peña, 2019. Therefore, the often limited degree to which autistic people with additional marginalized identities are represented in existing research is a major concern. Some studies have examined intersecting identities with autism. For example, by exploring associations between being autistic and LGBTQIA+ (Van der Miesen et al., 2018; Nabbijohn et al, 2019; Stang et al., 2018; Bush et al., 2021; George & Stokes, 2018). However, little remains known about how these identities may impact autistic individuals. Both LGBTQIA+ and autistic individuals face discrimination. This discrimination, in the form of minority stress (Meyer, 2003), may lead to worse mental health outcomes among LGBTQIA+ (Kelleher, 2009) and autistic (Botha & Frost, 2018) individuals. However, being part of either group can be rewarding and, for autistic individuals, being connected to the autistic community may help protect them from minority stress (Botha et al., 2021).

**Objectives:**

To explore the breadth of identities autistic individuals may identify with, which identities are central to how they see themselves, which are central to how they feel others see them, which are sources of discrimination, and which are sources of strength.

**Methods:**

Autistic college students ($n=18$; $M$Age$=25$; 75% male, 22% female, 17% nonbinary; 61% White) recruited from a participatory mentorship program completed a survey that included the following questions: Which identities are part of who you are?, Which of your identities that have the strongest effect on how you see yourself?, Which of your identities have the strongest effect on how others see you?, Which of your identities give you strength?, and Which of your identities have you experienced discrimination against?. For each question, participants could select from the options presented in Table 1. Participants could select as many options as they chose and could provide additional information within a text box below each option.

**Results:**

Most commonly, participants reported disability (56%), talents (44%), gender identity (44%), and sexuality (33%) as having the strongest effect on how they see themselves. Similarly, participants reported their talents (50%), disability (39%), gender (39%), and sexuality (33%) as having the strongest effect on how they are perceived by others. However, others’ perceptions of their physical attributes were also reported by 33% of participants as having a strong impact on how they are perceived by others. Disability was the most common reason for experiencing discrimination (44%), followed by sexuality (28%), race (22%), and gender (22%). However, disability was also the most commonly-reported source of strength (56%) along with talents (56%).

**Conclusions:**

While autistic people experience discrimination due to their disability, identifying with one’s disability can also provide a source of strength for the individual. People often drew strength from their talents, which can also be an important aspect of their identities, along with disability, gender identity, and sexuality.

**402.133** (Poster) What Is the Psychological, Behavioral and Physical Burden of Giving Care to Someone with Autism?

Background: People who give care to someone with an autism spectrum disorder (ASD-caregivers) experience on average more caregiver distress than people who take care for someone with other chronic conditions (non-ASD-caregivers) (Hayes and Watson, 2013). Also, caregiver distress is associated with physical health problems and increased mortality risk (Fairthorne et al., 2014; Hartley et al., 2021). Therefore, the health of ASD-caregivers should be of great concern. Nonetheless, significant psychological, behavioral, and physical aspects of distress in ASD-caregivers are still unknown. To improve ASD-caregivers’ health and reduce their morbidity and mortality risk, more insight into their caregiver burden is needed (Dijkstra-de Neijs et al., 2020).

Objectives: The aim of this study is to investigate the presence of psychological, behavioral, and physical burden in ASD-caregivers compared to non-ASD-caregivers.

Methods: We included 3354 adult caregivers from the Lifelines Cohort Study, who filled in a questionnaire about informal caregiving. With multivariable logistic regression models, correcting for lifetime, sex, and socioeconomic status (employment and educational attainment), we analyzed psychological, behavioral, and physical factors in ASD-caregivers (n=722; mean age 51 years old, 75% women) compared to non-ASD-caregivers (n=2632; mean age 54 years old, 68% women). The included psychological factors were defined as chronic stress (assessed with the Long-term Difficulties Inventory), quality of life (health-related QoL, based on RAND-36), and an anxiety and/or depressive disorder (based on a Mini International Neuropsychiatric Interview). Behavioral factors included physical activity (assessed with the Short Questionnaire to Assess Health-enhancing physical activity), alcohol use (based on the Flower Food Frequency questionnaire), and smoking (currently or in the past month). Investigated physical factors were body mass index, waist circumference (both measured during a physical visit), and leukocyte- and subtype-counts (drawn from blood samples).

Results: Multivariable regression models adjusted for confounders (Table 1) showed that ASD-caregivers reported more chronic stress (odds ratio (OR) 1.17, 95% confidence interval (CI) 1.13-1.22) and lower health-related QoL (OR 0.82, 95% CI 0.73-0.92) compared to non-ASD-caregivers. Moreover, the presence of an anxiety and/or depressive disorder was more common in ASD-caregivers than in non-ASD-caregivers (13.9% versus 7.8%; OR 1.83, 95% CI 1.38-2.44). With respect to the investigated behavioral factors, physical activity, alcohol use of more than two glasses per day, and smoking were not statistically significantly different between ASD-caregivers and non-ASD-caregivers. Regarding the included physical factors, lower lymphocyte-counts (OR 0.77, 95% CI 0.66-0.91) and monocyte-counts (OR 0.47, 95% CI 0.24-0.92) were found in ASD-caregivers than in non-ASD-caregivers. Furthermore, the neutrophil-to-lymphocyte ratio was higher in ASD-caregivers than in non-ASD-caregivers (OR 1.15, 95% CI 1.02-1.28). The other physical factors were not statistically significantly different between ASD-caregivers and non-ASD-caregivers.

Conclusions: In adults who are caregiver for someone with an autism spectrum disorder, the psychological burden is higher than in adults who are caregiver for someone with other chronic conditions. In addition, ASD-caregiving is related to an immune system disbalance. To improve ASD-caregivers’ health and well-being, more focus should be on reduction of psychological caregiver-burden.

Poster Experiences of Parents Who Have a Child with High Likelihood of Neurodevelopmental Conditions: A Systematic Review and Meta-Synthesis

G. Kaplan, S. Garg, D. Smith and M. W. Wan, (1)Division of Psychology & Mental Health, The University of Manchester, Manchester, United Kingdom, (2)School of Biological Sciences, University of Manchester, Manchester, UNITED KINGDOM, (3)School of Health Sciences, The University of Manchester, Manchester, United Kingdom, (4)University of Manchester, Manchester, United Kingdom

Background: Being pregnant with the knowledge that the child has an increased likelihood of developing a neurodevelopmental condition such as autism and ADHD can significantly impact on a parent’s experiences and perceptions of the child. Although a wide range of maternal conditions increase this likelihood, studies have tended not to consider commonalities (and divergences) in the parental experience of pregnancy across a range of groups.

Objectives: This meta-synthesis reviews the lived experiences of participants as expectant parents or a child under two years of age, and who has a high likelihood of developing a neurodevelopmental condition in the first 1001 days of life. High likelihood was defined in the most frequent conditions known to be associated with neurodevelopmental conditions, such as (a) substance use, (b) familial susceptibility and (c) advanced maternal age.

Methods: After screening 4015 English-language peer-reviewed qualitative (in part or full) studies retrieved from 4 databases, 23 studies were reviewed using a thematic synthesis approach (κ = 1 in abstract and title check, κ = 0.60 in full text check). CASP quality appraisal tool was also applied to the studies.
Results: Of the 23 studies reviewed, a broad range of samples (participants included 489 women and 18 men) were identified, with 14 studies of mothers with substance use, five studies on older mothers (over 35 years), one study of mothers with HIV exposure and one study of mothers with bipolar disorder. Only two number of studies focused on increased likelihood as defined by having an older child with autism. Three themes were identified around parental perceptions across these diverse groups: (a) Women’s readiness to have a baby was paired with anxiety around the uncertainty of the condition presenting, (b) Feelings of guilt impact on the mother’s role, and (c) Paternal anxiety and hopelessness are balanced with trying to enhance the infant’s environment. In autism-related research, readiness is specified as feeling ready to have a second child who has the same condition, yet in other studies, readiness is regarded as being prepared for pregnancy by parents. There were no studies of autistic parental perceptions and experiences. In terms of coping mechanisms, parents who have older autistic children monitored their younger child's development, whilst other parents concentrated on mothers’ health and lifestyle changes such as diet and sport.

Conclusions: The findings of this systematic review suggest similarities in concerns and experiences that healthcare professionals need to be aware of to help support parents, irrespective of the nature of the neurodevelopmental condition and its likelihood. There is a lack of research on early parental experiences of families who have a child or pregnant with high likelihood of autism, designing further qualitative studies is needed to enrich the existing knowledge.

402.135 (Poster) Experiences of Serbian Parents of Individuals with Autism

M. Colic, Department of Special Education, University of Hawaii at Manoa, Honolulu, HI

Background: As Serbia went through wars and economic instability for the last three decades it is particularly important to learn about experiences (e.g., positive parenting experiences, experiences with governmental institutions, support, etc.) of parents of individuals with autism in these circumstances. Although there are people with autism in Serbia there has not been any nationwide survey on its prevalence and thus it is an even greater challenge to support them. Many studies explored experiences of parents of individuals with autism worldwide, but there is limited information about experiences of Serbian parents of individuals with autism.

Objectives: The aim of the present study is to explore Serbian parents’ perspectives on (a) positive aspects of parenting children with autism and personal changes that occur through parenting, (b) sources of support, (c) potential changes in how the general public regards families of individuals with autism, and (d) experiences with the public sector.

Methods: This study is a part of a large project that included a convenience sample of 40 parents of individuals with autism. The parents were recruited through parental support organizations and public schools from the several cities across the country. Parents responded in a written format to five open-ended questions that explored (a) positive parenting experiences, (b) personal changes, (c) sources of support, (d) whether something needs to be changed in public (i.e., people’s opinions and public sector) regarding families of individuals with autism, and (e) experiences with the public sectors (e.g., state hospitals, public education, etc.). The parents’ ages ranged from 34 to 71 years, while the age of their children ranged from 4.5 to 41 years (M = 15.1, SD = 8.84). A total of 87.5% of the sample consisted of mothers. Data were analyzed using content analysis method.

Results: In total, six themes emerged: (a) positive experiences of parenting, (b) personal changes, (c) sources of support, (d) negative experiences with the public sector, (e) positive experiences with the public sector, and (f) necessary changes in public attitudes towards families of individuals with autism. Parents shared that the positive experiences were reflected through a feeling of sincere love, positive personal changes, and enjoyment in witnessing the child’s development. The most commonly reported negative personal changes were poorer health, depression, and loss of self-confidence. Spouse and close family members were the the most common source of support. Almost all parents agreed that general public’s attitudes towards families of individuals with autism need to be improved. Finally, negative experiences with the public sector were commonly reflected through the negative attitudes of employees and the lack of systematic support, while positive experiences were with some professionals.

Conclusions: The present study explored experiences of the Serbian parents of individuals with autism. Overall, parents shared a lot of positive examples of parenting experiences, although some groups of parents shared examples of negative personal changes. Parents agreed that changes in public and in the public sector are needed as stigma is still present, which is in line with other research.

402.136 (Poster) Interventions to Improve Mental Health and Well-Being in Parents of Adolescents with ASD and Other Neurodevelopmental Conditions: A Systematic Review of the Literature

M. Costa e Silva, A. Bogosian and S. B. Gaigg, (1)Health Services Research and Management, City, University of London, London, United Kingdom, (2)Health Services Research and Managemente, City, University of London, London, United Kingdom, (3)Autism Research Group, City, University of London, London, UNITED KINGDOM

Background: Parents of autistic children report higher levels of stress and mental health difficulties compared to parents of typically developing children (Padden & James, 2017) and parents of children with other developmental conditions, such as Down syndrome and cerebral palsy (Hayes & Watson, 2013). Adolescence often represents an additional level of pressure for parents as it is a period of significant change for autistic young people as well as for parents. There is therefore a need for parent mental health support programmes that are cost-effective and specifically tailored to the needs of parents during their child’s adolescence.
**Objectives:** To identify interventions focused on improving parental mental health and well-being of parents of adolescents with a diagnosis of ASD and/or other Neurodevelopmental Conditions (NDC) and synthesize details about their effectiveness.

**Methods:** The systematic review was informed by the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines and included: a) peer-reviewed studies published in English, b) parents of children between 10 and 19 years old diagnosed with ASD and/or other NDC, c) use standardised assessment measures to report mental health/well-being outcomes and d) include control groups or pre-post comparisons. Studies were retrieved from nine databases. Data extraction comprised papers’, studies’, participants’, and interventions’ characteristics, and significant results were further reported, analysed and discussed.

**Results:** A total of 27 papers containing 28 interventions and 1,752 participants were reviewed. Most of the papers (n = 19, 70.37%) were described as non-randomised studies and twelve studies (44.44%) did not comprise a control group as they made a pre-post comparison analysis within the experimental group only. Sixteen interventions had follow-up analyses conducted with a mean duration of eighteen weeks (SD = 37.55). Most participants were described as females (86.05%) and mothers. Participants’ mean age was 44.9 years old (SD = 3.26) and 13.03 years old (SD = 2.35) for their children. Most papers had a total or part of the sample of parents of adolescents with ASD (n = 22, 81.48%), and parents of adolescents with ASD only comprised a total of 601 participants (34.30%). Regarding the interventions, nineteen different programmes were identified and categorised into three groups: mindfulness-based (n = 12), psychoeducational (n = 5), and therapeutic approaches-based (n = 2). The most frequently measured outcomes in the studies were stress (n = 22), depression (n = 16), anxiety (n = 12), and mindfulness (n = 11). For mindfulness-based interventions, eleven studies reported improvements in stress, five in depression, five in anxiety, and eleven in mindfulness. Psychoeducational interventions had one study reporting improvements in stress, another one in anxiety, and three in depression. Finally, therapy-based interventions had one study reporting improvement in depression and another study in depression.

**Conclusions:** In summary, retrieved interventions showed promising results for improving parental mental health, but more investigation is needed to confirm their effectiveness, as most studies were framed as preliminary/pilot/proof-of-concept. Furthermore, studies did not report community involvement in the development of the reported interventions, which indicates a gap that needs to be addressed in further research.

**402.137 (Poster) Exploring Views on Future Directions of Research Involving Nonbinary Autistic People through Lived Experience**

**C. Brooks and P. Perepa,** (1) Disability, Inclusion and Special Needs, University of Birmingham, Edgbaston, United Kingdom, (2) University of Birmingham, Birmingham, UNITED KINGDOM

**Background:**

The research process usually starts with a problem, issue or idea. Autistic and disabled activists that they should be the leading authorities on issues that affect them - ‘Nothing about us, without us’ (Charlton, 1998). Participatory autism research should, therefore, involve stakeholders in decisions on research agendas and directions (Pellicano et al., 2014). Autistic people are 5 to 7 times more likely to be transgender or nonbinary (Warrier et al., 2020). An INSAR special interest group convened at the annual meeting in 2018 highlighted the need for further research into LGBTQ populations (Dewinter et al., 2020). However, to date no research has looked at what genderdiverse autistic people think about research that involves them or what future research should focus on.

**Objectives:**

This project sought to capture what nonbinary autistic people think about research that involves them and how this relates to their experiences. This included looking at their views on current research, what future research should focus on and how these views are informed by their experiences. A phenomenological lens was chosen to provide novel insights into how views on research draw on individuals’ experiences in their own lives.

**Methods:**

Nonbinary autistic participants were contacted directly on social media with a focus on selecting five individuals from a range of backgrounds. The project utilised interviews alongside creative and participatory methods where participants were asked to come up with their own research questions by drawing on themes from their own lives. Interview data was analysed using interpretative phenomenological analysis (Smith et al., 2022), which allowed connections to be made between individuals’ views and experiences.

**Results:**

Participants valued current research that included participants and experiences from a diverse range of backgrounds. They also prioritised current research that was relevant to the immediate needs of the community. Participants thought future research should be community-led and had ideas about the role of education in facilitating social change and meeting the needs of nonbinary autistic people. Participants’
views were informed by foundational experiences growing up, conflict throughout their lives and newfound self-discovery and empowerment in their present day as well as interactions with others in their communities.

Conclusions:

Exploring the views and experiences of gender diverse autistic people sheds light on insights that can be gained by considering those with multiple marginalised identities. Findings have implications for future research. These include considering how research can reflect the diversity of experiences and identities within the autistic community and how participatory methods can be employed across a broader range of areas of autism research, a message which has been echoed by both autism researchers and advocates (Pellicano, 2020).

402.138 (Poster) Exploring the Experiences of Families with Autistic Daughters in Seeking and Utilising Support: A Scottish Perspective. C. Ballantyne and M. Condie, (1)Department of Psychology, University of the West of Scotland, Paisley, United Kingdom, (2)University of the West of Scotland, Paisley, United Kingdom

Background:

In 2010, The Scottish Government invested £10M to support The Scottish Strategy for Autism, which highlights the need to consider autism in the early years, primary and secondary school stages (Scottish Government 2010) and should theoretically lead to increased awareness of all autistic children within education settings. Indeed, accessing and locating appropriate services of support is an essential aspect in improving quality of life, both for an autistic young girl and her family. Past research shows that autistic females are more likely to go unnoticed or diagnosed at a later age compared to their male counterparts, subsequently impacting the degree of support they receive from healthcare/social services, education, and local resources etc.

Objectives:

The study intended to bring attention to the discrepancies in the female presentation of autism and the possible impact this had on the quantity and quality of support provided to families for their daughter/s.

Methods:

Twelve mothers of autistic young girls across Scotland completed online semi-structured interviews. The mean age of the young girls the parents represented was 9.53 years, with ages ranging between 3 and 16 years old. Of the sample, 11 of the children had received a formal clinical diagnosis of autism, 3 children were currently awaiting an assessment for autism, and 1 child was suspected to be presenting with symptoms of autism. Additional information revealed that of the sample, 14 children attended a mainstream school while only 1 child attended an alternative provision. The discussions centred around their experiences of seeking and utilising the supports available to them.

Results:

Using Braun and Clarke’s (2006) thematic analysis, four key themes emerged: Experiences with education and school support (the consequences of masking; school interventions), Perceived barriers when accessing support (post code lottery; dependency on obtaining a diagnosis to access support; harmful professional stereotypes of autism), Involvement of parents (parent-led research efforts; fighting for access to support) and Scarce provision for post-diagnostic support.

Conclusions:

Findings indicated that a majority of parents experienced various difficulties with the accessibility of support service provisions, including their knowledge of existing autism-specific supports and experiences of stigmas leading to inadequate help or a reluctance to implement such. Findings can be utilised to inform other caregivers, educational and healthcare professionals about the presentation of autism in young girls. Future research should focus on exploring the influence of sex/gender disparities within autism from the perspectives of professionals, in order to prevent the frequent under-recognition and misdiagnosis of autistic females. This could ensure that the current support service provisions in Scotland and beyond are specifically designed to address the needs of autistic girls.

402.139 (Poster) Exploring the Measurement of Parental Perspectives of Implementation Effectiveness in Early Interventions for Autism: Findings of a Systematic Review. M. Frisch, M. Barton and D. A. Berger, Psychological Sciences, University of Connecticut, Storrs, CT

Background: The evaluation of implementation outcomes is critical to understanding treatment effectiveness and stakeholder groups provide important perspectives to this evaluation (Proctor et al., 2011). In autism early intervention, parents are a key stakeholder group. Parents determine what interventions their child engages in and serve as interventionists outside of direct provider hours (Burrell &
Borrego, 2012). Given the significant role of parents in autism early intervention, it is important to explore the perspectives of parents with regard to early intervention implementation outcomes and these perspectives should be evaluated as a component of intervention efficacy. Yet, there is limited literature which explores how parent perspectives of implementation effectiveness influence the determination of intervention effectiveness.

Objectives: This study aims to review how autism-specific early intervention studies measure parent perspectives of implementation outcomes and how those outcomes are integrated into determination of treatment efficacy.

Methods: A systematic review of autism-focused early interventions was conducted in accordance with PRISMA guidelines for systematic reviews (Page et al., 2021) and the protocol was pre-registered on the Open Science Framework (OSF; Record ID: osf.io/suaxk). Randomized studies that reported both child outcomes and parent perspectives of implementation effectiveness were included. Proctor et al.,’s (2011) taxonomy of implementation outcomes was used to determine whether a study measured parent perspectives of implementation effectiveness. Intervention outcomes assessed included acceptability, adoption, appropriateness, feasibility, fidelity, and cost.

Results: A total of 22 unique manuscripts met inclusion criteria; two manuscripts (Carr et al., 2016; Kasari et al., 2014) were identified to be the same study population but reported on different implementation outcomes and were thus grouped together, resulting in 21 studies reviewed. Intervention acceptability (14 studies) and fidelity (15 studies) were the most frequently assessed variables. No studies measured intervention appropriateness. Nine studies measured adoption, two studies measured feasibility, and one measured cost. Outcomes were assessed through a variety of measurement strategies; Likert scale questions were most commonly used across outcomes. The reviewed studies minimally integrated implementation outcomes into their conclusions regarding implementation effectiveness. Two studies measuring adoption did not report outcomes (Dawson et al., 2010; Schertz et al., 2013). Out of the 21 studies reviewed, Byford et al., (2015) was the only study to clearly utilize the measured implementation outcome, cost, to inform determination of intervention efficacy.

Conclusions: Overall, findings indicate considerable variability in implementation outcome measurement and these outcomes were not utilized to inform conclusions regarding intervention efficacy. These findings highlight a gap in autism early intervention research and a need for greater consistency of method when assessing implementation outcomes. Such efforts will allow for the uniform integration of parent perspectives into practice and greater comparability between studies. Increased consistency of implementation outcome measurement across studies would allow for greater understanding of parental perspectives of early interventions for young children with autism. Such understanding will allow researchers and clinicians to best evaluate interventions for both intervention and implementation efficacy and integrate findings to inform future treatment efforts.

402.140 (Poster) Exploring the Mental Healthcare Experiences of Autistic LGBTQ+ Young Adults: A Community-Partnered Study

L. M. Baczewski, R. Caplan, M. McDonald, B. R. Nachman, K. Rodriguez, R. Taylor, and M. L. Massolo, (1) UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2) Brandeis University, Heller School for Social Policy and Management, Waltham, MA, (3) Autistic LGBTQ+ Advisory Group, Los Angeles, CA, (4) NC State University, Madison, WI, (5) Division of Research, Kaiser Permanente Division of Research, Oakland, CA

Background: Autistic individuals are more likely than their non-autistic counterparts to identify as LGBTQ+ (Dewinter et al., 2017). LGBTQ+ autistic adults experience substantial disparities in access to healthcare compared to their non-LGBTQ+ autistic peers (Hall et al., 2020). Although rates of co-occurring psychiatric diagnoses are high amongst this population, very little is known about the mental healthcare experiences of autistic LGBTQ+ individuals. This is the first study to our knowledge that utilizes a community-partnered participatory approach to understand barriers and facilitators to accessing mental health care for autistic LGBTQ+ young adults.

Objectives: Explore the experiences of LGBTQ+ autistic young adults (18-28 years old) with regards to their mental health status and mental healthcare.

Methods: This study utilized a qualitative, phenomenological approach to examine the experiences of LGBTQ+ autistics in mental healthcare. We employed community-partnered participatory methods (Jones et al., 2009) to create an advisory group of 5 autistic LGBTQ+ adults. Participants were recruited through local organizations and social media. Semi-structured interviews took place via video call, phone, or synchronous text-based chat and were transcribed. We coded and analyzed interview transcripts using Braun and Clarke’s 6-phase approach to thematic analysis (Braun & Clarke, 2006). Three authors read the first 4 interview transcripts and identified key themes to create an initial coding dictionary. Thematic consensus was reached by the fifth coding meeting. The presenting author and a student researcher coded remaining interviews and met regularly to ensure consistency and reach consensus.

Results: 29 participants (18-28 years old, M_age= 23.3 years) completed a survey and signed up to participate. Almost half (48%) of survey participants identified as non-binary, gender fluid, or gender non-conforming and all participants reported at least 1 co-occurring mental health and/or disability diagnosis (e.g., ADHD, depression). Sixteen of the 29 participants opted into a semi-structured interview about their mental healthcare experiences. Interviews ranged in duration from 45 minutes to 2.5 hours. Six preliminary themes emerged from the data, including: 1) People don’t believe me about who I am: disbelief & misconceptions about LGBTQ+ and autistic identities, 2) Mental healthcare can also be individual practices & community care, 3) Being in community with other autistic people matters for my mental healthcare, 4) Being in community with other autistic people can lead to better care, 5) Mental healthcare should be accessible, and 6) Mental healthcare professionals should be trained in autistic cultural humility.

Conclusions: Overall, findings indicate considerable variability in implementation outcome measurement and these outcomes were not utilized to inform conclusions regarding intervention efficacy. These findings highlight a gap in autism early intervention research and a need for greater consistency of method when assessing implementation outcomes. Such efforts will allow for the uniform integration of parent perspectives into practice and greater comparability between studies. Increased consistency of implementation outcome measurement across studies would allow for greater understanding of parental perspectives of early interventions for young children with autism. Such understanding will allow researchers and clinicians to best evaluate interventions for both intervention and implementation efficacy and integrate findings to inform future treatment efforts.
Conclusions: Autistic LGBTQ+ young adults reported both positive and negative experiences in accessing mental healthcare. Participants shared concrete ideas for how mental health supports can be more autistic and LGBTQ+-affirming. Several themes highlight unique stressors that autistic LGBTQ+ young adults face living at the intersection of multiple-marginalized identities. Participants described community care, knowledge-sharing and connecting to other autistic queer people as buffers to mental health challenges. These findings can help guide clinicians in supporting their autistic and LGBTQ+ patients, and can help autistic LGBTQ+ adults find mental health support that feels right to them.

402.141 (Poster) Factor Analysis and Exploration of Parental Resilience and Parental Stress in Black Caregivers of Youth with ASD

R. Bradley, H. Onovbia, E. A. del Rosario, E. Shah, J. Kiefer and L. B. Quetsch; (1)University of Arkansas, Fayetteville, AR, (2)University of Arkansas - Fayetteville, AR, Fayetteville, AR

Background: There is a substantial body of work documenting high rates of stress among caregivers of youth with ASD, but focused research examining parenting stress across racial groups is mixed. Past studies have found greater levels of parenting stress among Black caregivers of youth with ASD compared to other groups. Disproportionate service disparities and treatment barriers may be implicated in increased stress among Black caregivers. However, emerging research has also found family resilience to protect against parenting stress in Black families. Indeed, research in the general population has postulated that adaptive, cultural coping in Black families may buffer against racial stressors (e.g., racism, microaggressions), but few studies have explored resilience among Black families of autistic youth. The present study investigated parental stress and resilience, and subsequent links to treatment barriers and family factors, among Black families of youth with ASD.

Objectives: To characterize parental stress and parental resilience in a sample of Black caregivers of youth with ASD; and to examine the relationship among parental stress, parental resilience, treatment satisfaction, racial barriers to treatment, household income, and caregiver age.

Methods: Caregivers (N = 101) of youth with ASD, ages 0 – 21, completed a demographic questionnaire, the Parental Stress Scale (PSS), and the Barriers to Treatment Participation Scale. Participating caregivers also completed a questionnaire developed by the research team which assessed racial barriers to treatment (e.g., experience of microaggressions).

Results: A maximum likelihood confirmatory factor analysis was performed; items from the PSS loaded onto two latent factors comprising parental stress and parental resilience. The parental resilience factor was specified to reflect current literature operationalizing parental resilience, in part, as positive perceptions of parenting. As chi square is often significant with complex models, fit was determined using the Comparative Fit Index (CFI > .90) and the Standardized Root Mean Square Error of Approximation (SRMR < .08). Fit indices suggested the model was an acceptable fit to the data, CFI = .91, SRMR = .07. Parental resilience and parental stress significantly and negatively covaried, and they were retained as factors for linear regression analyses. There were significant associations between parental resilience and both satisfaction with treatment services (F(1, 98) = 4.69, p = .03, R² = .05) and perceived racial barriers to treatment (F(1, 98) = 5.48, p = .02, R² = 0.05). Further, household income and caregiver age were both predictive of parental resilience F(2, 96) = 7.15, p = .001, R² = .13. However, when controlling for both, only household income was significantly associated with parental stress (F(2, 93) = 9.50, p = .01, R² = .09).

Conclusions: Findings support the strong association between increased parental resilience and decreased parental stress among Black caregivers of youth with ASD. It is possible that socio-demographic features (e.g., younger parent, financial strain) and barriers to care (e.g., perceived racial barriers, dissatisfaction with treatment) may interact and result in increased parental stress and depleted resilience. Future efforts should emphasize policy-, community-, and family-oriented research to decrease barriers to care and promote parental resilience.

402.142 (Poster) Factors Affecting Quality of Life in Adolescent Siblings of Children with Autism Spectrum Disorder

Y. Arya, D. Mishra, M. Juneja and S. Sairam; (1)PEDIATRICS, LOK NAYAK HOSPITAL, NEW DELHI, India, (2)Pediatrics, Maulana Azad Medical College and Lok Nayak Hospital, New Delhi, India, (3)Maulana Azad Medical College New Delhi India, New Delhi, India, (4)Maya Clinic, Ghaziabad, India

Background:

Siblings of children with autism (autism spectrum disorder, ASD) are reported to have poor quality of life (QoL), but not much Indian data is available regarding this aspect.

Objectives:
To compare the QoL of adolescent siblings of children with ASD, with siblings of typically developing children, and study the factors affecting the QoL.

Methods: Between 1st February, 2021 and 31st September, 2021 (expect periods of intermittent COVID-19 related discontinuation of non-COVID services), 40 children aged 10–18 y, whose child sibling was suffering from autism spectrum disorder, were enrolled (Study group). Forty age- and sex-matched siblings of children with no clinically apparent neuro developmental abnormality or behavioral problem were also enrolled (Control group). Those with obvious chronic medical/surgical disease affecting QoL, or clinically apparent speech or hearing problems were excluded. Severity of autism was assessed by using the Childhood Autism Rating Scale 2 (CARS-2) score. QoL was assessed by a validated version of the WHOQOL-BREF in Hindi language, which has four subsections viz., physical factors, psychological factors, social factors and environmental factors. QoL was compared between cases and controls using Wilcoxon rank sum test.

Results:

The mean (SD) age of the study participants was 13.55 (2.75) years. More than a third of children with ASD (14, 35%) had comorbid global developmental delay. None of the patients had any other diagnosed co-morbidity like epilepsy or Attention Deficit Hyperkinetic Disorder. The mean (SD) CARS-2 score of our sample was 35.78 (5.23). Mild to moderate autism was seen in 23 (57.5%) children and 13 (32.5%) had severe autism. The QoL in ASD-Sibs was worse than TD-Sibs in all four domains ($P < 0.001$). QoL was compared between ASD-Sibs with respect to severity of autism in their siblings. A statistically significant difference was found between the two groups only in social domain ($P = 0.04$). QoL was compared between ASD-Sibs with and without GDD. There were no differences in QoL in the two groups in any domain. No statistically significant difference in the QoL with respect to age, sex, type of family, nutritional status but a statistically significant difference in QoL in physical domain ($P = 0.01$) was obtained while comparing the socio-economic status.

Conclusions:

The observed poor QoL in adolescent siblings of children with ASD, with it being worse in those whose siblings had more severe ASD, suggests the need for targeting the family as a unit while formulating plans for the holistic management of children with ASD. Unaffected siblings may, in addition, require targeted counseling and other interventions.

402.143 (Poster) Factors That Predict Families’ Engagement in Publicly-Funded Early Intervention Services

S. R. Crabbe, S. Marcus, M. Xie, B. R. Ingersoll, D. S. Mandell and M. Pellecchia, (1)Penn Center for Mental Health, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)Psychology, Michigan State University, East Lansing, MI, (4)Penn Center for Mental Health, University of Pennsylvania School of Medicine, Philadelphia, PA

Background: Engagement in early intervention (EI) services improves outcomes for autistic children. Families from marginalized and minoritized backgrounds receive and engage in these services at disproportionately low rates (Bilaver et al., 2020). Previous research has shown that families from low-income households are more likely to disengage from services (Pellecchia et al., 2018). Additionally, mothers of autistic children report more psychological distress (Karp et al., 2018). These factors can have negative effects on treatment engagement, but little is known about their association with service retention in community-based EI. A deeper understanding of factors influencing service retention for families from historically minoritized and marginalized backgrounds can lead to the development of strategies to better support their service engagement.

Objectives: To evaluate demographic (education, income, and quality of life) and service level (treatment dosage) factors that are associated with family engagement in publicly-funded, community based EI services, in order to inform strategies to improve service engagement for marginalized families.

Methods: Through a community-based randomized pilot trial, children under 30 months of age who received publicly-funded EI services (N=60) and their caregivers were randomized to three conditions: 1) 4 hours/week of Project ImPACT, 2) 1 hour/week of Project ImPACT, or 3) 1 hour/week usual care. Intervention was provided by community-based service providers for six months. We used the number of hours of service delivered in each arm as a measure of treatment dose. Families completed a demographic questionnaire and the World Health Organization Quality of Life-Brief (WHOQOL-BREF) upon enrollment. Family session attendance, our measure of treatment engagement, was monitored weekly throughout the study period. Dropout rates were calculated for each demographic and service use factor. Adjusted odds ratios were calculated using a logistic regression model that included these factors as independent variables to predict dropout during the study period.

Results: Families randomized to 4 hours per week of Project ImPACT were more likely to continue EI services than families in either the 1 hour per week of Project ImPACT or treatment as usual groups. Lower household income, more than one adult living in the home, and greater psychological quality of life were associated with increased retention in services ($p's < .05$).
Conclusions: Families who received more hours of services each week were less likely to drop out of community-based services, suggesting that frequent and regular contact with a service provider enhances service engagement for low-income families. Families may feel they are being provided with greater support from their service providers with frequent contact since they have more opportunities to practice strategies. Families with more than one adult living in the home were also more likely to stay in services, suggesting the need for respite and social supports for families living in single-parent households as a mechanism to support service engagement. Lastly, caregivers who reported higher ratings of psychological quality of life were more likely to stay engaged in services, suggesting the need for strategies to enhance quality of life for caregivers, including referrals to social work and mental health services to improve service engagement.

402.144 (Poster) Family Experiences on Autism Diagnostic Process and Early Intervention Services in South Korea
G. Kim and H. H. Kim, (1) University of Kansas, Lawrence, KS, (2) Department of Psychiatry and Behavioral Sciences, University of California San Francisco, San Francisco, CA

Background:
While earlier identification and diagnosis of ASD allow early access to intervention services for children and families, delays in diagnosis are still common in Korea. Moreover, families of a child who received an early ASD diagnosis reported that information for early intervention was rare during the diagnostic process, which also contributed to delaying the service provisions. Such delays negatively impact the child's developmental trajectory, parental stress, and fiscal issues. In Korea, the need for a system to support early screening, identification, diagnosis, and intervention has been highlighted. However, a recent survey indicated families are experiencing challenges before, during, and after their child's ASD diagnostic process. Therefore, it is important to investigate families' experiences of ASD diagnosis and how that affected access to early intervention services in Korea.

Objectives:
This study aims to add literature in Korea that supports the idea that "the earlier that intervention begins in children's lives, the better the outcomes for children and their families (NRC, 2001)" by:

(1) Utilizing qualitative methods to explore the experiences of families who have a child with ASD on the identification, diagnosis, and early intervention services.

(2) Identifying barriers and facilitators to obtaining early identification/diagnosis and to receiving high-quality early intervention services.

Methods:
A semi-structured interview was used to explore the family's experiences with their child's ASD identification, diagnosis, and early intervention services. The participants include families in different regions across Korea who have a child under age 8 with an ASD diagnosis. Interview method will allow families to provide detailed information with open-ended responses to a consistent set of questions. The questions consist of items that focus on (1) initial concern about their children, (2) experiences with service providers, (3) perceptions of the services and the information they received, and (4) barriers and facilitators to early identification and early intervention.

Results:
Prior to diagnosis, families reported a lack of knowledge and resources to make informed decisions about diagnostic evaluation. They also experienced elevated stress, anxiety due to uncertainty about their child's development and the diagnostic process. During the evaluation, families raised concerns about the accuracy of diagnostic tools and environment for their child. They reported insufficient discussion with the providers about the evaluation results and financial burdens. After receiving the diagnosis, families felt less confident in understanding the results, experienced emotional difficulties accepting the diagnoses, and were confused about utilizing the evaluation reports to access appropriate services timely.

Conclusions:
Based on the preliminary findings, we propose three areas that can be developed in Korea. First, child at risk for ASD and their families may benefit from an early identification system that provides guidance on how to navigate from parental/caregiver concerns to accessing early intervention services. Second, a collaborative team approach for assessment may be created to involve families and stakeholders in the diagnostic process, which increases the opportunity to provide more individualized and accurate evaluation. Lastly, manualized procedure for families to access early intervention service is necessary after receiving an ASD diagnosis.

402.145 (Poster) Family Sex Communication As a Predictor of Sexual Knowledge and Self-Efficacy in Autistic Females
Research suggests that autistic youth trail their peers in obtaining medically accurate and timely sexual and reproductive health knowledge. Further, parents of autistic children have reported feeling unprepared to educate their children, and when sex education is received, autistic individuals commonly report feeling dissatisfied with the experience. There has been very little empirical focus on sexual education for autistic girls specifically. The current study was designed to explore factors that may guide the future design of effective sexual education programs for autistic girls. Parental communication about sexual health topics, known as family sex communication, has been shown to improve knowledge, safety behaviors, and relationships within non-autistic populations but this relationship has not yet been studied in autistic girls.

Objectives:

This study examined the impact of family sex communication on sexual knowledge and self-efficacy in young adult autistic women, as well as whether this association is moderated by autism symptom severity.

Methods:

Participants comprised 216 autistic women aged 19 to 39 (M=29.62, SD=5.40) who were recruited from the Simons Foundation Powering Autism Research for Knowledge (SPARK) cohort. Participants completed an online survey which included several previously validated measures. ASD severity was assessed via the Subthreshold Autism Trait Questionnaire (SATQ). Family sex communication was assessed via the Family Sex Communication Questionnaire (FSCQ). Sexual knowledge was assessed with the Test of Adolescent Sexual Knowledge (TASK). Self-efficacy was measured with the Sexual and Reproductive Empowerment Scale (SRES). A series of linear regressions were used to test study objectives.

Results:

Complete model results are reported in Table 1. Model 1 examined whether ASD symptom severity moderates the association between family sex communication and sexual knowledge. Lower levels of ASD traits were associated with greater levels of knowledge (β=-.20, p=.007). However, family sex communication was not associated with knowledge (β=.10, p=.17) and ASD severity did not moderate the relation between family sex communication and knowledge (β=.12, p=.08). Model 2 examined whether ASD severity moderates the association between family sex communication and self-efficacy. ASD severity interacted with family sex communication to predict self-efficacy such that the association between family sex communication and self-efficacy was stronger for those with higher levels of ASD symptoms relative to those with lower levels (β=.12, p=.049) (Figure 1).

Conclusions:

Results showed that young women with more ASD traits had less sexual knowledge than those with fewer traits. Family sex communication was associated with greater self-efficacy among young adult women with autism. Sexual self-efficacy, one’s belief in their own capacity to make decisions regarding sexual behavior, is believed to be critical for decreasing risky sexual behaviors and victimization. Further, those with higher levels of autism traits benefitted more from better family sex communication. Autistic girls and teenagers may benefit from sexual education that is tailored to their particular needs including more concrete information, visual aids, and teaching from trusted individuals who can assess engagement, coherence, and understanding in real time. Results provide foundational knowledge to support the design of parent mediated sexual education programs in childhood and adolescence for autistic girls.
Results: We conducted a cluster analysis using the Two-Step Clustering Algorithm (Shih, Cheng & Lai, 2010). The best model with good quality properties (ratio of sizes = 2.58) was taken into consideration, and two distinctive clusters emerged. The first cluster is made by 31 fathers (72.1% of the sample) displaying high levels of stress (especially concerning the representation of the child as difficult), a greater percentage of directive statements directed to the child, and fewer levels of symbolic play. Conversely, cluster 2 is made by 12 fathers (27.9% of the sample), showing less stress concerning child difficulties, fewer directives, and more symbolic play. Finally, through Linear Regression Models, we found that the directiveness level of cluster 1 but not of cluster 2 was associated with the child’s cognitive levels with a significant model (F(1,29)=9.05; p=.005). Specifically, cluster 1 increased levels of directiveness (beta=-0.49; t(30)=-3.01; p=.005) was negatively associated with cognitive functioning.

Conclusions: These findings may provide relevant clinical implications in implementing activities with children during the intervention considering different levels. On one side, interventions should focus directly on targeted cognitive domains to favor children’s developmental outcomes. On the other hand, interventions should indirectly consider paternal representations of the child to support fathers toward an increased understanding of the child’s difficulties. By comprehending the nature of parent-child interactions, it may be possible to devise more efficient intervention strategies. These findings may provide new insights considering paternal behaviors that need to be addressed in personalized interventions with fathers’ involvement.

Methods: We gathered paired data of 43 fathers (M=37.52 years; SD=5.34) during video-recorded interaction with their preschool children (M=40.74 months; SD=11.51), considering stress levels (Parental Stress Index - Short Form; Abidin, et al., 2006), affective quality (Emotional Availability Scales, Biringen et al., 2008), play (The Play Code, Bornstein & O’Reilly, 1996), and functional language (Penman Code, Penman, 1983). We analyzed the child’s cognitive functioning (Griffiths Mental Development Scales - ER, Luiz et al., 2006) and symptom severity (ADOS-2, Lord et al., 2012).

Results: VCI of autistic children was significantly lower than that of neurotypical children, p<.001. Father’s childcare participation was negatively associated with cognitive functioning of autistic children, M=5.39, SD=0.82) participated in this study. Children completed the Wechsler Preschool and Primary Scale of Intelligence–Fourth Edition (WPPSI-IV; Wechsler, 2012) and their language development was measured by the Verbal Comprehension Index (VCI) of the test. The caregiver who accompanied the child to the test completed an online questionnaire in which they indicated the child’s main caregiver(s) and family socioeconomic status (SES).

Conclusions: We found that fathers of autistic children participate less in childcare than fathers of neurotypical children. Having father as a regular caregiver predicts better language development in both autistic and neurotypical children. Among various types of caregivers, father seems to be especially critical in autistic children’s language development, and father’s childcare participation might play a protective role in language impairments in autistic children. Our findings highlight the importance of father’s role in autistic children’s
Feasibility and Acceptability of a Home-Based Collection Method for Identifying Risk Factors for Autism Spectrum Disorder

Paschou, M. Rispoli, C. Rocher, E. Wells, A. J. Schwichtenberg, A. Sereno, C. Shin and B. Kelleher, (1)Nutrition Science, Purdue University, West Lafayette, IN, (2)Institute for Advancing Health through Agriculture, Texas A&M, College Station, TX, (3)School of Health Sciences, Purdue University, West Lafayette, IN, (4)Public Health, Purdue University, West Lafayette, IN, (5)UC San Diego, San Diego, CA, (6)Psychological Sciences, Purdue University, West Lafayette, IN, (7)Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN, (8)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN, (9)Food Science, Purdue University, West Lafayette, IN, (10)Human Development and Family Studies, Purdue University, West Lafayette, IN, (11)Pediatrics, Indiana University School of Medicine, Indianapolis, IN, (12)Biological Sciences, Purdue University, West Lafayette, IN, (13)Educational Studies, Purdue University, West Lafayette, IN, (14)Neural and Behavioral Sciences, Pennsylvania State University, College of Medicine, University Park, PA

Background:

Research on autism spectrum disorder (ASD) causality has been primarily discipline-specific, despite strong evidence of symptoms emerging from intersecting mechanisms. One barrier has been the challenge of collecting multiple biological and environmental samples from individuals at elevated likelihood for autism, particularly among geographically dispersed cohorts. To address this, we developed the Purdue Omnityping Kit for Testing (POcKIT) a user-centered data collection kit to support remote assessment of features associated with autism outcomes.

Objectives:

Here, we examined the (1) success, (2) feasibility, and (3) acceptability of sample collections using POcKIT.

Methods:

This study included 20 families from: (1) a national genetic risk cohort of children with fragile X syndrome (FXS, n=8), (2) a regional environmental risk cohort of children (ER, n=3), and (3) a regional cohort of children with autism (ASD, n=9). Ages ranged from 21-60 months (mean 42mo) and 90% were male. Each family completed a web-based survey with demographics and several clinical batteries, a phone interview, and at-home sample collections. POcKIT was designed based on input from diverse stakeholders and included materials necessary to measure child and caregiver saliva for genetics and α-synuclein assays; child stool for gut microbiome analysis; and soil, water, and child toenails for heavy metal and pesticide assays. Instructional videos created for each collection were loaded onto a tablet monitoring user engagement. Caregivers shipped both frozen and non-frozen samples to a centralized processing site using pre-paid materials. Outcomes included: success (collection compliance, meaningful result), feasibility (user-rated ease, video engagement metrics), and acceptability (favorable evaluation). Key research questions were: (1) Was POcKIT successful (90% usable samples) and feasible (80% positive) across income and cohort? (2) Did engagement metrics predict successful sample collections? (3) Were users satisfied with the experience?

Results:

Upwards of 95% of families successfully collected samples. 85% of caregivers rated child saliva collection as “Difficult”/“Very difficult” on 5-point scale and this varied significantly by cohort (ASD 100%, FXS 87.5%, and ER 12.5%) but not by income. In contrast, fewer caregivers found stool (25%), soil (13%), water (7%) or toenails (21%) difficult to collect. Ratings for these collections did not vary by cohort or income.

Participants spent an average total of 47 minutes watching the 40 minutes of instructional video (range: 7-84 minutes). Metrics of success and feasibility were not associated with video use metrics. Most caregivers were “Very satisfied”/“Extremely satisfied” with all aspects of the study including overall experience (75%), length of time for each of the components [surveys (65%), phone interview (74%), and collections (55%)], quality and clarity of the instructions (95% and 85%, respectively), and support from our team (100%).

Conclusions:

Overall, families reported their experience with POcKIT as practical and acceptable, yielding high rates of successful sample collections. Modifications will need to be made to child saliva collections and to the length of study components prior to scaling up the study. The findings from this study bring us one step closer to personalizing risk assessment and treatment by providing a potential model for large-scale remote data collection across diverse users.
**402.149 (Poster) Fragmented Services and Parents' Marathon for Delivery of Early Intervention Services for Children on the Autism Spectrum in Greece**

*D. Papoudi, A. Fyssa and L. Tsermidou*, (1)Department of Special Education, University of Thessaly, Volos, Greece, (2)Department of Educational Sciences and Early Childhood Education, University of Patras, Patras, Greece, (3)Department of Early Childhood Education, National and Kapodistrian University of Athens, Athens, Greece

Background: The design and implementation of early intervention services is crucial for promoting the development, learning and inclusion of children on the autism spectrum. Such programmes should involve the activation of a variety of support services according to children’s and their parents’ needs which should be provided in their natural environments, including the home and community early childhood education and care settings with the support of education professionals. Yet, few studies at an international level focused on the experiences of parents with children on the autism spectrum in relation to early intervention services highlighting the need to ensure high quality support services for meeting the needs of the children and their families.

Objectives: Our aims were twofold: a) to conduct a qualitative study to examine the lived experiences of parents in relation to early intervention services who have a child on the autism spectrum attending general early childhood education settings in Greece and b) to include in our sample parents of Greek origin as well as parents of culturally and linguistically diverse children with autism.

Methods: Data were collected through semi-structured interviews with 13 parents of children on the autism spectrum who attended a class at general early childhood education settings in Greece during the spring term of the school year 2021-2022. The duration of the interviews with the participants lasted approximately 1 hour and thematic analysis was employed for the analysis of the collected data.

Results: The thematic analysis revealed that, first, parents described that existing services are fragmented and chaotic without being provided timely so that early intervention services are ensured. In this way, parents reported that they experience psycho-social stressful situations in their interactions with the services and with the professionals in the health, care, and education sectors. Another dimension that parents unveiled was their need to be fully engaged in high quality services during the assessment processes, in decision-making about their children’s education in child-care settings and early childhood education naturalistic environments, and not only to be passive informants of their child’s developmental profile. Lastly, parents expressed the need to belong in supportive network services with an emphasis on the whole family and their empowerment, so that they can better promote their child’s life-long development as well as educational and social inclusion.

Conclusions: Our study demonstrated that there is a lack of appropriate and co-ordinated high quality early childhood intervention services. Parents in Greece tend to experience many barriers, and, therefore, they described the processes from locating to activating these services as a marathon. It is expected that these findings will contribute to the effective design of inclusive and sustainable early childhood intervention policy, practices, and services for children on the autism spectrum and their families in Greece.

---

**402.150 (Poster) Gender Differences in the Portrayals of Autism in the Autism UK Press Corpus**

*T. Karaminis, C. Gabrielatos, U. Maden-Weinberger and G. Beattie*, (1)Department of Psychology, Edge Hill University, Ormskirk, United Kingdom, (2)Edge Hill University, Ormskirk, United Kingdom

Background: There is increasing recognition that the identification, diagnosis, study, and understanding of autism are heavily skewed towards the male gender. A similar bias is also found in media and press representations of autism, which reflect, construct and reconstruct public attitudes and beliefs towards autistic people and play a critical role in their acceptance and the successful integration into education, work, and society.

A recent study by our team (Karaminis et al., 2022) used corpus-based and critical discourse analysis methodologies to examine lexicogrammatical patterns in the portrayals of autism in British newspapers between 2011-2020. It found that accounts of autism in British newspapers focused on children - and especially boys. This gender bias was more pronounced in tabloids than in broadsheets and in right-than left-leaning newspapers, and it also decreased slightly over the years.

Objectives: In a follow-up study, we aimed to examine gender differences in the press portrayals of autism in further detail. More specifically, we aimed to examine how the representations of autism in British newspapers differed when newspapers referred to autistic boys vs. girls, as well as to mothers vs. fathers of autistic children.

Methods:
We analysed the Autism UK Press Corpus, a collection of all documents (around ~24K) referring to autism in ten major national newspapers between 2011 - 2020. We used a corpus-based critical-discourse-analysis framework, which involves a series of interconnected qualitative and quantitative analysis stages, to construct emergent representations of the terms “autism” and “autistic”.

In this study, we analysed separately corpus samples (~2,800) in which the terms autism and autistic co-occurred with words denoting age, gender and family roles and falling into four broad categories: BOY, GIRL, FATHER and MOTHER. We compared the prevalence of various attitudes and underlying discourses (identified based on the annotation scheme of the original study) in BOY vs. GIRL and FATHER vs. MOTHER samples. Similar to the original study, we also considered changes over time and differences in reporting style (tabloids vs. broadsheets) and political orientation (left- vs right-leaning).

Results:

Our results suggested that newspapers tended to discuss autistic girls in contrast to boys, i.e., as a newly-identified category of autistic individuals, which is different from boys. Furthermore, newspapers often highlighted “girl-specific” topics such as diagnosis and masking. With regards to parents of autistic children, both mothers and fathers were often discussed as someone conferring a risk for or causing their child’s autism through their lifestyle choices; however, mothers were associated with a more diverse range of liabilities than fathers. Finally, mothers, rather than fathers, were presented as someone who were dealing with challenges arising from their child’s autism, such as the diagnostic process or the lack of support and acceptance, and were also discussed as either victims or perpetrators in accounts of violent incidents.

Conclusions:

Our results offer new insights into gender-related biases in the (predominantly negative) press portrayals of autism and autistic children. We believe that these findings are useful for autism advocates and highlight the importance of employing intersectional research frameworks.

402.151 (Poster) Peer Support Provided By People with Autism and Intellectual Disabilities to Increase Research Engagement: A Scoping Review

B. Pfeiffer, Rehabilitation Sciences, Temple University, Philadelphia, PA

Background: Peer support is any organized method of support provided by a person with similar lived experiences. When provided formally, it can fill a much needed gap in specialized services for Autistic people as an effective approach that is founded on the concept that someone with lived experience can best understand the unique perspective of the individual. Peer support provides a mechanism to engage stakeholders in research.

Objectives: The objective of this scoping review was to identify important factors of peer support provided by Autistic individuals that could translate into methods for research engagement and then to organize this into a Peer Support Toolkit for Research Engagement.

Methods: A scoping review was completed using the guidelines for PRISMA-SCR. The search was developed initially for PubMed (NLM) and then was translated to ERIC (EbscoHost), CINAHL (EbscoHost) and PsycInfo (EbscoHost) using a combination of keywords and subject headings. The search resulted in 2,887 references that were eligible to screen. Studies were screened by title and abstract by two blinded and independent reviewers using Covidence. If there was a conflict between reviewers, a third reviewer was involved in the consensus discussion with the two initial reviewers. This process was repeated for full text article screening and article selection. For inclusion in the review, peer support had to be provided by an individual with Autism and/or an IDD for another Autistic individual. Included articles were extracted and coded for information on characteristics, strategies, and roles of peer supporters.

Results: We identified 26 articles that met the inclusion criteria. There were 10 reoccurring characteristics of a peer supporter identified during the coding process across the 26 articles. These included: 1) having a similar lived experience (n = 15) to the other person; 2) self-efficacy and self-advocacy (n =11); 3) reciprocity (n = 9); 4) friendship/comradery (n = 8); 5) role modeling or education (n = 7); 6) support for specific tasks (n = 7); 7) relationship building (n = 6); 8) creating a safe space for the peer (n = 5); 9) normalization of disability and positive disability identity (n = 5); and 10) commonality (n = 3). Coding identified 5 main peer support roles and strategies across the included articles. These included: 1) communication, 2) sharing experiences, 3) helping peers to learn, 4) peer development and 5) creating a welcoming environment. Coding across the articles also identified two main types of supports and accommodations for peer supporters. These included 1) individual supports and 2) environmental supports and accommodations.

Conclusions: Peer support provides a key mechanism for engaging stakeholders in inclusive research teams, which is essential for outcomes that are effective and meaningful. This scoping review identified the characteristics, as well as roles and strategies used by peer supporters. These findings were utilized to create a research-based toolkit to support the engagement of Autistic people on research teams.
H. S. Vu, H. Hoang, T. Quach, G. Le, C. Q. Tran, P. Hoang and T. Pham, (1)Center for Creative Initiatives in Health and Population, Hanoi, Viet Nam, (2)Center for Creative Initiatives in Health and Population, hanoi, Viet Nam

Background:

Children with autism spectrum disorder (ASD) require more types of special health services and interventions than their peers due to the complexity of ASD and comorbidities. However, their health needs are often unrecognized or unmet, especially in low-resourced setting countries like Vietnam. Unrecognized health needs and unavailability of services may prevent the accessibilities of children with ASD to health care services.

Objectives:

This study aims to explore health issues that children with ASD in Vietnam encountered and health seeking behaviors of their parents.

Methods:

This study was a cross-sectional research using data collected from caregivers of children with ASD using a structured questionnaire. The questionnaire was adapted from The Need Assessment tool developed by Autism Speaks. The study was conducted in 9 provinces/cities in Vietnam, including Hanoi, Nam Dinh, Ninh Binh, Thanh Hoa, Quang Binh, Quang Nam, Hue, Ho Chi Minh City, and Can Tho. Data were collected from October 2019 to January 2020. 413 responses were used for data analysis. Qualitative interviews and observation were supplemented for the survey data.

Results:

About three quarter (72.1%) of the children had other disability or comorbidities. The most common comorbidities reported were: ADHD: 43.2%, sleeping disorder: 31%, gastrointestinal difficulties 25.3%, and eating disorders 23.1%. About half of caregivers reported that they utilized public health facilities for medical treatment (24.5%) and rehabilitation (29.5%) for their children. More than 84.7% used private special education for their children’s intervention and they paid services by themselves. About half of families delayed treatment/intervention for their children with various reasons, in which one quarter (23.8%) reported no service available at their places, 21.4% lacked information on services availability and 16.4% could not afford service costs.

Conclusions:

Children with ASD have various health needs, including services for ASD and other comorbidities. Enhancing health care services, including capacity building for health care providers on ASD and other comorbidities, and developing referral pathways, is critical to meet the needs of the children.

D. Valdez and G. Herrera, (1)NIF 06687134E, Buenos Aires, Argentina, (2)IRTIC, University of Valencia, Paterna, Spain

Background: Does language influence the way we think? Can language be a tool for stigmatization or inclusion? Does it contribute to the creation of a system of discrimination or exclusion, or does it simply reveal and thematize it? These discussions lead us to explore how “news” related to autism circulates in the media, specifically in the written press. In recent years, the fight for rights and the construction of citizenship in the field of disability is also waged in language, in the framework of intertextuality, the media and social networks.

Objectives: Analyze the informative treatment that has been given to autism in a mass communication medium in Spain (El País, digital version) during 2019 and 2020, considering its possible impact on the opportunities for educational and social inclusion of autistic people. We chose this newspaper because according to statistics it is the most widely read in Spain.

Methods: A screening process was carried out with inter-judge evaluation. Content analysis: Categories include type of content addressed, projected social image, inclusion, considering the articles they write about inclusion (school, work, in the community) or experiences of stigmatization (situations of bullying, abuse) Corpus analysis through lexicometric analysis using the Voyant Tools tool.

Results: In relation to the content, the articles are mostly visibility, both in 2019 (67%) and in 2020 (73%). A very significant reduction has also been observed in articles on the causes of autism, which were 10% in 2019, with none (0%) in 2020. The percentage of articles whose central theme is intervention in autism has been remained relatively stable, being 17% in 2019 and 27% in 2020. If we analyze the social image, a vulnerable image of autism is projected by 53% in 2019 and 27% in 2020. There has also been an increase in articles highlighting
that these people require special attention, going from 20% in 2019 to 64% in the first year of the pandemic. Impersonal articles, mainly focused on the false link between vaccines and autism, fell from 7% in 2019, disappearing in 2020. The five terms that increased the most in their normalized relative frequency within the 2020 Corpus compared to 2019 were “people”, “TEA”, “disability”, “home” and “quarantine”. The five terms that most decreased their presence in the 2020 Corpus compared to 2019 were: “father”, “Greta”, “years”, “euros” and “education”.

Conclusions: We believe that the way in which the issue of disability in general and in particular the issue of autism is treated in the mass media is extremely important. What is at stake is not merely issues of political correctness or style norms, but the sensitivity to understand differences and build inclusive practices, cultures and policies. To the extent that people with ASD, their families and professionals and researchers in the area participate more in the public debate in the media, myths will be demolished and awareness of the subject will be contributed based on evidence and the real needs of people and improvements in their quality of life.

402.154 (Poster) How Older Sibling’s Autism and ADHD Traits Associate with Infant Sibling’s Adaptive Behaviour during Early Childhood

H. Halkola1, A. Pickles1, J. Begum Ali1, A. Gui2, G. Pasco3, M. H. Johnson4, T. Charman5, E. Jones6 and &. The BASIS-STAARS Team7,

Background:

Autism and attention deficit/hyperactivity disorder (ADHD) are both highly heritable neurodevelopmental conditions. Both conditions are characterised by difficulties in adaptive functions. Previous studies have shown that individuals with autism show difficulties in adaptive behaviour, including daily living, socialization, communication and motor skills. There is evidence found that individuals with ADHD show similar difficulties and that the difficulties might increase when combined with autism diagnosis. Having a family history of autism and/or ADHD increase the likelihood of being diagnosed with these conditions. Additionally, it has been found that older sibling’s adaptive skills associate with their infant sibling’s adaptive skills in families with a history of autism. In this study we aim to explore how older sibling’s autism and ADHD traits associate with infant sibling’s adaptive skills across early childhood.

Objectives:

To investigate how older sibling’s autism and ADHD traits associate with early childhood adaptive skills in infants with family history of autism and/or ADHD.

Methods:

The study included 408 infant participants (male=211, female=197) and their older siblings with autism (n=250), ADHD (n=31), both (n=21) or neither (n=106) from the British Autism Study of Infant Siblings (BASIS) and Studying Autism and ADHD Risks (STAARS) studies. Infant adaptive behaviour skills were measures at 8-, 14-, 24- and 36-months using the Vineland Adaptive Behavior Scales, Second Edition (VABS-II). Adaptive behaviour composite, daily living, socialization, communication and motor skills domains were used in the analysis. For older siblings’ autism traits parents completed the Social Communication Questionnaire (SCQ) lifetime version and Conners 3 parent/caregiver questionnaire was used for hyperactivity/impulsivity and inattention.

Bivariate correlations between older sibling’s autism/ADHD traits and infant sibling VABS-II scores were analysed using bivariate correlations, with the intention of further analysis using structural equation modelling.

Results:

Infants who had older sibling with high autism traits showed lower scores for adaptive behaviour, daily living, socialization, communication and motor skills at every time point except at 10 months. On the other hand, higher inattention in older sibling associated with lower scores in adaptive behaviour, daily living, communication and socialization at 24 months, but did not associate with motor skills at any time point. Older sibling hyperactivity/impulsivity did not associate with any of VABS-II domains.
Conclusions:

In this study we found that more severe older sibling’s autism symptoms associate with difficulties in infant sibling’s adaptive skills across the early childhood, starting at 14 months of age. Older sibling’s inattention also associates with difficulties in adaptive skills during toddlerhood. Further analysis needs to be done to better understand how these associations across infant sibling’s childhood.

402.155 (Poster) How about Us? Exploring the Mental Health of Parents with Children with ASD
D. Y. Song, Y. Hong, J. CHOI, G. Bong, J. Jung, J. H. Han, J. Kim and H. Yoo1, (1) Psychiatry, Seoul National University College of Medicine, Seoul, Korea, Republic of (South), (2) Bridgekids Behaviour Consulting, Richmond, BC, (3) Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (4) Psychiatry, Seoul National Univ Bundang Hospital, Seongnam, Korea, Republic of (South)

Background: Previous studies have found that parents of children with ASD report greater distress than parents with typically developing children (Estes et al., 2013). As parental psychological well-being is closely tied to the quality in relation to the child (Hickey et al., 2019), it is important to understand the mental health of the caregivers and explore factors by which it is influenced.

Objectives: This study aims to explore the mental health of parents whose child has been diagnosed with ASD.

Methods: Participants were recruited from a larger genetic cohort targeting ASD multiplex families in Korea. Therefore, parents and their children received a thorough assessment, including the Autism Diagnostic Observation Schedule, various questionnaires to measure autistic symptoms (i.e., Broad Autism Phenotype Questionnaire, Autism Quotient, Social Responsiveness Scale), as well as overall functioning and behavioral characteristics in their child. Parental mental health problems were assessed using the Korean-Symptom Checklist 95 (K-SCL 95), a self-report questionnaire that screens for 20 mental health conditions. Participants were coded as having difficulties with mental well-being if they received a T-score over 60 in any of the conditions. Independent t-tests and ANCOVA, covarying for age, were used to explore the clinical characteristics between parents with and without mental health problems.

Results: A total of 186 parents of children with ASD, whose ages ranged from 26 to 53 years, were included for analysis. Based on the K-SCL 95, 64.5% of the parents (n=120; age M=38.9, SD=5.17) were found to have at least one mental health condition at a concerning level. While 72.5% of the parents with mental health problems presented T-scores greater than 60 in more than two conditions, the average number with concerns was five conditions, with a wide range of 1~19. Mothers showed more vulnerability to mental health problems than fathers. Manic episodes (42.5%) were the most frequent and followed by stress vulnerability (40.8%), interpersonal sensitivity (39.2%), anxiety (38.3%), and depression (37.5%). When comparing the group of parents with and without mental health problems, those with mental health concerns had higher self-reported autistic traits (p < .001~.011) and reported greater difficulties related to pragmatic language in their spouse (F(1,177)=6.42, p=.012). However, the two groups showed no significant differences in the age of their child with ASD, number of children, number of affected children, the severity of ASD symptoms, or their child’s level of functioning (i.e., intelligence, adaptive behaviors).

Conclusions: A large proportion of parents with children with ASD experience concerning levels of various mental health conditions. While clinical characteristics of the child diagnosed with ASD did not differ between the two parental groups, those with mental health problems also presented higher scores on various self and spouse-reported questionnaires measuring autistic symptoms than parents without mental health problems. Therefore, parents of children with ASD also require support to address areas with difficulty to promote psychological well-being.

402.156 (Poster) Identifying Disparities in Care during Covid 19 for Families with Children with Developmental Disabilities
D. U. Menon, Neurology & Developmental medicine, Kennedy Krieger Institute, Baltimore, MD

Background: The 2019 SARS CoV-2 (COVID-19) pandemic created barriers to care for children with autism spectrum disorder (ASD), while highlighting long-standing racial and economic disparities and inequities. This study aimed to examine the relationship among sociodemographic factors, psychological factors, unmet medical and educational needs, and patients’ quality of life to identify disparities and barriers to care for children with ASD during COVID-19

Objectives:

1. How has COVID-19 impacted the overall quality of life and barriers to care for children with developmental disabilities?

2. Are there disparities in the impact of COVID-19 among families with children with developmental disabilities across demographic health factors?
Methods: Participants: The patient’s caregivers (n = 184) from CARD at Kennedy Krieger.

- Measures: (1) COVID-19 Patient Questionnaire – Survey designed for quality improvement in addressing family needs and service satisfaction during COVID-19. (2) Demographics – Drawn from medical chart review.
- Procedure: The patient’s caregiver received the COVID-19 patient questionnaire Qualtrics link electronically with their Zoom link prior to their appointment.
- Variables: Outcome – Quality of life; Psychological challenges Predictors – (1) Psychological challenges (including sleep, appetite, and mood) (2) Unmet medical needs (3) Distance learning (4) Family managing (5) Race (6) Insurance
- Response Scale: Quality of Life: 1 = severe to mod worse to 5 = mod to great improvement; Distance Learning & Family Managing: 0 = Doing well 1 = Getting by 2 = Really struggling
- Analyses: Descriptive statistics and multiple linear regression analyses in STATA

Results: The study did not find that sociodemographic factors, such as race, ethnicity, and insurance type, were associated with the overall quality of life for children with ASD. This study suggests that the majority of caregivers felt the medical and educational needs of their children with ASD were met or they were “getting by.” Significant percentages of the families however, were experiencing challenges. Almost a quarter (24%) of families were struggling to manage daily needs, 30% had medical concerns that needed to be addressed, and 36% were struggling to provide distance education. Caregivers who were having difficulty with receiving medical services, family managing, and distance education during the COVID-19 pandemic reported higher psychological challenges and decreased quality of life.

Conclusions:

In our limited study we found that Caregivers who were having difficulty with receiving medical services, family managing, and distance education during the COVID-19 pandemic reported higher psychological challenges and decreased quality of life.

402.157 (Poster) Identifying Gaps in Oral Care Knowledge, Attitudes, and Practices of Latino/a Parents/Caregivers of Autistic and Non-Autistic Children

L. I. Florindez, D. C. Florindez, D. H. Como, F. M. Florindez, and S. A. Cermak, (1) Nursing Research and Performance Improvement, Cedars-Sinai Medical Center, Los Angeles, CA, (2) Mrs. T. H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3) Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (4) Cedars-Sinai Medical Center, Los Angeles, CA, (5) Division of Occupational Therapy and Occupational Science, University of Southern California, Los Angeles, CA

Background:

Oral care is the most prevalent unmet healthcare need in children. Gaps in Latino/a parental oral care knowledge and practices may contribute to increasing oral health disparities experienced by Latino/a children with and without disabilities.

Objectives:

This pilot study used data from a survey to examine the knowledge, attitudes, and practices about oral care of Latino/a parents/caregivers of autistic and non-autistic children to identify gaps to focus future oral care intervention.

Methods:

Sixty English-speaking Latino/a parents/caregivers with an autistic or non-autistic child between 4 and 14 years (n = 31 autistic, n = 29 non-autistic) completed a questionnaire on oral health knowledge, practices, access to care, and demographics. Caregiver responses were compared, and gaps in knowledge and practices were identified.

Results:

There were no significant differences in parent age, child age, income, insured status, or overall knowledge scores, only a significant difference in education (p = 0.02), with the autistic group reporting less. Scores for knowledge, attitudes, access, and practice were all nonsignificantly positively correlated, as was attitudes with access and practice. However, knowledge and attitudes were significantly negatively correlated. Additional significant findings were parents who had lower income and education had lower oral knowledge scores, decreased frequency of dental visits, increased feelings of being discriminated against, children with increased fear of the dentist, and decreased ease of finding a dentist.

Conclusions:
Factors such as income, education, ethnicity, and having an autistic child can influence what Latino/a parents and caregivers know about oral health and how their children experience receiving dental care. Latino/a parents/caregivers of autistic and non-autistic children report barriers to dental care, including difficulty attending visits or feeling stigmatized by their dental provider due to their ethnicity. Fear of the dentist is significantly correlated with autism diagnosis and lower social demographics of the parent, and may contribute to a reduction in preventative oral care visits as well. Health care providers should consider these perspectives when providing care to this population to mitigate further oral health inequities.

402.158 (*Poster*) Identity-First Versus Person-First Language: An Examination of Abstracts from 11 Autism Research Journals

**J. Gudknecht** and M. C. Zajic*, (1)Human Development, Teachers College, Columbia University, New York, NY, (2)Health & Behavior Studies, Teachers College, Columbia University, New York, NY

**Background:** The most recent 7th Edition of the *Publication Manual of the American Psychological Association* specifically emphasized the intentional choices researchers make when choosing to use person-first language (PFL) or identity-first language (IFL). While PFL was once the preferred approach in autism research, advocacy primarily from autistic stakeholders has highlighted the importance of IFL to many autistic individuals. Existing research has focused on surveying large samples of autistic and non-autistic stakeholders to learn more about language preferences. However, approaches examining changes in how autistic individuals are referred to in research publications remains limited.

**Objectives:** This study analyzed the abstract text from research studies published in 11 autism research journals to identify trends in use of PFL and IFL. We examined articles published in the last three decades to identify potential patterns of change across journals.

**Methods:** We selected 11 journals that publish research related to autism and extracted publication years and full abstract data (*n = 11,906*) using the Web of Science. Journals include (with earliest publication year and sample size) *Advances in Autism* (AdiA; 2017; 138), *Autism* (2001; 1,485), *Autism & Developmental Language Impairments* (ADLI; 2017; 113), *Autism in Adulthood* (AuiA; 2019; 99), *Autism Research* (AR; 2008; 1,418), *Education and Training in Autism and Developmental Disabilities* (ETADD; 2010; 430), *Focus on Autism and Other Developmental Disabilities* (FOCUS; 2008; 336), *Journal of Autism and Developmental Disorders* (JADD; 1991; 5,280), *Molecular Autism* (MA; 2010; 640), *Research in Autism Spectrum Disorders* (RASD; 2007; 1,741), and *Review Journal of Autism and Developmental Disorders* (RJADD; 2015; 226). We excluded any in press publications (as of October 2022) and removed non-peer reviewed articles. We used Python to search for text associated with PFL (e.g., individual with autism) and IFL (e.g., autistic individual). We categorized abstracts into four categories based on having at least one mention of PFL, IFL, both, or neither. We also searched for “on the [autism] spectrum,” given that it has been highlighted as a preferred intermediary term.

**Results:** Over the years, some journals reported almost complete use (*Ms > 85%*) of PFL (FOCUS, ETADD, RJADD) or IFL (AuiA). Other journals showed an initial preference for PFL with an increase in IFL in the last five years that either approached (AdiA, ADLI, AR, JADD, MA, RASD) or surpassed (Autism) PFL. Abstracts using both remained relatively low across years and journals (*M = 11%). Use of “on the [autism] spectrum” remained low across journals (*M = 5%) with all journals below 3% except for AdiA, ADLI, and AuiA (8-11%). Publication trends will be further discussed during the presentation.

**Conclusions:** Language use across autism research journals highlights an increasing trend of IFL and a decreasing trend of PFL. However, the rate of this trend was not consistent across journals nor was the trend apparent in all journals. Findings highlight the importance of considering the role that language plays in writing about research involving autistic individuals and showcases the changing landscape in how researchers write about autism in scholarly publications.

402.159 (*Poster*) Impact of Companion and Assistance Dogs on Caregiver Stress in Autism Spectrum Disorder (ASD)

**Background:** Elevated levels of stress have been well-documented in caregivers of individuals with special needs; prior research has shown that assistance-dogs, trained to perform specific tasks to help their human partners, can reduce perceived stress and cortisol concentration levels in autistic individuals as well as their caregivers/parents (Tseng, 2021, Fecteau et al., 2017, Viau et al., 2010). Yet, given the prohibitively high costs in time and resources required, well-trained assistance-dogs are beyond the reach of many families. While psychosocial benefits arising from human-canine relationships have been reported from both companion- and assistance-dog bonds, empirical data comparing the impact of assistance and pet-dogs on caregivers and families affected by ASD is lacking.

**Objectives:** Our goal was to deepen our understanding of how companion and trained assistance-dogs impact the lives of ASD families. We hypothesized that the potential benefits of canine companionship on caregiver well-being may improve overall family outcomes through a mediating pathway. However, these effects will vary considerbly with individual human and canine characteristics.
Methods: Primary caregivers (N=637) of autistic individuals were recruited from the Simons Foundation Powering Autism Research for Knowledge (SPARK) online research initiative (SPARK Consortium, 2018). Parents/Caregivers (Male: N=55; Female: N=582) from SPARK families with at least one canine in the household provided informed consent online. Families with a trained assistance-dog (Male Child: N=146, Mean Age=11.88±3.56 years; Female Child: N=89, Mean Age=11.32±2.82 years) and those with a companion-dog (Male Child: N=319, Mean Age=11.59±3.66 years; Female Child: N=87; Mean Age=11.18±3.60 years) were asked to complete online surveys consisting of self-report and parent-report questionnaires on stress and coping, human-canine interactions and relationships, as well as family demographics, medical history, and life events. We also asked caregivers to provide phenotypic data, training, and signalment for the primary canine companion/assistance dog for the autistic child.

Results: After covarying for child age and sex, families with assistance-dogs reported significantly lower levels of stress F (3, 637) = 426, p = .005) on the Autism Parenting Stress Index (APSI; Silva & Schalock, 2012), a measure of parenting stress specific to ASD. However, we did not find a significant difference F (3, 606) = 1.086, p = .354) between caregivers with assistance and companion dogs as assessed by the Perceived Stress Scale (PSS; Cohen, 1994), a general measure of the degree to which situations are appraised as stressful. Data analysis is ongoing and we will examine variability in how caregivers handle difficult experiences (COPE Inventory; Carver, 2013) as related to their perceived stress levels.

Conclusions: Caregiver stress, coping, and resilience are key factors in ASD family outcomes; our data suggest that both companion- and assistance-dogs may help to relieve some of the multifaceted strain experienced by caregivers and their families. Further analyses will evaluate the canine traits and behaviors that correlate with positive outcomes on family survey measures and how these outcomes are modulated by human phenotypes. Ultimately, these data may be used to inform the development of improved assistance-dog selection and training approaches and to help match pet-dogs with family needs.

E. Baldimtsi; E. Papadimitriou and E. Verykouki, (1)School of Medicine, 1st Department of Neurology, Aristotle University of Thessaloniki, Thessaloniki, Greece, (2)Aristotle University of Thessaloniki, Hreklion, Greece, (3)Department of Agriculture Crop Production and Rural Environment, School of Agricultural Sciences, University of Thessaly, Volos, Greece

Background: During the COVID-19 pandemic, governments around the globe, among which Greece, implemented strict measures such as lockdowns (i.e., stay-at-home mandates), physical distancing, mask protection, and closure of non-essential businesses [1]. Even though these measures aimed to limit the transmission of the virus, these measures, especially lockdowns, may have left a substantial negative impact on daily life, psychosocial state, education, and mental health of parents and autistic children [2,3,4,5].

Objectives: In the present study, we further characterize the experiences of parents and autistic children, and adolescents associated with pandemic-related disruptions. Our goals were: (1) to characterize the effects on various aspects of family life, children’s functioning, psychosocial state, behavior, education, and development following the changes in daily routines as dictated by the Greek lockdown and (2) to contribute to the growing literature on the concerns and challenges of families of autistic children in the post-COVID-19 era providing evidence to shape future interventions.

Methods: Participants. The parents of 154 Greek-speaking autistic children and adolescents participated in the study (123 males and 31 females) (Mage: 6.29, Age range: 2-17 yrs.). Materials. An online parent survey constructed via google forms was sent out at the height of the lockdown (05/20/2020-01/02/2021). The questionnaire consisted of 82 questions divided into four sections: (i) information on COVID-19 and containment measures, (ii) managing quarantine with the child, (iii) children’s functional skills: feeding, sleeping, toileting, (iv) sensory issues and self-regulation, (v) cooperation and support from intervention services and special education, (vi) school, the management of the academic assignments and homework, (vi) parental professional activity, (vii) parent’s affective status during lockdown (stress) and support.

Results: During the COVID-19 lockdown, several autistic children remained calm (42.2%), while a sufficient number of children were stressed, upset, asked repeated questions, and even became aggressive (21.4%). Even though some parents during quarantine had the opportunity to communicate and play (51.3%) more with their autistic children being calm (due to the reduction of social demands) (25.3%), a significant percentage of children (36.4%) exhibited more hyperactivity than prior to the lockdown. Additionally, parents reported an increase in autism-related symptoms (stereotypic behaviors and echolalia (26.6%), tantrums (21.4%), and whining (31.2%)). Moreover, parents reported sleep disturbances with autistic children sleeping later than usual (44.1%) and an increase in sensory issues, such as auditory, tactile, and motor (43.4%). Moreover, most intervention and educational programs were interrupted during the lockdown (50%). When educational support was available in a virtual form, 36% of the children displayed aggressive behavior during those lessons. Finally, some parents (14.9%) found managing their children's behavior during the quarantine challenging.

Conclusions: Study findings showed that disruption of daily routines and services due to the COVID-19 lockdown had been proven especially challenging for Greek autistic children and their families. Most parents of autistic children and adolescents reported significant difficulties and concerns regarding their children’s developmental, behavioral, psychosocial setbacks due to COVID-19 lockdown. The impact of the restrictive measures of COVID-19 on autistic children and their families is still unfolding, with concerns regarding long-term effects on various aspects of their lives.
402.161 (Poster) Impacts of the COVID-19 Pandemic on Autistic Children and Youth, Their Families and Their Service Providers: Perceived Experiences and Recommendations

D. B. Nicholas, L. Zwaigenbaum, and R. Zulla, (1)University of Calgary, Edmonton, AB, Canada, (2)Autism Research Centre, University of Alberta, Edmonton, AB, Canada, (3)School of Public Health, University of Alberta, Edmonton, AB, Canada

Background: The impacts of the COVID-19 pandemic on autistic children/youth and their families as well as on service providers are not yet well-understood.

Objectives: This study aimed to identify lived experiences of autistic children and youth, their families and their service providers in the pandemic. We elicited perceived impacts of the pandemic on service access and support provision, and recommendations for pandemic recovery and preparedness for future health emergencies.

Methods: Autistic children/youth, parents and community service providers (e.g., early intervention, professional services, school providers) supporting children/youth and families were qualitatively interviewed. Participants were recruited from autism diagnostic and service organizations. Thematic analysis determined key themes in the data.

Results: Two autistic youth, 13 parents of autistic children/youth, and 18 service providers participated in interviews. Findings reveal that the pandemic and public health protocols resulting from the pandemic, imposed largely negative impacts on autistic children/youth and their families as well as on the practice and well-being of service providers. Challenges required prolonged efforts to cope, as many services were discontinued or reduced during pandemic ‘peaks’. Families were unclear about what services were available, generally with insufficient resources. The rapidly shifting environment and disruption in routines and services were challenging for children/youth, and for some, were difficult to understand and navigate. Parents reported their children to variably experience more problematic behaviors due to increased anxiety, disrupted routine and interrupted support, which in turn increased stress for parents as they tried to find ways to support their children. Service providers rapidly shifted practice, including transition to technology-mediated supports that incurred service delivery challenges. Safety protocols, such as the use of personal protective equipment (PPE), rendered service providers’ concern about their ability to optimally engage with children/youth. Resiliency emerged as families relied on individual (e.g., learning to create socially distanced activities) and community assets (e.g., one-to-one online school support) to buffer negative impacts. Likewise, service providers became creative and adapted supports in seeking to better meet children’s needs. In moving forward, all participant groups generally sought continued use of technology in service delivery, as appropriate, given convenience and access, but also raised concern with its ongoing use in some instances and with some individuals. Social narratives and other approaches to help children/youth better understand public health protocols were recommended, as were self-care protocols for parents and service providers. Timely, clear, and tailored communication regarding service delivery changes was desired.

Conclusions: Results highlight the need for autism-focused supports in pandemic or other disaster-related circumstances, including technological and preparedness capacity within community, therapeutic and educational sectors. Recommendations amplify the need for clear and targeted communication of risks, viable safety protocols, mental/psycho-emotional wellness strategies, and guidelines for person and family centeredness in emergent and shifting circumstances. There is critical need for principle-based pandemic recovery supports for autistic children/youth and their families, and proactive planning to ensure that when faced with pandemics or other geo-health crises or disasters, services are maintained and adapted to ensure that the support needs of autistic individuals and their families are met.

402.162 (Poster) Integrating Acceptance and Commitment Therapy (ACT) and Parent Meta-Emotion Philosophy (PMEP) with Parent Training

D. F. Stovall, B. Hansen, C. Yang, and R. A. Lundwall, (1)Psychology, Brigham Young University Psychology Department, Provo, UT, (2)Counseling Psychology and Special Education, Brigham Young University, Provo, UT, (3)Brigham Young University, Provo, UT, (4)Psychology & Neuroscience, Brigham Young University, Provo, UT

Background: Parents of autistic children experience significantly more stress when compared to parents of typically developing children. It is critical that parents have strategies to care for themselves to be effective in caring for their autistic children. With ACT and PMEP parent coaching, the goal is to increase psychological and emotional flexibility in parents while building the parent-child relationship.

Objectives: A virtual parent training intervention featuring ACT and/or PMEP was created to teach effective parent coaching skills. We anticipated parent training would lead to reductions in child negative behavior across intervention groups when compared to the control group.

Methods: Our sample consisted of 51 mothers representing 12 US states. All had at least one autistic child between the ages of two-five years for whom they were the primary caregiver (seven participants had two children who fit this criteria). Participants were recruited through social media and through local autism agencies. All interactions with participants were remote. After 2 weeks of baseline data collection, mothers were randomly assigned to one of four groups: (1) ACT & PMEP, (2) ACT, (3) PMEP, or (4) control group. Live ACT training occurred virtually for approximately 60 minutes, weekly during the 4-week intervention period (totaling 4 hours group training). Live PMEP parent group training occurred virtually for approximately 60 minutes during the 4-week intervention period (totaling 4 hours group training). Further implementation of ACT and PMEP was employed through parent-led, shared reading of widely available
children’s books by all groups. Mother assessments of child maladaptive behavior occurred prior, during, and following treatment (totaling seven measurements). A four-group latent growth curve model with Bayesian estimation was applied to examine the differences in the changes of child maladaptive behavior between the three intervention groups and the control group. The model fit the data satisfactorily ($p_{ppp} > .45$, and $CFI > .96$). The four groups started similarly at baseline in behavior as indicated by non-significant dummy-coded group effects. The model was specified to have two slope factors. The first piece examined changes from the baseline to the third measurement and the second piece examined changes from the third to the seventh measurement. The ACT group reduced child maladaptive behavior by $\beta_{1} = -2.09$, $p = .03$, $95\% CI [-4.26, -1.0]$ in the first three measurements, while the combined group, ACT & PMEP, reduced maladaptive behavior by $\beta_{2} = -2.24$, $p < .01$, $95\% CI [-3.77, -66]$ from the third to the seventh measurement.

Results: Parent training intervention that combined ACT with PMEP was more effective than either intervention alone in reducing child maladaptive behavior.

Conclusions: This novel design intervention was successful in identifying solutions for mothers and their autistic children through ACT and PMEP in a virtual parent training model. Our findings show that the combination of psychological flexibility with emotion coaching was superior to either intervention alone in reducing child maladaptive behavior.

402.163 (Poster) Intergenerational Pathways to Emotional Regulation: Implications for Parenting Stress and Preschoolers’ Challenging Behaviors
E. Glenn, C. L. Neece and L. L. McIntyre, (1)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (2)Psychology, Loma Linda University, Loma Linda, CA

Background: Parents play a significant role in shaping children’s behaviors and their responses to emotions. Research has established a strong, bi-directional effect between parenting stress and children’s challenging behaviors. Research also suggests the ways in which parents respond to their own emotions to accomplish goals, termed emotion regulation (ER), may affect the same process in their children. The role of parents in the development of ER is especially pronounced during the preschool period, and among autistic children. However, research has yet to clarify how both parent and child ER shape the relationship between parenting stress and children’s challenging behavior.

Objectives: This study aimed to explore the extent to which parent and child ER explain the pathway between parenting stress and children’s challenging behavior, among culturally diverse families of children with developmental delays (DD), including autism spectrum disorders (ASD).

Methods: Baseline data from 265 families enrolled in a multisite intervention study were used for this analysis. Many families were from culturally and linguistically diverse backgrounds, with 50% of the sample identifying as bilingual. 47% of children had a formal diagnosis of ASD. Multi-modal measurement methods (parent-report and observation) were used to measure ER for parents and children (DERS, ERC). Parenting stress was measured as a latent variable constructed from the Parenting Stress Index and Parenting Daily Hassles, while children’s challenging behaviors were measured using the CBCL. Confirmatory Factor Analysis indicated distinct constructs for different measurement modalities of ER, and thus, were tested separately in models. Thus, parental ER was modelled both as a broad “trait” level construct, as well as ER within the parenting context. Structural Equation Modeling was utilized to test parenting stress as a moderator of the relationship between parent and child ER (Figure 1A), and child ER and parenting stress as mediators of the relationship between parent ER and child behaviors (Figure 1B).

Results: Parenting stress moderated the relationship between parent and child ER ($CFI = 0.96; RMSEA = 0.055$, $SRMR = 0.060$; Figure 2), only for observational data. Hypotheses that parenting stress and/or child ER mediates the relationship between parent ER and children’s challenging behaviors (Figure 1B) were unsupported. Models indicated parenting stress and child ER were strong predictors of children’s challenging behaviors. Exploratory models suggested that child ER mediates the relationship between parenting stress and challenging behaviors.

Conclusions: These results indicate having low to average levels of parenting stress was a protective factor in the transmission of parental emotion dysregulation to children’s dysregulation. This study also showed from a multi-modal perspective, children’s ER capacities are strongly predictive of challenging behavior problems. The results of this study entail implications for both intervention and future research. Interventions which focus on either parenting stress or child ER may prevent the development of behavioral challenges in autistic children. Future research must work to clarify the interaction between parent ER and parenting stress, as well as from a developmental perspective, investigate how child ER mediates the relationship between parenting stress and children’s challenging behaviors.

402.164 (Poster) Examining the Impact of Relationships on Australian Autistic Adults’ Quality of Life: Preliminary Findings
Background: Quality of life (QoL) is an all-encompassing concept capturing an individual’s perception of their situation in life, comprising of physical, psychological, social and environmental factors set within the societal and cultural construct of the individual. People with diverse experiences of disabilities, health conditions and neurotypes can experience high QoL, even though they may objectively have functional challenges.

Relationships are one social factor important for QoL in neurotypical populations. The unique challenges autistic adults experience with social communication could impact their success in developing relationships, particularly with non-autistic individuals. Autistic adults report a strong desire to establish successful relationships, with research demonstrating the psychological impact of negative social experiences such as bullying or a lack of social relationships. Despite this, little exploratory research has been conducted to examine the impact of relationships on autistic QoL.

Objectives: This study sought to explore the impact of relationships on autistic QoL, specifically investigating relationship satisfaction, loneliness and subjective QoL of autistic adults in Australia.

Methods: Data from the Australian Longitudinal Study of Autism in Adulthood collected before the COVID-19 pandemic was utilised for this study. Demographic information (age, gender, marital status), loneliness (University of California, Los Angeles Loneliness Scale- 8 item [UCLS-8]), subjective QoL (World Health Organisation QoL- Bref [WHO-QOL Bref]), autistic traits (Autism Quotient-Short [AQ-S]), and social support satisfaction (Social Support Questionnaire [SSQ]) were collected from 205 autistic adults across Australia. Data were analysed using univariate statistics (Pearson’s and Spearman’s correlations), and four backwards entry multiple linear regression analyses were run to determine factors contributing to each of the four domains of QoL as specified in the WHO-QOL Bref.

Results: Satisfaction with social support was the only variable to appear in all four backward linear regression models and was the largest contributing variable in each model (p<.05, with fewer social supports correlating with poorer QoL across all domains. Loneliness appeared in both the social relationship and psychological domains of QoL and was the second largest contributor to these models (p<.05). Increased loneliness was associated with poorer QoL in the psychological and social-emotional domains. Higher autistic traits were associated with both lower physical health and psychological domain scores of QoL (p<.05). Age was associated with lower psychological QoL scores (p<.05). Gender only contributed to the social relationship model (p<.05). Marital status did not appear in any of the models.

Conclusions: The findings of this study demonstrate that social relationships influence all domains of autistic QoL, with loneliness being additionally associated with poorer psychological and social relationship QoL for autistic adults. Marital status did not influence autistic QoL, but the quality of marital relationships was not assessed. Our findings suggest that other types of relationships may influence autistic QoL. Future research should investigate the influence of different relationships, such as friendships, as well as the quality of marital relationships on autistic QoL.
Objectives: To qualitatively explore factors that contribute to autistic adults’ QoL from autistic perspectives.

Methods: This study utilised a qualitative semi-structured interview method to capture the experiences of autistic QoL. Guided by a co-production approach, two autistic researchers and a steering group of five autistic adults were involved in developing the methodology and the interview guide; 29 autistic adults aged 18 – 55 who lived in Australia were interviewed. All interviews were transcribed verbatim and thematically analysed by the lead author (RK). Excerpts from the first two interviews were shown to the steering group (trained in thematic analysis), who reviewed the coding structure prior to analysis of the additional transcripts. The steering group then met to refine the codes into themes. Similarities between the themes and the International Classification of Functioning Disability and Health (ICF) were identified. Therefore, some results are presented according to level two ICF codes (table 1).

Results: Co-produced thematic analysis identified four themes (Table 1). Activities and participation comprised six subthemes summing meaningful activities and the routines autistic adults constructed around these. Many of the activities within these subthemes enhance autistic QoL when autistic adults can engage in them. Mind and body refer to aspects of the individual and consist of five subthemes. Participants described aspects of their mental and physical health and the influence of sensory preferences on their QoL, with many interconnected factors having a compounding impact on QoL. The environment theme consists of four subthemes, with societal attitudes said to negatively impact autistic QoL and social supports and relationships described as positively influencing QoL when autistic adults had relationships they wished to establish. Finally, the theme of personal experiences encompassed subthemes of self-identity, independence, and strengths. Participants described the profoundly positive impact of understanding themselves on their QoL.

Conclusions: Autistic adults described factors unique to their experience of QoL, including understanding their self-identity, sensory experiences, and the impact of societal attitudes. While other elements appear in non-autistic conceptualisations of QoL, the impact and importance of these factors may vary from non-autistic experiences. Further research should establish how existing QoL measures compare to autistic adults’ conceptualisation of QoL.

402.166 (Poster) Autistic Patients, Caregivers and Staff Experiences of the Acute Hospital Setting: What Are the Gaps? Results from a Scoping Review.
E. Greenwood, A. Cooklin, J. Barbaro and C. Miller, (1)Nursing, Judith Lumley Centre, Bundoora, VIC, Australia, (2)Judith Lumley Centre, Bundoora, VIC, Australia, (3)Australian Research Council Future Fellowship (FT200100209), Bundoora, VIC, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (5)University of Melbourne, Parkville, VIC, Australia, (6)La Trobe University, Bundoora, VIC, Australia

Background: Due to co-occurring conditions and complex health care needs, autistic individuals make significantly more hospital visits compared to the general population and are 2.1 times more likely to attend the Emergency Department (ED) with longer length of stay and higher associated medical costs. Despite the increasing rate of hospital presentation, autistic patients’ experiences with hospital services have been mixed. While positive experiences about hospital admission have been shared and reported, significant challenges and negative experiences exist that impose barriers and predict care satisfaction. It is critical to understand the unique experiences of autistic patients to improve care and facilitate better hospital experiences.

Objectives: The overall objective of this scoping review was to explore the patient, caregiver, hospital system and staff that affects the experiences of autistic patients in the hospital setting, highlight the gaps in knowledge, and inform future research to support better health outcomes during hospitalisation.

Methods: Using a formal scoping review methodology, a literature search was conducted to include international, peer-reviewed literature about autistic patients and their hospital experiences. Citations were double-screened according to predetermined eligibility criteria, yielding a total of 30 articles.

Results: Autistic patients face several barriers affecting their experiences in healthcare delivery in the hospital setting, as do their families and health staff. Two themes emerged; the first was “barriers that impact negative hospital experiences,” which related to communication (pain, communication difficulties, inconsistent handover), heterogenous presentation (increase fear and agitation), parents and carers (disregard for their expertise, lack of accommodation), and systemic related barriers (minimal staff knowledge, environment, and sensory issues). The second theme was “facilitators that improve hospital experiences,” which included autism care pathways to address individualised needs, collaborative care for parents and expert partnership and systemic support (staff training, ease waiting time and minimising patient transition).
Conclusions: The evidence supports that autistic individuals are susceptible to chronic health conditions alongside lower quality and unmet healthcare needs than others. The findings of this review highlight barriers and facilitators to support autistic patients to adapt to the complexity of hospitalisation. A collaborative, inclusive approach is required to meet the significant challenges overwhelming the autistic patient both in health care access and hospitalisation. Furthermore, the review highlighted the critical need for co-design initiatives to include the lived experience of the autistic community, so that change is created with autistic voices at the forefront.

402.167 (Poster) General Practitioners’ Perspectives Regarding Early Developmental Surveillance for Autism within the Australian Primary Healthcare Setting: A Qualitative Study

J. Barbaro,1,2, M. Gilbert,3, T. Winata,4, F. Khan,5, C. Dissanyake4, and V. Eapen5,6,1,2, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), The University of Queensland, Indooroopilly, QLD, Australia, (3)Discipline of Psychiatry and Mental Health, Faculty of Medicine, University of New South Wales, Sydney, NSW, Australia, (4)Academic Unit of Infant, Child and Adolescent Psychiatry, South Western Sydney Local Health District, Sydney, NSW, Australia, (5)Ingham Institute for Applied Medical Research, Liverpool, NSW, Australia, (6)Olga Tennison Autism Research Centre, Olga Tennison Autism Research Centre, Melbourne, VIC, Australia

Background: Significant challenges remain in the early identification of developmental disabilities, including autism, in the community. Access to appropriate supports early in the life course has been shown to promote positive developmental outcomes for children at high likelihood of developmental disabilities, including autism.

Objectives: As part of a cluster randomised control trial, this study sought to examine and compare the perspectives and experiences of Australian general practitioners (GPs; family doctors) in primary care clinics using a digital developmental surveillance program for autism with those using the usual care pathway.

Methods: A qualitative research methodology (semi-structured interviews and thematic analysis) was utilised in this study. All GPs from South-Western Sydney (New South Wales; NSW) and metropolitan Melbourne (Victoria) who participated in the main study, “GP Surveillance for Autism” (Barbaro et al., 2021), were invited to be interviewed. GPs who provided consent were interviewed over the phone, online, or in person. Interviews were audio-recorded, transcribed, and coded using NVivo12 software. An inductive interpretive approach was adopted, with data analysed thematically.

Results: A total of 23 GPs across the two sites (NSW: n = 11; Victoria: n = 12) agreed to be interviewed, with data saturation reached following this number of participants. Inductive semantic coding and analysis yielded nine major themes. Common enablers highlighted by participants included the role of GPs in early identification and supports/services, enhanced communication between clinicians/professionals, relationship-building with patients, and access to standardised screening tools. Specific facilitators to the feasibility and acceptability of the digital screening program included having access to specific assessments and resources for the early identification of developmental disabilities, including the early signs of autism, with access to such tools increasing their confidence in conducting developmental surveillance. Those in the digital screening program also highlighted the importance for GPs to participate in further research and education as part of their ongoing fellowship training. Several practical and socio-economic barriers were identified, as were the barriers of limited knowledge and uptake of developmental screening tools. Additional recommendations involved supporting GPs in developmental/paediatrics training, streamlined screening processes, and funding and resources in the primary health care setting. The impact of the COVID-19 pandemic and associated lockdowns was also highlighted. While some participants noted feeling more comfortable with traditional paper-based work than digital interfaces, an unexpected benefit of the COVID-19 pandemic was a shift towards digital systems, delivering greater efficiencies for GPs and families.

Conclusions: The findings from this study provide valuable insights into the perceptions and experiences of Australian GPs regarding the contextual enablers and barriers that impact their participation in developmental surveillance programs and, in particular, the potential and beneficial usage of digital screening tools for developmental surveillance of autism and other developmental disabilities. The study highlighted the need for practice and policy changes, including further training of GPs in developmental disabilities, alongside the provision of sufficient time and public healthcare funding to complete developmental surveillance. Further education is needed on implementation and scale of a national surveillance program for the early identification of developmental disabilities including autism.

402.168 (Poster) Exploring Caregiver Perspectives on Acceptance and Commitment Therapy and Application to Early Intervention for Young Autistic Children

C. Lee,1 J. A. Brian,2 Y. Lunsky,3 R. Ashcroft,4 K. Fung,5 R. Lerner1 and M. Penner1, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)University of Toronto, Toronto, ON, Canada, (5)UHN - Toronto Western Hospital, Toronto, ON, Canada

Background: Caregivers of young autistic children face high levels of stress. With increasing focus on caregiver-mediated early intervention, which requires that caregivers learn and implement skills to address their child’s developmental needs, the stress experienced by caregivers may impact their participation. Currently available mental health interventions, including acceptance and commitment therapy (ACT), target caregiver stress but are not well-studied in caregivers with young autistic children and who are participating in early intervention.
Objectives: To identify caregivers’ perspectives on: i) the benefits and disadvantages of participating in ACT, and ii) the potential application of ACT to those caregivers whose children are participating in early intervention.

Methods: This qualitative study utilized reflexive thematic analysis with a constructivist approach to explore caregivers’ perceptions of ACT. Demographic information was collected and semi-structured interviews were conducted with 8 caregivers from Ontario, Canada. Interviews were coded and themes generated from the codes. Themes were revised based on feedback from the research team and member checking.

Results: Participants included mothers from single or dual parent households with 1-2 autistic children or adults diagnosed before age 5 years who had taken an in-person or virtual ACT workshop between 2012-2020. In exploring the benefits and disadvantages of ACT, the theme changing caregiver’s perspective on prioritizing self/highlights the shift in our participants’ focus to their own needs through accepting and managing their emotions and stress, aligning their actions with their chosen values, and moving towards acceptance of their child. Participants acknowledged feeling supported through establishing a community of other caregivers with whom they could share experiences and process emotions in a psychologically safe environment. Despite practical barriers to accessing ACT, participants noted their experiences in learning ACT were facilitated by their shared philosophies, use of imagery and hands-on activities to reinforce complicated concepts, and participation in a group designed to train ACT facilitators. Participants also shared their views on applying ACT to early intervention, providing their recommendations about accessibility, workshop timing and features, and community support.

Considerations prior to participating in ACT included addressing gaps in messaging around the importance of caregiver mental health and wellness and a caregiver’s readiness to seek wellness support. Participants also maintained the importance of highlighting a child’s strengths and acceptance of the child.

Conclusions: This qualitative study is the first to explore the experiences of caregivers of autistic children with learning and practicing ACT. Themes from this study highlight the internal process whereby caregivers begin shifting their focus on their own mental health needs, as well as the relational aspects of the group that contribute to the feeling of support. Though ACT participants had varying personal experiences with early intervention, their insights into integrating ACT along with early intervention provide a starting point in developing a truly family-centred intervention that honours the reciprocal relationship between child and caregiver.

---

**402.169 (Poster) Caregiver Mental Health Needs in Caregiver-Mediated Early Intervention**

C. Lee1, J. A. Brian1, Y. L Lansky1, R. Ashcroft1, K. Fung1, R. Lerner1 and M. Penner1, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)UHN - Toronto Western Hospital, Toronto, ON, Canada

Background: Caregivers of autistic children face high levels of stress and are at risk of developing mental health disorders. Caregivers participating in caregiver-mediated early interventions (CMIs), such as the Social ABCs, where they provide the intervention to their young child, juggle many responsibilities to their child and family, leaving self-care as the last priority. Caregivers may not seek mental health support, though interventions for caregiver stress, such as acceptance and commitment therapy (ACT), exist. This study represents the first step in addressing the gap in mental health supports for caregivers who are participating in CMIs.

Objectives: To understand the mental health needs of caregivers participating in a CMI.

Methods: This study utilized reflexive thematic analysis with a constructivist approach to explore caregivers’ experiences of a CMI, the Social ABCs. Demographic information was collected and semi-structured interviews were conducted with 13 caregivers from the Greater Toronto Area (Ontario, Canada). Interviews were coded and themes were generated from the codes. Themes were revised based on feedback from the research team and member checking.

Results: Demographic data revealed that participants included mothers and fathers from a range of racial/ethnic backgrounds and from mainly dual parent households with 1-2 autistic children. Participants of the Social ABCs verbal and in-person group-based and individual formats from 2018-2021 were included. Four central themes derived from this study illustrate the mental health needs of caregivers participating in the Social ABCs, including: social emotional connection, caregiver wellness tied to child’s success, perceived wellness needs and culturally sensitive care (Figure 1). Given the emotional intensity of caregivers’ experiences early in their journey with their young child, social emotional connection refers to the caregiver’s need to connect with other caregivers or professionals with understanding of their experiences in a psychologically safe environment. In navigating supports for their child and early intervention in particular, caregivers may place an overwhelming focus on building their child’s skills. This emphasis on seeing their child progress directly impacts a caregiver’s own wellness, as illustrated by the theme caregiver wellness tied to child’s success. Despite caregivers acknowledging the importance of their own mental health and well-being or their perceived wellness needs, caregivers may prioritize their own wellness needs below the needs of their child and family. The provision of culturally sensitive care was also highlighted as it poses a barrier to accessing wellness supports for already marginalized caregivers.
Conclusions: This qualitative study is one of the first to explore caregiver wellness and mental health needs in the context of a CMI. Caregivers identify a need for culturally sensitive, psychologically safe formal and informal social supports, which includes mental health support. Given the intense focus caregivers may have on accessing and participating in supports for their child, clinicians should deliver balanced messaging about the importance of the child’s skill development and caregiver mental health and wellness as there may be bidirectional impacts. Future research on CMI should consider ways to address caregiver mental health needs during the intervention to optimize overall family functioning.

Background: Since autism diagnosis is directly linked to the availability of supportive services, identifying best practices for early diagnosis of autism has long been a concern of professionals and families. Meanwhile, studies show persistent racial disparities in autism diagnosis. Although numerous clinical diagnostic guidelines have been published, there is not enough discussion of diagnostic procedures through the lens of culturally diverse families.

Objectives: This study focuses on the autism diagnostic experiences that Korean immigrant mothers had with their children.

Methods: Eleven first-generation Korean-American mothers of children with autism were included in the study. The data was collected using semi-structured interviews in Korean. The interview data were inductively analyzed through a cyclical analysis identifying patterns and themes throughout the interview transcripts. Major categories of codes were developed from the open codes by making connections between category and subcategories. The major categories functioned as informing and illustrating the key factors contributing to the identification process of the children of the participants.

Results: The main five factors (i.e., cultural beliefs and values, language barriers, complex emotions, immigration and navigating systems, and facilitators and assets) that mainly influence the diagnosis process were identified through thematic analysis. Dynamics are interactive within and between the factors, influencing the entire diagnostic process by either delaying or facilitating the identification of a child’s autism and the provision of treatment. The analysis highlighted culture as a crucial factor in the diagnostic process for the participants. There were three areas through which culture influenced participant perception of what disability entails and the stigma of being diagnosed with autism in Korea. These areas included the perception of autism as a severe disorder, word choices reflecting medical model approach to autism, and insufficient awareness about autism as a result of limited historical interactions with individuals with disabilities of the parents themselves. The participants also experienced a language barrier which contributed to the challenges in accessing resources and services for their children and or understanding the extent of their child’s needs. More, participants received inconsistent recommendations regarding using the native language versus English. However, regardless of the recommendations received, all participants reported speaking only English in the home.

Conclusions: Findings from this study imply that there are several barriers for toddlers with autism to receive a formal diagnosis in Korea. For instance, participants who attempted to pursue evaluation in Korea struggled to receive a diagnosis despite recognizing their child’s early signs of autism. It was reported by participants that the heightened threshold for diagnostic criteria was one of the barriers in timely identification in Korea. Additionally, mothers were told that clinicians were unable to provide a formal diagnosis of autism for children under three. As previous literature suggests that the prevalence of autism in Korea will increase as more accurate diagnoses are made and awareness of the autism spectrum increases (Kim et al., 2011), future studies must examine the extent to which these factors contribute to the discrepancy between the actual prevalence of autism and the identified diagnosis.

Background: Participation in leisure activities for children with Autism Spectrum Disorder (ASD) is important in supporting their psychological well-being and peer relationships, enabling exploration of their interests and enjoyment. While previous research has shown that participation in leisure activities can significantly improve the well-being of children with ASD, there is a need for more research on the specific factors that influence and facilitate participation in these activities.
examined the differences in the participation of adolescents with ASD and their peers in leisure activities, little is known regarding the levels of interest and participation for younger children with ASD and the barriers and facilitators of their participation.

Objectives: To compare the interest and participation in leisure activities between children with ASD aged 4 to 12 years and their neurotypical developing (TD) peers and identify the barriers and facilitators to participating in leisure activities for children with ASD from caregivers’ perspectives.

Methods: A cross-sectional online survey using a modified version of the Pediatric Interest Profiles (PIP) (Henry, 2000) to capture the interest and participation profiles of children with and without ASD. The leisure domain covered eight categories including club, creative, exercise, intellectual, outdoor, relaxation, socialising and sports across 100 items. Caregivers of children with and without ASD completed the PIP together with their child. Open-ended questions followed each domain for caregivers to provide further details on the barriers and facilitators to participating in each category. The Mann-Whitney U test was used to compare the two sample scores. Directed content analysis was used to analyse the barriers and facilitators of leisure activity participation based on the framework developed by King et al. (2009). A total of 38 children (17 with ASD, 21 without ASD) aged between 4 – 12 years (53% female) participated. All sixteen caregivers of children with ASD were parents (95% mother).

Results: We found great similarity among the activity categories in which both children with ASD and their TD peers were interested and participated in. Both groups were interested in creative, outdoor, socialising and relaxation activities. However, children without ASD showed a significantly higher level of interest in the categories of creative ($p=0.002$, $r=0.5$), exercise ($p=0.002$, $r=0.5$), outdoor ($P<0.001$, $r=0.6$) and socialising ($p=0.006$, $r=0.4$). The most engaged activities by both groups were in the areas of creative, intellectual, relaxation, and outdoor. Similarly, children without ASD showed a significantly higher level of participation in the categories of creative ($p=0.009$, $r=0.4$), exercise ($p=0.034$, $r=0.3$), outdoor ($p=0.002$, $r=0.5$) and socialising ($p=0.002$, $r=0.5$).

The barriers and facilitators of leisure activities were grouped under environmental factors, family factors and child factors. Environmental factors included the attitudes of society, physical environment, programs and activities, system and policy, informational support, and supportive relationships for the child. Family factors comprised financial, time impact on family and supportive home environment. Child factors included child’s emotional, behavioural and social function, child’s physical, cognitive and communication function, child’s perception own athletic and scholastic competence and child’s preferences.

Conclusions: While children with ASD show interest in a range of activities including outdoor and social activities, however, their participation rate is significantly lower than their TD peers. Understanding the barriers and facilitators to participation could help improve their participation and bridge the gap for children with ASD.

423.146 (Poster) Lessons of Remote Learning: Perspectives of Parents of Students with Special Education Needs

H. McAvoy*, G. B. Salinas*, C. Nettle*, K. J. Leon*, Y. Bolourian† and J. Blacher*, (1)University of California, Riverside, Riverside, CA, (2)School of Education, University of California Riverside, Riverside, CA, (3)Independent Researcher, Los Angeles, CA, (4)School of Education, University of California, Riverside, Riverside, CA

Background: The pandemic halted in-person teaching for most school-aged children, bringing rise to remote learning globally. The full impact of this disruption to education is not fully known, especially among students in special education, though early research indicates negative impacts on services and mental health (Rosencrans et al., 2021). There is a small body of evidence indicating some benefits to remote learning, especially among autistic students (Reicher, 2020).

Objectives:

The current study aims to better understand the parent experience of remote learning for children with special education needs. With half of this sample representing autistic students, this is of particular interest.

Methods:

Participants were from the Parent Experience of Remote Learning Study (PERLS), a longitudinal study funded by the National Institute on Minority Health and Health Disparities that surveyed parents of school-aged children in Southern California, once a month for six months starting in March 2021. At timepoint one, respondents were asked what would have made at-home schooling more effective for their child with special needs. 281 respondents reported having at least one child who received special education services, with 43.2% qualifying under the eligibility of autism. Among these participants, 61.6% (n=173) responded to this optional, open-ended question. Responses of ‘no’ or ‘n/a’ were excluded from qualitative analysis (n = 28), leaving 145 codable responses to be analyzed using thematic analysis. Three responses were double-coded, yielding a sample of responses 148. A team developed a codebook of common themes; responses were coded with 75% agreement.

Results:
Results of the thematic analysis are shown in Figure 1. 10.14% of respondents reaffirmed their satisfaction with remote learning. 24.32% of the responses were related to themes that centered around socialization or relationships. These themes included Relationship with Teacher, Socialization Opportunities with Peers, and Social Support; the most common theme was Relationship with Teacher (13.5%). 6.8% of responses indicated a desire for more socialization with peers, and 4.1% of parents desired social support for themselves. Quantitative analysis revealed that these participants reported overall satisfaction with their child’s current schooling, with 79.0% indicating being at least somewhat satisfied that school year, and 83.6% reported satisfaction with the delivery of their child’s special education services. When asked how often they were concerned about their child’s social development, 80.7% of respondents indicated that they were concerned at least half the time.

Conclusions: The current study demonstrated that the sample were overall satisfied with remote learning, with some expressing preference for this method of teaching. Though parents were satisfied with their child’s schooling, they expressed concern over their child’s social development. In fact, qualitative analysis revealed that a common support parents desired was related to building relationships with peers and the teacher. Students who choose to remain in remote learning may benefit from supports related to building relationships with teachers and peers, especially autistic students in remote learning who are already prone to poorer student-teacher relationships than their non-autistic peers (Caplan et al., 2016).

423.147 (Poster) Life Experiences of Siblings of Autistic Individuals in a Low Resource Country: Impact of a Peer Support Group
D. Taneja and S. P. K. Jena1, (1)Jindal School of Psychology and Counselling, O. P. Jindal Global University, Sonipat, India, (2)Delhi University, New Delhi, India

Background: Having a person with autism can be challenging for all family members, including typically developing siblings of the autistic individual. While seeking support and services for the person on the spectrum, Parents usually interact with other parents, and thereby form a support system. However, for siblings, the experience of living with a brother or a sister with autism can feel ‘alone’, as it is common for siblings to be left behind. Siblings spend most of their life resenting their sibling, without understanding the implications of having an autistic sibling. In a country like India, where there is no state support, typically developing siblings are an answer to most parent’s ‘what after us’ question. This unspoken daunting cultural expectation often leaves typical sibling with many unanswered questions. The present study seeks to understand experiences of siblings of individuals with autism, and also study impact of peer-support programme based on an American model Sibshops on sibling relationships.

Objectives: This study aimed at understanding needs of typically developing siblings, including their feelings, emotions, adjustment and coping. It further aimed at exploring impact of peer support programme on feelings, emotions and relationship of typically developing siblings of autistic individuals.

Methods: Nine typically developing siblings participated in peer-support programme at an autism organisation in New Delhi, India. A safe place for siblings to share their feelings with other participants, twelve 3-4 hours long sessions were conducted over four months. The sibling support model Sibshops was adapted for the Indian culture and was a mix of fun and discussion activities focussing on peer support. The programme was a safe place for siblings to share their feelings with other sibling participants. The typically developing siblings and their parents were interviewed at the beginning and at the end of the programme. In addition, activities of the peer-support programmes were designed to capture different emotions and feelings towards the typically developing siblings. These discussion activities as well as the pre and post interviews were audio recorded and transcribed. Qualitative analysis using grounded theory was utilised to understand various emotions, feelings and to understand the relationship of typically developing children with their brother or sisters with autism.

Results: Findings from sibling measures indicated increase in knowledge of autism; decrease in anger/resentful feelings towards autistic siblings; use of more positive coping styles; decreased emotional, conduct, and peer problems of typically developing siblings. Parents reported decreased negative behaviours towards autistic siblings, and improved relationship.

Conclusions: This is one of the first studies in a low resource country like India studying typically developing siblings of autistic individuals, which also tries to study impact of providing peer-support. Results support need for group interventions and evaluation to improve mental health functioning of this group. Study has implications for running sibling support groups in LMIC.

423.148 (Poster) Maternal Early Deleterious Conditions Shape the HPA Axis of Her Future Offspring: A Nonhuman Primate Model of Intergenerational Stress Transmission
E. K. Wood, S. G. Lindell, M. L. Schwandt, C. S. Barr, S. J. Suomi and J. D. Higley, (1)School of Medicine, Oregon Health and Science University, Portland, OR, (2)National Institute on Alcohol Abuse & Alcoholism, National Institutes of Health, Rockville, MD, (3)National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, MD, (4)Eunice Shriver Kennedy National Institutes of Child Health and Human Development, National Institutes of Health, Poolesville, MD, (5)Brigham Young University, Provo, UT

Background: Children are born with a limited capacity to regulate their own emotional state. A sensitive caregiver promotes infant development of self-regulation over time by coregulating their infant’s arousal. Identifying factors that influence a caregiver’s capacity to sensitively coregulate with their infant is important for supporting caregivers in their role. Certain early life events associated with chronic
dysregulation of the stress response impact hypothalamic-pituitary-adrenal (HPA) axis development and behavioral outcomes. Nonhuman primates studies show that rearing in the absence of a mother leads to dysregulated HPA axis functioning over the lifespan. The impact of this dysregulation on future caregiving behaviors and future offspring outcomes is unclear, particularly as they relate to infant arousal regulation.

Objectives: We examine the consequences of deleterious early conditions on maternal HPA axis functioning and caregiving behaviors, as well as their impact on the HPA axis development of future offspring.

Methods: 569 rhesus monkeys, including 276 mother-infant dyads, were followed from infancy to adulthood. Mothers were reared in one of three conditions: 1) mother-reared (MR) in normative conditions, 2) peer-reared (PR) without mothers but in the constant presence of same-age peers, or 3) surrogate-peer-reared (SPR) without mothers and with limited daily contact with same-age peers. Stress-induced plasma cortisol and adrenocorticotropic hormone (ACTH) were collected from mothers on six occasions, from day-14 to day-180 of life. Those females that eventually became mothers themselves reared their own offspring in normative, MR conditions. Stress-induced cortisol and ACTH concentrations were collected from offspring on six occasions, from day-14 to day-180 of life. Maternal caregiving behaviors were recorded twice-weekly from birth until day-180 of offspring life. We examined associations between maternal early rearing conditions and: 1) maternal stress-induced ACTH and cortisol concentrations in her own infancy, 2) maternal caregiving behaviors, and 3) offspring stress-induced ACTH and cortisol concentrations.

Results: Results showed that stress-induced plasma ACTH and cortisol concentrations were blunted among PR and SPR subjects, particularly during the first 90 days of life. During stress-inducing conditions, offspring raised by PR or SPR mothers exhibited blunted ACTH and cortisol levels over the first 180 days of life, while those reared by MR mothers showed elevated ACTH and cortisol concentrations (see Figure 1). The caregiving behavior of PR and SPR mothers was characterized by high rates of infant rejection, particularly in the first 30 days of life.

Conclusions: These results suggest that offspring HPA axis functioning is shaped by their mothers’ own early experiences, and that these effects may result, in part, from maternal difficulties in regulating their own arousal. A study exploring factors that may alleviate the relationship between maternal adverse childhood experiences and offspring socioemotional outcomes is underway in humans. To the extent that these results generalize to humans, they suggest that caregivers come into their role with their own life histories and experiences, which may impact offspring socioemotional outcomes. While infants play a role in dyadic caregiver-infant interaction, these findings suggest that enhancing a caregiver’s capacity to coregulate their infant’s arousal is an important target for promoting healthy socioemotional outcomes.

423.149 (Poster) Maternal Health Habits and Observed Parenting in Mothers of Preschool Children with Autism Spectrum Disorder

M. Johnson; M. Brassard; and L. B. Jahromi; (1) Teachers College, Columbia University, New York, NY, (2) Brassard Practice, New York, NY

Background: Mothers of children with Autism Spectrum Disorder (ASD) report high levels of stress, depression, marital strain, and divorce, with little time to devote to their own health (e.g., sleep, diet) due to the high demands of their child’s care. Despite their well-documented high levels of stress and the relationship of stress to negative parenting, there are few observational studies of parenting in this population and few on health habits impact on quality of parenting. Health habits are modifiable and experimentally related to reduced stress and better health and functioning. There is a need to identify areas of possible intervention to better support parents of this population.

Objectives: This study examined parents health habits (e.g., sleep, exercise, diet) which have a known relationship to overall wellbeing. The purpose of this study was to investigate whether these habits demonstrated a relationship to observed parenting behaviors of mothers of children with ASD.

Methods: Participants were 42 mother-child dyads, with children ages 2-6 to 5-6 recruited from a preschool utilizing an Applied Behavior Analysis (ABA) approach to schooling. All children had a clinical diagnosis of autism that was confirmed with the Autism Diagnostic Observation System – Two (Lord, Rutter, DiLavore, Risi, Gotham, & Bishop, 2012). Parenting behaviors were observed across three tasks designed to mirror naturalistic mother-child interactions, which were videotaped for later coding using the Psychological Multifactor Scale – ASD Adapted Preschool Version (Brassard, Donnelly, Hart, & Johnson, 2016). Mothers completed questionnaires on parental stress, maternal depressive symptoms, and health habits. Parental stress was measured with the Parenting Stress Index – Fourth Edition, Short Form (Abidin, 2012). Depressive symptoms were measured through the Patient Health Questionnaire-9 (Kroenke, Spitzer, & Williams, 2001). Health habit questions were adapted through the Promise Neighborhoods RFA Indicators and the Promise Neighborhoods Research Consortium [PNRC] Measurement System: Promise Neighborhoods Research Consortium: Measures, 2001).

Results: More than half of the mothers demonstrated sufficient sleep, eating habits varied significantly in quality, exercise was infrequent, and most mothers did not smoke and had not been asked to lose weight. Observed parenting behaviors were found to be skewed with most
Mothers using high levels of positive parenting behaviors and low levels of harsh parenting behaviors. Those who did engage in negative parenting reported higher levels of stress.

Health habits were significantly related to quality of parenting for both positive and harsh parenting in a serial multiple mediation model. Higher levels of health habits related to lower levels of maternal depressive symptoms, which related to lower levels of parental stress, which related to more instances of positive parenting (r=.64) and fewer instances of harsh parenting (r=.24).

Conclusions: Mothers in this sample reported higher levels of stress and maternal depressive symptoms compared to normative samples, consistent with the literature on parents of children with ASD. Promoting good health habits in mothers of children with ASD should be explored as an intervention for reducing stress and depression and improving quality of parenting.

423.150 (Poster) Maternal Mental Health and Early Child Cognition in Infants at Elevated Risk for Autism

Background: Research suggests that autism risk is conferred by a gene x environment interaction, weighted higher on the side of environment (Bolte, Girdler, & Marschik, 2019). One suggested form of environmental influence is maternal mental health. Mothers with depression and anxiety experience stress during and after pregnancy, which leads to perinatal environmental differences that influence development (Karimi et al., 2017; Gudsnuck & Champagne, 2012). In the general population, parental depression and anxiety has been shown to have an impact on early child cognition (Glover, 2014). Past research suggests infants at elevated-risk for ASD at 6 months have lower visual reception (VR) skills compared to typical-risk infants (Estes et al., 2015).

Objectives: This project aims to understand how maternal mental health relates to child early cognitive functioning in infants at elevated-risk or typical-risk for autism outcomes. We first examine visual reception as a domain of cognitive skill in 6-month old infants in elevated-risk vs typical-risk infants. We then examine if maternal mental health scores are related to early child cognition and if this relationship differs for the elevated-risk mother-infant dyads vs the typical-risk mother-infant dyads. We will also explore, in our longitudinal design, relationships between child cognition at 6 and 12 months and maternal mental health.

Methods: Data from 102 participants in the Washington Study of Outcomes, Neural Development and Early Risk (WONDER) was used in the analysis. Participants included families with children who are divided into three groups for analysis: (1) Elevated-Risk-Familial (ER-F) (n=65, 50.8% Male) with at least one incidence of autism in the direct family; (2) Elevated-Risk-Low Birth Weight (ER-LBW) (n=27, 55.6% Male) were infants born with low-birth weight but no familial history of ASD; (3) Typical-Risk (TR) (n=10, 40% Male) were infants with no familial history of ASD. Mental health was assessed using the Beck Anxiety Inventory (BAI) and Beck Depression Inventory (BDI). Self report was included from the biological maternal caregiver (individuals epigenetically related and involved in gestation). Mullen Scale of Early Learning (MSEL) was used to assess child VR scores across two time points (6 and 12 months).

Results: Preliminary analysis shows no significant differences between groups for VR at 6 months (F=0.307, p=.736). One-way ANOVA was run to compare depression and anxiety total scores by group. A significant main effect of group existed for anxiety (F=4.846, p=.01) but not depression (F=2.703, p=.072); mothers in TR (M=11.25, SD=3.56) compared to ER-F (M=4.48, SD=4.27) and ER-LBW (M=5.15, SD=5.47) reported higher anxiety. Bivariate correlation found no significant correlation between VR scores at 6 months and maternal mental health. Future analyses at 12 months will be conducted for presentation.

Conclusions: In our preliminary analyses, no significant difference was found in VR skills at 6 months between groups at elevated-risk and typical-risk for ASD. While maternal anxiety was increased in TR compared to ER-LBW and ER-F at 6 months, there was no relation between maternal mental health and child cognition.

423.151 (Poster) Measurement Invariance of the Promis Emotional Distress and Subjective Well-Being Domains Among Autistic and General Population Adolescents

Background: Quality of life (QoL) is a high priority for autism research, but psychometric validation of QoL measures in autistic populations is lacking. To accurately measure autistic QoL with a scale developed on the general population, researchers must confirm it functions similarly for autistic people.
**Objectives:** Determine whether scales within the Emotional Distress and Subjective Well-Being domains of the Patient-Reported Outcomes Measurement Information System (PROMIS) demonstrate measurement invariance across autistic and general population teenagers (14-17 years).

**Methods:** We evaluated the pediatric self-report forms of the Emotional Distress (Anger, Anxiety, Depression, and Psychological Stress) and Subjective Well-Being (Life Satisfaction, Meaning & Purpose, and Positive Affect) domains of the PROMIS. We conducted secondary confirmatory factor analyses (CFAs) on data from 140 autistic and 1,627 general population adolescents. We fit CFA models to the baseline PROMIS model for each group independently, then combined data across groups to establish configural invariance. Next, we evaluated metric invariance by constraining factor loadings to be equivalent across groups, with freely varying intercepts, and compared fit to the configural models. This analysis tested whether the pattern of item loadings is equivalent across groups. Third, we evaluated scalar invariance by constraining factor loadings and item intercepts to be equivalent across groups and compared fit to the metric models. This analysis tested whether equivalent scores on the scales imply equal levels of the construct in autistic and non-autistic teens.

**Results:** Invariance was determined based on nonsignificant chi-square difference tests (p values > .05) and minimal deterioration in model fit (ΔCFI values < -.002). Within the Emotional Distress domain, only Depression demonstrated full scalar invariance across groups. Anger and Psychological Stress met criteria for configural and metric invariance, but not scalar, as model fit deteriorated between metric and scalar invariance. Anxiety did not demonstrate metric or scalar invariance. Within the Subjective Well-Being domain, only Positive Affect demonstrated full scalar invariance across groups, although notably the base model fit for Positive Affect was marginal (CFI = .87). Life Satisfaction and Meaning & Purpose scales did not meet criteria for metric or scalar invariance (see Table for results).

**Conclusions:** PROMIS scales demonstrated varying degrees of measurement invariance across groups of autistic and general population adolescents. Because Depression and Positive Affect demonstrated scalar invariance, scores can be meaningfully compared across groups. Anger and Psychological Stress demonstrated metric, but not scalar, invariance, indicating that while variables are measuring the same latent construct, comparing group means is not psychometrically supported. However, scores on these scales can be validly used to measure these constructs within the autistic population. Anxiety, Life Satisfaction, and Meaning & Purpose did not meet criteria for metric or scalar invariance, indicating that they may function differently for autistic and general population adolescents, and scores for autistic and non-autistic individuals may not indicate comparable levels of the construct being measured. Our findings provide guidance about which PROMIS scales can be used to compare across autistic and general population teens or within an autistic sample only, and which are not psychometrically supported for autism research.

**Background:** Wellbeing is the measure of a person’s overall happiness, satisfaction with life, and positive outlook on life. Wellbeing of autistic people and their families is an important construct to understand, particularly in the realm of therapies meant to assist in improving the person’s life. While there are therapeutic methods believed to improve wellbeing or a person’s overall life, clinicians in behavioral health treatment often solely focus on areas such as goal attainment and miss out on the bigger picture - are the therapeutic methods improving a person’s wellbeing? In 2021, a large behavioral health organization set out to understand the wellbeing of their over 11,000 participants. To do this, these authors set out to find a wellbeing scale which would measure accurately an autistic person’s wellbeing, as well as the wellbeing of their family. After months of research into existing wellbeing scales, these authors determined it was necessary to create a wellbeing scale with an emic approach for the autistic population and their families due to challenges of finding a wellbeing scale which met certain criteria such as being shorter than 20 questions and was specific to the autistic population.

**Objectives:** To create a wellbeing scale for families with an autistic child with good validity and reliability. Additionally, it was important for these authors to create a scale with less than 20 questions due to the challenges in the completion rate of longer scales the behavioral health organization has historically experienced.

**Methods:** To do this, the authors began to research factors contributing to wellbeing and then created questions based on what was determined to be the top three factors. From there, the authors received stakeholder feedback from autistic youth, autistic adults, and families with autistic children and made necessary changes based on their feedback. Once all necessary updates were made, a sample population of 809 families of autistic children took the family version of the wellbeing scale in order to determine the psychometric properties of the scale.

**Results:** The three factors incorporated into the family wellbeing scale were family self-determination, family relationships, and family management. Factor analysis of the 809 respondents resulted in a three-factor scale with a very good alpha coefficient of 0.88, demonstrating the scale to have strong reliability.

**423.152 (Poster) Measuring the Wellbeing of Autistic People and Their Families: Looking Beyond Goal Attainment in Behavioral Health Treatment**

L. Sneed, D. A. Samelson and B. Fitchett, (1)Research Institute, Catalight, Walnut Creek, CA, (2)Clinical Excellence, Catalight Foundation, Walnut Creek, CA
Conclusions: It is vital for organizations serving a particular population in the realm of intervention to measure meaningful progress and change. Wellbeing is an important construct to understand in the life of the family of an autistic child due to the additional burden of care for the family, additional time for intervention, and the additional cost associated with having a family member with a developmental disability. The family wellbeing scale allows for an understanding of overall family wellbeing, has a good response rate, and also has strong reliability, thus allowing for any organization to understand how their client’s and their families are being impacted by their respective therapies, services, and interventions.

423.153 (Poster) Mothers' Postpartum Mental Health: The Early Environments of Infants at Elevated Likelihood of Autism
E. Kushner, J. D. Douglas-Brown, L. A. Edwards, S. Goodman and A. Klin, (1)Marcus Autism Center, Atlanta, GA, (2)Psychology, Emory University, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA

Background: Postpartum depression and parenting stress have been shown to be associated with adverse child social-emotional, cognitive, and linguistic outcomes outside the context of autism. Studies commonly show elevated rates of depression and stress among caregivers of children with autism, beginning at the youngest ages when autism is typically diagnosed. Given the importance of depression and stress in the postpartum based on general population samples, it is essential to better understand depression and parenting stress over the course of the early months of infancy in mothers of infants at elevated likelihood (EL) of autism due to familial history.

Objectives: We aimed to compare levels of depression and parenting stress between mothers with EL infants and mothers with no family history of autism (typical likelihood of autism; TL), in the first six months following birth.

Methods: Participating mothers completed the Edinburgh Postnatal Depression Scale (EPDS), a validated self-report screening measure for postpartum depression (Total: n = 103; EL: n = 43) and the Parenting Stress Index-Short Form, a self-report measure of parenting related stressors including sub-scales of parental distress, parent-child dysfunctional interaction, and perceptions of child difficulty (Total: n =151; EL: n = 58) at 1, 3, and 6 months postpartum. A score of 10 or greater on the EPDS indicates clinically significant levels of depression. Multilevel models were used to assess the association between autism likelihood and infant age on mothers’ depression symptom severity and parenting related stress.

Results: Significantly more mothers in the EL sample had clinically elevated levels of depression symptoms in the first six months postpartum (20.9%) compared to the TL sample (8.3%). Autism likelihood status had a main effect on mothers’ depression symptom severity ($F(1, 218) = 4.23$, $p < 0.05$) and parenting stress ($F(1, 300) = 6.94$, $p < 0.01$) with no effect of age or interaction between age and autism likelihood status.

Conclusions: Adding to the literature on parents of older children with autism, we found that mothers of EL infants, within the first six months of life, endorse greater symptoms of postpartum depression and higher levels of parenting related stress than mothers of TL infants. Further, our finding that 21% of mothers of EL infants had clinically significant levels of depression symptoms adds meaningful new information in relation to previous studies’ findings that rates of postpartum depression are roughly 13% in community samples. Given the goal of longitudinal sibling studies is often to explore the earliest development of children at elevated likelihood of autism and the important role stress and depression can play in influencing child trajectories, future studies should analyze the role of maternal mental health in shaping child outcomes. Ongoing analyses will explore longitudinal interactions between postpartum depression and stress levels and the possible impact of depression and stress on EL children’s developing social attention and communication skills.

423.154 (Poster) My Emotions and Me: A Coproduced Study on Emotion Responses with Autistic Young People to Inform the Development of Future Emotion Responses Measurement
G. Pavlopoulou, M. Kakoulidou, S. Chandler, S. Lukitor, S. Baker, E. Sonuga Barke and Y. Youth Research Panel, (1)Department of Psychology and Human Development, Institute of Education, Group for Research in Relationships in Neurodiversity, London, UNITED KINGDOM, (2)KCL, IONDON, United Kingdom, (3)King’s College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (4)Department of Child and Adolescent Psychiatry, Institute of Psychiatry, Psychology, and Neuroscience, King’s College London, London, United Kingdom of Great Britain and Northern Ireland, (5)Royal Central School of Speech and Drama, LONDON, United Kingdom

Background: Neurodivergent young people are particularly at risk for mental health conditions, yet traditional models of translational mental health research often rely on concepts defined by and for non-neurodivergent adults. This study is part of a wider programme, Regulating Emotions–Strengthening Adolescent Resilience (RE-STAR), which places the voices of young neurodivergent people at its heart, through the use of a co-intentional translational model of mental health research.

Objectives:

In this study, we aim to understand how neurodivergent young people with a diagnosis of autism, adhd or both experience and manage their emotions.
1. What triggers strong emotion reactions for young people? (e.g., what types of situations)

2. How do young people experience those emotions? What does it feel like? How do they describe these feelings?

3. How do young people regulate these emotions? How do they manage these feelings? What helps them get their emotions under control?

Themes from the qualitative interviews will feed into the development of a new self-report measure of Emotion Responses in Neurodiversity (ERNI)

Methods:

10 young neurodivergent adults (aged 18 – 25 years) were recruited to form RE-STAR’s Youth Researcher Panel. The panel worked with RE-STAR researchers to co-produce an interview schedule, creative tasks, and vignettes which were then administered to a sample of 57 young people (aged 11-15 years-old) with a diagnosis of autism and/or ADHD. The interviews were recorded and transcribed, and reflexive thematic analysis was employed to answer the research questions above

Results:

In this presentation we will report on rich data from 21 autistic young people aged 11-15 years old. Results will include the following themes i) The stresses and strife of everyday life (stressors/triggers/challenges) ii) Expressing vs camouflaging emotions iii) Perceived barriers to recovery from emotional outburst iv) reducing chances of distress iv) Tolerating big emotions.

Conclusions:

RE-STAR, through its co-intentional approach to translational science, combines science-based approaches with neuro-divergent perspectives to inform the development of future mental health support, tailored to the needs of neuro-divergent young people. Methodological strengths of the approached presented are intended to offer novel, inclusive and reflective tools for mental health research with (not on) neuro-divergent young people. Importantly, results shed light to how autistic teenagers think and talk about their emotion regulation and coping strategies. Challenges, limitations and future research steps will be considered.

423.155 (Poster) Older Sibling Impact on Clinician- and Parent-Reported Autism Features from Toddlerhood through Early Adulthood

N. E. Rosen, H. K. Schiltz and C. Lord, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

Background: Siblings impact multiple aspects of autistic individuals’ development from childhood through early adulthood (Rosen et al., 2022). While having an older sibling, in particular, has been associated with fewer challenges in social communication (SC) at a single timepoint in toddlerhood (Ben-Itzchak et al., 2016) and earlier age of autism diagnosis (Mishaal et al., 2014), it is unclear how having an older sibling may influence core autistic domains across time. Additionally, given that autistic females may present with autism differently than males (Chellew et al., 2022), there may be differential effects of older siblings on autism features over time based on gender.

Objectives: This study aimed to 1) examine differences in SC and restricted/repetitive behaviors (RRBs) between autistic individuals with and without older siblings from toddlerhood through early adulthood, 2) test gender as a moderator of these effects, and 3) account for clinician observation when examining sibling effects on parent-interviewed SC and RRBs.

Methods: This study involved 253 individuals with autism spectrum disorder or non-spectrum developmental delays followed longitudinally from ages 2-18. Autism symptoms (SC and RRBs) were captured at 5 timepoints using the Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview–Revised (ADI-R). Participants were administered standardized intelligence quotient (IQ) measures to assess verbal IQ (VIQ). A series of regression analyses were run using sibling variables as predictors (dummy coded with “has older sibling/s” as a reference group) and each interaction with gender (controlling for VIQ) to assess the effect of older siblings for males and females on autism features at each timepoint. Models predicting ADI-R were re-run with ADOS as a covariate.

Results: Findings revealed that the impact of having older siblings on autism features was most prominent early in life (ages 2-5), with more effects on SC than RRBs, according to both clinician observation and parent interview.

Although there were initially no main effects of older siblings on SC (ADOS or ADI-R), differences emerged on parent-reported ADI-R-SC after accounting for clinician observation. Autistic individuals with older siblings were reported to have more SC challenges than individuals with only younger siblings at ages 2 ($B=-2.20, p<.05$) and 3 ($B=-3.03, p=.004$).
Additionally, gender emerged as a significant moderator of the effect of older siblings such that female autistic children with older siblings demonstrated fewer autism features than those with only younger siblings (age 2: $B=2.734$, $p=.02$; age 3: $B=8.19$, $p=.02$; age 5: $B=4.45$, $p=.006$; age 18: $B=5.142$, $p=.015$; Figure 1), while the opposite was true for males. Interactions replicated across ADOS and ADI-R.

Conclusions: Overall, the effect of older siblings on autism features was complex. Parents who have older children to reference development for their autistic children may be more sensitive to atypicalities or may even overreport SC symptoms, particularly for male children in early childhood. Female children, however, may benefit from having older siblings with/from whom to practice social skills and model behavior. Clinicians should consider these effects when assessing for autism in early childhood and may wish to leverage the effects of older siblings for autistic females.

423.156 (Poster) Parent Couple Experiences in the Context of Broad Autism Phenotype

Background: The quality of parent-couple relationships is a robust predictor of adult physical and psychological well-being (Carr & Springer, 2010). Specific traits (e.g., neuroticism) and conditions (e.g., depression) have long been associated with difficulties establishing and maintaining romantic relationships. Broad autism phenotype (BAP) traits are also linked to couple outcomes such higher levels of conflict (Hartley et al., 2019) and lower levels of relationship satisfaction (Pruitt et al., 2018).

Objectives: The current study examined the association between parent-couples’ individual level of BAP traits (actor and partner) on parent-couples use of positive and negative dyadic coping in couples parenting a child with ASD and those with children with no known developmental disability using the Broader Autism Phenotype Questionnaire (BAPQ; Hurley et al., 2007) and the Dyadic Coping Inventory (DCI; Bodenmann, 2005).

Methods: This study draws upon time-1 of an ongoing longitudinal study which includes 184 couples parenting a child with ASD and 183 couples parenting a child without neurodevelopmental disabilities. Parent-couples completed questionnaires separately during a two-hour lab or home visit. BAP was examined as a continuous and dichotomous variable. A one-way multivariate analysis of covariance (MANCOVA) was used to examine the subdomains of BAPQ (Hurley et al., 2007) (aloofness, pragmatic language deficits, and rigidity) across parent-couple groups. Multilevel models were conducted to test Actor-Partner Interdependence Models (APIM).

Results: MANCOVA results indicated significant group differences in BAP subscale traits and BAP total scores with parents of children with ASD reporting higher levels of BAP traits than parents of neurotypical children. In our sample, 20% of mothers and 21% of fathers in the ASD group had BAP when using the BAPQ cut-offs in comparison to 16% of mothers and 8% of fathers in the comparison group. APIM findings evidenced an actor effect of rigidity on positive and negative dyadic coping. Additionally, mothers evidenced higher negative dyadic coping when their partner (fathers) evidenced a higher (versus lower) level of aloofness.

Conclusions: Overall, findings suggest that mothers and fathers are impacted by BAP traits within the parent-couple relationship. Specifically, our findings suggest BAP traits may impact positive dyadic coping by inhibiting communication through deficits in partner perspective taking and empathetic response in both ASD and non-ASD parent-couples. Implications for these findings include the development of targeted interventions aimed at recognizing and managing the negative effects of elevated rigidity and aloofness on couple-level processes and the enhancement of engagement and empathy in couples’ communication.

423.157 (Poster) Parent Perspectives on Early Intervention for Children with a High Likelihood for Autism
A. Garza, E. Rodriguez, S. Potter and L. H. Hampton, The University of Texas at Austin, Austin, TX

Background: There is a high prevalence of hearing loss in autistic children (Kancherla et al., 2013). Toddler siblings of children with autism have a higher likelihood for developmental delays, beyond an autism diagnosis, but it is not yet understood if the risk of hearing loss extends to siblings. Currently, there are few studies that focus on parent concerns of infants/toddlers that have an older sibling with autism and no known studies that focus on sibling hearing loss. Parent self-efficacy impacts family outcomes of children with autism because self-efficacy contributes to the parent’s perception of their own competence to fulfill their role of parenting in a successful way (Russell & Ingersoll, 2021). It is essential to know these specific concerns, regarding concerns about overall development, hearing, and intervention, to proactively help with planning of interventions (Hampton & Rodriguez, 2021). The purpose of the study is to understand the relationship between parenting self-efficacy scores and different levels of parent concern over their child’s hearing, communication development, and attitudes toward preemptive intervention.

Objectives: (a) How concerned are parents regarding infant/toddler’s sibling development? (b) How concerned are parents regarding their infant/toddler’s hearing status and do parents report a higher rate of hearing loss in infant/toddler siblings? (c) How willing are parents to seek out intervention services for infant/toddler siblings? (d) How do parent concerns correlate with their parenting self-efficacy?
Methods: 139 Parents of children (11-60 months of age) diagnosed with autism completed an online survey. Parents were asked demographic questions, yes/no questions regarding concern for their child’s hearing loss and development, and questions about beliefs in regard to intervention and monitoring developmental milestones. Parents were also asked to complete the Early Intervention Parenting Self-Efficacy Scale (EIPSES). The EIPSES was utilized as part of the survey to understand the parent’s perception of themselves and to understand their overall beliefs in their parenting (Guimond et al., 2008).

Results: Over 20% of parents reported their infant/toddler having hearing loss and over 35% reported passing their newborn screening hearing test but having hearing concerns afterwards. Results also indicated that parenting self-efficacy correlates with the parent’s concern level, showing that parents who have concern of their infant/toddler’s development, also have a higher self-efficacy score compared to those who do not have concern (t=2.549, p<0.05). Additionally, results indicated that parents will have higher concern of their infant/toddler if their older autistic child has more severe autism symptoms (OR=1.74, SE=0.39). Results also indicated that, regardless of the parent self-efficacy scores, parents will still be interested in participating in preemptive interventions (β=0.078, SE=0.12, p=0.46).

Conclusions: It is recommended that practitioners/researchers help facilitate accessible intervention opportunities for parents of children with autism who have an infant/toddler sibling. Results will also be discussed with interpretation from an autistic community board, which includes self-advocates, parents of autistic children, and siblings of autistic people.

423.158 (Poster) Parent Support Following an Initial Autism Diagnosis; A Mixed Methods Pilot Study of "Autism 101"
B. H. Brukilacchio1,4, A. Krishnan1,4, M. Brinster1,4, M. Cannady1,4, C. Turner1 and H. Hooper-Boyle1, (1)Massachusetts General Hospital, Boston, MA, (2)Lurie Center for Autism, Lexington, MA, (3)Harvard Medical School, Boston, MA, (4)Dell Children’s Medical Center, Austin, TX

Background: Following an initial autism spectrum disorder (ASD) diagnosis, parents of young children face unique practical and psychosocial challenges, for which very few targeted interventions exist. Within this population, caregivers often report very high rates of parenting stress (Pinquart, 2017), emotional reactions such as denial, fear, and grief (Gentles et al., 2019), and unmet needs (Cramm & Neibor, 2011; McStay et al., 2014). Psychoeducation programs have been associated with improved parental quality of life, increased understanding of a child’s disorder, and decreased parental feelings of isolation (Garcia Rodriguez et al., 2022). Several non-experimental studies of psychoeducation programs for parents of children with autism report increased levels of autism knowledge and family empowerment (Pillay et al., 2011; Farmer & Reuter, 2013). Based on this emerging literature, Autism 101 was developed as a manualized 6-week psychoeducational intervention designed to address the unique post-diagnostic needs of families of young children with ASD.

Objectives: This non-experimental pilot study evaluates patient satisfaction, engagement, and treatment adherence. Rates of parenting stress, parental coping, parental perceptions of ASD, and sense of empowerment were also explored pre- and post-intervention using both quantitative and qualitative methods.

Methods: This is a convergent mixed-methods open trial of Autism 101. A convenience sample of participants was recruited through a developmental behavioral pediatrics clinic located in Texas. 12 groups were led by 8 trained facilitators and conducted via telehealth. Treatment adherence was rated by independent observers who attended each session. Quantitative data (questionnaires completed pre-/post-intervention) were analyzed using one-sample t-tests and Wilcoxon sign rank tests. All survey measures were selected for their adequate psychometric properties and had previously been validated for use with this population. Qualitative data (focus group interviews) were collected by an independent non-facilitator following the final session.

Results: Participants were 38 caregivers of 40 children (67.50% White, 12.50% Black/African American, 7.50% Asian, 12.50% Other/Decline to Respond; 37.50% Hispanic/Latino) who had received an ASD diagnosis within the past 6 months. Patient satisfaction was rated highly, such that 96.60% reported being “mostly” or “very” satisfied and 91.70% reported that “most” or “all” of their needs had been met. Participant engagement was high, with an overall attendance rate of 91.90%. Treatment adherence was rated as 85.80% overall. Participants reported increased rates of cognitive reframing, illness coherence (i.e., parental understanding of ASD), and family empowerment, and decreased rates of negative emotional reactions. No significant differences were observed in parenting stress or social support. Focus group data provided rich descriptions of participant experiences and insight into cognitive and emotional change processes. Table 1 summarizes the quantitative and qualitative findings, including statistical results for significant findings.

Conclusions: The current study provides strong initial evidence for Autism 101. Participants rated the intervention as useful and reported high rates of satisfaction. Attendance and engagement rates were high and preliminary findings suggest the potential clinical utility of this intervention. Future directions include the addition of a randomized control group to assess whether observed changes are attributable to the intervention.

423.159 (Poster) Parent and Clinician Perspectives on the Acceptability of Pediatric Autism Therapies
Babyn, A. F. and M. Penner, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada

Background: Autistic children and their families may access different services, such as occupational therapy (OT), speech language pathology (SLP) services, applied behaviour analysis (ABA)-based therapies and physiotherapy (PT). There are varying levels of evidence supporting the efficacy of these therapies, and some autistic-led advocacy is critical of the methods and aims of certain services. There is limited information about the perspectives of parents of autistic children and clinicians on the acceptability of these services. Exploring stakeholder perspectives is critical to ensure services are appropriate and informed by lived experiences. This work is part of a larger survey that also explored autistic individuals’ perspectives.

Objectives: This study explored how parents of autistic children and clinicians perceived the acceptability of pediatric autism therapies (OT, SLP services, ABA-based therapies, PT).

Methods: Using the Theoretical Framework of Acceptability (TFA), a mixed methods survey was built with input from autistic people, parents of autistic children and clinicians. The survey was shared online to a wide group of parents and clinicians. Demographic data and perspectives on the therapies were captured. An acceptability sub-score was produced for each therapy, ranging from 0 (least accepting) to 64 (most accepting). The sub-scores were combined into an overall acceptability score. Following the TFA, open-ended questions were qualitatively analyzed using deductive content analysis, and constructs of intervention coherence and ethicality are presented.

Results: For the 140 clinicians who completed the survey, the median (range) sub-scores were: OT 46 (16 – 59), SLP 47 (24 – 60), ABA 34 (9 – 60), PT 40 (14 – 60). For the 87 parents and carepartners who completed the survey, the median (range) sub-scores were: OT 40 (16 – 60), SLP 41 (14 – 58), ABA 28 (7 – 54), PT 35 (25 – 57). Qualitative categories within the TFA construct of ethicality included concerns about compliance or external reinforcement, reported or potential harms, and importance of engaging with autistic adults. The construct of intervention coherence reflects an individual’s understanding of a therapy, and respondents viewed goals as unacceptable or acceptable. With respect to intervention coherence, acceptable goals highlighted by respondents included those that are client and family-driven, inclusive of multi-modal communication, and support sensory needs. The goal of behaviour change was variably viewed as acceptable or unacceptable. Respondents who viewed this goal as acceptable identified that ABA could teach skills (i.e., toileting) or decrease behaviours (i.e., self-injury). Conversely, respondents who described the goal of behaviour change as unacceptable were often critical of the promotion of neurotypical behaviors.

Conclusions: For both parent and clinician respondents, the ethicality of these therapies was important to their acceptability. ABA-based therapies have been critiqued elsewhere, and many respondents shared similar criticisms, most often related to promoting neurotypical behaviour. However, many respondents viewed skill-building as an acceptable goal. This research contributes to the important conversation as to how and why therapies, or aspects of therapies, can meaningfully support autistic children. Notably, many respondents were wealthy, well-educated, and white. Future work should learn from more diverse samples of parents and clinicians.

423.160 (Poster) Characteristics of the Sibling Relationship from the Perspective of Young Autistic Adults
S. M. Fecteau and A. Ndongeyingoma, (1)psychoeducation and psychology, Université du Québec en Outaouais, Saint-Jérôme, QC, Canada, (2)Nursing, Université du Québec en Outaouais, Gatineau, QC, Canada

Background: The immediate environment, including the family, influences the adoption of values and behaviors promoting the health and well-being of young people. Family relationships are a topic of interest for research and a focus for interventions carried out by health professionals. The role of parents in the development is amply addressed. The role of siblings and sibling relationships, whether positive and harmonious or conflictual, contribute to psychosocial health. In autism, most research documents the sibling relationship by taking into account solely the perception of the non-autistic sibling. Research taking into account the point of view of young people with autism is still rare. It is necessary to develop a bilateral portrait of this relationship. This study gives space so that they can voice their experience in their fraternal relationship. Objectives: We aim to develop a tool and determine the elements characterizing the sibling relationship from the perspective of young people with autism.

Methods: Following a review of the literature and consultation of six young people on the autism spectrum (mean age: 23.7 years old; 2 women), we developed a guided interview composed of 28 questions. With this guide, a descriptive qualitative study was carried out with 15 young autistic adults (mean age: 22.2 years old; 8 women) in Quebec, Canada. We asked the participants to answer the questions with mind patterns and mind relationships with a specific brother or sister. We organized and categorized the data into themes through discourse analysis to identify patterns and establish connections (Given, 2008).

Results: Four dimensions and 16 themes structure the elements characterizing the fraternal relationship. These are: characteristics of contacts composed of 3 themes (frequency, mean to make contact, physical proximity), characteristics of the interactions defined by 2 themes (content, common interest and activities), quality of the relationship consisting of 8 themes (acceptance, expectations, admiration, appreciation, affection, trust and confidence, conflict and rivalry, evolution) and support defined by 3 themes (reassurance, model, mutual aid).
Conclusions: People with autism play an active role in sibling relationships. This study brings support to the demonstration of their ability to reflect and share their introspection on their relationship, roles, desires and needs. According to the perception of young autistic people, the sibling relationship is an evolving one. During childhood, the rivalry seems more pronounced. When they become young adults, they evoke the presence of reciprocal advice during the adult transition and emotional support as the consideration of parental advice decreases. Recognizing the role and understanding the elements that characterize the sibling relationship in young autistic people would allow professionals to acknowledge the nature of this relationship better and adjust their support from an ecosystemic approach by considering the sibling relationship as a resource in health promotion.

423.161 (Poster) Parent-Reported Positive Attributes in Children and Adolescents with Autism during the COVID19 Pandemic

S. M. Kaku1,2, A. Mukkannan3, S. Kalmud4, S. Chandran5, J. Ramesh6, S. Somashekariah7, S. Kuduvalli8, V. Rao9 and A. Mysore10, (1)St John's Medical College Hospital and Research Institute, Bangalore, India, (2)Center for Advanced Research and Excellence in Autism and Developmental Disorders (CARE-ADD), St John's Medical College Hospital, St John's Medical College Hospital, Bangalore, India, (3)University of Mysore, CAREADD (intern), Bangalore, India, (4)Center for Advanced Research and Excellence in Autism and Developmental Disorders (CARE-ADD), St John's Medical College Hospital, Bangalore, India, (5)Psychiatry, St. John's Medical College Hospital, Bangalore, India, (6)Academy for Severe Handicaps and Autism (ASHA), Bangalore, India, (7)Shristi Special Academy, Bangalore, India, (8)HOPE The Early Intervention Centre, Bangalore, India, (9)Sunshine Autism Trust, Bangalore, India, (10)CAREADD, St.John's Medical College Hospital, Bangalore, India

Background:

The COVID19 pandemic has impacted individuals with autism spectrum disorder (ASD) and their families. In our study conducted during lockdown in 2020, we found that individuals with ASD had difficulty understanding the concept of lockdown and had new onset behavioral issues (1). Interestingly, families also reported positive changes, which are not frequently cited (2). To investigate the ongoing impact of the pandemic and understand coping within families, we conducted a mixed methods study in mid-2021. This report is based on part-data from this study.

Objectives:

We catalogue positive attributes reported by parents of individuals with ASD during the COVID19 pandemic.

Methods:

Using phone numbers from our database, we randomly contacted parents / care givers for online Focused Group Discussions (FGDs) on Google Meet platform. We had five discussions in all. Two involved parents of children between 2-12 years of age and two sessions where the index children were 13-25 years of age, while one involved parents of index subjects between 2 and 25 years of age. The meetings were audio and video recorded and the recordings anonymized. Two members of the research team then independently analyzed this data to derive themes using standard qualitative research methods. We report the analysis of positive changes shared by parents during these meetings.

Results:

A total of 25 parents participated in FGDs across 5 sessions. Index ASD subjects had moderate to severe ASD. Parent’s report could be grouped into four major themes – positive coping, hobbies that could be introduced regularly, sports and interpersonal skills. With respect to positive coping, individuals engaged in activities such as cleaning, household chores, cooking and gardening regularly during the pandemic. Many showed willingness to get introduced to and learn new hobby skills such as drawing, handwriting, piano, keyboard, and foreign language. They also were interested in sports such as badminton, cycling and skating. Many parents noticed positive changes in interpersonal skills such as initiating communication, better play skills, caring when family members were unwell, bonding with siblings, and improvement in verbal skills for social communication.

Conclusions:

We have showcased positive attributes in individuals with ASD during the pandemic as reported by parents. The pandemic enabled the caregivers to appreciate strengths and positive qualities even in those with moderate to severe ASD. Our study included parents with children from 2 years of age, unlike most studies in literature that highlight positive qualities in older adolescents and adults with ASD (2,3). Such positive attributes can provide a much-needed perspective to families and also help clinicians to manipulate therapy techniques. In limited resource contexts like in India, especially for younger individuals with ASD, it is possible that strength-based models could effectively supplement parent-led home-based interventions. There is need for further research to understand how to strengthen these skills without causing caregiver burnout and promote them to improve quality of life in individuals with ASD and their families, in the post-pandemic world.
Background: Parenting an autistic adolescent with intellectual disability (ID) and anxiety can be challenging, particularly when difficult daily decisions need to be made surrounding anxiety management and/or accommodation (i.e., whether behavior or demands are reduced as a means of minimizing distress within anxious situations; Frank et al., 2022). These decisions are further complicated if anxiety is contributing to challenging behavior, such as aggression or disruptive behavior (Moskowitz et al., 2013), which pose safety risks for families. However, excessive accommodations sometimes result in parents “taking over,” leading to reduced child independence and autonomy (Sandjojo et al., 2018). In autistic youth without ID, excessive accommodation is often associated with increased anxiety and externalizing symptoms, thus negatively impacting anxiety treatment outcome (Frank et al., 2022). This study seeks to understand the relationship among teen anxiety, challenging behaviors, and the parent accommodation of anxiety in autistic teens with ID, given the gap in the literature. These findings may have important implications on treatment and community participation.

Objectives: Evaluate the relationship between parent-reported anxiety, challenging behavior, and parental accommodation in anxiety treatment-seeking autistic teens with ID and anxiety.

Methods: Twenty-eight autistic teens (mean age 15.7 years) with ID and anxiety completed a baseline evaluation for participation in a cognitive behavioral therapy (CBT) anxiety-treatment program (Facing Your Fears: IDD). All participants met criteria for autism spectrum disorder (ASD) on the ADOS-2 (Lord et al. 2012), had IQ and adaptive behavior scores below 76, and met criteria for at least one anxiety diagnosis on the ADIS-Autism Spectrum Addendum (ADIS-ASA; Kerns et al., 2017). See Table 1. Parents completed the Anxiety Depression and Mood Scale (ADAMS; Esbensen et al., 2003), a measure designed to screen for psychiatric disorders in individuals with ID. Challenging behavior was assessed using the Irritability subscale on the Aberrant Behavior Checklist-Community (ABC-C; Aman, 2012). The Family Accommodation Scale-Anxiety (FASA; Lebowitz et al., 2013) was used to assess parental accommodation of anxiety-specific behaviors, with higher scores indicating more parental accommodation and possible scores ranging from 0-36. Data collection is ongoing.

Results: All parents reported some accommodation for their teen’s anxiety symptoms (FASA; M = 22.07, SD = 7.65). Results suggest significant positive correlations between parental accommodation and the ABC-C Irritability (r = .43, p = .02) and ADAMS General Anxiety subscales at pre-treatment (r = .41, p = .03). Increased anxiety severity and irritability is associated with more parental accommodation of anxiety symptoms in autistic teens with ID.

Conclusions: Consistent with research on autistic youth without ID (Frank et al., 2022), our results suggest a significant positive relationship between anxiety, challenging behavior, and parental accommodation in autistic teens with ID. While some parental accommodation may be necessary given the co-occurring cognitive impairments in their teens, too much accommodation may be concerning as it may interfere in treatment outcome. Tailored approaches to anxiety treatment are likely needed to address the complex needs and presentation of this population. Limitations include a small sample size, the reliance on parent-report, and that the FASA has not been normed on youth with ID.

Background: It is well-documented that family members of individuals with autism display elevated autistic traits, known as the broader autism phenotype (BAP; Piven et al., 1997), which has been associated with comorbid mental health challenges, such anxiety and depression (e.g., Lau et al., 2014, Su et al., 2017).

Independent of these traits, parental stress associated with raising a child with autism is higher compared to parents of typically developing children and those with other developmental delays (e.g. Hutton & Caron, 2005).

Finally, recent work points to high rates of family accommodation (i.e., proactive modifications made by family members intended to decrease their child’s distress, stemming from the child’s psychopathology) of RRBs among parents of autistic children. Such accommodation is associated with elevated child symptomatology and reduced adaptive functioning, as well as increased parenting stress (Feldman et al., 2019; Koller et al., 2021).
Given the above, it is important to examine how parents of autistic children cope with parenting stress and how such coping strategies associate with parental characteristics and behavior.

Objectives: To examine the associations between parental autistic traits, family accommodation and coping strategies among parents of young children with autism. Secondarily, to ascertain the correlation between FA patterns reported by co-parents in two parent families.

Methods: These data are part of a longitudinal study of children recently diagnosed with autism and their families. Participants were 31 children at time of diagnosis (26 males; mean age: 39.84 months). Children received a gold-standard evaluation including measures of child development (Mullen Scales of Early Learning; Mullen, 1995) autism symptomatology (ADOS-2; Lord et al., 2000; RBS-R; Bodfish et al, 2000) and adaptive functioning (ABAS-3; Harrison & Oakland, 2015). For the current study, parents completed self-report measures of their own autistic traits (BAP;Hurley et al., 2007), coping strategies (Brief COPE; Carver, 1997) and accommodation behavior (FAS-RRB; Feldman et al., 2019).

Results: Pearson correlations were calculated to examine the association between family accommodation, the BAP and Brief COPE questionnaires.

Significant negative correlations were found between mothers’ and fathers’ BAP scores and their coping strategies in stressful situations, including strategies to regulate emotional distress, (r(30)=.507, p<0.01), (r(27)=-.402*,p< 0.05) to try to solve problems (r(30)=-.405, p< 0.05), (r(27)= -.449, p<0.05) and to receive emotional comfort and soothing (r(30)=-.484, p<0.01) (r(27)=-.415*,p< 0.05). No correlation was found between parents’ coping strategies and accommodation, although a significant positive correlation was found between co-parents reported accommodation behavior (r(26)= 684,p<0.01).

Conclusions: This study sheds light on the relationship between parental autistic traits, behavior, and coping strategies. These results indicate that parents with elevated autistic traits display fewer coping strategies in stressful situations. The current study did not find a correlation between coping and accommodation, but did indicate that, in two-parent families, co-parents display similar levels of accommodation. These findings are a stepping stone to future research designed to elucidate profiles of parents of autistic children who may benefit from targeted support.

423.164 (Poster) Parental Coping Stategies in Mothers of Children with Autism, and Children with Attention Deficit Hyperactivity Disorder

Background: Coping strategies are considered a stabilizing factor, since it facilitates the individual adjustment and adaptation when faced with stressful situations. Most studies have indicated that raising a child with Autism spectrum disorder (ASD) or Attention deficit hyperactivity disorder (ADHD) can result in marked psychological distress for many parents (Graig et al., 2020; Hastings, 2008). However, parents vary substantially in their ability to successfully face the challenges linked to their child’s difficulties (Benson & Karlof, 2009). Despite a growing interest in parental coping strategies used with ASD children and ADHD children, few studies have analyzed in depth the dimensions of coping strategies developed by mothers of children with neurodevelopmental problems.

Objectives: The aim of this study is to explore parental coping strategies in mothers of children with neurodevelopmental disorders (ASD and ADHD) and to analyse the differences with a typically developing group.

Methods: This study includes 3 groups of mothers of children with a range of age between 7 to 11; 22 with Autism Spectrum Disorder without intellectual disability, 24 with ADHD and 32 typically developing children. The three groups of children, with ASD, ADHD and TD, were matched on age (F(2,75) = 1.98, p = 0.14), IQ (F(2,75) = 0.41, p = 0.66), and also vocabulary. The mothers’ mean age was 39.15 (SD = 3.7). Families were recruited through specialized centres from Spain. Mothers full filled the Coping Orientation to Problems Experienced (Brief COPE) questionnaire using the factorization of Benson (2010), and clinical psychologists confirmed the diagnosis of the clinical sample.

Results: The analyses of variance conducted yielded statistically significant differences between mothers of children with neurodevelopmental disorders and mothers of typically developing children in the dimensions of Disengagement and Distraction, with moderate effect sizes. Moreover, the results evidenced that the mothers of children with ASD did not differ significantly from the mothers of children with ADHD in any of the coping dimensions analysed.

Conclusions: The findings suggest that mothers of ASD and ADHD children show similar trend than parents of typical developing children on some coping strategies such as, active planning, problem-solving, or seeking support from others. However, mothers of children with neurodevelopmental disorders tend to develop maladaptive coping strategies focused on distracting, denying, or avoiding stressful situations, in line with other studies (Benson, 2014; Smith et al., 2008). In addition, factors such as child’s age, sociodemographic variables
and parental mental health should be taken into consideration in future studies. It is noteworthy the need to design interventions that seek to reduce parents’ use of disengagement and distraction, while facilitating their use of engagement and cognitive reframing strategies.

423.165 (Poster) Parental Experience of an Early Developmental Surveillance Program for Autism within Australian General Practice: A Qualitative Study

M. Gilbert, J. Barbaro, T. Winata, F. Khan, C. Dissanayake and V. Eapen, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), The University of Queensland, Indooroopilly, QLD, Australia, (3)Discipline of Psychiatry and Mental Health, Faculty of Medicine, University of New South Wales, Sydney, NSW, Australia, (4)Academic Unit of Infant, Child and Adolescent Psychiatry, South Western Sydney Local Health District, Sydney, NSW, Australia, (5)Ingham Institute for Applied Medical Research, Liverpool, NSW, Australia, (6)Olga Tennison Autism Research Centre, Olga Tennison Autism Research Centre, Melbourne, VIC, Australia

Background: Implementing supports early in the life course has been shown to promote positive developmental outcomes for children at high likelihood of developmental disabilities, including autism. Around one in five Australian children are “developmentally vulnerable” when they start primary school, with evidence that in some areas, particularly rural or remote areas, only 20-30% of preschool age children access recommended developmental surveillance and/or early support programs. These programs promote child health and development via developmental surveillance, and provide advice to promote child and family wellbeing.

Objectives: This study examined parents/caregivers’ experiences and perceptions about a digital developmental surveillance pathway for autism, the Autism Surveillance Pathway (ASP), and usual care, the Surveillance as Usual (SaU) pathway, in a primary healthcare setting with general practitioners (GPs; family doctors).

Methods: This qualitative study utilised a convenience sampling from the full sample of parents/caregivers that participated in the main program “GP Surveillance for Autism” (Barbaro et al., 2021), a cluster-randomised controlled trial study. Semi-structured interviews were conducted over the phone, with all interviews audio-recorded, transcribed, and coded using NVivo 12 software. An inductive thematic interpretative approach was adopted for data analysis. Twelve parents/caregivers of children with or without a developmental disability participated from the main program in South-West Sydney and metropolitan Melbourne, Australia.

Results: Seven major themes and 20 sub-themes were identified and classified as: overlapping enablers for both pathways; ASP pathway-specific enablers; overlapping barriers for both pathways; SaU pathway-specific barriers; ASP pathway-specific barrier; overlapping recommendations for both pathways; and SaU pathway-specific recommendations. These included positive experiences, such as pre-existing patient-doctor relationships and their perceptions on the importance of knowing about and accessing early supports and services. Barriers or challenges experienced while using the SaU pathway included long waiting periods, poor communication and lack of action plans, complexity associated with navigating the healthcare system, and lack of understanding by GPs. As much of the study was conducted during the COVID-19 pandemic and associated lockdowns, the effects of reduced access to supports and services, particularly in-person appointments, was a barrier for all families. Common suggestions for improvement included parents/caregivers having greater awareness of and education on child development, as well as access to accessible resources on child development for families.

Conclusions: Multiple factors influencing parents/caregivers’ utilisation of general developmental and autism surveillance tools within primary healthcare services emerged from this qualitative study. While participants in both pathways identified common enablers and barriers, and made similar improvement recommendations, those in the SaU pathway identified more barriers. Most parents/caregivers reported positive attitudes towards and experiences with their GPs, which improved their overall health-care experiences and wellbeing. The findings of this study support the use of digital screening tools for developmental surveillance, including for autism, using opportunistic contacts in the general practice setting. The inclusion of developmental surveillance and time to discuss developmental concerns in public health-care programs should be considered. The results also suggest that education for GPs, families, and the wider community about child development and developmental disabilities, including autism, is needed.

423.166 (Poster) Parental Hopes and Young Adult Futures: Caregiver Perspectives on the Transition to Adulthood with and without IDD

G. B. Salinas, M. R. Galligan, E. Baker, B. L. Baker and J. Blacher, (1)School of Education, University of California Riverside, Riverside, CA, (2)College of Education, San Diego State University, San Diego, CA, (3)UC Riverside, Riverside, CA, (4)Psychology, UCLA, Los Angeles, CA, (5)School of Education, University of California, Riverside, Riverside, CA

Background: The transition to adulthood for individuals with intellectual and developmental disabilities (IDD) creates unique challenges, especially limited or non-existent services (Howlin & Moss, 2012; Taylor & Seltzer, 2011). Literature suggests that young adults with IDD experience poor outcomes, e.g., low employment and postsecondary graduation rates (Mason et al., 2021). Previous work highlights the need to develop services and supports available to youth with IDDs before leaving high school, particularly in comparison to their neurotypical (NT) peers.

Objectives: This study aims to explore support received (i.e., services and resources) by young adults with and without IDD in preparation for the transition into adulthood, as well as needed supports reported by caregivers and youth. Research questions include: (1) What support
did young adults with and without IDD receive during the transition into adulthood? (2) What support do caregivers wish existed for their young adults with and without IDD during the transition into adulthood?

Methods: Caregivers (N = 118; 89% were mothers) were interviewed about their overall experience with their young adults’ (n=114, age range: 20-25 [M=21.8]; IDD n=57; NT n=57) transition into adulthood. The IDD group includes young adults with autism spectrum disorder (ASD), intellectual disability (ID), and ASD+ID. A thematic analysis was conducted on two interview questions addressed to caregivers: (1) Was there anything that they, their young adult, or the school did that helped in the transition? and (2) Were there any ways the service systems could have better supported the transition?

Results: Two main themes emerged for question one: Types of Support Sought and Sources of Support Provided (i.e., who provided the resource/service). The most reported types of support included: social support (26.4%), adaptive skills (18.3%), and transition-specific preparation (14.9%). As for the Source of Support, the most frequently reported included: caregiver/family (41.3%), school (25.7%), and young adult (17%). Differences across the two groups emerged in terms of Types of Support; the NT group reported academics in the top three instead of transition-specific preparation. Question two identified two main themes: Barriers and Facilitators (13 codes total) during the transition period. Although caregivers were asked how the service systems could have better supported the transition, some mentioned facilitators. The most frequently reported Barriers included: accessibility of services/information (24.1%), career planning/preparation (13.4%), and adaptive skills/executive functioning (13.4%). The most frequently reported Facilitators included: guidance on transition (38.9%), adaptive skills/executive functioning (13.9%), and accessibility of services/information (13.9%). Differences were seen across groups for barriers to accessibility of services, which was almost exclusively mentioned in the IDD group (36% vs. 2.4%).

Conclusions: Interestingly, both groups report similar types of support received, and barriers encountered, suggesting that overall, caregivers of young adults with and without IDD seek similar support during the transition period. However, the types of support varied depending on the young adult’s postsecondary goals (e.g., NT group reported academics more frequently). These findings may provide insight into how to individualize transition support and consider the presence of a disability when evaluating needs and support.

Background:
Responsive and sensitive parenting are pivotal to support a child’s social engagement and to promote an enriching environment that maximizes both cognitive and social learning opportunities. Responsive parents are aware of their child’s, even subtle, behavioral cues and interests, affirming them in a warm and comfortable atmosphere. Conversely, a more structured and directive parental interaction style tends to lead children’s behavior, anticipating their initiatives, instructing and prompting them.

Autism is a neurodevelopmental condition that affects, very early on, parent-child interactions. Autism risk infants show significantly less interest and motivation toward the social world and the parental initiatives ultimately influencing the parent’s interactive attitude.

Previous evidence suggests that mothers of autism children are more directive than mothers of typically developing (TD) ones, are focused on their child’s skills achievement and tend to have more structured interactions.

Objectives: Based on prior research, we aimed to investigate interaction style’s characteristics in mothers of young children with and without autism during naturalistic joint play activities.

Methods: Our sample included 40 young children with and without autism (n=22 children with autism; 8 females and n=18 TD; 9 females), matched according to the developmental age of the autistic children (21.4 months, SD=4.6).

Parent-child interaction (PCI) consisted in a standardized paradigm of free play with a set of developmentally appropriate toys. Parents were instructed to play with their children as they normally used to do and play interactions of both mothers and fathers were video-recorded for a 10 minute time. For the purpose of this preliminary study we analyzed the sample of mothers by using the Maternal Behavior Rating Scale - revised (MBRS - Mahoney, 2008) to measure mother’s interaction style. The MBRS assesses four interactive style factors: responsive/child oriented, affect/animation, achievement orientation and directive.

Results: We found that mothers of typical development children are significantly more responsive (W(40)= 137, p<0.001) and display higher positive affect and animation (W(40)= 125, p= 0.002) than mothers of children with autism.
Conclusions: Parent-child interaction is a key factor to promoting social learning and early development. Our study highlights lower responsiveness and positive affect in mothers of young children with autism during naturalistic parent-child interactions. These findings have important implications on parent-mediated intervention programs that aim to support a positive parental style and to maximize child’s joint engagement, communication opportunities and social motivation.

423.168 (Poster) Parental Perspectives on the Everyday Experiences of Uncertainty Among Young Children on the Autism Spectrum
C. Ong1, I. Magiati2, M. T. Maybery1, J. Rodger1, M. Ugljevic1 and G. A. Alvare3, (1)Telethon Kids Institute, Perth, Western Australia, Australia, (2)School of Psychological Science, University of Western Australia, Perth, Western Australia, Australia, (3)School of Psychological Science, The University of Western Australia, Perth, Western Australia, Australia, (4)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (5)Melbourne School of Psychological Sciences, Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Parkville, VIC, (6)Telethon Kids Institute, Telethon Kids Institute, Perth, Western Australia, AUSTRALIA

Background: People on the autism spectrum are at an increased risk for mental health difficulties across the lifespan, with anxiety being the most common. Heightened anxiety also appear in early life for children on the spectrum, which can increase in severity over time. Exploring and better understanding potential underpinning mechanisms contributing to and maintaining anxiety in the early years is therefore important in informing effective and timely supports. Several potential mechanisms of anxiety have been suggested, with recent evidence highlighting the prominent role of Intolerance of Uncertainty (IU). IU, a tendency to find uncertainty difficult, is a transdiagnostic mechanism contributing to the development and maintenance of anxiety in the general population, but little is known about how IU may present in or impact upon young children on the spectrum.

Objectives: The study investigated parents’ perspectives of their child’s experiences of uncertainty, exploring presentations, the impact on children and families, and parental management strategies.

Methods: Parents of 13 children aged 4-7 years with an autism diagnosis participated in focus groups. Five research questions were explored: (1) Situational triggers of anxiety and distress relating to uncertainty; (2) Manifestations of IU in young children; (3) Differences in experiences with uncertainty compared to non-autistic children; (4) Impact of IU and anxiety; (5) Parental management of children’s IU. Participants were recruited until data saturation was reached. Applied thematic analysis using a framework analysis approach was employed. Although specific research questions were identified deductively, a primarily inductive approach was adopted in the coding and analysis process. A codebook was used to facilitate dialogue and reflexivity between researchers and inter-coder reliability was established at 97.5%.

Results: 18 themes were identified in relation to the five research questions. Parents identified anticipatory unknowns and unexpected events as triggers of anxiety relating to uncertainty. Parents also described several different anxious and distressing child emotional and behavioural responses to uncertainty, which were perceived as more intense compared to the responses of non-autistic children. Some behaviours were associated with or exacerbated by autism characteristics, such as sensory sensitivities and insistence on sameness. Most parents reported that difficulties with uncertainty had a significant negative impact on child and family well-being. Parents also described various strategies aimed to reduce uncertainty, create certainty or increase children’s ability to cope with uncertainty.

Conclusions: Our findings suggest that parents perceive IU as an important and relevant construct that manifested in their child’s heightened reactivity to uncertain situations. Parents discussed the complex overlap and intertwined relationship between autism characteristics and IU, consistent with previous findings with older children and adults on the spectrum. Given that IU can present early in life for children on the spectrum, with distressing experiences that can negatively impact the everyday lives and well-being of children and family, further research into early and targeted interventions is needed as it may potentially alter the onset and/or trajectories of childhood anxiety and longer-term impact associated with anxiety. These findings have informed the evaluation of a targeted parent-mediated intervention to support children in managing difficulties with uncertainty.

423.169 (Poster) Parental Views of Families of Children with Autism Spectrum Disorder and Developmental Disorders during the COVID-19 Pandemic
B. F. Meral. Special Education, Sakarya University, Sakarya/Hendek, Turkey

Background: The COVID-19 pandemic, the infection caused by the novel coronavirus detected in December 2019 by World Health Organization (WHO), has detrimentally impacted human life in a variety of areas. Many concepts including outbreak, pandemic, and quarantine have been an inseparable part of our lives. This kind of dialectic change naturally affects persons with autism spectrum disorder (ASD) and developmental disorders (DD) and their families. The present study using a mixed-method evaluation aims to reveal the impacts of the COVID-19 pandemic on the family functioning of children specifically with ASD in Turkey. This study promises a holistic understanding of how the lockdown depending on the COVID-19 pandemic affects families and their children with ASD with positive and negative sides.
Objectives: The purpose of the present study was to investigate the impact of the lockdown and curfew associated with the COVID-19 coronavirus pandemic on the family life of children with ASD in Turkey by integrating qualitative and quantitative methods.

Methods: A concurrent (or convergent) mixed methods design was used to investigate the research questions and the results were compared simultaneously, which is also called Type D: Concurrent triangulation design (Creswell & Plano Clark, 2006; Creswell et al., 2003).

Results: Considering the viewpoints of parents, a predominant subcategory within the study’s themes was “shared more family time and increased family interaction” under the positive effect of the COVID-19 on family life. Most parents, especially fathers, expressed lack of time to spend time together with families because they need to work as either white or blue-collar workers in the workforce until lockdown and curfew depending on the COVID-19 pandemic. Undoubtedly, “the unmet educational needs of the children with ASD” has been the most emphasized issue by parents during the pandemic in the present study. Suspending of educational services depending on pandemic lockdown was highlighted as a significant challenge for children in other some research (Fontanesi et al., 2020; Masters et al., 2020). However, parents expressed increased verbal behaviors of their children with ASD as a result of increased family interaction during the pandemic. Increasing the verbal behavior has always become one of the main goals of early and intensive behavioral services which are a widespread treatment approach for children with ASD (Eldevik et al., 2009; Ingvarsson, 2016). Therefore, positive appraisals of parents on especially expressive language skills that sounds promising in communication development of children with ASD is a remarkable result during the quarantine.

Conclusions: One of the most critical lessons that emerged from the current study is that more comprehensive research needs to be conducted on the effects of COVID-19 on families of children specifically with ASD. Secondly, all stakeholders including families, researchers, professionals, or policymakers should use a holistic lens indicating negative as well as positive aspects to understand the impacts of the COVID-19 pandemic.

423.170 (Poster) Parenting Autistic Adults As They Enter the Job-Market: A Qualitative Exploration of the 'tal-Program' Parents' Group Meetings

Y. Goldfarb, T. Kapicetzky and M. Kalfon Hachmigeri, Occupational Psychology, School of Behavioral Sciences, The Academic College of Tel Aviv-Yafo, Tel-Aviv-Yafo, Israel

Background:

Family support is a central part of the eco-system promoting employment goals for autistic adults (Nicholas et al. 2018). Parental factors such as participation in educational activities and having high expectations of their children predicted functional performance and employment outcomes in adulthood (Kirby et al., 2016; Wong et al., 2020). Additional studies suggest that parental involvement, combined with ‘real-life’ experiences and exploration the autistic adults, can promote a realistic and effective transition plan (Chen et al., 2018). The ‘Tal-Program’ is a government funded employment intervention for autistic adults in Israel. Along with a broad curriculum of employment-related skills and job market experience, the program offers biweekly group meetings for the parents of the participants. Exploring the parents’ group-related experiences can shed light on their main issues of concern regarding the transition to employment, as well as general views, self-concepts, roles and self-perceptions.

Objectives:

To explore the parental experience of parents of autistic adults participating in an employment transition program, as they enter adulthood and employment.

Methods:

Participants were 12 parents of autistic adults (11 females; mean age: 55) who were purposefully sampled according to a high attendance rate and participation in the group meetings. Semi structured narrative interviews were carried out (Rosenthal, 1993) beginning with an open question concerning the experience of taking part in the group meetings, with minimal interruption. Next, specific questions covered subjects that called for further inquiry and other aspects of the transition to adulthood and employment. Background data were collected. A Dialogical Narrative Analysis (Smith & Monforte, 2020) was employed for data analysis.

Results:

Parental experiences and views emerged along three central themes: Autism diagnosis. Participants shared accounts of acceptance vs. rejection of the child’s autism diagnosis and possible consequences, mentioning comparisons to the same-aged typically developing peer group. Such conflicts also echoed in reports of disclosure vs. concealment of the diagnosis, even to the close circle of friends and relatives.
Through dynamic conversations in the group meetings, possible relationship between parental acceptance of the child's autism, autism disclosure and choosing attainable employment goals were realized; Independence vs. support. Questions were raised in the group meetings discussing if and how to be involved in the child’s vocational activities. Contradictions between statements about the child’s high independence alongside stories portraying significant parental involvement demonstrated the difficulty attaining a balance in relation to vocational activities. Parents' expectations for workplace accommodations and job adaptations were not always feasible in the job-market context; The significance of the group. Parental accounts indicated that the group provided them an opportunity to feel that they are not alone, receive support and validation for their feelings, actions and concerns and expand their point of view.

Conclusions:

Supporting the developmental tasks of adult autistic children can make old conflicts rise and new ones emerge for parents. The group sessions offered a space in which central issues were discussed and reconciled, promoting well-being of parents along with better support for their children. Appropriate phase-related guidance for parents is valuable throughout the life-span.

423.171  (Poster) Parenting Behavior Among Autistic Children with or without ADHD

(1)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Mount Sinai, New York City, NY, (3)Seaver Autism Center for Research & Treatment, New York, NY, (4)The Seaver Autism Center for Research & Treatment, New York, NY, (5)Psychiatry, Seaver Autism Center at the Icahn School of Medicine at Mount Sinai, New York City, NY, (6)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY

Background: Although attentional and behavioral problems often co-occur in children with ASD, few studies have explored differences in parent-child interactions among autistic children with and without comorbid attentions-deficit/hyperactivity disorder (ADHD). Yet, emerging evidence suggests that parenting factors, such as parenting styles, attitudes, and attunement, may be linked to externalizing problems in children with ASD. Positive parenting, characterized by parental support, sensitivity, and responsiveness, has been associated with decreased ADHD symptoms in longitudinal studies involving mother-child dyads. This small, but growing body of literature, may be expanded with further exploration involving direct observation of parent and child behavior during dyadic interactions.

Objectives: This study investigated whether there are differences in dyadic interactions in a sample of children with ASD with and without ADHD symptoms.

Methods: Twenty-six autistic children (ages 3-11, 50% ADHD) participated in comprehensive clinical evaluations, including caregiver interviews and standardized assessments. Dyads participated in 20-minute parent-child interactions, including a warm-up period and three five-minute tasks: child-directed play, parent-directed play, and clean-up. Interactions were coded using the dyadic parent-child interaction coding system (DPICS). Repeated measures ANOVA was used to explore the interaction and main effects of task and diagnostic group on parenting and child behaviors.

Results: A main effect for task was observed for overall number of parent verbalizations, F=11.37, p<.001, reflections, which reflect child speech without changing the meaning, F=4.67, p=.02, praise, F=3.70, p=.03, questions, F=11.04, p<.001, commands, F=12.66, p<.001, and child compliance, F=8.40, p=.001. Parents spoke more during parent-directed play compared to other tasks. During child- and parent-led play, parents used less praise and more questions relative to clean-up, during which parents used fewer reflections. Commands and child compliance were significantly greater during parent-led play and clean-up.

An interaction effect was observed for neutral talk, which does not describe, qualify, or direct child behavior, F=3.29, p<.05, where parents of autistic children with ADHD used more neutral talk during child- and parent-led play, while dyads without ADHD used more during clean-up.

A main effect for diagnostic group was observed for parent use of negative talk, encompassing criticism of the child or their behavior, F=4.28, p=.05, with parents of autistic children with ADHD using more negative talk relative to those without ADHD, regardless of task.

Conclusions: In this sample, parent-child interactions differed in the context of changing task demands, often regardless of ADHD comorbidity. When instructed to direct their child’s play, parents of children with autism often spoke more, directing their child’s attention and engagement with commands and questions. However, while parents appear to be attuned to the usefulness of praise during a structured, routine clean-up task, they used less praise during unstructured tasks, whether child- or parent-directed. Parents of autistic children with comorbid ADHD were more likely to use criticism across situational contexts but fewer neutral verbalizations during clean-up. Overall, parents across groups may benefit from learning strategies to engage their children in play to promote positive adjustment and wellbeing.

423.172  (Poster) Parents' Adaptive Coping Strategies & Perceptions of Social Standing As Predictors of Youth Anxiety

T. DeMotta, K. Drafoin, L. Perovsek and B. J. Wilson;
(1)Clinical Psychology, Seattle Pacific University, Seattle, WA, (2)Seattle Pacific University, Seattle, WA
Background:

Research on the association between parent coping strategies and anxiety in youth with autism spectrum disorder (ASD) is limited despite children with ASD experiencing elevated levels of anxiety in comparison to typically developing children (Gillot et al., 2001) and research supporting the relation between parent behaviors and youth anxiety (Dadds et al., 1997). Furthermore, research is very limited in investigating differences in this association amongst populations of diverse, socioeconomic backgrounds. Therefore, the purpose of this study was to examine anxiety levels in youth with ASD and parents’ perceptions of social standing as predictors of parents’ adaptive coping strategies.

Objectives:

The aim of this study was to examine parents’ perceptions of social standing and anxiety in children and adolescents with ASD as predictors of parents’ adaptive coping strategies.

Methods:

The data utilized for this study stems from a larger web-based survey involving adults with developmental disabilities (DD), parents of children with DD, and parents and children with DD. Data was collected within a 13-week period and aimed to understand the experiences of individuals impacted by DD during the COVID-19 pandemic. The participants in this study included 35 parents of children and adolescents with ASD. Children and adolescents ranged from ages 3 to 19. Parents completed the Brief Resilient Coping Scale (BRCS; Sinclair & Wallston, 2004) to assess adaptive coping strategies, the Generalized Anxiety Scale (GAD-7; Spitzer et al., 2006) to measure youth anxiety symptoms, and the Community Ladder subscale of the MacArthur Scale of Subjective Social Status (Adler et al., 2000) to assess parents’ perceptions of social standing within their communities.

Results:

Results from a multiple regression analysis indicated a statistically significant interaction effect of youth anxiety and parents’ perceptions of social standing on parents’ use of adaptive coping strategies. The interaction effect accounted for 12% of the variance in the parents’ adaptive coping scores. A Johnson-Neyman interval was conducted and indicated that the association between parents’ adaptive coping and youth anxiety is not significant when perceptions of social standing are at the mean or 1 SD below the mean. Inversely, the relation between parents’ adaptive coping and youth anxiety is significant when perceptions of social standing are 1 SD above the mean.

Conclusions:

Overall, these results demonstrate that anxiety in children and adolescents with ASD is substantially elevated when caregivers perceive themselves as within groups of high social standing in their communities and use the least amount of adaptive coping strategies.

423.173 (Poster) Parents’ Perceptions of Service Needs and Expectations for Their Autistic Children during the Transition to Adulthood

M. Pecukonis, R. M. Hantman and H. Tager-Flusberg. (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA. (2)Department of Psychology, University of South Carolina, Columbia, SC

Background: The transition to adulthood can be a turbulent period for autistic individuals and their family members. Previous studies have identified various service needs of autistic individuals as they transition to adulthood (Anderson et al., 2018), often by collecting qualitative data from parent interviews. However, no studies have explored whether parents’ perceptions and expectations during this transition period differ based on their children’s language level and communication skills.

Objectives:

1. What services do parents believe will help their children transition to adulthood, and do these perceptions differ by child language level?
2. Do parents’ expectations for their children’s future relate to child language level and communication skills?

Methods: The sample (N=56; 44M, 12F) included 34 parents of verbal individuals with autism (Parents-V) and 22 parents of minimally/nonverbal individuals with autism (Parents-MV). Autistic individuals ranged in age from 16.00 to 25.45 years old (M=19.29). Child language level was measured using one question from our parent-report demographics form: “What is your child’s verbal ability?” with response options: verbal, minimally verbal, nonverbal. The Vineland Adaptive Behavior Scales (VABS-3) domain level form was also used to assess child communication skills. A trained researcher conducted semi-structured interviews with parents via Zoom. Interviews included questions related to sensory sensitivities and the transition to adulthood. To address our first objective, we used qualitative content analysis to code responses from two interview questions: “What services or interventions would help your child move into adulthood?” and
“Are there gaps in available services or interventions?” To address our second objective, we used a questionnaire created by Ivey (2004), in which parents rated the extent to which they believed that their child would accomplish different milestones in adulthood (Table 1).

**Results:** Content analysis revealed nine service types that parents believed would help their children transition to adulthood (Table 2). Chi-square tests showed that the proportion of parents who mentioned each service type did not significantly differ between child language level groups ($p^{2}=.129$), except for mental health care, which was endorsed more frequently by Parents-V than Parents-MV ($\chi^{2}=4.38, p=.036$). Independent samples t-tests showed that Parents-V ($M=3.88$) reported higher scores than Parents-MV ($M=2.90$) on the Ivey (2004) questionnaire ($t=4.76, p<.001$), with higher scores indicating greater likelihood of accomplishing milestones. Scores on this questionnaire were also positively correlated with VABS-3 communication domain standard scores ($r=.58, p<.001$).

**Conclusions:** Parents-V and Parents-MV believed that their autistic children would benefit from similar services during the transition to adulthood, except for mental health care, which was endorsed more frequently by Parents-V. This finding suggests that similar services could be provided to all autistic individuals, regardless of their language level, to address the dearth in available services during the transition to adulthood (Laxman et al., 2019). When compared to Parents-MV, Parents-V had higher expectations for what their children would accomplish in adulthood; parents’ expectations were also positively associated with their children’s communication skills. This finding suggests that parents’ expectations for their children’s “success” in adulthood differ based on their children’s language level and communication skills.

**423.174 (Poster) Participation and Quality of Life in Primary and Secondary Caregivers of Autistic Children**

G. Davy, M. Clark, P. Date, M. Muniandy, K. L. Unwin, J. Barbaro, and C. Dissanayake, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Olga Tennison Autism Research Centre, Olga Tennison Autism Research Centre, Melbourne, VIC, Australia

**Background:**

Parents of autistic children, particularly primary caregivers, often modify their participation across leisure, social, and workforce contexts to meet the caregiving needs of their child. Research suggests reduced participation in desired activities may play a role in the quality of life (QoL) of parents of autistic children. However, the literature focuses mostly on mothers and/or primary caregivers with the participation and QoL of fathers and/or secondary caregivers relatively unknown.

**Objectives:**

The aim in the current study was twofold: to examine differences in leisure, social, and workforce participation and QoL between primary and secondary caregivers of school-aged autistic children as well examining the contribution of participation on their QoL.

**Methods:**

Participants were recruited from a wider longitudinal study with 79 primary (94% mothers) and 54 secondary (89% fathers) caregivers of autistic children (aged 7-12 years). Health-related QoL (HRQoL), overall QoL, parenting stress, leisure participation, occupational gaps (i.e., activities that parents wish to engage in but currently are not), time pressure, and social support were measured via online questionnaires.

**Results:**

Significant differences were found with primary caregivers reporting poorer HRQoL ($p=.02, d=-.40$), added time pressures ($p=.01, d=-.51$), increased household labour hours ($p<.001, d=.74$), more childcare responsibility ($p<.001, d=1.03$), and fewer employment hours ($p<.001, d=-1.15$) than secondary caregivers. Differences were not found between primary and secondary caregivers in frequency of leisure participation, the number of occupational gaps, or overall QoL. Despite no differences in total parenting stress, primary caregivers reported significantly higher scores on the parenting distress domain than secondary caregivers ($p=.03, d=-.39$).

For primary caregivers, hierarchical multiple regression identified household labour hours ($\beta=-.23, p=.03$) and occupational gaps ($\beta=-.40, p<.001$) as significant predictors of overall QoL, with the model accounting for 30% of the variance, $R^{2}=.30, F(3,70)=10.17, p<.001$. Adding total parenting stress ($\beta=-.66, p<.001$) and HRQoL ($\beta=0.19, p=.003$) in the second step reduced the unique contribution of household labour hours ($\beta=-.19, p=.002$) and occupational gaps ($\beta=-.19, p=.01$) to overall QoL, with the final model accounting for 77% of the variance, $R^{2}=.77, F(7,66)=32.23, p<.001$.

For secondary caregivers, hierarchical multiple regression identified occupational gaps ($\beta=-.63, p<.001$) as a significant predictor of overall QoL, with the model accounting for 41% of the variance, $R^{2}=.41, F(2,51)=17.41, p<.001$. When total parenting stress ($\beta=-.48,$
Conclusions:

Despite differences in role responsibilities (e.g., employment, home duties), time pressure, and HRQoL between primary and secondary caregivers, access to meaningful activities was identified as important for QoL in all caregivers. When adding parenting stress and HRQoL to the model, the contribution of occupational gaps to QoL in primary caregivers reduced. However, for secondary caregivers occupational gaps no longer predicted QoL while also accounting for parenting stress and HRQoL. Further investigation into the interrelationships between these variables and QoL is needed to better understand how best to support both primary and secondary caregivers of autistic children in meeting occupational and QoL needs.

423.175 (Poster) Participatory Approaches in Autism Research: A Systematic Review
S. L. Curtiss1 and M. Subih2, (1)School of Education, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE

Background:

Participatory research (PR) provides a framework for centering the voice of autism stakeholders in research, ensuring that research is relevant, and improving the efficacy of implementation (Fletcher-Watson et al., 2018). The use and appreciation of PR are growing across disciplines, yet, to our knowledge, there have been just two systematic reviews identifying participatory methods in autism research. Jivraj and colleagues (2014) identified seven studies using participatory methods. Of the seven, only two identified the participants as autistic. Yusuf and Elsabbach (2015) conducted a scoping review of participatory research in autism biomarker discovery. They found just one that had a participatory component to their research.

Objectives:

The aim of this review is (1) to provide an update on the current state of the literature, (2) to provide a review that is specifically focused on autism, and (3) to expand previous reviews to include a broad definition of the autism community.

Methods:

We followed the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines to conduct a systematic review (Moher et al., 2015). The scope and purpose of this review were guided by a research advisory board consisting of three autistic adults. A librarian guided the search, including the selection of databases and refinement of search terms. The initial article search was conducted on December 4th, 2020, and updated on July 1st, 2022. Articles selected needed to (1) be published in a peer-reviewed journal before the year 2022, (2) be focused on autism, (3) have a direct mention of a key term related to PR, (4) be available in English, and (5) be original empirical research (e.g., qualitative or quantitative) and include a methods section. Articles focused on PR were excluded as they often blended the lines between empirical and methods and/or reported on the process of doing research of other articles that were included in the review. See figure 1 for an overview of the study search and selection process.

Results:

See table 1 for the articles identified and the full results. Of the 48 articles we identified, 24 had autistic people as their collaborators, 10 had other types of stakeholders (e.g., family members or service providers), and 14 had both autistic and non-autistic stakeholders as collaborators. The stakeholders contributed to various aspects of research, and in 37 of the studies, there was collaboration on multiple, specifically listed research activities. The majority of the studies were qualitative (n = 33). Although all articles specifically listed participatory methods, studies referred to a variety of specific participatory traditions, including community-based participatory research (n = 13), participatory action research (n = 7), and visual methods (n = 8).

Conclusions:

This study indicates that stakeholder engagement in autism research has been increasing over time and is influencing a variety of research topics. Participation in multiple areas of the research process suggests engagement beyond tokenism. Our inclusion criteria often excluded participatory design focused articles which is an important area for future research.

423.176 (Poster) Participatory Research on Support for Autistic Individuals and Their Family Members: Good Practices, Challenges and Success Factors
Background: The Academic Collaborative Centre for Autism (ACCA) is a collaborative network in Flanders (Belgium) funded by the Flemish government. Within ACCA, we perform participatory and practice-oriented research on support for autistic children, adolescents and adults and their family members. Autistic children and adults and their family members. Autistic individuals are part of the cross-project steering board, expert panels for the selection of projects and guidance committees for each project. We will present challenges and success factors within the different phases of research. Challenges are for example related to the question of representation, or tensions between autism community representatives and between representatives and researchers. Identified success factors over the past years include mutual respect, time and effort to build bridges, inclusive communication, and a flexible approach.

Conclusions: By conducting participatory research we try to ensure that our research is and remains relevant for autistic individuals. Although participatory research is an important endeavour in autism research, appropriate engagement of autistic individuals in all phases of research requires effort, evaluation and a continuous process of adaptation to improve participation.

423.177  (Poster) Perceived Support Needs of Young People on the Autism Spectrum and Their Caregivers

K. Evans1,2, A. J. Whitehouse3,4, E. D’Arcy2,7,8, M. Hayden-Evans9, K. Wallace7, R. L. Kazminski2,15, R. Thorpe6, S. J. Girdler1,2,4,17, B. T. Milbourne1,2,16, S. Bolto20,21,22 and A. Chamberlain11,12,13, (1)Telethon Kids Institute, The University of Western Australia, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)School of Allied Health, University of Western Australia, Crawley, Western Australia, Australia, (4)Telethon Kids Institute, Perth, Western Australia, Australia, (5)University of Western Australia, Perth, Australia, (6)School of Allied Health, Curtin University, Bentley, Western Australia, Australia, (7)School of Psychology, University of Western Australia, Crawley, Western Australia, Australia, (8)Autism Research Team, Telethon Kids Institute, Subiaco, Australia, (9)Curtin Autism Research Group, Curtin University, Bentley, Australia, (10)School of Occupational Therapy, Speech Pathology and Social Work, Curtin University, Perth, Australia, (11)Telethon Kids Institute, Nedlands, Western Australia, Australia, (12)School of Allied Health, School of Allied Health, Curtin University, Bentley, Western Australia, Australia, (13)Cooperative Research Centre for Living with Autism (Autism CRC), Longpocket, QLD, Australia, (14)Curtin Autism Research Group, Curtin University, Bentley, Western Australia, Australia, (15)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (16)Karolinska Institutet, Stockholm, Sweden, (17)School of Allied Health, Curtin University, Perth, Australia, (18)enAble Institute, Curtin University, Perth, Australia, (19)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (20)Child and Adolescent Psychiatry, Stockholm Health Care Services, Stockholm, Sweden, (21)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, QLD, Australia, (22)Curtin Autism Research Group, Curtin School of Allied Health, Curtin University, Perth, Australia, (23)Cooperative Research Centre for Living with Autism, Long Pocket, QLD, Australia

Background: With an increasing number of young people on the autism spectrum requiring health, disability and education services, wait-times and expenditure have become problematic. Innovative approaches are needed to determine and provide necessary supports in a timely and cost-effective manner, enabling individuals to achieve their prioritized goals and maximize their quality of life.

Objectives: The aim of this study was to explore the perceived support needs of Australian young people on the spectrum and their caregiver(s).

Methods: Phenomenographic Support Needs Interviews were conducted by occupational therapists during home-visits with caregivers of 68 young people on the spectrum (5–17 years) living in four states of Australia. Caregivers were asked to identify and describe up to ten new (unmet) or existing (partially or fully met) support needs, before ranking these from most to least important. The interview summaries were de-identified before importing into NVivo for phenomenographic analysis using a seven step process.

Results:
Caregivers described a total of 403 support needs, averaging approximately six support needs each, where the recipient included the young person, caregivers and/or others. Almost all caregivers reported that at least one support need was being partially met and further support was required and two-fifths of the caregivers described at least one support need that was not currently being addressed at all. The most important support needs frequently spanned multiple aspects of functioning. Where the difficulty underlying these support needs could be attributed to a single aspect, this was most frequently Mental functions, Major life areas (especially school) or Interpersonal interactions or relationships. Qualitative data analysis resulted in two hierarchical outcome spaces, one each for young people and their caregivers, indicating interacting levels of support need areas that could be addressed through a combination of suggested supports. These support needs and suggested supports aligned with almost all chapters within the Body Functions, Activities and Participation and Environmental Factors domains of the International Classification of Functioning, Disability and Health. The overall goals of meeting these complex and interacting support needs were for the young people to optimize their functioning to reach their potential and caregivers to ensure the sustainability of their caregiving capacity. These support need areas most frequently related to difficulties with Mental functions, Learning and applying knowledge, Interpersonal interactions and relationships, Major life areas and Community, social and civic life. Suggested supports were most frequently associated with Support and relationships and Services, systems and policies.

Conclusions:

The caregivers who participated in this study described a vast array of complex and interacting support needs and suggested supports related to 68 Australian young people on the spectrum and their support people. A series of recommendations for support services, researchers and policy makers have been made to position support needs as central during the assessment, support and evaluation phases.

423.178 (Poster) Physical Activity Practices of Mothers and Fathers Caring for Autistic Children

Background: Many US adults do not meet physical activity (PA) guidelines, and those caring for children with disabilities may face additional barriers to PA. However, little is known about the physical activity practices of parents caring for children with an autism diagnosis.

Objectives: We aimed to describe the PA practices of mothers and fathers of autistic children, including the change in maternal PA upon entering a subsequent pregnancy. Additionally, we aimed to examine predictors of PA in this sample, including the proband child’s autism severity.

Methods: PA practices were collected as part of the Early Autism Risk Longitudinal Investigation (EARLI) study, which enrolled pregnant women who already had a child with autism (the proband child). Participants retrospectively reported their frequency and duration of walking/biking for transport, moderate intensity house/yard work, and vigorous intensity exercise. At enrollment (during early pregnancy), mothers reported their PA in the 3 months before the study pregnancy and fathers reported their PA in the 6 months before enrollment. At the 3-month postpartum visit, mothers reported their PA during pregnancy. Minutes per week of moderate and vigorous intensity PA were calculated and compared to Physical Activity Guidelines for Americans (150 mins/week of moderate intensity PA and, for non-pregnant adults, 75 mins/week of vigorous intensity PA). Sociodemographic variables were tested as predictors of each PA measure using simple linear regression and p<0.05. Variables included: household income, parity; maternal and paternal occupational activity level (sedentary to very active), perceived health status (poor to very good), age, education, race/ethnicity; proband’s autism trait severity, measured by the Social Responsiveness Scale; and, during pregnancy only, maternal diet quality, total energy intake, prenatal vitamin usage, and self-reported maternal depression.

Results: Mothers (pregnancy n=177, pre-pregnancy n=229) and fathers (n=135) reported similar levels of moderate intensity PA (median ~31 mins/week). However, levels of vigorous intensity PA varied across groups, with only 16% of mothers engaging in any vigorous intensity PA during pregnancy, compared to 54% in pre-pregnancy and 69% among fathers. Only 29% of mothers who were vigorously active in pre-pregnancy continued during pregnancy, despite recommendations to continue if vigorously active. Furthermore, only 7% of pregnant women met guidelines for minutes of PA per week, whereas 40% of non-pregnant women and 23% of men met guidelines. For all groups, the percent meeting guidelines was lower than published estimates from the US National Health and Nutrition Examination Survey. Income, parity, occupational activity category, age, education, and race/ethnicity were associated with at least one PA measure, but proband’s autism trait severity was not. Parental perceived health status was the only variable consistently associated with PA across groups, with those reporting better overall health also reporting more PA.

Conclusions: Few caregivers in this sample met US guidelines for PA, especially during pregnancy. Because PA contributes to parents’ physical and mental capacity for caregiving, further research is needed to understand barriers to PA (potentially including lack of
awareness regarding PA guidelines) and develop better supports to increase moderate and vigorous intensity PA among caregivers of autistic children.

**J. Blagrave** and **T. Kemper**, (1)Kinesiology, California State University, Chico, Chico, CA, (2)Department of Teacher Education, California State University, East Bay, Hayward, CA

**Background:**

Individuals on the autism spectrum have atypical communication skills, social interactions, and repetitive behaviors and interests compared to those of their neurotypical peers according to the American Psychiatric Association (2013). This condition currently affects 1 out of 44 individuals in the United States, with each affected person expressing symptoms to varying degrees (Maenner et al., 2021). Autism can impact an individual’s social pragmatics, expressive and receptive language, and nonverbal communication cues. There is limited research regarding individuals on the autism spectrum who struggle with expressive language, and as such, the definitions are inconsistent, with descriptions ranging from no spoken language to those who can speak, but with speech patterns that are echolalic (Tager-Flusberg & Kasari, 2013).

In addition to the abovementioned diagnostic criteria for autism, individuals on the autism spectrum often have motor control concerns (Cavallo et al., 2021; Ming et al., 2007; Ozonoff et al., 2008) and sensory avoidance or seeking behaviors (DeBoth & Reynolds, 2017) that can impact their engagement in various physical activity settings (Blagrave, 2017; Blagrave et al., 2021; Colombo-Dougovito et al., 2021; Healy et al., 2013). Limited studies have explored the physical activity (PA) perceptions of children on the spectrum from the parent or caregiver perspective (Blagrave & Colombo-Dougovito, 2019; Kirby et al. 2015; Pan & Frey, 2006; Must et al., 2015), and to date, no studies have explored these experiences through the lens of those with minimal verbal expressive language skills and/or complex communication needs.

**Objectives:** Limited research has examined the experiences of children with ASD who have verbal expressive language, and no research to date has explored the physical activity (PA) preferences children and the autism spectrum with complex communication needs (CCN). This exploratory qualitative study aimed to understand the PA preferences of children on the autism spectrum with CCN, based on previous PA experiences and the PA experiences of these families.

**Methods:** A picture preference chart interview was utilized to capture the PA preferences child participants. Pictures were coded based on activity type to explore themes in preferences. Semi-structured interviews were conducted with the children’s parents to explore PA experiences for the family and coded using thematic analysis.

**Results:** Children on the autism spectrum with CCN were able to express preferences for certain physical activities. Preferences were triangulated with semi-structured parent interviews and parental perceived child preferences. Additional semi-structured parental interviews presented the following themes regarding PA participation for family engagement: (a) the importance of PA and exercise; (b) sensory experiences participating in PA and; (c) atypical struggles.

**Conclusions:** Children on the autism spectrum with CCN were able to convey PA preferences (as triangulated by parental reports), and their opinions should be incorporated when designing physical activity programs and physical education experiences. PA participation of families who have a child on the autism spectrum with CCN has unique challenges, and more support is needed to promote engagement and improve health outcomes for both these affected individuals and their families.

423.180 (Poster) Political Experiences and Barriers to Voting Among Autistic Adults in the United States

**A. U. Tassone**, E. A. DeLucia, K. E. Breitenfeldt and C. G. McDonnell, (1)Department of Psychology, University of Wyoming, Laramie, WY, (2)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA

**Background:** Political participation is an important and meaningful aspect of civic engagement for adults. Existing research suggests disabled persons do not participate in politics at the same rates as the general population, likely due to societal barriers and inaccessible participation structures (Argan et al., 2020). Effectively no research has examined specifically how autistic adults engage in politics, and limited research has considered political attitudes among autistic adults (Taylor et al., 2021). Interventions to improve and support political participation are likely to be most effective if they are tailored to specific barriers autistic adults face and specific policies they value.

**Objectives:** The present study sought to advance understanding of political participation among autistic adults in the United States by 1.) presenting descriptive information about voting history, political views, and policies autistic adults value most, and 2.) evaluating how autistic and non-autistic adults differ in barriers to voting, methods of engagement, and emotional experiences surrounding politics.
**Methods:** Participants included 276 autistic adults and 361 non-autistic adults (nationally representative United States sample). Autistic adults (46.4% cisgender men, 74.3% non-Hispanic white, \( M_{\text{age}} = 29 \) years) included those who reported having a diagnosis (n=214) and those who self-identified (n=62). Participants completed an online survey regarding political attitudes, barriers to voting, frequency of engagement methods, and affective experiences.

**Results:** The majority of autistic adults were registered to vote and identified themselves as part of the Democrat party and as very liberal (Table 1). On average, autistic adults strongly or very strongly supported policies that proposed 1.) increasing representation and access for disabled individuals, 2.) increasing spending for schools, teachers, and childcare, 3.) investing in fighting climate change, 4.) ensuring gender equality, 5.) Medicare for all Americans, 6.) ensuring rights and protection for LGBTQ+ people, 7.) background checks for all gun sales, and 8.) legalizing marijuana.

An independent \( t \)-test was conducted to examine group differences in barriers to voting (Table 2). Large and medium effect sizes were found with greater barriers for autistic adults due to mental health difficulties, fear of crowds, fear of leaving the house, and lack of/difficulties with transportation. These results suggest greater mental health support is needed for autistic adults in political processes.

Group differences in frequency of political engagement methods showed that autistic adults reported higher levels of engaging in these ways: through social media outlets (following \( p=.029, d=.175 \) and commenting \( p=.002, d=.252 \)) and signing a petition (\( p<.001, d=.287 \)). Autistic adults reported lower levels of engaging in these ways: watching political debates (\( p=.007, d=.214 \)), watching news (\( p=.010, d=.207 \)), and reading about politics in print newspapers (\( p=.003, d=.236 \)). When asked about the current political climate, autistic adults reported higher feelings of being upset (\( p<.001, d=.425 \)), hostile (\( p<.001, d=.388 \)), ashamed (\( p<.001, d=.391 \)), nervous (\( p<.001, d=.611 \)), and afraid (\( p<.001, d=.525 \)). They reported lower feelings of being determined (\( p=.01, d=.207 \)) attentive (\( p=.01, d=.208 \)), and active.

**Conclusions:** Results of this study suggest autistic adults face unique barriers to political participation and have unique experiences related to participation. Limitations and future directions will be discussed.

423.181 (Poster) Predictors of Change in Wellbeing and Mental Health in Parents of Autistic Pre-Schoolers  
C. C. Green, J. A. Smith, C. A. Bent, L. Chetcuti, M. Ulijarevic, P. Benson and K. Hudry, (1) La Trobe University, Melbourne, VIC, Australia, (2) Childhood Autism Phenotype Team, La Trobe University, Melbourne, VIC, Australia, (3) La Trobe University, Melbourne, VIC, AUSTRALIA, (4) Melbourne School of Psychological Sciences, Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Parkville, VIC, (5) University of Massachusetts, Boston, Boston, MA

**Background:** Parents of autistic children report decreased wellbeing and elevated mental health difficulties compared to other parents. Previous studies have identified concurrent correlates of wellbeing and mental health, but few have investigated predictors of subsequent wellbeing and mental health, or of change over time, particularly among parents of young autistic children.

**Objectives:** We examined which among various child, parent, and family/socioeconomic factors predicted reliable change over time in self-reported mental health and wellbeing outcomes, amongst parents of autistic pre-schoolers.

**Methods:** Fifty-three autistic pre-schoolers aged 17 to 44 months (\( M = 35.44, SD = 6.31 \)) and their primary caregivers were assessed at three timepoints (T1-T3) approximately 5-months apart. A subset (n=18) of families were randomised immediately after their T2 assessment for additional parent-coaching ESDM (P-ESDM) sessions delivered between T2 and T3. Parent mental health (DASS-21) and wellbeing (WEMWBS) outcomes were analysed at all three timepoints, while all other parent (e.g., coping strategies), child (e.g., level of autistic traits), and family factors (e.g., resources, income) were from T1. To assess individual-level change, Reliable Change Index (RCI) \( z \)-scores were computed as indicators of psychometrically reliable change for DASS-21 and WEMWBS total scores between T1-T2 and T1-T3.

**Results:**

Pattern of Change in Wellbeing and Mental Health: There was no significant group mean-level change over time in WEMWBS total scores, nor in DASS-21 total scores. At each timepoint, parents reported lower levels of wellbeing and higher levels of mental health difficulties compared to normative data.
Change in Wellbeing: Children’s adaptive behaviour (VABS ABC) was a significant unique predictor (above and beyond mental health [DASS-21] and family resources [Clarke QRS]) of WEMWBS RCI scores from T1-T2. Parents’ participating in parent-coaching ESDM between T2 and T3 was a significant unique predictor (over DASS-21 and parents’ initial statement of their child [AFMSS]) of WEMWBS RCI scores from T1-T3.

Change in Mental Health: Children’s level of autistic traits (ADOS CSS), parents’ coping strategies (Brief COPE), and parents’ initial description of their child (AFMSS) significantly predicted DASS-21 RCI scores from T1-T2; however, none of the predictors made a significant unique contribution. Parents’ initial description of their child (AFMSS) was the only significantly predictor of DASS-21 RCI scores from T1-T2.

Conclusions:
A combination of parent- and child-related traits predicted short-term change in wellbeing and mental health, while parent-related factors alone predicted medium-term change in wellbeing and mental health.

423.182 (Poster) Predictors of Stress in Mothers of Preschool Children with Autism Spectrum Disorder
S. Simlesa and M. Zovko, (1)Faculty of Education and Rehabilitation Sciences, Child Communication Research Laboratory, University of Zagreb, Zagreb, Croatia, (2)Faculty of Electrical Engineering and Computing, Zagreb, Croatia

Background: To this day, majority of interventional approaches for children with autism spectrum disorder (ASD) are oriented towards the child or its parent with the primary goal of adopting strategies for developing joint attention and communication skills. Still, these strategies are not meeting the needs of parents and psychological stress they are exposed to by raising a child with ASD. Since parental stress level is affected by a number of negative daily events, as well as many protective factors, it is extremely important that the expert helps the parent to identify both - daily stressors and appropriate types of support suited for the parent, his/her child and the whole family.

Objectives: This aim of this study was to explore the predictors of maternal stress in order to identify the best predictor among sociodemographic factors, coping styles, characteristics of the child, social support as well as characteristics of intervention.

Methods: The study included total of 80 mothers of preschool children with ASD. Parenting Stress Index, Fourth Edition Short Form (PSI-4-SF), COPE inventory and Sociodemographic inventory were administered to all participants.

Results: Research showed that 22% of mothers that have children with ASD perceive severe parental stress levels. Social support, characteristics of the child and avoidance coping strategies were found to be significant predictors of parental stress. Neither sociodemographic factors, intervention, problem-focused or emotional coping were found to have an effect on parental stress level.

Conclusions: Although there is strong tendency for professional support to be directed towards the child, the results of this research point that the role of experts is also to help parents identify sources of stress as well as direct the parents to appropriate forms of support with regard to the needs of the child, as well as the needs of the parents.

423.183 (Poster) Prevalence of Interactions with First Responders: Reports from Caregivers of Children Diagnosed with ASD Who Exhibit Challenging Behaviors
N. Nuhu, A. Pavlov and M. Scheithauer, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Pediatrics, Emory University School of Medicine, Atlanta, GA

Background: Children with autism spectrum disorder (ASD) are prone to challenging behavior that can escalate into behavioral crises requiring the involvement of first responders (e.g., police officers) to ensure safety or provide transportation for psychiatric or other medical care. Unfortunately, despite the need for help, parents that seek emergency services when managing challenging behavior report frustration with how first responders interact with them and respond to their child. Currently, there is a gap in the literature regarding how racial and/or ethnic status affects families of individuals with co-occurring developmental disorders use of emergency services to manage behavioral crisis situations.

Objectives: Study 1 examined whether caregivers report differential use of first responder services based on their child’s demographic characteristics (e.g., race/ethnicity, gender, etc.). Study 2 surveyed caregivers regarding their encounters with and attitudes towards calling first responders during behavioral crises.

Methods: For Study 1, researchers conducted a retrospective review of 579 patient health records of children who sought services for the assessment and treatment of challenging behavior. Researchers extracted data including demographic information and endorsement of contacting emergency services due to challenging behavior. For Study 2, we conducted a thematic analysis of caregiver descriptions.
regarding their encounters with first responders when managing their child’s challenging behavior during a behavioral crisis using responses on free-text questions. A total of 23 caregivers participated.

Results: Study 1 findings indicated 72 caregivers (12.4%) reported calling emergency services in the last 12 months. Families did not differ in emergency service utilization based on identified race. There was a difference in service utilization based on reported ethnicity, with families who identified as non-Hispanic/Latino more likely to report calling emergency services than those who identified as Hispanic/Latino. For Study 2, with respect to race, 63.6% of caregivers who identified their child as Black endorsed thinking about race when deciding how to manage their child’s challenging behavior whereas no respondents (0%) who identified their child as White endorsed thinking about race. Ten respondents (43.5%) endorsed a “bad” interaction with first responders. Families did not differ in endorsement of negative experiences with first responders per their racial identity. Thematic analyses identified four themes present in caregiver descriptions of their encounters with first responders when managing their child’s challenging behaviors: inexperience with autism, physical restraint, poor communication, and de-escalation strategies.

Conclusions: Exploratory results from both studies indicate families from racial/ethnic minority groups experience barriers to seeking first responder assistance. Although most interactions between first responders and community members are positive, families of children with ASD frequently indicate frustration with the outcome of their attempts to seek assistance with behavioral crises. When this frustration leads to hesitancy to seek help from first responders, the burden already experienced by families of children with ASD who engage in challenging behavior is compounded. Negative interactions between caregivers and first responders, or parent perceptions that these encounters will be negative, are a social determinant of health because they diminish willingness to seek assistance, creating disparities in access to needed medical and mental health services.

423.184 (Poster) Priorities for Intervention: Perspectives of Parents of Preschool Children with Autism in Bosnia and Herzegovina

H. Memisevic, Faculty of Educational Sciences, University of Sarajevo, Sarajevo 71000, Bosnia and Herzegovina

Background: Parents of children with autism spectrum disorder are involved in creating Individualized Education Programs for their children. Together with other professionals (teachers, psychologists, and special education teachers), they decide on the most urgent developmental areas that need intervention.

Objectives: The present study aims to examine what parents of preschool children with ASD in Bosnia and Herzegovina believe are the most important priorities for intervention.

Methods: We used a survey to examine the perspectives of parents of children with ASD about intervention priorities. The survey asks how much of a priority the intervention is in various developmental fields, such as communication, social skills, behavior, motor skills, and self-care. A total of 60 parents of preschool children with autism completed the survey.

Results: The results indicate that the highest priorities for parents are in the domain of communication skills. More specifically, the top six priorities were: 1. expressing interests and wishes, 2. following instructions, 3. communicating with others, 4. naming objects, 5. initiating conversation, and 6. responding appropriately to questions. Other intervention priorities in the top-10 list were playing with peers, initiating interactions, toileting, and feeding.

Conclusions: Given that communication deficits are one of the hallmarks of autism, it is not surprising that parents consider intervention in the communication domain the most important for their children. This information is important for the stakeholders and professionals working in the field, as it can help tailor interventions that are aligned with parental priorities.

423.185 (Poster) Promoting Meaningful Collaboration between Autism Researchers and the Autistic Community: An Example from the Campus Belonging Network

(1) Educational Psychology, University of Alberta, Edmonton, AB, Canada, (2) Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada, (3) Counselling Psychology, University of Calgary, Calgary, AB, Canada, (4) University of Alberta, Edmonton, AB, Canada, (5) Ryerson University, London, ON, Canada, (6) First Nations Technical Institute, Elphin, ON, Canada, (7) Alberta Health Services, Edmonton, AB, Canada, (8) Department of Psychology, Center for Mind and Brain, UC-Davis, Davis, CA, (9) University of Calgary, Calgary, AB, Canada, (10) University of Western Ontario, London, ON, Canada, (11) Carleton University, Ottawa, ON, Canada, (12) School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, (13) University of Calgary, Edmonton, AB, Canada

Background: Autistic advocates have expressed frustration with the lack of community engagement in autism research (den Houting, 2021). At the same time, autistic advocates feel they would benefit from training in the underlying philosophies of participatory research (Pickard et al., 2020). The Campus Belonging Network uses a community-based participatory research (CBPR) approach to explore the experiences of autistic postsecondary (PS) students in Canada to ensure our research was inclusive, transparent, and focused on improving...
quality-of-life as defined by autistics (Pellicano et al., 2014). Autistic Community Partners (ACPs) with lived experience within PS contexts informed research design and methods.

**Objectives:** To capture ACP perspectives on the impacts of engaging as co-researchers in exploring how to build the capacity of PS institutions to foster belonging for all autistic members of our campuses.

**Methods:** Four ACPs (aged 27-46), including Indigenous and queer participants, completed survey questions that focused on what they hoped to gain from being an ACP. ACPs then completed training in research processes (Research 101 Training), research ethics, and qualitative interviewing. For six months, ACPs participated in monthly virtual meetings. They provided feedback on research design and materials in partnership with autistic researchers from the project’s steering committee. As the project ended, ACPs reflected upon what they gained from participating as co-researchers in our project.

**Results:** Their feedback revealed two main themes: enhanced knowledge/skills and well-being. Enhanced knowledge/skills. Our ACPs reported they gained more understanding of the research process and felt more confident to be co-researchers in the future. They also reported benefiting from exposure to new and differing perspectives. Lastly, they all indicated a strengthened desire to pursue higher education or future career paths related to research. Enhanced Well-being. ACPs all experienced increased well-being from participating in the project. All described benefiting from the sense of community that emerged within this autistic group, which one ACP called “a safe place to be”. Having their contributions valued and their recommendations enacted also allowed ACPs to see their own gifts more clearly and feel more confident in their abilities. ACPs likewise reported increased well-being because they believed they were making a difference. For example, one ACP said she “gained a sense of fulfillment from contributing to something important to both academia and society as a whole”.

**Conclusions:** Including ACPs in our study benefited both ACPs and overall project quality. ACPs reported learning new knowledge and skills and increased well-being. Our commitment to providing opportunities for ACPs to gain new competencies and professional skills moved this project beyond participatory research and into emancipatory research, wherein the participatory experience generates new transferable skills for the former layperson (Chown et al., 2017). In sum, amplifying autistic perspectives within our project empowered ACPs personally and professionally while also improving the overall quality, relevance and impact of our research to enhance autistic PS students’ sense of belonging within Canadian PS institutions.

**423.186 (Poster) Psychiatric Diagnoses of Parents and Siblings of Children with Autism Spectrum Disorder (ASD) in Specialized Inpatient Units and Their Relationship to Problem Behaviors**

K. A. Pedersen, E. Touchette, S. L. Santangelo and M. S. Siegel, (1)Center for Clinical and Translational Science, MaineHealth, Portland, ME, (2)Department of Medicine, Tufts University School of Medicine, Boston, MA, (3)Psychiatry, Tufts School of Medicine, Boston, ME, (4)Spring Harbor Hospital, Westbrook, ME, (5)The Glickman Lauder Center of Excellence in Autism and Developmental Disorders, Portland, ME.

Background: Several studies have examined psychiatric diagnoses of parents and siblings of children with autism spectrum disorder (ASD). However, there is little research examining psychiatric diagnoses of parents and siblings of children with profound autism and severe challenging behavior, such as those who are hospitalized in specialized inpatient units. The relationship of parent psychiatric diagnoses to their child’s problem behaviors is also unclear.

**Objectives:** To describe psychiatric diagnoses of parents, and full- and half-siblings of children with ASD hospitalized in specialized inpatient units. To examine the relationship between parent psychiatric diagnoses and child problem behaviors.

**Methods:** Data from 1014 hospitalized children and adolescents with an Autism Diagnostic Observation Schedule-2 confirmed ASD diagnosis from the Autism Inpatient Collection (AIC), and data from a biological parent, were analyzed. The AIC is a multi-site study of patients hospitalized in inpatient units specialized for the psychiatric treatment of children with ASD and other neurodevelopmental disorders. Parents provided information regarding their own psychiatric diagnoses, and those of any full- and half-siblings, as well as parent-rated behavioral measures for their child with ASD upon admission. Data was collected on the following psychiatric diagnoses: anxiety, depression, post-traumatic stress disorder (PTSD), obsessive compulsive disorder (OCD), attention deficit hyperactivity disorder (ADHD), conduct disorder, oppositional defiant disorder (ODD), ASD, intellectual disability (ID), Tourette’s, learning disorders (LD), psychosis, bipolar disorder, and schizophrenia. Descriptive statistics, including means and standard deviations for continuous variables and proportions for categorical variables, were computed. Multiple regression analysis was conducted to examine the relationship between psychiatric diagnoses and child problem behaviors.

**Results:** The most common psychiatric diagnoses for mothers were anxiety (44%) and depression (43%); for fathers it was depression (18%) followed by anxiety (15%); and ADHD (14%) and ASD (14%) for full-siblings, and half-siblings 14% and 6% respectively (Figure 1). Only 1% of mothers and 2% of father’s reported an ASD diagnosis in our sample. Mothers with versus those without anxiety ($M=28.8\pm9.9$, vs $26.5\pm9.7$, $p=.02$), depression ($M=28.4\pm8.8$ vs $26.3\pm9.8$, $p=.04$), ADHD ($M=29.5\pm9.5$ vs $27.2\pm9.3$, $p=.05$) or bipolar disorder ($M=30.3\pm9.6$ vs $27.5\pm8.4$, $p=.03$), had children with significantly higher problem behavior scores. Fathers with versus those without ID ($M=33.7\pm7.2$, vs $27.4\pm9.2$, $p=.05$), or conduct disorder ($M=34.1\pm3.9$, vs $25.8\pm4.5$, $p<.001$), had children with significantly
higher problem behavior scores. Interestingly, fathers with OCD (M=26.3±8.7, p=.02), had children with significantly lower problem behavior scores than fathers without OCD (M=30.6±8.8). See Table 1 for descriptive statistics for the complete sample.

Conclusions: Children with ASD who have mothers with self-reported anxiety, depression, bipolar disorder, or ADHD, and fathers with self-reported ID, or conduct disorder, have significantly higher problem behaviors in our sample. Both mothers and fathers reported anxiety and depression as their most common psychiatric diagnoses, indicating the need for interventions to reduce anxiety and depression in both mothers and fathers with a child with ASD who are psychiatrically hospitalized. Further exploration into how parents’ psychiatric diagnoses may relate to their child’s problem behaviors as well as the potentially protective effects of OCD in fathers requires further investigation.

423.187 (Poster) Psychological Wellbeing in Parents: A Comparison in Relation to Their Infant to Adult Children with Autism, Cerebral Palsy, and Neurotypicality

M. Franco, L. M. Zeuch and A. P. Costa, University of Luxembourg, Esch-sur-Alzette, Luxembourg

Background: Considering the many joys of parenthood, raising a child can also be fairly demanding. While parents of neurotypical children may experience their parenthood as challenging, it has been found that, in comparison, parents of a child with a developmental disorder, such as autism, experience poorer mental health and psychological well-being (Scherer et al., 2019). This may be related to their increased caregiver burden due to, for example, additional financial costs (Oh & Lee, 2009), decreased employment and social isolation (Currie & Szabo, 2021), concerns about the future (Auerbach et al., 2019), and challenging behavior of the child (e.g. aggression, hyperactivity, defiance; Jones et al., 2014).

Objectives: The current study aims to investigate the psychological wellbeing of parents of autistic children (i.e. a cognitive developmental disorder), in comparison to parents of children with cerebral palsy (i.e. a physical developmental disorder), or neurotypical children. In addition, personal and social factors contributing to parents’ general psychological wellbeing were identified.

Methods: The data was collected via an online survey, from N=187 parents (94.7% mothers, 17 different nationalities, M_age=35.16; SD_age=7.44), of which n=49 had an autistic child, n=28 had a child with cerebral palsy, and n=110 had a neurotypical child. Children were aged between 2 months and 41 years (M_age=5.65; SD_age=6.40), 110 were male, 76 were female, and one identified their child as diverse. Parents reported general socio-demographic data, as well as several mental health assessments. These included the WHO-5 Well-being Index (World Health Organization, 1998), the Major Depression Inventory (MDI; Cuijpers et al., 2007), the Zung Self-Rating Anxiety Scale (SAS; Zung, 1971), the Parental Stress Scale (PSS; Berry & Jones, 1995), the Brief-COPE questionnaire (Carver, 1997), the Brief Resilience Scale (BRS; Smith et al., 2008), and an adapted version of the Care Dependency Scale (CDS; Dijkstra et al., 1998).

Results: The results of multivariate analyses of variance indicated a significant group difference in the five outcome variables (i.e. anxiety, stress, depression, resilience, and general wellbeing) based on the children’s diagnosis, F(4, 182)=2.68, p=.004, η^2=.07. Separate analyses of variance on the outcome variables suggested significant diagnosis-effects for anxiety F(2,184)=3.82, p=.024, η^2=.04 and resilience F(2,184)=3.50, p=.032, η^2=.04. Parents of autistic children and children with cerebral palsy each experienced significantly more anxiety, and parents of autistic children were significantly less resilient than parents of neurotypical children or children with cerebral palsy. Using a multiple linear regression analysis, we found that certain parent-characteristics (i.e. depression scores, stress scores, and income satisfaction) as well as the child’s age, were predictors of the parents’ general well-being (Table 1).

Conclusions: This study supports previous research finding that parents of children with cerebral palsy and autism each experience poorer psychological wellbeing than parents of neurotypical children. In general, however, a child’s diagnosis was not found to significantly predict their parents’ psychological wellbeing. These results bring further knowledge into the specific demands parents of autistic and other neurodivergent children may experience in comparison to parents of neurotypical peers, and how their psychological wellbeing can be catered for and supported more specifically.

423.188 (Poster) Public Health Implications of the Accuracy of Informational Videos about Autism on Tiktok

Background: The internet is the most common source of information about autism spectrum disorder (ASD) for parents, with 93.9% having accessed the internet as a source in a 12-month period (Lindly et al., 2022). Although the internet, and social media in particular, have made information about ASD readily accessible to the general public, concerns have been raised about the unfiltered nature of the content. TikTok is a popular short video format social media platform boasting over one billion active users in 2021. Although the app is designed for entertainment, it has grown to include videos intended to be informational. The #Autism hashtag on TikTok has accrued 11.5 billion views as of September 2022. Concerns related to ASD content on this platform include the possibility that video creators may
sensationalize content to attract viewers at the expense of accuracy. It is imperative to analyze the accuracy of information on TikTok and identify misleading information. To our knowledge, no studies have reviewed the accuracy of ASD content on TikTok.

**Objectives:** This exploratory study seeks to be the first to evaluate the accuracy of TikTok videos that are designed to disseminate information about ASD.

**Methods:** Videos were sourced from the #Autism hashtag. This hashtag is approximately sorted by video views. Informational videos (n=133) were defined as videos designed to share information about ASD generally (for example, videos that include statements about an intervention or diagnostic tool beneficial to the ASD population), as opposed to an individual’s personal experience. Videos that did not specifically mention or relate to ASD or were not in English were excluded from analysis. Videos were then coded as either accurate or inaccurate based on their consistency with existing literature; any overgeneralization was coded as inaccurate. Two coders independently coded videos as either accurate or inaccurate with intercoder reliability at 80.1%. Discrepancies were resolved by a third coder. Additional data were collected on the videos’ views and likes, whether the video creators disclosed a diagnosis of ASD (ASDC) and creators’ status as healthcare professionals (HCP).

**Results:** Ninety-five (71.4%) of the videos were from ASDCs, seven (5.26%) were from HCPs, and thirty-one (23.3%) were from creators that did not identify themselves as ASDCs or HCPs. 72.9% of the analyzed videos were classified as inaccurate. Videos posted by HCPs were more likely to be accurate (X^2 (1, N = 133) = 7.4, p = .007). Videos classified as being inaccurate totaled 144,584,203 views and 16,724,125 likes, while those classified as being accurate totaled 54,111,743 views and 8,468,277 likes. There were no significant differences in mean views and likes for accurate versus inaccurate videos.

**Conclusions:** Although TikTok is a prominent source of information about ASD, most of the informational content on the platform appears to be inconsistent with existing research. Misunderstanding of ASD is a public health problem and may impact how families, professionals, stakeholders, and autistic individuals relate to evidence-based services and supports. Awareness of information and misinformation spread through social media is critical for professionals to better serve the autism community.

423.189 (Poster) Quality of Life in Parents of Children with Autism in Singapore: Examining the Role of Courtesy Stigma, Affiliate Stigma and Psychosocial Variables Using the Double ABCX Model of Adaptation

**J. H. Tan**^1,2 and **H. C. Koh**^1,3, **1Psychology, National University of Singapore, Singapore, Singapore, 2Autism Resource Centre, Singapore, Singapore, 3Department of Child Development, KK Women’s and Children’s Hospital, Singapore, SINGAPORE

**Background:**

Caregiving for a child with autism can be a challenging experience for parents. In addition to the physical demands of caregiving, studies have shown that parents of children with autism can be negatively affected by the stigma of having a child with autism. Courtesy stigma refers to the prejudices, stereotypes and discriminatory behaviour that may be perceived by parents of children with autism, for their close association to their child with autism. An internalisation of courtesy stigma can lead to affiliate stigma, whereby these parents develop negative self-evaluation and negative emotions towards themselves.

Much of caregiving research investigated how various sources of stress and psychosocial factors interact and shape caregiver outcomes. However, courtesy stigma and affiliate stigma, has yet to be examined alongside other psychosocial factors.

**Objectives:** This study used the McCubbin & Patterson (1983)’s Double ABCX model of Adaptation to explore the interplay of courtesy stigma, affiliate stigma, with other psychosocial variables, namely caregiving demands, social support and active avoidant coping, in influencing quality of life (QOL) among parents of children with autism.

**Methods:** Parents of children with autism aged between 3 to 18 years old were invited to participate in an anonymous online survey. The survey consisted of six questionnaires on caregiving demands, courtesy stigma, social support from significant others, family and friends, use of avoidant coping strategy, affiliate stigma and QOL. Data on the parents’ socio-demographic characteristics and child’s level of need was also be collected. Mediation and moderation effects were examined using Multiple Regression Analysis.

**Results:** A total of 111 parents (88.3% mothers) completed the survey. All variables were found to be significantly correlated with one another (r=−.22-.64, p<.05). Results from regression analysis found that in the relationship between caregiving demands and parent QOL, active avoidant coping was a partial mediator, and social support from significant others and family, not from friends, were moderators. Results also found that in the relationship between courtesy stigma and parent QOL, affiliate stigma was a full mediator, although social support from significant others, family, and friends were not significant moderators.

**Conclusions:**
Typical caregiving arrangements for individuals with autism are usually kept tightly within the immediate family circle, hence it is not surprising that social support from significant others and family but not friends, were significant moderators of the relationship between caregiving demands and parent QOL. The hypothesized moderation effects of social support from significant others, family and friends, between courtesy stigma and parent QOL was unsupported. It is possible that courtesy stigma may be widely prevalent at the community and societal level, such that even a strong social support system may be unable to buffer its negative impact on parents.

Increasing social support from significant others and family can help ease the caregiving burden experienced by individual caregivers and improve the caregivers QOL. There is a need for further community and societal efforts to reduce the stigma surrounding individuals with autism and their families, so as to building a more supportive social context for these parents and their children.

423.190  (Poster) Quality of Mother-Child Interaction in Dyads with an Autistic Children: How Different from Normative Dyads? Preliminary Results from a Prospective Cohort in Canada.

Background:

Autism is no longer considered a rare condition with a prevalence of 1%. Autism is characterized by challenges in social interaction and communication, restricted interests and repetitive behaviors present since early childhood. These particularities in social interaction and communication are likely to influence the nature and quality of parent-child interactions. While more interventions focus on supporting and teaching parents strategies to promote child socio-emotional development and well-being, the need to better understand relationship quality between a parent and their autistic children is essential. However, few studies have observed the parent-autistic child interaction and the determinants of this relationship.

Objectives:

To further our understanding of the mother-autistic child relationship, the current study compared the quality of mother-autistic child interaction with that of mothers with their neurotypical child on several relationship dimensions (e.g. dyad coordination, the tension in the interaction, maternal sensitivity).

Methods:

Sixty-one (N=61) mother-child dyads participated in this study (n= 33 dyads including an autistic child, M-AC dyads; and n=28 dyads of mothers and their neurotypical children, M-NC dyads). The mothers were between 26 years old and 46 (mean = 3.48; sd = 4.94), and the children were between 2 and 6 years old (mean = 4.45; sd = 1.32). The quality of mother-child interactions was assessed by a behavior observation of a 10-minute video session using the Dyadic Interaction Grid. It includes eight 7-point subscales and a global quality score: coordination (1), communication (2), role (3), emotional expression (4), maternal sensitivity – appropriate responding (5), tension – relaxation (6), mood (7) and pleasure (8).

Results:

Preliminary results suggest that M-AC dyads global quality of interaction (mean = 3.91; sd = 1.47) is significantly different than M-NC dyads global interaction quality (mean = 5.21; sd = 1.07; t(59) = 3.91, p < .001). In addition, every components of the interaction (e.g. coordination, pleasure, maternal sensitivity, etc..) is different among M-AC dyads in comparison with M-NC dyads.

Conclusions:

The M-AC dyads' global social-affective quality of interaction is significantly different than the normative dyads, which implies challenges for both the mother and the autistic child to maintain a good, coordinated, communicative and pleasurable relationship. The present study demonstrates the need to better identify the factors associated with the quality of parent-autistic child interaction. These potentially influencing factors could represent targets for complementary intervention supporting the child's optimal development and, at the same time, facilitating daily family relations.

423.191  (Poster) Barriers to Providing Quality Transition Supports to Autistic Students
Background: In the United States, the Individuals with Disabilities Education Act (IDEA, 2004) requires implementation of school-based transition planning to prepare students with disabilities for adulthood. Since this legislation was passed, researchers have recommended particular components of transition planning to promote autistic youths’ successful transition from high school to adulthood. These components include focusing on students’ strengths, needs, and goals for adulthood; developing relevant skills (e.g., self-determination); fostering career-related experiences; and providing access to support systems (Lee & Carter, 2012; Wehman et al., 2014). Even with such recommendations, several issues remain. First, it is unclear whether school professionals attempt to enact appropriate transition supports. Second, barriers may make it challenging for school professionals to implement quality transition supports. Both issues could contribute to disengagement of autistic youth following high school (Shattuck et al., 2012). Previous studies have gathered perspectives of key stakeholders (e.g., health care professionals) regarding barriers that limit successful transition to adulthood (Kuo et al., 2018; Snell-Rood et al., 2020); however, these studies did not specifically address school-related barriers.

Objectives: To examine barriers school professionals report make it difficult to prepare transition-age autistic youth for adulthood.

Methods: Participants had to have a role as special educator, transition specialist, school psychologist, or other school professional, and work directly with at least one transition-age (14-22 year-old) autistic student. Participants completed an open-ended online survey which was developed based on Kohler’s Taxonomy for Transition Planning 2.0 (Kohler et al., 2016) and included questions about the transition supports they provided autistic transition-age youth and barriers that made it difficult to provide transition supports. Here, we focused on the barriers identified by participants. NVivo software was used to organize and code participant responses. Two coders used qualitative content analysis to inductively identify categories (e.g., autistic youth, familial) and themes (i.e., transition supports and barriers) (Hsieh & Shannon, 2005).

Results: Twenty-one school professionals completed the survey. All participants identified as White women in a variety of roles (see Table 1 for additional participant characteristics). Barriers described by participants pertained to autistic students, their families, the classroom and school context, and community. Table 2 provides descriptions of each barrier category with transcript extracts that illustrate each category. Most of the participants perceived deficits of autistic students and their families as barriers to providing transition-related services. In contrast, a few participants understood barriers to providing transition supports as issues beyond the autistic youth and their families, such as school professionals’ own lack of knowledge regarding transition services.

Conclusions: Barriers to providing transition-related support were framed as stemming from autistic students and their families, consistent with deficit ideologies (Gorski, 2011). We recommend teacher preparation programs and professional development trainings create spaces that promote a social model understanding of disability, so that insufficient accommodation, and not student and family deficits, are viewed as the source of barriers to service provision. Furthermore, school professionals should receive autism-specific training that focuses on transition-related resources and supports to provide autistic transition-age youth.

Background: Parents of autistic children report that their children’s primary care physicians (PCPs) are “not good” at addressing autism-specific needs, and PCPs themselves report a lack of self-perceived confidence and need for greater education about autism. Latino families of autistic children report even greater barriers than white families in accessing high-quality, family-centered healthcare for their autistic children. There is a dearth of research, however, focusing on environmentally-related factors influencing the healthcare experience. As recognized by the International Classification of Functioning, Disability, and Health (ICF), environmental factors (e.g., physical, social, attitudinal, and political environments in which people live and conduct their lives) have the potential to facilitate or constrain function. Understanding the environmental barriers and facilitators impacting the healthcare experiences of Latino families of autistic children has the potential to reduce these documented healthcare disparities.

Objectives: The purpose of this study was to understand the environmental barriers and facilitators impacting the healthcare experiences of bilingual Latino families of autistic children in Los Angeles County.

Methods: This study utilizes a subsample obtained from a 12-month ethnography carried out in two phases. Phase 1: Two audio-recorded interviews were conducted with 12 families to understand experiences obtaining an autism diagnosis and services for children. Six of these families were then recruited using heterogeneity sampling to continue to Phase 2: Narrative interviews and observation in home, clinic, school, and community contexts. Children’s health records provided data triangulation. For this study, we identified healthcare stories using NVivo 10 software and a narrative analytic approach, resulting in a subcorpus of 10 interviews, 2 observations of PCP visits, and 2
Results: Common environmental barriers impacting families’ healthcare experiences were found in ICF categories Support and Relationships (e.g., lack of perceived support from PCP); Attitudes (e.g., perceived negative attitudes of PCP towards autism, PCPs not taking health-related reports of child symptoms seriously); and Education and Training (e.g., lack of adequate autism-specific training for PCPs). Most parents viewed their child’s PCP as helpful for dealing with the child’s physical illnesses but “hands off” in addressing the child’s autism-specific symptoms and developmental and behavioral challenges. All parents reported that they learned about autism resources without support from their PCP. Environmental facilitators included Support and Relationships and Attitudes (e.g., PCPs who were open to learning about autism and acknowledged parental expertise).

Conclusions: Findings suggest that the perceived “hands off” nature of PCPs in addressing the child’s autism-related developmental and behavioral challenges may be perceived by Latino parents as a lack of support and failure to provide expected guidance, and could negatively impact parent-provider trust and communication. PCPs might better meet families’ needs for support and education by engaging with and educating parents about the safety and efficacy of a wider range of autism treatments. These findings have implications for both PCP and parent education.

423.193 (Poster) Research 101 Training Development: A Participatory Process with Autistic Adults

J. Ryan, L. Hull, H. M. Brown, S. Thompson-Hodgetts and S. Fletcher-Watson. (1)Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada, (2)Population Health Sciences, University of Bristol, Bristol, UNITED KINGDOM, (3)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (4)Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (5)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, UNITED KINGDOM

Background:

Autistic people have been advocating for inclusion in research as collaborators or co-researchers to enhance the relevance of autism research, support the self-determination of autistic individuals, and improve their quality of life. Yet, autism researchers continue to be reluctant to engage the Autistic community in research. One potential way to mitigate that reluctance is to provide training for Autistic people on research processes and collaboration.

Objectives:

To co-develop open-access Research 101 training to increase Autistic adults’ knowledge of the research processes and skills for collaboration to effectively engage in participatory autism research.

Methods:

The Research 101 training course was initially co-developed by an autistic and a non-autistic researcher based on information gathered from a marketing-style survey. This first version was piloted with six Autistic adults who had varying experiences with participatory autism research. Feedback was collected from the participants form using Likert scales and open-ended questions, and changes were made to the training based on the evaluations. The revised training was then piloted with three groups of Autistic adults (n=17); two groups were already involved in research as Autistic Community Partners and one group was comprised of Autistic adults who were not yet involved in research. The training was led by an autistic researcher and consisted of three, 2-hour, synchronous online sessions. Session topics include: Introduction, Being a collaborator, Getting to the research question, Answering the research question, Practical details, and Outcomes, publications, and implementation. Research participants were interviewed individually (n=10) or in a group (n=4) about perceived strengths and weaknesses, and recommended adjustments or criteria for the training. Interviews were audio-recorded and transcribed verbatim. Data analyses, guided by Braun and Clarke’s six-stage approach to thematic analysis, involved an iterative process of coding and theme development. These themes and sub-themes were then reviewed and refined with the assistance of Autistic Community Partners (n=5).

Results:

Three themes were identified. The first theme concerned edits to the existing training which will be reflected in the PowerPoint presentation with items related to content changes, order changes, physical presentation, and activity changes. The second theme was optional adaptations to tailor training for different individuals and groups and included optional training, tailoring logistics such as breaks, session length, and whether activities are done in whole or small groups. These will be outlined in the manual. The third theme was the importance of opportunities for connectivit and included having an autistic trainer, check-ins during the session, and ‘get to know you’ activities. Overall, the trainees appreciated that the training was developed specifically for autistic people and delivered by an autistic person. Additionally, trainees identified that their ability to collaborate in autism research would be impacted by the non-autistic researchers’ attitudes.
Research 101 training focused on research processes and skills for collaboration has been created as an open-access resource that will be hosted by the University of Edinburgh. This training could increase the capacity of Autistic adults to contribute to research as collaborators and increase autism researchers’ willingness to conduct participatory autism research.

**423.194 (Poster) Resiliency to COVID-19-Related Challenges in Preschool-Aged Children with Autism Spectrum Disorder**

(1) Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (2) Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO, (3) Psychology/Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (4) Counseling, University of North Dakota, Grand Forks, ND, (5) Epidemiology, University of Colorado Anschutz Medical Campus, Aurora, CO, (6) Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7) University of Wisconsin-Madison, Madison, WI, (8) University of Colorado Anschutz Medical Campus, Aurora, CO, (9) Children's Mercy Kansas City, Kansas City, MO, (10) Division of Human Development and Disability, CDC, Atlanta, GA, (11) Centers for Disease Control and Prevention, Atlanta, GA

**Background:** The COVID-19 pandemic had numerous negative effects on children. Some children were able to recover from these challenges more easily than others. A deeper understanding of this phenomenon, also known as resiliency, may suggest ways to improve child outcomes.

**Objectives:** This study modeled the relationship of child, family, and social characteristics on resiliency in children during the COVID-19 pandemic. Given the increased challenges posed to children with ASD, we hypothesized children with ASD would show reduced resiliency compared to children without ASD.

**Methods:** The Study to Explore Early Development (SEED) is a multi-site case-control study of children aged 2-5 years with ASD conducted during 2007-2020. Children were classified as having ASD using standard diagnostic measures; children in the population control group were randomly selected from birth records. Mothers completed questionnaires on developmental and behavioral problems, demographics and their own mental health conditions. During January-June 2021, a questionnaire measuring the impact of the pandemic was collected (N = 641). We created a sum score of child resiliency as our outcome measure, with one point assigned to each of the following factors demonstrating improvement or no change: 1) sleep habits; 2) physical activity habits; 3) diet; 4) anxiety; 5) sadness/depression; 6) communication abilities; 7) time spent with extended family, virtually, or 8) in person; and 9) time spent with friends virtually, or 10) in person. We used a multi-step forward selection process to exclude unrelated independent variables from the following list of factors: child demographics, child developmental characteristics (e.g., ASD status, ASD symptoms, early learning abilities, and behavioral problems), maternal demographics, family income and parent’s reduced work, maternal mental health conditions, maternal health promotion practices, and child having a positive response to being able to spend more time with family. A Tobit regression was used to model the impact of the remaining independent variables on child resiliency with all independent variables entered as fixed factors.

**Results:** ASD case status was not associated with child resiliency. Resiliency was negatively associated with maternal anxiety and depression, in addition to child behavioral problems and delayed early learning abilities. Maternal Asian/Pacific Islander and Native American race/ethnicity also were negatively associated with resiliency, although cell sizes for these groups were small and therefore estimates were imprecise. Child having a positive response to the ability to spend more with their family was positively associated with resiliency. There was an interaction between loss of work and family income level. For the middle-income group, resiliency was higher when work was maintained but decreased when work was limited. The lower- and higher-income groups had similar resiliency regardless of work status.

**Conclusions:** Child resiliency is a complex phenomenon. Further research is needed to understand how to address factors negatively associated with child resiliency and promote factors positively associated with child resiliency. Focusing on maternal mental health may be important to mitigate barriers to resiliency in all children, as well as developmental characteristics among children with behavior problems or lower learning abilities.

**423.195 (Poster) Resisting Ableism and Affirming Neurodiversity: First-Person Perspectives on the Power of Student-Teacher Interactions**

(1) Department of Psychology, University of Massachusetts Boston, Boston, MA, (2) Psychology, University of Massachusetts Boston, Boston, MA, (3) Labs of Cognitive Neuroscience, Boston Children's Hospital, Boston, MA, (4) University of Massachusetts, Boston, MA, (5) University of Massachusetts Boston, Boston, MA, (6) Organization for Autism Research, Arlington, VA, (7) Eating Disorders Center for Treatment and Research, University of California San Diego, San Diego, CA, (8) University of California - San Diego, La Jolla, CA, (9) School of Education, University of California, Riverside, Riverside, CA

**Background:** Strong relationships and a sense of belonging in school are crucial to students’ well-being (Maciver et al., 2019). However, many autistic students (Mueller, 2021) and their teachers (Hodge et al., 2019) describe the school context as ableist, marginalizing, or
Objectives: To examine student-teacher interactions as a space of resistance and neurodiversity affirmation, drawing from teachers’ and autistic students’ perspectives on resisting ableism in schools.

Methods: We conducted interviews with autistic individuals (N=10; 40% current high schoolers; ages 15-35; 40% people of color; 40%/20% women/non-binary) and focus groups with teachers of autistic students (N=18; grades K-3; 72% with Master’s; 72% white; 94% women) in the U.S. Using a critical constructivist qualitative approach informed by grounded theory, we coded interviews inductively. Focus groups were coded deductively to determine whether teacher responses evidenced similar themes.

Results: Both teachers and students described student-teacher interactions that embodied resistance. These positive encounters in the classroom included intentional efforts by teachers and students to disrupt ableism in school norms, practices, and policies. In the context of marginalizing school structures, and other student-teacher interactions that perpetuated this marginalization, positive student-teacher interactions reflected several themes, italicized below.

Autistic students reported that positive student-teacher interactions empowered them to engage in self-advocacy through accepted routes (e.g., sharing their needs at IEP meetings; staying in touch with supportive school staff). Students also challenged neurotypical expectations in ways that risked further punishment or stigma (e.g., not complying with ableist policies; speaking out about overlooked needs); their comfort in challenging these expectations with some teachers was at times fostered by their strong connections with other teachers. Likewise, within these positive relationships, teachers actively challenged neurotypical expectations for behavior (e.g., “We all fall into [this trap of] wanting our kids to sit on the carpet nicely. [But] I have students that don’t conform to those [behaviors]. We have to be open to their needs in allowing them to do what they need”). Teachers pushed back against deficit-based views of autistic students, in favor of embracing students’ strengths and autism characteristics. Teachers resisted ableist structures and school practices (e.g., rejecting state-mandated grade-level standards by giving students alternative ways to demonstrate skills; breaking the no-students-inside-during-recess rule to enable preferred peer interactions). Further, teachers subverted school structures in favor of student mental health (e.g., “she [found a way around the attendance requirement and] would let me come in during lunch... instead of having to sit in the cafeteria which was a goddamn nightmare”).

Conclusions: Results highlighted the presence of individual and collective resistance to ableism through student-teacher interactions. This resistance occurred in the context of systemic ableism in schools and carceral practices in regulating student behavior (Annamma et al., 2019; Lalvani et al., 2015). Findings elucidated the potential for teachers and students to challenge and dismantle ableist structures in schools through activism engagement (Hodge et al., 2019).

Background: The COVID-19 pandemic has disproportionately increased the number of stressors experienced by autistic families (e.g., financial instability and social disruptions) and recent research has suggested that this has negatively affected caregiver mental health, family functioning, and children’s well-being (Calvano et al., 2021; Lee et al., 2021; Wade et al., 2021). Guided by the Family Stress Model (Conger et al., 1994) we used a newly developed COVID-19 Family Stressors Scale (CoFaSS, Prime et al., 2021) to measure the impact of pandemic-related psychosocial stressors and tested its effectiveness in screening for mental health concerns in service-seeking caregivers of autistic children.

Objectives: This study used receiver operating characteristic (ROC) curves to analyze the clinical sensitivity and specificity of the CoFaSS in screening for mental health concerns as experienced by service-seeking caregivers of autistic children.

Methods: 213 (Meanage = 39.91, SDage .75, 91% Female) service-seeking caregivers of autistic children who self-referred to the Autism Ontario Services Navigator Program participated in the study. Caregivers completed online surveys including demographics, a brief standardized depression and anxiety scale (K6, Kessler et al., 2002) and the CoFaSS (Prime et al., 2021).

A confirmatory factor analysis was done to examine the factor structure of the CoFaSS scale by subjecting 16 items from the original CoFaSS (Prime et al., 2021) to a three-factor model. Reliability of each CoFaSS scale was examined with Cronbach’s alpha. An ROC curve analysis was used to determine the ability of the CoFaSS to discriminate between the presence vs. absence of clinical levels of caregiver psychological distress and to choose the optimal cut-off point of the CoFaSS. The area under the curve (AUC) statistic was used as a measure of the overall performance of the CoFaSS and to determine the optimal cut-off point on the CoFaSS, we used sensitivity of at least 80% at the expense of specificity.
**Results:** The internal consistency was good for Income Stress (5 items, \( \alpha = .82 \)) and Family Stress scales (7 items, \( \alpha = .79 \)). There were significant associations between the Income Stress and Family Stress subscales (rs = .29, p < .001). The AUC was .74; with a moderate level of accuracy in identifying caregivers with clinical levels of psychological distress. Using a cut-off on the CoFaSS of 29.5 (participants classified as ‘positive’ if greater than or equal to 29.5), the sensitivity and 1-specificity of the test were 82% (true positives) and 44% (false positives), respectively.

**Conclusions:** Results indicate that the CoFaSS showed good reliability and consistency using data collected from a sample of caregivers of autistic children. The measure demonstrated relatively moderate accuracy for detecting clinical levels of depression, anxiety, and distress in caregivers; suggesting its potential effectiveness as a screening measure for autistic caregivers in crisis due to pandemic stressors.

**423.197 (Poster) Shareholder Suggestions: Implications for Policy Changes to Improve Publicly Funded Early Intervention for Autistic Children**

**L. Tomczuk, R. E. Stewart, R. S. Beidas, D. S. Mandell and M. Pellecchia,** (1)Center for Mental Health Policy and Services Research, University of Pennsylvania, Philadelphia, PA (2)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (3)Northwestern University Feinberg School of Medicine, Chicago, IL, (4)Penn Center for Mental Health, University of Pennsylvania School of Medicine, Philadelphia, PA, (5)University of Pennsylvania, Philadelphia, PA

**Background:** Intensive early intervention (EI) can be critical for autistic children and their families, but accessing these services can be difficult. Even among families who access the EI system, canceled and missed appointments are high, and families vary in their reports of satisfaction with EI (Bradhaw, Steiner, Gengoux, & Koegel, 2015). Clinicians and system administrators also report challenges delivering effective EI. Yet, policy decisions affecting early intervention are often made using a top-down approach, where system officials establish and implement policies with little or no community input. Shareholder input is needed to address the issues families, providers, and leaders find most important to inform policy changes aimed at improving publicly funded EI for young autistic children.

**Objectives:** This study aimed to learn about community providers’, leaders’, and families’ experiences with the publicly funded EI system. Specifically, we used a qualitative approach to solicit shareholder input on strategies that could improve the EI system.

**Methods:** Semi-structured interviews were conducted with 38 early intervention providers, 6 agency leaders, and 20 families receiving publicly funded EI in two distinct geographic regions serving highly under-resourced populations within the United States. Clinician and leader interview questions probed for barriers and facilitators to supporting families who receive publicly funded EI and suggestions for improving service delivery and the service system broadly. Families were queried about their attitudes towards EI and suggestions for improving EI for families of young autistic children based on their personal experiences with the system. Transcripts were analyzed iteratively based upon an integrated approach incorporating both inductive and deductive features.

**Results:** Shareholders described three important areas that have direct implications for policy reform in the provision of publicly funded EI services: the billing/funding structure of EI, adapting the content and scope of services, and where and when EI is delivered. Providers described challenges with the billing structure and the fee for service model often used in EI. Agency leaders mentioned difficulties with delivering services to families who have experienced poverty and trauma; they suggested adopting a trauma-informed approach and providing additional funding to support struggling families. Families suggested greater flexibility in scheduling (e.g., weekend sessions) and in mode of delivery (e.g., telehealth vs. in-person), as well as session flexibility to improve access to services for working families.

**Conclusions:** Community shareholders have valuable insight about how to improve publicly funded early intervention. When provided the opportunity, caregivers, clinicians, and agency leaders offered actionable steps, such as allowing clinicians to bill for time spent teaching strategies to caregivers, to improve publicly funded EI for young autistic children. Policy should be informed by shareholder input and include their feedback in every step of the policymaking process.

**423.198 (Poster) Single Mother Parenting of Children with ASD**

**Y. Kimhi and R. Hillel Lavian,** Levinsky College of Education, Tel Aviv, Israel

**Background:**

A child with special needs presents parents with a significant challenge on a personal and a family level. Having a child with special needs is often experienced as a crisis, after which life will no longer be as it was until that point. Parenting a child with a disability affects the parents’ feelings, leading to higher stress and lower well-being, and even more–so when parenting children with ASD due to the children's core characteristics. In recent decades, there has been a change in the traditional family model, allowing different models, including single-parent models. Research has demonstrated that in general, single mothers are more likely to exhibit parenting stress. There is a paucity of research on single mothers of children with ASD. The few studies that have been published show that their challenges are unique, stemming from their dual challenge in comparison to two-parent families of children with ASD.

**Objectives:**
The purpose of this study was to extend the small body of research on this topic and better understand the mothers' experiences via a qualitative, non-judgmental research design. The research question posed was “What is the experience of single mothers parenting children with autism?”

Methods:

The study was a qualitative photo-narrative study in which life stories are told. It included seven single mothers parenting at least one child diagnosed with ASD who told their life stories and took photographs depicting their motherhood experience. Three assessment measures were used – an open in-depth interview, photographs that the participants took, and a reflective researcher's diary written during and after the interviews. The data analysis was carried out in two stages. In the first stage, a holistic analysis was conducted for each participant separately and in the second stage, a thematic content analysis was carried out regarding the interviews and the stories about the photographs that the participants took.

Results:

The content analysis yielded five major themes and five subthemes related to the mother's life experience of parenting children with ASD. The first theme was the shattering of the dream; the second was the mothers and the educational setting and included two subthemes - the kindergarten and the transition from kindergarten to school; the third was the present in the shadow of the future and included three subthemes - daily challenges, the shadow of the future, and different parenting; the fourth was resilience; and the fifth finding meaning.

Conclusions:

This study expands and enriches knowledge concerning the mothers' experience as single mothers parenting a child with ASD. The findings show that there is a dire need to assist the mothers throughout their life, whether at the first stage, before and during the diagnosis, during the educational transition periods, and with much-needed continuing support systems. Notwithstanding, the data indicate that although the mother's daily life is challenging, they develop and draw strength from their love for their child and their surrounding support systems.

423.199 (Poster) Sleep Quality and the Broad Autism Phenotype in Mothers of Autistic Children

L. Friedman and J. Klusek, (1)University of South Carolina, Columbia, SC, (2)Communication Sciences and Disorders, University of South Carolina, Columbia, SC

Background:

It is well-documented that sleep quality is poorer among autistic adolescents and adults relative to their nonautistic peers (Morgan et al., 2020), and autism symptoms are related with sleep quality (Holloway et al., 2013; Schreck et al., 2004). Issues with sleep have also been reported in mothers of autistic children relative to mothers of nonautistic children (Hodge et al., 2013; Lopez-Wagner et al., 2008). While environmental factors, such as child awakenings, can impact maternal sleep quality, there is also growing recognition that genetic factors play a major role in sleep-related phenotypes (Madrid-Valero et al., 2020), and that shared genetic mechanisms may underlie autistic traits and sleep difficulties (e.g., Taylor et al., 2022). In this study we examined the interface between sleep disturbances in mothers of autistic children and the expression of the broad autism phenotype (BAP; i.e., subclinical markers associated with autism that are thought to reflect genetic liability for autism). Documenting associations between sleep disturbance in mothers of autistic children and BAP markers of genetic liability can inform potential shared mechanisms that may lead to the co-occurrence of sleep disturbance and autism.

Objectives:

- Compare sleep quality between mothers of autistic children and control mothers.
- Examine associations between the BAP and sleep quality within mothers of autistic children.

Methods:

Participants included 69 mothers of autistic children and 105 control mothers who had children without any history of developmental disorders. Mothers were 32–62 years old. Participants completed the Pittsburgh Sleep Quality Index (PSQI; Buysse et al., 1989), which is a well-validated 19-item questionnaire that yields total and subscale scores marking difficulties in various aspects of sleep (e.g., quality, latency). Mothers also filled out the Broad Autism Phenotype Questionnaire (Hurley et al., 2007), which contains 36 items related to BAP features. Groups were divided into BAP+ and BAP- groups for the total score and each subscale based on cut-offs outlined in Sasson et al. (2013).

Results:
Mothers of autistic children had higher total sleep scores and had higher scores in the domains of sleep latency, disturbance, medication, and daytime dysfunction (Table 1). Among mothers of autistic children, those who were BAP+ for the rigidity subscale had poorer overall sleep scores relative to those who were BAP- for this subscale (p=.043, partial-eta squared=.07). There were no other sleep differences between groups from the other BAP subscales or overall score (ps>.218).

Conclusions:

Our findings build on a body of research documenting sleep issues among mothers of autistic children relative to control mothers. Additionally, mothers of autistic children who showed more rigid BAP traits had poorer sleep quality. Prior findings suggest that poor sleep is associated with worse cognitive flexibility (Honn et al., 2019), which may be reflected in our findings, such that poorer sleep quality leads to increased rigidity (i.e., less flexibility). Alternatively, those with more rigid personality traits may have more issues with falling and staying asleep. This association between the BAP and sleep quality support further study into potential shared mechanisms underlying the co-occurrence of sleep disturbance and autism.

423.200 (Poster) Stakeholder Consultations Towards the Development of Local Models of Care for Children with Developmental Disabilities in Low Resourced Settings in Kenya

Background: Nearly one million people live with disabilities in Kenya, though data disaggregated by disability is scarce (KNBS 2019). A nationwide survey of 7609 children found that 11.4% had a disability and 2.5% were identified with an intellectual disability (KISE 2018). Children with developmental disabilities (DD) including autism and intellectual disabilities remain undiagnosed, many are identified at a later age when they are likely to present with severe disabilities and comorbidities. Families of children with DDs experience multiple challenges, including stigma and discrimination, care burden, social isolation, and limited access to formal care and essential services. SPARK (SuPPorting AfriCAN communities to increase the Resilience and mental health of KiDS with developmental disorders and their caregivers) is a multi-site study in Kenya and Ethiopia. This paper examines a sub-set of findings from consultative workshops with Kenyan stakeholders conducted between March and July 2022.

Objectives: 1) to identify and map out available services and support systems for caregivers and children with DDs in rural and urban informal settings; 2) to explore and understand local resources and approaches used in identifying children with DDs, to enrich the content development of SPARK’s sensitization training package and a novel case detection tool for use by lay community resource persons.

Methods: SPARK Kenya is implemented in the rural coastal town of Kilifi and Nairobi’s informal settlements. Community representatives and professionals participated in consultative workshops that were organised separately (n=8, one of each group per site in two workshops). Fifty-two participants were purposively selected to represent carers of children with DDs or persons with lived experiences; professionals from health, education, and social service sectors; and community leaders/representatives such as religious leaders, community health volunteers, and community-based organisations. Workshop findings were later presented in three meetings with SPARK’s community advisory boards (Kilifi and Nairobi), and SPARK’s national advisory board for validation. Presentations were structured with guided topics, and data were captured through detailed notes, and audio recordings transcribed verbatim. Workshop summaries were developed capturing emerging themes and future systematic analysis will be performed using a thematic approach.

Results: Stakeholders mapped out service points that met different needs of families of children with DDs within these settings (Table 1). However, workshop discussants and advisory board members raised concerns that many caregivers lack awareness of location and access to these services. A by-product of these consultations led to the development of preliminary resource-guides tailored for each of these contexts. These consultations also generated a wealth of local resources including: training manuals; assessment forms used by health professionals for diagnosis and education professionals for school placement for learners with various DDs; educational resources with information on disability awareness, and advocacy for the rights of persons with disabilities.

Conclusions: Stakeholders identified the need to proactively promote linkages and support for families of children with DDs and their families. Upon verification and refinement of these resource guides, they will be used by trained community resource persons tasked with identification of children with DDs, to promote and increase referral uptake of locally-available services.
Background: The transition to adulthood can be a particularly vulnerable period for autistic individuals. Research efforts are needed to identify accessible supports for this population, often neglected in intervention research. Existing programs for autistic adults have limitations which include minimal representation in program creation, implementation, and evaluation of program outcomes (Monahan et al., 2021). Programs are needed to build upon the self-reported priorities of autistic people and minimize the pressure to camouflage their true selves. To address these limitations, this study utilizes a community based participatory research (CBPR) approach. Autistic young adults and their allies were involved as both research participants and partners to explore the benefits of Toastmasters for autistic young adults as a program to promote social communication skills and self-efficacy in a “no-pressure, supportive” environment (Uttal, 2013).

Objectives: Utilizing an inclusive model to yield important practice-based findings, the present study aimed to provide a comprehensive understanding of whether, for whom, and under what circumstances Toastmasters is a meaningful community-based program for autistic participants. To address this aim, we conducted qualitative interviews to understand first-hand experiences of autistic Toastmasters participants and their caregivers/mentors.

Methods: Participants included 20 autistic adults (ages 18-54, 60% White, 65% male) who were (former or current) Toastmasters and 10 caregivers/mentors who served in support roles. Each participant was individually interviewed for 45-60 minutes. The interview protocol, developed in collaboration with our community partners, involved open-ended questions, including probes for information on previous involvement in interventions, as well as specific information about their participation in Toastmasters (e.g., What motivated you to participate in Toastmasters? Did the program meet this need and/or your expectations? Why or why not? What benefits have you received from participation in Toastmasters?). Interviews were audio-recorded and transcribed verbatim. Inductive qualitative coding (Braun & Clarke, 2006; Thomas, 2006) is currently being utilized to assess data and explore relevant themes and recommendations. A preliminary codebook and protocol have been developed and interrater reliability (pooled Kappa of 80%+) will be established between four doctoral level coders trained in this method.

Results: Data analysis is ongoing. Preliminary analysis of the interviews revealed themes related to developing friendships and social connections, comfort with speaking and communicating, and benefits and barriers related to participation in Toastmasters. We anticipate additional themes related to specific interview questions (e.g., format of Toastmasters meetings, reasons for joining, perceptions of others, and time commitment) will emerge.

Conclusions: Autistic perspectives are an essential component to the implementation of community-based services and research design. Through this CBPR study, we hope to amplify autistic voices and experiences. Data from this study will inform the implementation of a pilot study of a Toastmasters for autistic participants who are first time participants. With the inclusion of autistic perspectives to guide our work, we hope the experiences of these individuals will improve, specifically those related to communication, leadership skills, self-confidence, and social participation.

Background:
Parents of children with ASD report considerable higher levels of stress compared to parents of neurotypical children and parents with other neurodevelopmental conditions (Davis & Carter, 2008; Hayes & Watson, 2013). Although their mental health is extensively investigated, studies regarding their eating behavior and physical health, and specifically stress-related health factors, are scarce, and have only been performed in mothers, not in fathers. In addition, most studies focused on parents of children with ASD in a broad age-range, while the early childhood may be particularly important period to study as early processes may lay foundation for the health of parents later in life.

Objectives:
We investigated whether (1) there are differences between mothers and fathers of a child with ASD in early childhood and males and females from the general population regarding stress, eating behavior and adverse health, (2) stress is related to eating behavior and adverse health in mothers and fathers of a child with ASD in early childhood.

Methods:
In total, 91 parents (48 mothers and 43 fathers) of 49 young children with ASD (3-7 years) participated in the study. Parents filled in self-report questionnaires, including the Parenting Stress Questionnaire (OBVL) and the Dutch Eating Behavior Questionnaire (DEBQ). Adverse health was measured using physical measurements of Body Mass Index (BMI), waist circumference, blood pressure, cholesterol,
triglycerides, glucose. The percentage of parents scoring above a certain cut-off was compared to the percentages of same-aged individuals from the norm-population (OBVL and DEBQ) or the Lifelines Cohort Study (Slagter et al., 2017).

**Results:**
More than half of the mothers and one third of the fathers of children with ASD experienced a clinical level of parenting stress, which is more often than parents of neurotypical children (10%). Mother’s prevalence rates of obesity (39%), abdominal obesity (60%) and metabolic syndrome (22%) were respectively 2.7, 1.6, and 2.6 times higher than in females from the general population. There were no differences between fathers of ASD children and the general population regarding adverse health. Parenting stress was significantly related to emotional (r = .53) and external eating (r = .47) in mothers, but not in fathers. There were no correlations between parenting stress and adverse health in mothers or fathers of a child with ASD.

**Conclusions:**
Stress impacts quality of life and could cause health-risks later in life. It is therefore crucial to diagnose and treat stress symptoms in mothers and fathers of a child with ASD, to enhance QoL and to prevent health problems later in life.

---

**423.203 (Poster) Supporting Diversity, Equity & Inclusion (DEI) Recruitment with SPARK Research Match**

P. Thind, C. W. Lehman, T. Ramsey, L. Adams, P. Feliciano and W. K. Chung; (1)Simons Foundation, New York, NY; (2)Tempus Dynamics, Baltimore, MD; (3)Department of Pediatrics, Columbia University, New York, NY

Background: SPARK (Simons Foundation Powering Autism Research) is an online, longitudinal research study with the largest autism spectrum disorder (ASD) cohort. To date, there are over 296,000 participants enrolled, including over 117,000 individuals with ASD and their families. All participants who sign the SPARK consent agree to be contacted for future studies related to autism research. Research Match (RM) is a core program of SPARK, through which researchers can recruit participants into new research studies. Aiming to address historic disparities in research participation by Black or African American individuals, the SPARK RM diversity equity and inclusivity (DEI) initiative requested and supported applications that recruited Black/African American participants.

**Objectives:**
- Report recruitment metrics for DEI projects using SPARK Research Match
- Assess the likelihood of Black/African American participants to respond to DEI studies compared to studies that did not specifically focus on DEI (non-DEI studies)

**Methods:** The SPARK Research Match DEI initiative provided researchers with up to $20,000 in incentive funding. Applicants were required to have completed previous work in the area of diversity/inclusion and special consideration was given to projects that addressed topics of high impact and/or addressed a specific need for Black communities. Investigators, upon approval, recruited from SPARK. Applications were reviewed by the SPARK participant access committee, including researchers and community representatives. RM studies were approved to recruit for one year with the possibility of renewal and were categorized as either in-clinic studies or online survey studies with additional support to build the survey workflows. Eligible participants were identified based on study inclusion/exclusion criteria and were invited via email. Participants indicated if they were interested and provided authorization for SPARK to share contact information with the study team.

**Results:** As of October 2022, SPARK approved 7 applications for Research Match projects providing support for DEI studies. For 4 completed DEI studies consisting of online surveys, the number of eligible SPARK participants ranged from 1,630 to 25,553. Of the participants invited, on average 22.3% of participants expressed interest in participating in the DEI studies. Participants received a range of $10-$75 per person. All 4 projects met their recruitment targets. In comparison, among 43 non-DEI studies, 31 (72.1%) projects met their recruitment targets. Of the participants eligible to participate in the DEI studies, on average 23.0% expressed interest in participating in DEI studies and 40.8% expressed interest in participating in non-DEI studies. This poster will assess other factors related to study participation, such as study burden to the participants and a comparison of interest in participation across racial/ethnic groups.

**Conclusions:** SPARK Research Match is an effective program for supporting recruitment of Black/African American participants in DEI and non-DEI studies.

---

**423.204 (Poster) Supporting School Participation for Autistic Children: Caregiver Perspectives of School Transport**

M. H. Black, B. Bernhardt, C. Keron, M. Plester, P. Weaver, H. Lindner, E. Clarkson and S. McGarry; (1)Center for Neurodevelopmental Disorders & Center for Psychiatry Research, Dept. of Women’s and Children’s Health, Karolinska Institutet, Stockholm, WA, Sweden; (2)Curtin School of Allied Health, Curtin University, Perth, Western Australia, Australia; (3)Mobility and Accessibility for Children in Australia Ltd, Melbourne, VIC, Australia

Background:
The right to access education is enshrined in the Declaration of the Rights of the Child. Despite having the same rights, autistic children can face more challenges accessing education than other children. Getting to and from school is essential to supporting school participation for autistic children, yet there has been limited research on experiences related to school transport and the barriers and enablers to getting to school. Given that caregivers are often the primary decision-maker regarding transport for their child, understanding their experiences of transporting their child to school is essential to supporting the engagement and participation of autistic children in school.

Objectives:
This study explores the experiences of caregivers on transporting their autistic children to school, with the aim of providing insight into transport related challenges and enablers.

Methods:
This study utilised a qualitative approach guided by interpretive phenomenology to explore the lived experiences of caregivers. Semi-structured interviews were conducted with nine caregivers of autistic children aged between 8 to 16 years of age. Interviews were focused on examining a typical trip to and from school, caregiver experience, challenges and enablers. Interviews were transcribed and analysed using Colaizzi’s qualitative data analysis framework.

Results:
There were three distinct phases describing the transport experiences of caregivers: the morning routine, the journey, and the destination. The morning routine was stated by caregivers to be essential in preparing their child to transport to school. Caregivers reported carefully tailoring their morning routine to facilitate a smooth start to the day for their child. Deviations to routine could result in challenges on the way to school that consequentially negatively impacted their child’s performance and engagement in the classroom and during peer interactions. Caregivers who used bus services specific for children with disabilities reported a “negative”, “disappointing” or “sad” experience for their child, reporting that bus services were often understaffed, undereducated, and ill-equipped to transport autistic children. When driving their child to school, caregivers reported high levels of stress and challenges including behaviours such as removing seatbelts, self-injury or physical aggression to the driver and/or passengers. Parent described these behaviours occurring as a result of sensory overstimulation or a disruption to the morning routine. Once arriving at school, caregivers reported challenges associated with poor communication with bus drivers and school staff. This was believed to impact the safety of their child and could often result in their child becoming more distressed if they were not adequately supported once arriving at school.

Conclusions:
Challenges getting to and from school have the capacity to negatively impact the ability of autistic children to gain an education. Caregivers require additional support to ensure their child gets to school safely. We make recommendations for funding distribution, resources and education that may be beneficial in supporting autistic children in fulfilling their right to access to education.

423.205 (Poster) Supporting the Educational Experiences of Autistic Children during COVID-19: A Focus on Motivating and Encouraging Takeaways from Parents
J. Pattammady, J. Gudknecht, M. C. Zajic and N. S. McIntyre, (1)Health & Behavior Studies, Teachers College, Columbia University, New York, NY, (2)Human Development, Teachers College, Columbia University, New York, NY, (3)School of Communication Sciences and Disorders, University of Central Florida, Orlando, FL

Background: COVID-19 disrupted the educational and health services provided to autistic children. Parents played an important role in supporting their child’s development and access to services during COVID-19, which included frequent changes to modalities across the pandemic and ways to access everyday services. Given the challenging context, it is critical to understand the experiences families faced, especially regarding what aspects families found potentially motivating and encouraging.

Objectives: This study sought to learn more about how parents supported their autistic children during COVID-19 with a focus on what kept families motivated and encouraged in supporting their child’s academic learning and engagement. This study used qualitative methods to identify and understand the various themes highlighted by parents reflecting on how they supported their child’s educational journey during COVID-19.

Methods: Data come from an online survey project focused on literacy and educational support during COVID-19. Participants (n = 402) were enrolled in the Simons Powering Autism Research for Knowledge, a national database of families with a child with a verified autism diagnosis. All families completed the survey about a child (80% male) who was in the K-6th grades during the 2019-2020 and 2020-2021 school years. We used qualitative approaches to analyze an open-ended question that asked parents to reflect about motivating and encouraging aspects in supporting their child’s access to educational resources during COVID-19. Thematic coding was completed by two
Results: Seventeen broad themes emerged. The most prevalent theme was Areas of Positive Support (47%), with parents frequently acknowledging the support given by their child’s teachers, service providers, and school systems. Other common themes included Learning Spaces (28%, including homeschool and online learning spaces), Services (25%, often praising service providers for ease of access/commitment to supporting their child), Child’s Positive Progress (20%, highlighted child growth in academic learning), and Parent Role (16%, often focused on the parent commenting positively on educating their child). Less prevalent themes included Communication/Relationship (11%, focused on maintaining conversations with teachers and families), Parent Understanding (11%, often through watching their child engage in online learning), Establishing Routines/Schedules (11%, focused on creating structure for their child’s learning), Technology (7%, focused on using online software programs for learning and communication), Child Attributes (7%), Pre-COVID-19 Comparisons (4%), Non-School Activities (3%), and Assessment/Evaluation (2%). Approximately 11% of responses were Nothing (i.e., explicitly wrote that nothing was motivating). Twenty-five families left the question blank.

Conclusions: While we continue to understand the effects of COVID-19 on the educational achievement of students across the world, our findings highlight that parents and caregivers identified a number of encouraging and motivating aspects of the experience. Findings highlight the important role that schools, teachers, and service professionals played in supporting autistic children during COVID-19 and the ways that parents were able to learn more about how to support their child’s learning due to the remote learning context.
Conclusions: Our findings indicate that the association between having ASD and poorer social competence is moderated when parents have good PRF, emphasizing its essential role when parenting children with ASD. These findings highlight PRF as a potential target for intervention among parents of children with ASD.

423.207 (Poster) Teachers’ Affect within Interactions with Their Autistic Students during Preschool through 3rd Grade Literacy Activities

J. Vega Garcia, H. Fann and N. Sparapani, (1)School of Education, University of California, Davis, Davis, CA, (2)Human Development Graduate Group, University of California, Davis, Davis, CA, (3)UC Davis MIND Institute, University of California, Davis, Sacramento, CA

Background: Teacher affect is an important, yet understudied, feature that impacts students’ instructional experiences (e.g., McLean & Connor, 2018). Studies centering on neurotypical children have found that teachers’ positive affect or emotional expressions have led to positive student outcomes (e.g., Buric, 2019; McLean & Connor, 2017). Few studies have examined teacher affect with autistic students and whether or how affect impacts academic outcomes.

Objectives: This study expands on McLean and Connor’s (2017) measure, the Teacher Feedback Coding System—Academic (TFCS-A), by adapting and creating new teacher affect types based on autistic students’ experience inside the classroom. We examined teachers’ responses and affect types following students’ communication initiations, as well as the relations between teachers’ affect and student characteristics (autism features, cognitive functioning, and teacher-perceived behaviors).

Methods: Our study included a subset of teachers and students who were recruited for a larger study that evaluated the efficacy of a classroom-based intervention (R324A140005). The sample included 34 teachers and their 43 preschool–3rd grade autistic students ($M_{age} = 7.68; SD = 2.14$). Using archival video observations and Noldus Observer® Video-Pro Software (XT 14; 2017), we examined teachers’ affect across two dimensions: Response Type (contingent, not contingent, responds to attention) and Affect Type (positive, negative, negative/neutral). Interrater reliability was high (≥80%). We used the DAS-II (Elliot, 2007) and MSEL (Mullen, 1995) to assess students’ cognitive functioning, the ADOS-2 (Lord et al., 2012) to understand autism symptomology, and the Teacher PDD Behavior Inventory (Cohen & Sudhalter, 1999) to assess student behavior.

Results: Thirty-six students received at least one positive, contingent response ($M = 3.56; SD = 3.25$), and 33 students received at least one response that was neutral/negative and non-contingent ($M = 1.98; SD = 2.53$). Twenty-nine students received at least one positive, non-contingent response from their teacher ($M = 1.30; SD = 1.46$). We found strong negative relations between students’ cognitive functioning and teachers’ negative affect ($r = - .50, p < .001$), and moderate negative relations between autism features and positive affect ($r = - .38, p < .05$). We also found moderate negative relations between teacher-perceived problem behaviors, neutral affect ($r = -.34, p < .05$), and contingent responding ($r = - .42, p < .05$).

Conclusions: We found that the majority of students received at least one positive, contingent response, and one neutral/negative, non-contingent response from their teachers. Furthermore, we documented links among negative affect with more autism features, perceived problem behaviors, and less developed cognitive functioning. These student characteristics were also related to fewer neutral and contingent responses from teachers. These findings raise some concern regarding the quality of interactions between students with autism and their classroom teachers, which in part, is associated with individual student characteristics.

423.208 (Poster) The Convergent Validity of the Family Outcome Questionnaire (FOQ) for Measuring the Effectiveness of Early Intervention Services in Taiwan

M. R. Liu, G. Yao, I. N. Fu, L. C. Huang, F. L. Chen, T. J. Lu and J. N. Wu, (1)Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan, (2)Department of Psychology, National Taiwan University, Taipei, Taiwan, (3)School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (4)Child Developmental Assessment & Intervention Center, Taipei City Hospital, Taipei, Taiwan

Background:

The importance of measuring family outcomes in evaluating the effectiveness of early intervention (EI) programs has been emphasized during the past decades as more research shows that the participation of families plays a vital role in enhancing the development of children with special needs. On the other hand, the content of the family outcome measure should reflect the status and cultural values of the community to meet the needs of the families receiving EI. In Taiwan, comprehensive and culturally sensitive family outcome measures for EI service are scarce. The Family Outcome Questionnaire (FOQ) is developed with the cultural adaptation of tools from western countries to assess the outcomes of families receiving EI in Taiwan. In this study, we examined the psychometric properties of FOQ by investigating its convergent validity.

Objectives:
The purpose of this study was to investigate the convergent validity of the FOQ when used to measure family outcomes in EI service delivery.

Methods:

A total of 52 primary caregivers whose children received EI services in a city hospital participated in the study. They completed the FOQ, the Family Outcomes Survey Revised (FOS-R), and the Parenting Stress Index-Fourth Edition (PSI-4). The FOQ was modified from the FOS-R and aims to measure eight aspects of family outcomes of EI services in Taiwan. The FOS-R has been mainly used to measure the family outcomes and the helpfulness of early intervention in the USA. The PSI-4 assesses three domains of parental stress: child characteristics, parent characteristics, and situational/demographic life stress. To verify the convergent validity, we conducted Pearson's product-moment correlation to examine the correlation between the total score of the FOQ, the two parts of the FOS-R, and the three domain scores of the PSI-4. The FOS was expected to be positively correlated with the two parts of the FOS-R and negatively correlated with the child domain, parent domain, and life stress domain scores of the PSI-4.

Results:

The mean age of 52 primary caregivers receiving EI services was 39.37 (SD=4.89), 84.6% of the participants were mothers, and the diagnoses of their children were autism spectrum disorders (30.8%), developmental disorders (25%), and attention-deficit/hyperactivity disorder (23.1%) and others. The total score of the FOQ positively correlated with the family outcomes part of the FOS-R ($r=0.74, p<0.01$) and the helpfulness of the early intervention part ($r=0.58, p<0.01$). In addition, the total score of FOQ significantly negatively correlated with the child domain, parent domain, and life stress domain scores of the PSI-4 ($r=-0.42, p<0.01; r=-0.43, p<0.01; r=0.47, p<0.01$).

Conclusions:

The FOQ has a moderate to good convergent validity with the FOS-R and PSI-4, providing preliminary evidence of adequate validity in measuring family outcomes in EI services. To construct more solid psychometric evidence and investigate the suitability of usage of FOQ across families with different needs of EI, we expect to examine discriminative validity and include more children with diverse diagnosis in the future. Clinicians can use the FOQ with families who receive EI to understand the different factors of family outcomes comprehensively.

423.209 (Poster) The Development and the Reliability of a Family Outcome Questionnaire (FOQ) for Measuring Effectiveness of Early Intervention Services in Taiwan

I. N. Fu1, G. Yao1, M. R. Liu1, L. C. Huang1, F. L. Chen2, J. N. Wu1 and T. J. Lu1, (1) Child Developmental Assessment & Intervention Center, Taipei City Hospital, Taipei, Taiwan, (2) School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (3) Department of Psychology, National Taiwan University, Taipei, Taiwan

Background: When evaluating the effectiveness of early intervention (EI) programs, we should focus on measuring family as well as child outcomes. The core concept of family-centered in EI services has prompted services providers to value input from families and plan services accordingly. Therefore, in the past two decades, measurement tools focusing on family outcomes have been developed in western societies. However, as the main concerns of families and the service delivery models may vary across cultures and societies, a family outcomes measure that could reflect the needs and reality of the society should be developed when evaluating the effectiveness of EI services. A culturally sensitive family outcomes measure with adequate psychometric properties can serve as a useful reference and guidance for service providers in improving service quality. In Taiwan, with the increasingly accessibility and involvement of families in EI programs, there is an urgent need of developing appropriate family outcomes measure to appraise service quality and guide the service planning.

Objectives: This study aimed to develop a Family Outcome Questionnaire (FOQ) that is applicable to the evaluation of effectiveness of the current EI services at the medical facilities of Taiwan, and investigate the reliability of the FOQ.

Methods: The FOQ was developed in two stages: item construction and item revision. The initial items of FOQ were constructed based on current family outcome measures and focus group interviews with 10 EI professionals working in medical facilities. We then revised the items based on eight experts consultations about the measurement structure, item format, and appropriateness for caregivers. Next, we interviewed ten main caregivers receiving at least six months of services to comment on the ease of understanding and sentence fluency of the items. Finally, we revised the items according to their comments, then obtained the first edition of the FOQ. A total of 30 caregivers receiving EI services were recruited for reliability examination and assessed with FOQ for family outcomes. We calculated Cronbach's alpha coefficient to show the internal consistency of the FOQ.

Results: The FOQ was composed of 49 items using a 5-point Likert scale, producing Total Scale Scores and 8 Subscale Scores. A total of 30 caregivers receiving EI services, whose children mostly were autism spectrum disorders, developmental disorders, and attention-
Methods: A survey of parents of ASD children was conducted in June 2022. There were 679 participants enrolled, among whom 605 were mothers of children with ASD and 74 were fathers. The measures were Parental Discrimination Perception Scale, Social Anxiety Scale, Mindfulness Scale and Flourishing Scale. The descriptive statistics, including mean, standard deviation, minimum, and maximum values, were calculated for each scale. The differences between groups were analyzed using independent samples t-tests. The mediations were tested using the PROCESS Macro for SPSS (Model 4; Hayes, 2017). The significance level was set at 0.05.

Results: The results show that: (1) The perceived discrimination of parents of children with ASD was positively correlated with their social anxiety and negatively correlated with mindfulness and psychological well-being ($\beta = -0.51$, $P < 0.001$). Social anxiety was negatively correlated with mindfulness ($\beta = -0.43$, $P < 0.001$) and positively correlated with ASD severity ($\beta = 0.19$, $P < 0.001$). The mediation analyses revealed that social anxiety fully mediated the relationship between parental discrimination perception and psychological well-being, while mindfulness partially mediated the relationship. The results also indicated that the interaction between child age and ASD severity was significant, with older children with more severe ASD having lower psychological well-being.

Conclusions: The results suggest that parental discrimination perception and social anxiety have significant impacts on the psychological well-being of parents of children with ASD. Mindfulness plays a role in mediating these effects. The interaction between child age and ASD severity should be considered in future studies.
correlated with mindfulness and psychological well-being, while mindfulness was positively correlated with mental health \( (P < 0.001) \). (2) The perceived discrimination of parents of children with ASD can not only directly predict psychological well-being, but also indirectly predict psychological well-being through the mediating effect of social anxiety \( (P < 0.001) \). (3) The first half of the mediating effect of social anxiety is regulated by mindfulness \( (P < 0.001) \).

Conclusions: In summary, the psychological well-being of parents of children with ASD can be effectively improved by the reduction of their discrimination perception, social anxiety and the increase of their mindfulness level. Social anxiety has a mediating effect and mindfulness has a regulating effect.

423.212 (Poster) The Experiences of Autistic and Non-Autistic Youth and Their Caregivers Completing an Autism-Tailored Measure of Stress and Trauma: A Qualitative Study

M. C. Hunsche, C. I. Stewardson and C. M. Kerns, University of British Columbia, Vancouver, BC, Canada

Background: Adverse childhood experiences (ACEs) are more common among autistic people compared to the general population. Quantitative and qualitative findings also suggest that many autistic individuals experience chronic stressors (e.g., social adversity, discrimination, sensory distress) that can detrimentally affect well-being, but which are not systematically assessed by ACEs measures.

From this evidence base, the Childhood Adversity and Social Stress (CASS) Questionnaire was developed to assess both traditional (e.g., physical and sexual violence) and autism-related adversities and traumatic reactions.

Objectives: We gathered qualitative feedback from autistic and non-autistic youth and their caregivers who completed the CASS to examine common themes and differences in their experience (e.g., useability, acceptability) of this novel tool.

Methods: Thirty youth (age 14-22; autistic n=16, non-autistic n=14) and their caregivers participated in a think-aloud cognitive interview while completing the CASS. Two autistic youth and one caregiver of a non-autistic youth were excluded due to language difficulties. The CASS contains two sections: Symptoms (symptoms of traumatic stress in the past month) and Adversities (lifetime history of adversities).

At the end of the cognitive interview, participants were asked for their general impressions of the CASS (Feedback). Thematic analysis was conducted to develop and apply a coding scheme to these three interview sections. Coding was completed by MH and CS along with a team of 4 undergraduate research assistants (>80% inter-rater reliability) with supervision from CK. To mitigate potential bias, this team represented varying sociodemographic characteristics and training/expertise. Autism diagnoses were confirmed using the ADOS Module 4 in 11/14 autistic youth with valid interview data.

Results: Common themes included strengths of the CASS (endorsed by >75%), but also comments about question and response option wording, the operationalization of trauma, and reporting challenges faced by caregivers. CASS strengths included question clarity, helpfulness of visual cues, and inclusion of stressors that captured participant experiences. Most (>50%) autistic and non-autistic youth and caregivers suggested additional adversities to include (e.g., moving, parents separating, interpersonal conflict) and expressed difficulties remembering details of past adversities and determining whether they were “severe enough” to report. In terms of differences, more caregivers of autistic youth expressed difficulty reporting on their child’s ACEs and symptoms due to lack of knowledge/insight into their child’s experiences and differences in their vs. their child’s perception of the event. More autistic than non-autistic youth expressed difficulty providing details about adversities, in part due to autistic youth experiencing more chronic and/or repeated adversities. For the full coding scheme and code frequencies, see Tables 1 and 2.

Conclusions: Findings support and extend prior work by illustrating that adversities may not only be more prevalent and more complex in autistic youth but also that, as a result, autistic youth and their caregivers may experience more difficulty and confusion when reporting on trauma. Multi-informant approaches, clear examples and overall specificity in language may help autistic youth and their caregivers provide the most accurate, complete picture of their experiences of stress and trauma as possible.

423.213 (Poster) The Family Experience of Early Supports When Attitudes Are Changing, Funding Is Available and Families Have Choice and Control

K. Pye, T. Iacono, H. Le and L. Gold, (1) School of Health and Social Development, Deakin University, Geelong, VIC, Australia, (2) La Trobe Rural Health School, La Trobe University, Bendigo, Australia

Background:

Attitudes towards autistic people and supports have changed considerably since the emergence of developmental and behavioural interventions. While these approaches have demonstrated positive child outcomes, less is known about other effects including those relevant to the family unit, or indeed which outcomes families see as priorities. Family wellbeing is known to play a critical role in child development.
In Australia, the National Disability Insurance Scheme (NDIS) provides individualised funding for supports to enable people with disabilities to exercise “choice and control” over their supports. Families can theoretically choose their supports based on individual need. This Australian context provides an important opportunity to understand the family experience of service choice for autistic children.

Objectives:

We collected information about 1) supports families access for their autistic preschoolers, 2) potential outcomes they value most, and 3) caregivers’ wellbeing and family experience of autism.

Methods:

This mixed methods study comprised a survey (target n=100) followed by semi-structured interviews (target n=20), both conducted online. The study targeted families in Australia with at least one autistic child who had not yet started school, with study promotion via advocacy groups and social media. Survey participants completed the EuroQol-5D-5L, a generic measure of their health-related quality-of-life, and the Autism Family Experience Questionnaire (AFEQ). Interview participants provided more detailed information about their supports, factors influencing their choices, and potential outcomes they considered most valuable.

Results:

Preliminary survey results to date are from 72 respondents from varied socioeconomic and family backgrounds, reflecting children ranging from 25 to 71 months of age, most (94.4%) accessing the NDIS.

Caregivers’ self-reported global health (EuroQol-5D-5L visual analogue scale where 100=best imaginable health) averages 56.59 (95%CI 51.33, 61.86), much lower than previously published general population means in Australia and other developed countries (e.g., 78.55; (McCaffrey et al., 2016)). The mean total AFEQ score is 144.43 (95%CI 138.84, 150.03), broadly in line with previously published results (e.g., 141.0; (Leadbitter et al., 2018)).

Preliminary analysis of fifteen interviews completed to date reveals emerging themes of caregivers’ evolving competence in parenting and advocating for an autistic pre-schooler, and difficulty navigating an unfamiliar and under-resourced system. Therapists who offer flexibility and neurodiversity-affirming practices are clearly preferred by some caregivers. Participants have often been unaware of specific techniques implemented, but seek a flexible approach to their changing needs. Prior knowledge of autism and/or the support system appear to improve access to services and clarity about desired outcomes.

Possible association between the family experience and caregivers’ HRQOL will be explored via regression analysis. Thematic analysis will be completed to explore the diverse views and values of participants.

Conclusions:

Australian families access supports—predominantly speech pathology, occupational therapy and psychology services—using public funding available through the NDIS. While financial burden may be reduced and/or the level of support increased, likely inequities persist, reflected here in the heavy reliance on prior knowledge of autism and caregiver time to attend appointments and implement strategies at home. Many are actively seeking neurodiversity-affirming practices.

423.214 (Poster) The Impact of Disclosing an Autism Diagnosis in an Online Dating Context.
M. Brosnan and J. Gavin, (1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom

Background:

Previous cross-sectional research has highlighted that an explicit autism label in an autistic male’s online dating profile has a differential impact, depending upon the potential partners’ level of stigmatisation towards autism. Females with higher stigmatisation towards autism rate dating profiles with an explicit disclosure of autism more negatively in terms of ‘desire to date’. However, females with lower stigmatisation towards autism rate the same profile more positively in terms of ‘desire to date’. This is consistent with other research identifying negative first impressions of autistic people. What is unknown is how first impressions may change after a diagnosis of autism is revealed.

Objectives:

To identify the impact of females’ stigmatisation towards autism upon changes in their perceived ‘desire-to-date’ an autistic male.
Methods:

Participants were 204 females aged 18-25, residing in the UK, who would date a male. All participants indicated they were aware of having had contact with an autistic person.

Participants read an online dating profile of a male that included a number of autistic-like traits but did not explicitly mention autism (from previous research). Participants were then asked to rate their desire-to-date the person in the profile. Participants were then told the person in the profile is autistic with an explanation of autism, and were asked if they had realised the person in the profile was autistic. 168 said no and were included in the analysis. Participants then completed a questionnaire assessing their experience of and stigmatisation towards autism. Finally, participants rated again their desire-to-date the same profile that they had rated previously, except with the addition of the sentence ‘I am autistic’.

Results:

For those who had not previously considered the profile might be an autistic male, there was a significant decrease in the desire-to-date the person in the dating profile after a diagnosis of autism had been stated (t=2.34, df=167, p=.02). Increased stigmatisation towards autism correlated with a larger decrease in the change in desire-to-date ratings (before and after autism was stated, r=-.33, df=168, p<.001). The stigmatisation item relating to dating specifically was analysed separately. Those who would be definitively unwilling or somewhat unwilling to date an autistic person, had a significant decrease in their desire-to-date ratings. Those who would be somewhat willing to date an autistic person did not change their desire-to-date ratings. Those who would be definitely willing to date an autistic person saw a significant increase in their desire-to-date ratings (F(3,167)=2.50, p<.001). (Note: none of these findings were significant for the 36 participants who said that they had initially thought the person in the profile might be autistic).

Conclusions:

For males online dating, disclosure of an autism diagnosis has a negative impact on females with stigmatising views about autism. However, disclosure can also have a positive impact on females who do not hold stigmatising views about autism. This is consistent with previous research as well as anecdotal accounts indicate that highlighting an autism diagnosis does not result in fewer potential dates, rather more suitable dates.

423.215 (Poster) The Influence of Older Siblings on Language Development from Toddlerhood through Adulthood Among Individuals with ASD and Non-Spectrum Developmental Delays

K. Byrne, N. E. Rosen, H. K. Schiltz and C. Lord, (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

Background: Language development is heterogenous across autistic people and impacts a myriad of adaptive outcomes (e.g., long-term well-being, academic performance, and vocational independence; Friedman et al., 2019). While research among typically developing youth consistently highlights a linguistic advantage for first born children (Nafissi, Z., & Vosoughi, 2015), a dearth of studies has explored this possibility among autistic youth. One cross-sectional study suggests that the effect of birth order on language milestones may not apply to autism (McFayden et al., 2022). However, previous longitudinal studies have shown that older siblings serve as positive models of behavior to supplement skill development for autistic people (Rosen et al., 2022). Therefore, further research is needed to determine the potential longitudinal effects of older siblings on language development in autism.

Objectives: Among people with autism or non-spectrum delays, this study examined (1) whether the presence of an older sibling influenced expressive language from early childhood through adulthood and (2) if effects were moderated by individual-level factors (i.e., NVIQ, ASD diagnostic status).

Methods: Participants included 253 individuals with ASD or non-spectrum developmental delays longitudinally assessed from ages 2 through 25. The Vineland Adaptive Behavior Scales (VABS) expressive language age equivalents (EXP), Autism Diagnostic Observation Schedule (ADOS) overall level of language (OLL) (adjusted across modules), and Autism Diagnostic Interview-Revised (ADI-R) verbal communication (VC) items were administered between 6–9 times. Participants also completed standardized IQ measures. Growth curve modeling with individually varying times of observation was conducted. For aim 1, sibling variables (dummy coded with “has an older sibling” as the reference group) were regressed on the latent intercept and slope. For aim 2, interactions between sibling variables and proband factors (NVIQ and diagnostic status) were tested.

Results: Parameter estimates are presented in Table 1. Across all three language measures, having autism or lower NVIQ was related to less language initially. Lower NVIQ was also related to slower language development over time. Those with an older sibling demonstrated slower language gains over time than only children on the ADOS-OLL. Sibling effects on initial level of language demonstrated interactions with NVIQ and ASD status on the VABS-EXP and ADOS-OLL. Having an older sibling (vs only younger siblings) was
related to less initial language on the ADOS-OLL, but only for those without autism, and to less initial language on the VABS-EXP, especially for those with lower NVIQ. No effect of siblings emerged on the ADI-VC.

Conclusions: Our finding that having older siblings is related to less expressive language and slower language development over time is consistent with the Resource Dilution Theory (RDT; Nafissi, Z., & Vosoughi, 2015), and in contrast to the positive effects of siblings on skill development in autism more broadly (e.g., Rosen et al., 2022). According to RDT, the presence of an older sibling necessitates greater sharing of resources and parental attention. These effects may be specific to expressive language structure (VABS and ADOS) vs pragmatic use of language (ADI). Those with older siblings may benefit from additional linguistic support throughout their development.

423.216 (Poster) The Interagency Autism Coordinating Committee Strategic Plan: Guiding Research, Services, and Policy Activities across the Autism Community
A. Mitrakas, S. Daniels, K. Ferrara, T. Mar, O. Celestin and L. Valdez-Lopez, (1)Office of Autism Research Coordination, Bethesda, MD, (2)National Institute of Mental Health (NIMH), Rockville, MD, (3)National Institute of Mental Health (NIMH), ROCKVILLE, MD, (4)6001 Executive Blvd, Interagency Autism Coordinating Committee (IACC), Rockville, MD, (5)OARC, NIMH/NIH, Bethesda, MD, (6)NIH, Bethesda, MD

Background: The Office of Autism Research Coordination (OARC) of the U.S. National Institutes of Health (NIH) will present updates on recent activities of the Interagency Autism Coordinating Committee (IACC) and the upcoming 2021-2022 IACC Strategic Plan for Autism Research, Services, and Policy.

OARC/NIH coordinates and manages the IACC, a federal advisory committee composed of federal officials and public stakeholders (researchers, self-advocates, clinicians, and family members) representing the many perspectives that make up the autism community. The current IACC membership reflects the largest and most diverse Committee to date. The Committee was established by Congress to coordinate federal agency activities and to provide advice to the Secretary of Health and Human Services (HHS) related to autism spectrum disorder (ASD). The IACC’s Strategic Plan provides a framework and serves to guide the activities of U.S. federal agencies and partner organizations by outlining priorities and directions for autism-related efforts. The Strategic Plan is one of the main ways the IACC provides advice to the HHS Secretary and includes recommendations that address research, services, and policy activities.

Objectives: OARC will present background information about the IACC and a description of the latest updates to the IACC Strategic Plan, which serves as a guide for federal agencies and partner organizations on autism-related activities in the U.S.

Methods: The IACC Strategic Plan is developed through a consensus process by the IACC, with input from the public in the form of public comments and a special Request for Information. The IACC considers the current autism research, services, and policy landscape, and discusses what topics should be prioritized to maximize positive outcomes for individuals on the autism spectrum. The Strategic Plan is approved by the IACC through a majority vote, and the document is published and used by federal agencies and other community members.

Results: The 2021-2022 IACC Strategic Plan for Autism Research, Services, and Policy is organized around seven topic areas, each of which is associated with a community-based Question and has a dedicated chapter. The seven topic areas are: Screening and Diagnosis (Question 1), Biology (Question 2), Genetic and Environmental Factors (Question 3), Interventions (Question 4), Services and Supports (Question 5), Lifespan (Question 6), and Research Infrastructure and Prevalence (Question 7). Each Question area includes three Recommendations; there are also two Cross-Cutting Recommendations, one focused on sex and gender differences in autism and one on disparities and equity in autism. The Strategic Plan also includes a section on the impact of the COVID-19 pandemic on the autism community and key lessons to be learned. Also included is a budget recommendation and high priority topics for research identified by the IACC. The full Strategic Plan will be free to download and available to the public on the IACC website: https://iacc.hhs.gov/publications/strategic-plan/2022

Conclusions: The 2021-2022 IACC Strategic Plan for Autism Research, Services, and Policy provides advice and recommendations to the HHS Secretary on autism-related issues related and provides a framework to guide the autism research, services, and policy efforts of U.S. federal agencies and partner organizations.

423.217 (Poster) The Missing Voice: A Comparison of Autistic Adults and Inclusive Employers Perspectives of Work Readiness Skills Needed to Enter the Calgarian Workforce
K. M. Mckiernan and A. McCrimmon, (1)University of Calgary, Calgary, AB, Canada, (2)Werklund School of Education, University of Calgary, Calgary, AB, Canada

Background: To successfully enter the workforce, young adults need to be ready, willing, and able to work. Work-readiness is defined as having the basic job and life skills needed to maintain employment. Research has described the construct in various ways, with current theories primarily identifying two to six common employer-reported clusters of skills required for one to be work-ready and successful in
the workplace. Researchers have additionally reported that individuals with disabilities who graduate from high school are often unequipped with the skills necessary to enter the workforce. One such (neuro) disability, autism (spectrum disorder), has troublesome statistics, with a low percentage of individuals entering the workforce after graduating high school in Canada. In Canada, autistics have one of the lowest labor force participation among those with developmental disabilities. Although service providers have sought to improve these employment statistics through work-readiness programs to bridge the gap in the skills needed to enter the workforce by consulting with stakeholders such as experts and employers, autistic voices have largely been absent.

Objectives: This study investigated autistics’ and inclusive employers’ perspectives of work readiness and how to improve it for autistic individuals. Two questions guided this study: (1) How do autistic individuals’ and inclusive employers’ opinions of work readiness compare to current research on work readiness? and (2) What are autistic individuals’ and inclusive employers’ opinions about how we can improve work readiness in autistic individuals?

Methods: In a qualitative design, eight semi-structured interviews (five autistics and three inclusive employers) were conducted with employers and autistics from Calgary, Alberta, Canada. Interviews were transcribed, and data were analyzed via reflexive thematic analysis.

Results: Four themes arose from the autistic viewpoint: (1) Holistic perspective of work readiness; (2) Work readiness is not a static concept; (3) Work readiness consists of position-dependent skills; and (4) Increasing work readiness for autistic individuals. Additionally, four themes resulted from the employer viewpoint: (1) Work readiness includes a holistic view of the person; (2) Work readiness consists of the same standards with adjustments; (3) Work readiness consists of position-dependent skills; and (4) Improving work readiness for autistic individuals.

Conclusions: The current study provides a glimpse into the autistic and inclusive employer perspectives of work readiness (i.e., beliefs and components), and how work readiness can be improved for autistic individuals. The findings of this study fill a gap within the literature by exploring how autistics and inclusive employers understand work readiness, which skills should be taught within work readiness programs, and how to improve work readiness for autistic individuals. The perspectives, skills, and strategies outlined within this research can be used as a springboard for stakeholders to understand work readiness from multiple perspectives. Further, this study can inform practice by allowing researchers and other stakeholders to know the areas to focus on to improve employment odds for autistic individuals and potentially influence policy to break down employment barriers for autistic individuals.

423.218 (Poster) The Networked Village: How the Ecosystem of Support and Emotion Around Autistic Youth Shapes Independence during the Transition to Employment

Background: Over 66% of young adults with Autism Spectrum Disorder (ASD) are disconnected from opportunities for work or schooling in the first few years after high school. Unequal access to social capital (resources and connections) from work, community and school contexts could adversely impact their transition to employment and other life course outcomes. Our study used qualitative methods to investigate the social support networks of transition-age youth with autism during transition.

Objectives: To identify key themes about the social support networks of autistic youth in extended high school using qualitative methods with the youth and their ecosystem of support at home, school and the community.

Methods: A purposeful sample of young autistic adults in extended high school (N=4), their caregivers, teachers and community providers (N=13) were asked to participate in semi-structured qualitative interviews about the youth’s transition experiences. A total of 22 interviews (N=13,530 words) were conducted, transcribed, coded and analyzed. Qualitative analysis was implemented across three stages. The precoding phase utilized deductive concepts (derived from the semi-structured protocol which was based on prior research findings) and emergent, inductive concepts (derived from qualitative data from interviews that were not related to the protocol, which were then compiled into a thematic database using R-programming to cluster summaries by theme. Summary memos were drafted based on the precoding data base. A code book, including 10 top codes and 22 subcodes, was derived from the precoding memos (see Table 1). During stage 2, coders reaching reliability (>70% agreement with master coder on at least 2 tests) on the codebook before participating in a systematic process of double coding (20% of all data was doubled coded with joint reconciliation) and solo coding using NVIVO. All codes and associated text were then extracted from NVIVO and, during Stage 3, analyzed through iterative memo writing and small group analysis meetings using thematic analysis.

Results: Two main findings were identified including (1) how emotional processing impacted social capital during the transition to employment and (2) the impact of ecosystems on the social production of independence for youth during transition (see Figure 2). Emotional dynamics among network supporters operated by a three step process. Step 1 included observations of youth transitions experiences by ecosystem members. Step 2 involved self and joint management of emotions by ecosystem supporters. Step 3 was characterized by the successful access of instrumental resources by supporters with durable ties that could support emotional processing and the lack of instrumental resources for supporters with weak ties where emotional processing resulted in mistrust and misunderstanding.
(see Figure 1). The social production of independence varied for autistic youth where some youth were embedded in re-made ecosystems characterized by strength-based and accommodating interactions, organizational and institutional supports and inclusive norms, while others experienced traditional ecosystems characterized by isolated, mistrusting ecosystem supporters, organizational silos and ableist norms (see Table 1).

Conclusions: The ecosystem of emotional dynamics for autistic young adults is rarely studied and new findings can help shape future interventions designed to address inequalities for autistic youth.

423.219 (Poster) The Perceptions of Teachers on the Critical Skills Required for Primary School Transition in Singapore
G. Zhang and C. Ong; (1)KTP-NUCMI, Child Development Unit, National University Hospital, Singapore, (2)KTP-NUCMI, Child Development Unit, National University Hospital, Singapore, Singapore

Background:

The transition to primary school is a challenge for children with autism spectrum disorder (ASD) (Kemp, 2003). In Singapore, transition support is implemented either by parents, preschools or early intervention centers. The differences in their perceptions, resources, knowledge and skill levels would affect how they plan and implement transition support (Choy & Karuppiah, 2016). In a society which values academic success, the focus of preparation is typically on academic competencies.

Objectives: The study aimed to understand teachers’ perceptions on the critical skills required for primary school transition in Singapore.

Methods:

The transition questionnaire comprises 73 skills derived from literature. The items were reviewed by seven educational psychologists for face validity and categorized into: Communication, Self-help, Social, Adaptability, Classroom, Transition, Fine Motor and Academic. Respondents were asked to rate the importance of each skill for transition using a five-point, Likert-scale ranging from 1 (not important) to 5 (must have). The survey was hosted on a secure online form builder platform. After approval from the institution’s ethic review board, the survey link was sent to the authors’ personal contacts who forwarded the link to the potential respondents via email and social media. Through this snowball sampling method, preschool teachers, early intervention educators and primary school teachers were recruited to complete the anonymous survey from July 2021 to May 2022. Data were analysed using the Statistical Package for Social Sciences (SPSS) software and a one-way ANOVA used.

Results:

121 (male=8, female=113) participants completed the survey. The ethnic makeup of the respondents mirrors the racial proportion in Singapore. 25.6% of the respondents were Preschool teachers, 29.8% were Early intervention educators, while 32.2% were Primary school teachers. 12.4% were in occupations working with special needs children.

As shown in Figure 1, three toileting related skills were rated as the most important skills for transition. At the category level (shown in Figure 2), transition skills (what children need to do to change from one activity to another, such as locating the school bus line) were ranked as the most important skills.

The three groups of respondents rated differently on the importance of communication (F= 3.495, p< 0.05), fine motor (F= 4.982, p< 0.05), and academic skills (F = 4.951, p< 0.05) for transition. Post-hoc tests indicated that preschool teachers rated communication (p = 0.014) and academic skills (p =0.01) as more important than early intervention educators. Preschool teachers also placed higher value on fine motor skills than primary school teachers (p = 0.028). Compared to preschool and early intervention educators, primary school teachers rated the communication skills as more important skills required for transition.

Conclusions:

The findings shed light of teachers’ perceptions on the critical skills required for primary school transition. The current local emphasis on academic preparation needs to shift toward training of self-help and transition skills. The discrepancies in perceptions among the different groups of teachers highlights the need for a unified transition checklist to be used by various stakeholders and the need for further work on alignment to ensure continuity of support.

M. Zhang and G. Y. H. Lam, Department of Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background:

Genetic or biological factors (biogenetic factors) are popularly perceived to be the causes of autism. According to the biogenetic explanation model (Kvaale, Gottdiener, & Haslam, 2013), although these uncontrollable factors may reduce the blame on individuals, these may also inadvertently hinder social inclusion by priming people to think that autism is unchangeable and conforming to stereotypical images (e.g., autistic people are dangerous). The model also predicts that biogenetic explanation may exacerbate stigma through essentialist thinking, which is the belief that social categories have a fixed and identity-determining essence. It is critical to understand the mechanism of how biogenetic explanation of autism may impact people’s attitudes towards autism.

Objectives:

The aim of the present study was to test the biogenetic explanation model in autism by investigating the relationships between biogenetic explanatory factors, essentialist thinking, perceived dangerousness, prognosis expectation, and social distance toward people with autism.

Methods:

247 laypeople without professional experience with autism (62.9% female) aged 18 to 60 years participated in this study via an online panel in Hong Kong. Participants completed questionnaires about casual attribution (to what extent participants believed each factors cause autism), essentialist thinking (to what extent participants believed autism has a fixed and identity-determining essence), perceived dangerousness (how dangerous people believe interacting with people with autism is), prognosis expectations (how confident people believed people with autism would change with appropriate interventions), and social distance. Exploratory factor analysis (EFA) was performed to determine the underlying structure of participants’ beliefs about ASD causes. Structural equation modeling (SEM) was used to examine the interrelation among target variables.

Results:

Five categories of perceived causes of autism were revealed by EFA, including biogenetic factors, mental health factors, physical factors, volitive/religious factors, and maternal factors. Figure 1 illustrated the SEM results and the final model with estimated coefficients. The goodness of fit of the model was satisfied ($\chi^2(289) = 501.11$, RMSEA = .06, GFI = .917, TLI = .906, SRMR = .06). The mediation coefficient was found to be significant for perceived dangerousness ($\beta = -.12$, $p = .035$) and prognosis expectation ($\beta = -.45$, $p = .001$). The direct effect of essentialist thinking on social distance was not significant ($\beta = -.07$, $p = .594$). These results suggested the more people believe that autism is a fixed group, the more people perceived individuals with autism are dangerous and cannot be improved, which in turns leads to increased social distance.

Conclusions:

However, the more laypeople believed in biogenetic explanation, the lower level of essentialist thinking was found. Future research is needed to explore whether other factors (e.g., diversity appreciation) may be associated essentialist thinking about autism even though laypeople deeply believe autism is caused by biogenetic factors. Decreasing essentialist thinking will be beneficial to promote social inclusion because people would see the possibility of changes in people with autism and diversity of autistic personhoods.

423.221 (Poster) The Relationship between Maternal Optimism and Transition Outcomes in Young Adults with and without Developmental Disabilities

Background: Transition to adulthood can be a stressful time for all parents, but particularly so if their young adult child has a developmental disability (DD). The loss of eligibility for services after high school places a greater burden on parents of youth with disabilities to provide help and support during this time, often impacting parental wellbeing. Previous research has shown that mothers of youth with autism spectrum disorder (ASD) and intellectual disability (ID) experience greater parenting stress and mental health problems compared to parents of typically developing (TD) youth (Blacher & Baker, 2017). Research has identified various protective factors for parents caring for children with disabilities, including dispositional optimism, or generalized positive expectancies about future outcomes (Carver & Scheier, 2014). The relationship between maternal wellbeing/optimism and young adult transition outcomes has yet to be examined.
**Objectives:** This study examines maternal wellbeing and optimism during adolescence as predictors of young adult transition outcomes among youth with ASD, ID, and TD participating in a longitudinal study.

**Methods:** 109 young adults ages 20-25 [ASD=23, ID=33, TD=53] and their mothers completed questionnaires and interviews at two time points (adolescence and young adulthood). Mothers’ stress and mental health, perceived impact of the child on the family, and dispositional optimism were assessed at youth age 13 or 15 using mothers’ reports on the Symptom Checklist (SCL), Family Impact Questionnaire (FIQ), and Life Orientation Test (LOT), respectively. Overall young adult transition outcome (Transition Outcome Composite; TOC) was coded on a 0-9 scale based on youth and parent responses to interviews and questionnaires regarding employment, education, independence, and socialization. A multiple linear regression was conducted to examine maternal wellbeing variables in adolescence and youth diagnostic status (i.e., TD or DD) as predictors of young adult outcomes on the TOC.

**Results:** Results revealed that transition outcomes in all areas were significantly poorer for young adults with ID or ASD (all \(p < .001\)). In both adolescence and young adulthood, mothers in the TD group reported lower parenting stress and mental health symptoms and higher optimism, compared to mothers of young adults with ASD and ID. Interestingly, higher maternal optimism in adolescence predicted more successful young adult transition outcomes on the TOC, regardless of the youth’s diagnostic status \( (p < .05\). Mothers’ mental health and perceived impact on the family did not predict young adult outcomes when controlling for diagnostic status and optimism.

**Conclusions:** Consistent with previous research, young adults with ASD and ID had poor transition outcomes. In addition, their mothers reported considerable mental health symptoms and stress, as well as lower optimism and perceived positive impact of the youth on the family. Nonetheless, young adults whose mothers were more optimistic during adolescence were more likely to have successful outcomes in adulthood, regardless of the youth’s diagnosis. Findings suggest that parental attitudes are likely to impact youth transition outcomes. Thus, maintaining an optimistic outlook may be especially important for parents of youth with disabilities. These findings reflect the importance of harnessing positivity early on to foster more positive young adult outcomes.

---

**423.222 (Poster) The Role of Parental Emotion Regulation on Child Behaviors in Autistic and Other Developmentally-Disabled Children during the COVID-19 Pandemic: Mediation By Dysfunctional Parent-Child Interactions**

*B. Jeyanayagam, S. Khawar, F. Mahmud, M. I. Cargill, E. Lynche, C. Tilson and E. Kang*; (1)Department of Psychology, Montclair State University, Montclair, NJ, (2)Helping Hands ABA, P.C., NEW YORK, NY

**Background:** During times of heightened stress, such as the COVID-19 pandemic, children’s adjustment may be especially dependent on their parents’ ability to manage emotions and cope with stress themselves (Shorner & Liebovich, 2020). Notably, parental difficulties in emotional regulation (ER) have been linked to increased child internalizing and externalizing behaviors (Zimmer-Gembeck et al., 2021). Prior research suggests that parents of autistic children engage in more maladaptive ER strategies (e.g., self-blaming, catastrophizing) compared to parents of non-autistic children (Megrey et al., 2020). Despite the suspected effects of parental ER on child adjustment, these relationships have not been studied in families with developmentally- and intellectually-disabled children (DD/ID) children.

**Difficulties in parent ER have also been linked to increased parenting stress and less positive and collaborative parent-child relationships (Hu et al., 2019; Shaffer & Obradovic, 2017).** Further, parenting stress and parent-child relationship quality may be a driving force for child psychological outcomes (Brock & Kochanska, 2015; Osborne & Reed, 2009). Thus, parental stress, specifically concerning parent-child interactions, may mediate the effects of parental ER on child outcomes. Moreover, better understanding these relationships may indicate ways to better support DD/ID children and their parents, especially following the COVID-19 pandemic.

**Objectives:** The current study investigated the impact of parental ER on child behaviors and explored the mediating effects of parent-child dysfunction in a diverse sample of families with DD/ID children during the COVID-19 pandemic.

**Methods:** Participants included 40 parents (87.5% female; 60% Non-White; 80% aged 35-54) of DD/ID children (72.5% autistic; mean age=11.60 years, SD=5.62; 77% male). Parents completed measures of parental ER (DERS; Gratz & Roemer, 2004) and parenting stress (PSI-4; Abidin, 1995), which includes the Parent-Child Dysfunctional Interaction (PCDI) subscale. Parents also reported on their child’s overall behavior (Maladaptive Behavior Index of the VABS-III; Sparrow et al., 2016).

**Results:** Child behaviors were positively correlated with difficulties in parental ER \((r=.423, p < .01)\) and overall parenting stress \((r=.749, p < .001)\). Further, the PCDI subscale was positively correlated with parental ER \((r=.431, p < .01)\) and child behaviors \((r=.657, p < .01)\). Parental ER significantly predicted child behaviors \((B_{max}=.217, p < .01)\). Mediation analysis indicated a significant indirect effect of parenting stress between parent ER and child behaviors \((B_{indirect}=-.189, 95\% \text{ CI } [.07, .38])\). Similarly, a significant indirect effect of PCDI subscale fully mediated the relationship between difficulties in parental ER and child behaviors \((B_{indirect}=-.125, 95\% \text{ CI } [.03, .28]; \text{ Figure 1})\). Parental ER and PCDI accounted for 45.9% of the variance in child behaviors, which was statistically significant, \(F(2,37)=15.7, \ p < .001\).

**Conclusions:** These findings highlight an important mechanism through which difficulties in parental ER may relate to DD/ID child behavior. Crucially, they contextualize findings about the relationship between parent ER and child behaviors by underscoring the mediating role of parenting stress, including stress concerning parent-child interactions, in predicting child behavior. Given the proximal
role of family processes on DD/ID children’s well-being, teaching parents adaptive strategies for managing emotions and stress reduction, especially during times of unusually high stress, may be an important avenue for improving parent-child relationship satisfaction and thus minimizing children’s risk for challenging behaviors.

423.223 (Poster) The Scholarly Neglect of Black Autistic Adults in Autism Research
J. Pearson, K. M. Malone and D. Mason Martin, (1)Teacher Education and Learning Sciences, North Carolina State University, Raleigh, NC, (2)Applied Developmental Science and Special Education, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)2310 Stinson Drive, North Carolina State University, Raleigh, NC

Background: Although we know about disparities in Black autistic children, little research has focused on the experiences of Black autistic adults. Most of what we know about autistic adults is based on the experiences of white participants. In the U.S., autism is most commonly diagnosed and validated by medical professionals’ observations and/or parent reports. The traditional medical model of autism identification often fails to account for culture, and introduces concerns related to healthcare provider and measurement bias. As a result of identification biases, Black autistic children, adolescents, adults, seniors, and their families experience disproportionate systemic barriers to services and unmet mental healthcare needs compared to white peers. Estimates suggest that nearly 5.4 million autistic adults live in the United States, yet Black autistic adults are largely missing from lifespan and disparities research. Researchers have begun to document disparities in Black autistic children, however, few sources accurately capture how these disparities translate into adulthood. For example, Black autistic adults experience unmet employment support needs and experience higher unemployment than white autistic adults. This lack of scholarship—the neglect of Black autistic adults in autism research—contributes to limited knowledge about the strengths, celebrations, joys, barriers, and needs of Black autistic adults.

Objectives: Following this presentation, attendees will be able to: (a) describe how Dis/ability Studies and Critical Race Theory (DisCrit) theories help to contextualize Black autistic adults’ experiences, (b) identify disparities that persist among Black autistic adults, and (c) implement practical guidelines to engage in more inclusive research with Black autistic adults.

Methods: The purpose of this conceptual paper presentation is to (a) use intersectionality and Dis/ability Studies and Critical Race Theory (DisCrit) theories to contextualize Black autistic adults’ experiences, (b) describe the systemic disparities that contribute to the scholarly neglect of Black autistic adults, and (c) provide guidelines to support researchers in moving from neglect to inclusive research with Black autistic adults. Our research team included racially, gender, and neuro-diverse researchers who represent a broad range of diversity of lived experiences and expertise.

Results: While this is not an exhaustive list of potential contributors of neglect, we argue that systemic disparities and methodological issues have had a cumulative impact on Black autistic individuals. Implicit racial biases continue to permeate across social systems despite explicit racial discrimination being illegal. Black Americans view their encounters with social institutions through a racial lens that is informed by past and current experiences of racial discrimination.

Conclusions: First, we recommend that researchers work to understand how their own perspectives, values, and experiences shape their research (e.g., cultural reciprocity). Second, we recommend that researchers intentionally include the perspectives and experiences of Black autistic adults. This can include collaborating on research with Black autistic scholars and highlighting autistic and Black autistic led research. Finally, we advocate for systemic changes in institutions of higher education (e.g., reduce barriers to admission) and in communities (e.g., culturally responsive supports) to better address the inequities that impact the representation of Black autistic adults in autism research.

E. Koukouriki and D. Papoudi, Department of Special Education, University of Thessaly, Volos, Greece

Background: Although previous research assessing the behavioral and emotional functioning of typically-developing (TD) siblings of children with autism spectrum disorder (ASD) has been frequently mentioned in the ASD literature, studies including more than one informant are scarce. Furthermore, studies focusing on TD siblings in middle childhood and using a parent-report and a self-report behavioral screening instrument are extremely limited, while no such study exists in the Greek cultural context.

Objectives: The present study aimed to explore possible discrepancies between parent and siblings self-report in the Strengths and Difficulties Questionnaire (SDQ).

Methods: The sample consisted of 118 TD sibling-parent pairs (98 mothers and 20 fathers) with a child with ASD in their family. Both parents and siblings completed a demographic questionnaire, and the 118 school-aged siblings were 9 to 13 years old. Parents were administered the parent version of the SDQ and the TD siblings answered the self-report children’s version of the SDQ.
Results: Initial results using the Wilcoxon signed rank test showed that the median scores in the parent and child versions of the SDQ were found to be comparable concerning the total score and the scores on almost all subscales of SDQ except for the ADHD subscale. In the ADHD subscale, the parental score was clearly higher than the child’s score. In addition, the mean difference was close to zero for most of the SDQ subscales. It is noteworthy that there was not a clear pattern of either overestimation or underestimation on behalf of the parent compared to the siblings’ report. In some cases, it was the parent that perceived the children’s state as worse whereas in roughly the same number of cases it was the child itself that did so. In the Presocial and Emotions subscales of SDQ, the agreement and consistency scores were high for the siblings and parent scores while in the ADHD subscale the highest disagreement and inconsistency was found between parents’ and siblings’ score.

Conclusions: This study addresses an important gap in the literature in relation to the assessment of behavioral functioning of TD siblings of children with ASD. The results highlight the importance of utilizing both parent- and self-report measures when examining TD siblings’ behavioral functioning in order to ensure that the gathered information is reliable and siblings of children with ASD are appropriately supported in their developmental trajectory.

423.225 (Poster) The Use of Parent-Focused Supports during Parent-Implemented Early Autism Intervention

J. L. Kuhn, R. Nunez Pepen, N. Menon, R. Patel, M. Much-Hichos, S. Delacruz, A. M. Wetherby and E. Feinberg, (1)Pediatrics, Boston Medical Center, Boston, MA, (2)Boston Medical Center, Boston, MA, (3)Pediatrics, Boston University, Boston, MA, (4)Florida State University Autism Institute, Tallahassee, FL, (5)Brown University School of Public Health, Providence, RI

Background:

Parents of young children with early autism symptoms tend to experience elevated stress and reduced well-being. Parent-focused supports, including problem-solving approaches, have been shown to improve parent coping skills, decrease parenting stress, and prevent depressive symptoms. Many early autism interventions train parents to deliver evidence-based strategies to their children in natural environments. To better support parents as they take on active roles in their children’s intervention, it is important to understand types of problems they face and the helpfulness of added parent-focused supports.

Objectives:

Among parents who were being encouraged to implement evidence-based strategies with their children, we sought to understand the types of problems that parents chose to focus on when provided with a parent-focused support called Problem Solving Education (PSE). Additionally, we aimed to explore parent perspectives on the use, helpfulness, acceptability, and feasibility of PSE alongside parent-implemented early autism intervention.

Methods:

Primary care providers referred families of young children (18-to 24-months old) with concerns for early autism symptoms to a larger NICHD-funded ACE ACTION Network study on individual and combined effects of two evidence-based interventions: 1) Problem-Solving Education and 2) the Early Social Interaction (ESI) parent coaching model. Family Navigators delivered PSE to participating parents (n = 45; see Table 1 for sociodemographic factors), who had access to online resources on how to incorporate ESI strategies into everyday activities. Families were randomly assigned to also receive individualized coaching with the ESI Model. PSE sessions were delivered with a mean fidelity score of 92.0%. Family Navigators recorded the content of all PSE sessions on a structured form following each PSE session, including a description of the problem addressed.

We used a mixed methods explanatory sequential study design. We developed a coding structure to categorize PSE problem descriptions based on 1) who the problem was about and 2) the nature of the problem. Two coders independently coded problems with inter-rater agreement of 92.4%. Next, 13 parents completed a standardized questionnaire of intervention acceptability and feasibility and a semi-structured qualitative interview. We used applied thematic analysis to identify themes from the qualitative interviews.

Results:

Approximately half of the problems were about the child and half were about the parent or nuclear family (see Figure 1 for additional details). The most common type of child-related problem had to do with addressing behaviors and supporting development. The most common parent/family-related problems surrounded household management, parental emotional well-being, and parent education and employment. Key qualitative themes included that PSE was useful for addressing any type of life stressor, encouraged self-care, and complemented the process of learning ESI strategies (see Table 2 for qualitative results). Overall, parents agreed that PSE was acceptable to them (m = 4.0 on a scale of 1 [completely disagree] to 5 [completely agree], SD = 0.84) and feasible to use (m = 4.2, SD = 0.8).

Conclusions:
Our combined quantitative and qualitative findings suggest that PSE provided a beneficial space for parents to further support their child’s development, as well as to manage other stressors in their lives.

**423.226 (Poster) To Create or Not to Create?: For Some Autistic Adolescents, There’s Very Little Question**

**Background:** Research on autism and creativity has yielded mixed results; while some research suggests enhanced creativity in autistic people (Kasirer & Mashal, 2014; 2016), other research suggests diminished creativity (Cassella, 2010; Takeuchi et al., 2014). However, research has rarely examined if autistic people benefit from, and how they feel about, creative engagement more generally and in terms of specific projects.

**Objectives:**

1. Assess whether autistic students feel they benefit from creative engagement generally, and if so, how.
2. Compare perceived benefits of creative engagement more generally and creative engagement in a 4-week game design and employment workshop.
3. Examine whether general or workshop-specific benefits are impacted by type of workshop activity and divergent thinking skills (a proxy for creative potential; Runco & Acar, 2012).

**Methods:**

22 autistic students participated in a 4-week game design and employment workshop delivered by an informal technology education nonprofit (Mage = 16.82). Pre-workshop, students completed a measure of divergent thinking (AUT; Silvia et al., 2008). During the workshop, students made video games and personal websites. Post-workshop interview questions included:

1. Does working on creative activities benefit you? Why or why not?

*After indicating which project they focused on most during the workshop:*

1. Why did you decide to make this particular project?
2. What did you gain from making this project?

Two raters inductively coded responses after obtaining inter-rater reliability >80% agreement on 20% of the data.

**Results:**

When explaining if and how creative activities more generally benefit them, students reported benefitting from creative engagement (90.9%) with enjoyment/fun as their primary gain (27.3%; Table 1). Students reported technical skills as their primary gain from working on a tech-focused creative project in the workshop (47.6%; Table 2). Common reasons for pursuing workshop projects included being inspired by certain workshop topics (31.8%) and platforms (22.7%) and a desire to build new skills (13.6%).

Increasing positive affect was only cited as a benefit of general creative engagement (13.6%) and not creative engagement in the workshop. Students who chose to make a personal website were more likely than students who created video games/other projects in the workshop to cite building creativity mindset (i.e., “it teaches me to be creative”) as a benefit to general creative engagement, $p = 0.034$, and functionality as a reason for making their project, $p = 0.031$. Divergent thinking scores were not related to the project students chose to focus on in the workshop or reported benefits of general and workshop-specific creative engagement, $ps > 0.082$.

**Conclusions:**

Autistic students overwhelmingly reported that creative engagement is beneficial. While enjoyment/fun was a general and workshop-specific gain, students most commonly described building technical skills as the primary gain of workshop-specific creative engagement.
These findings suggest that general creativity may be beneficial for wellbeing, whereas tech-focused creativity may be beneficial for learning skills or gaining experience in a related domain.

Programs for autistic adolescents which seek to effectively build skills through creative engagement should consider the creative motivations of the students during curriculum development and delivery.

423.227 (Poster) Understanding Stress and Mindfulness in Parents of Children with Autism
M. Gillies and R. A. Lundwall, (1)Psychology Department, Brigham Young University Psychology Department, Provo, UT, (2)Psychology & Neuroscience, Brigham Young University, Provo, UT

Background: Due to the symptom set which may be present in some children with autism and many time demands for appointments, care, or other services, parents raising a child on the autism spectrum may experience more significant chronic stress than parents of neurotypical children. Family functioning may therefore be affected, perhaps influencing the well-being of the family as a whole and as individuals.

Objectives: The purpose of this study was to investigate methods of measuring chronic stress in parents of children with autism and to consider the usefulness of mindfulness as an intervention to reduce stress levels by way of an online training program. This was a longitudinal study meant to determine if mindfulness practice by parents leads to improvements in stress coping mechanisms in both groups of parents; those raising autistic children and those raising neurotypical children.

Methods: Our sample consists of 43 families, 24 of whom have at least one child with autism, and 19 families with children and no known relatives with autism. All families needed an infant/toddler between 8 and 15 months to begin the study (i.e., the proband). Probands were age and sex matched for the infants in the ASD sibs’ group (M = 21.2; SD = 6.7). The study is longitudinal, but here we report on phase 1. Phase 1 included collecting a hair sample from a primary caregiver and the completion of questionnaires designed to assess level of stress and wellbeing of the parent and/or the family. Approximately one month of chronic stress is captured in 1 cm of hair. We collected a pencil width of hair from the nape of the neck of the primary caregiver. We also asked parents to complete a self-compassion (mindfulness) course. 27.12% participated, though only 13.56% completed the course, with the most common reason for not completing being a lack of time to devote to the course.

Results: Findings from questionnaires indicate higher levels of perceived stress in parents of children with autism, based on the experienced frequency and demand of their daily hassles and parent stress index (PSI) scores. Analysis of hair cortisol concentration indicated more variability in means for levels of cortisol present in parents of children with autism compared to parents of neurotypical children, perhaps indicating more stress experienced day-to-day by some of these parents. This difference in stress was exacerbated by low SES, suggesting a lack of resources for parents and families with children on the spectrum.

Conclusions: Parents of children on the autism spectrum experience more chronic stress than parents without children with autism, as evidenced by self-report and hair cortisol. Results suggest a continued need for research to improve the well-being of parents of children with autism to reduce their stress levels significantly. Because parents did not participate in mindfulness at a high rate, our lab is investigating other methods of meeting the needs of parents.

423.228 (Poster) Use of Autistic Self-Report in Autism Research: A Systematic Review of Literature Published in 2021
H. E. Morton, S. Bottini, K. A. Buchanan and K. Gould, (1)Oregon Health & Science University, Binghamton, NY, (2)Binghamton University, Binghamton, NY, (3)May Institute, Randolph, MA

Background: Autism research has historically relied on proxy reports (i.e., from parents, teachers, or other adults). Yet, autistic individuals contribute unique perspectives not captured by proxy reports (Ferenc et al., 2021; Keith et al., 2019; Kenworthy et al., 2022; Santore et al., 2020). As such, it is crucial to include autistic self-report in research, including from individuals with varying verbal and communication support needs (DePape & Lindsay, 2016; Nicolaidis et al., 2019). It is not yet known how often autistic self-report is incorporated within recent literature nor the methodologies used to capture autistic voices.

Objectives: To identify the frequency of autistic self-report in recent literature and subsequently to describe the methodology and participant demographics of these efforts, with exemplars for incorporating autistic perspectives in future research and practice.

Methods: A systematic review of the autism literature published in 2021 (online first or in-print) was conducted following PRISMA guidelines. Included articles (n=2322) were coded (>80% IOA) according to study demographics, broad topic area, and journal type.

Results: Autistic self-report was included in 18% of studies (n=423), with an additional 25% of studies (n=523) not reporting if respondents were autistic. Autistic self-report was most frequently included in articles about lifespan experiences/quality of life and inclusion/acceptance (54-60% included) and was infrequent (3-11%) in articles on the topics of autism mechanisms/biology, traits,
Using Cognitive and Behavioral Science to Facilitate COVID-19 Vaccination for an Autistic Adult

Background: Autistic adults and their caregivers frequently report barriers accessing medical and psychiatric care in community settings, despite high rates of co-occurring conditions like anxiety and specific phobia. Trypanophobia, an intense and persistent phobia of needles, limits access to essential immunizations and has been especially concerning during the COVID-19 global pandemic. Despite cognitive and behavioral science holding promise to improve vaccination rates for autistic adults, medical personnel rarely receive training in specific intervention strategies to support patients with trypanophobia, underscoring the importance examining collaborative efforts between cognitive-behavioral therapy (CBT) trained clinicians and medical providers when caring for autistic adults in community clinics.

Objectives: To explore the utility of implementing CBT interventions to facilitate vaccination for an autistic adult with trypanophobia in a community clinic.

Methods: A 26-year-old autistic male, “AP”, presented to a sensory-friendly vaccination clinic in July 2022 (dose 1) and August 2022 (dose 2) with his mother. AP was diagnosed with ASD, without co-occurring intellectual/language impairments, as a child and noted that trypanophobia prevented several previous attempts to obtain COVID-19 vaccine. Following a brief history, a licensed psychologist with expertise in ASD and anxiety implemented strategies from the Facing Your Fears manual (Reaven et al., 2011) to facilitate the vaccination process and a family medicine physician administered the vaccination. Steps of AP’s fear hierarchy included: 1- Look at needle in package; 2- Vaccine rehearsal on stuffed animal; 3- Roll up sleeve/prep arm for vaccine; 4- Needle out of package, with gradual cues from AP to move needle towards injection site; 5- Vaccine administered in arm, when AP cued “Go”. AP also created a “Plan to Get to Green”, which outlined specific strategies to facilitate somatic management and cognitive restructuring as the needle approached his arm: 1) Take deep breaths 2) Listen to relaxing music 3) Remember helpful thoughts (“I can handle this.”; “I am in control.”) 4) Say “closer” each time I’m ready for the needle to move towards my arm 5) Tense fists tightly before signaling “Go” for vaccine in my arm. Throughout this graded desensitization process, AP identified his subjective units of distress scale (SUDS) with the psychologist and physician guiding fear hierarchy progression collaboratively, based on AP’s SUDS feedback.

Results: AP was successfully vaccinated at both visits, with dose 1 session duration=90 minutes of intervention/support and dose 2 session duration=60 minutes of intervention/support.

Conclusions: This case study illustrates that CBT interventions in community clinics can facilitate access to essential medical care for autistic adults. During a post-clinic interview with AP & his mother, they noted that despite seeking specialized vaccination services for over 20 years, AP was unable to receive vaccinations elsewhere due to lack of accommodation for autistic patients with trypanophobia. AP and his mother noted that the most helpful aspects of this clinic included the flexibility, patience, and collaboration demonstrated by the clinicians throughout both sessions. Future directions include examining the efficacy of specialized medical clinics for autistic individuals and the feasibility of incorporating CBT-trained clinicians into inpatient and outpatient medical care settings.

Using Experience Based Co-Design and Design Thinking to Improve the Accessibility and Inclusivity of Research for Autistic Individuals with Complex Support Needs.

Background: Autism and other developmental disabilities are underrepresented groups. Journals of autism, education, or disabilities (20-23%). Journals of the highest frequency of articles that included autistic self-report were from the fields of child/family development, neuroscience, medicine, and other practitioners (e.g., speech, social work, OT/PT). Descriptives for participant demographics in studies that included self-report will be presented (e.g., gender, race/ethnicity, SES, IQ), as well as exemplars for future work.

Conclusions: Fewer than 20% of autism studies published in the last year follow literature recommendations to include autistic self-report in research. Another quarter of studies did not report if respondents were autistic, which was largely due to lack of characterizing parents or professionals according to neurotype. Autistic-self report is more frequently included in studies examining lifespan experiences and autism inclusion, suggesting that literature on these topics may best align with the views and experiences of autistic people. Articles on the topics of autism mechanisms, traits, assessment, and family/provider experiences, as well as from journals in the fields of child development, neuroscience, medicine, and other practitioners had the lowest rates of autistic self-report and would be enhanced by doing so. Participant demographics and exemplar studies will be used to inform recommendations for including autistic self-report in future work, including for underrepresented groups.
Background: Autistic people with complex support needs (ACSN) remain underrepresented in research (Russell et al., 2019), partly because of challenges adapting research procedures and methods effectively to accommodate diverse needs (Maes et al., 2020). For example, in recent literature reviews of studies claiming to involve ACSN (Donald et al., in prep; Edwards et al., in prep) we found that participants are often excluded when perceived to be unable to cope with, or understand, task demands; rarely were adjustments to research procedures or methods reported to maximise participant inclusion. Collaborating with the community concerned is critical to ensuring that research procedures and methods are adapted appropriately so that research effectively and meaningfully meets diverse needs.

Objectives: We aim to show how Experience Based Co-Design (EBCD) and Design Thinking (DT) methodologies provide effective frameworks for involving the communities concerned in the co-development of more accessible and inclusive research practices to serve ACSN.

Methods: EBCD has been used in healthcare settings to improve care pathways for patients together with patients (Donetto et al., 2014). It involves a cyclical process that begins with capturing the experiences of everyone concerned through formal observations and interviews that are combined into so-called ‘Touch-Point videos’. These videos are then shared in co-design meetings to stimulate discussion of the changes needed to improve services. These changes are implemented and subjected to further observation. Similarly, DT brings together stakeholder communities to co-develop solutions for complex challenges, involving an iterative process of design and review (Brown, 2008). We are adapting these methodologies to work in partnership with autism researchers, school professionals, children, and their families in order to co-develop improvements in how research answers questions meaningfully about language and communication functions and the communication of distress in ACSN. Specifically, we are exploring how best to adapt standardised assessment tools of verbal (e.g., BPVS) and non-verbal (e.g., Ravens) ability, as well as procedures for collecting psychophysiological data.

Results: Key findings to date include the co-development of multi-modal project information resources that supplement typical information sheets to facilitate engagement with frequently marginalised groups (e.g., those with English as an additional language). In addition, school professionals and parents have been involved in co-designing touch-screen based adaptations to traditional assessment tools by advising, for example, on the inclusion of symbol-based instructions to improve accessibility. Autism researchers working in the field have also been candid about their experiences working with ACSN, offering suggestions for adapting research practice and methods. We are continuing to gather the experiences of multiple stakeholder communities about being involved in this research and will share ‘touch-point videos’ detailing these experiences, as well as further adaptations and tools emerging from the work.

Conclusions: Adopting co-design methodologies positively shapes research procedures and tools to be more accessible and inclusive for ACSN and other marginalised and under-represented groups. Adapting research processes in collaboration with communities ensures researchers remain reflective of how well suited their research practices are to answering questions most important to those communities.

423.231 (Poster) Using Sentiment Analysis to Study Attitudes Towards Autism in the UK Press 2011-2020
J. Burns-Black and T. Karaminis; (1)Edge Hill University, Ormskirk, United Kingdom, (2)Department of Psychology, Edge Hill University, Ormskirk, United Kingdom

Background:

The press reflects constructs and reconstructs public attitudes towards a range of social categories, including autistic people. A recent study (Karaminis et al., 2022) investigated the portrayals of autism in the UK press between 2011-2020 using quantitative and qualitative methodologies from the fields of corpus linguistics and critical discourse analysis. One of the key findings was that newspapers tended to highlight adversities associated with autism and used negative language when referring to autistic people. This bias was more pronounced in tabloids than broadsheets, and in right- than left-leaning newspapers, and also tended to decrease slightly over the years.

While corpus analysis offers valuable insights into attitudes expressed in texts, which are useful for advocacy and public policy, it is a cumbersome and time-consuming approach. Computational linguistics offers alternatives that may automate these analyses. For example, the so-called pre-trained sentiment models are off-the-shelf tools that may be applied to identify asymmetries and changes in attitudes towards autism. However, the validity of these methods is unknown.

Objectives:

In this study, we aimed to apply computational sentiment analysis methods in the corpus of UK newspapers to assess attitudes towards autism and autistic people in different newspapers and over time. We aimed to establish how the computational results compare to the original study.

Methods:

We used the Autism UK Press corpus, a collection of ~24K articles relevant to autism published in ten national newspapers between 2011-2020. We performed sentiment analysis on every article of the corpus considering three alternative models: Vader, Flair and TextBlob. For
each model, we generated average sentiment measures [0 = negative; 0.5 = neutral, 1 = positive] per newspaper type (broadsheets vs. tabloids or left vs. right-leaning) and per year. As a baseline, we performed sentiment analysis on a reference (non-autism relevant) corpus of similar makeup to the Autism UK Press Corpus.

Results:

We present results from the FLAIR model, however, similar patterns can be seen in all three sentiment models. Overall, the mean sentiment score was lower in the Autism UK Press Corpus (average= 0.35) than the reference corpus (average = 0.43), indicating that British newspapers expressed relatively negative sentiments when referring to autism. Furthermore, and consistent with the original study, the sentiment towards autism was more negative in tabloids (0.32) than in broadsheets (0.37) (Figure 1) and in right-leaning (0.33) compared to left-leaning (0.38) newspapers (Figure 2). This pattern was unique to the autism corpus, as differences were, indeed, in the opposite direction in the reference corpus (right panels). However, there were no systematic differences in sentiment expressed in texts referring to autism over the years, unlike the original study.

Conclusions:

The results of the automated sentiment analysis were consistent with the original study on asymmetries related to reporting style and political orientation; but did not show changes over time. We conclude that sentiment analysis methods have potential to measure sentiment towards autism in the Autism UK press. Further improvements might be possible by using models tuned into this corpus.

423.232 (Poster) Variables Predicting Autistic Identity and Its Impact on Wellbeing

J. Cuda Pierce, Curry College, Chestnut Hill, MA

Background: Positive autistic identity can protect against depressive symptoms and promote mental health and wellbeing (Cooper et al., 2017; Mainland et al., 2021). Autistic identity and other identity-related constructs like self-compassion, self-acceptance, and pride are associated with increased autism knowledge (Hickey et al., 2018; Lewis, 2016), greater alignment with neurodiversity perspectives (Kapp et al., 2013), lower stigma (Cooper et al., 2021), and higher levels of outness and disclosure (Cage & Troxwell-Whitman, 2020). Understanding how these variables relate to each other and predict autistic identity development can highlight pathways to supporting wellbeing.

Objectives:

1. To identify whether (a) autism knowledge, (b) orientation to neurodiversity perspectives, (c) stigma consciousness, and (d) outness predict variance in autistic identity when controlling for gender, sexuality, and number of years knowing about autism.
2. To determine if autism identification mediates the effect of stigma consciousness on mental wellbeing.

Methods: 169 autistic adults ranging in age from 18 to 61 years ($M = 29.92$ years) completed an online Qualtrics survey composed of measures indexing autistic identity, autism awareness and knowledge, alignment with neurodiversity perspectives, autism-related stigma consciousness, level of outness about being autistic, and mental wellbeing. Hierarchical regressions determined the degree to which the four variables of interest (autism knowledge, orientation to neurodiversity perspectives, stigma consciousness, and outness) are associated with autistic identification (Objective 1). A mediation analysis addressed Objective 2.

Results:

1. Multiple hierarchical regression models with iterations of block two are examined (Table 1). In all models, gender, sexuality, and number of years knowing about autism were entered into the first block as controls. For models 2-5, each predictor variable was entered in block two and significantly predicted autistic identity (Autism knowledge - Model 2; Neurodiversity perspectives - Model 3; Stigma consciousness - Model 4; Outness - Model 5). In Model 6, all four variables were simultaneously entered into block two to determine which variable(s) uniquely explain autistic identity.

See Figure 1 for the mediation analysis. In the presence of autistic identity, the direct effect of stigma consciousness on wellbeing was negative and significant ($b = -2.215, t(169) = -2.243, p = 0.026$). The total effect of stigma consciousness on wellbeing was negative and not significant ($b = -0.907, t(169) = -0.998, p = 0.320$). The indirect effect of stigma consciousness on wellbeing via autistic identity ($ab = 1.079$) was positive and significant, with confidence intervals not including zero (CI = [0.407 – 2.340]).

Conclusions:
Alignment with neurodiversity perspectives uniquely predicted positive autistic identification suggesting that agreement with the neurodiversity paradigm and its positive/neutral views of autism promote autistic identity development.

Greater consciousness of autism-related stigma had a positive relationship with mental wellbeing via autistic identity. Findings suggest that the effect of positive autistic identity may outweigh the negative influence of stigma consciousness on wellbeing.

Implications include how supporting autistic identity development through increased autism knowledge, orientation to perspectives of neurodiversity, stigma consciousness, and outness can positively influence mental wellbeing in autistic adults.

423.233 (Poster) What Are Autistic’s Housing Preferences and Needs? - a Descriptive Study
M. Désormeaux-Moreau, A. Grondin and M. Couture, (1)École de réadaptation, Université de Sherbrooke, Sherbrooke, QC, Canada, (2)Université de Sherbrooke, Sherbrooke, QC, Canada, (3)Rehabilitation, Université de Sherbrooke, Sherbrooke, QC, Canada

Background: In Canada, rental housing is often too expensive for modest incomes. This is of greater concern for Autistic adults, whose financial resources are often lower than those of the general population. Meanwhile, although they live in the same material world as allistic (non-autistic) people, Autistics perceive and experience their environment differently and many characteristics common to built environments are problematic for them. A mismatch between the person's needs and the characteristics living environments can impact both his or her health and well-being.

Objectives: To document Autistics’ preferences and needs in terms of independent private rental housing (i.e., without community support or supervision) to: i) establish a portrait of Quebec Autistic adults in relation to housing; ii) explore the needs and preferences of Autistics tenants in terms of rental housing.

Methods: Initiated in partnership with a real estate developer, this participatory study, which was led by an autistic researcher, brought together four autistic citizens and one (other) non-autistic researcher. The study consisted of a mixed concurrent (quant + qual) online descriptive study, launched between November 1, 2021, and March 7, 2022. To take part in the study, participants needed to be Autistics (≥ 18 years of age) living in Quebec at the time of the study and capable of completing the online survey, offering an introspective perspective of their preferences and needs regarding independent private rental housing. Participants completed an electronic questionnaire (Sociodemographic = 8 questions; Current living situation = 11 questions - measuring scale; Preferences and needs = 1 open qualitative question). Quantitative data were subjected to descriptive statistical analyses (percentage, average, standard deviation) while qualitative data were subjected to content analysis.

Results: 64 Autistic adults participated in the study (M:34.5 years old; SD:9.7), a little more than half of which being female (56%). 78% of the participants reported being tenants (mostly in non-subsidized rental housing – 64%). Only 4% of participants reported that their current home was fully aligned with their preferences and needs, with 49% considering it to be moderately to not at all aligned with their preferences and needs. Characteristics reported as necessary for rental housing to meet the rental housing needs and preferences of participants were organized into 16 themes, the most recurrent of which involving soundproofing, lighting, proximity to services/public transportation, pet ownership, and proximity to nature.

Conclusions: Results show that the most frequently mentioned needs and preferences were in the sensory sphere, which is not surprising. As most participants indicated that their current housing situation was not aligned with their needs, it appears that Autistics living in independent housing (i.e., without supervision) are frequently forced to live in environments that cause sensory overload or require increased adaptation. The characteristics highlighted in this study call for rethinking the way Autistics’ needs are approached and embracing macro and mesosystemic environmental levers (e.g., rethinking construction standards for rental buildings or regulating sensory accessibility standards in the same way as physical accessibility standards) - moving away from individual levers of intervention, which are currently the most common.

423.234 (Poster) What Do You Mean I Have Autism? Perspectives of the Impact and Lived Experiences of Individuals on the Autism Spectrum Being Uninformed of Their Diagnosis
B. R. Lorentz, University of Calgary, Calgary, AB, Canada

Background: Many autistic individuals complete a diagnostic assessment as minors, with parents often serving as translators of the outcomes of the assessment with their child. Parents frequently struggle to decide whether to tell their child about the diagnosis as there are considerable stereotypes and stigma associated with the label of autism, and parents often associate this when receiving the diagnosis from clinicians; considerable time and thought go into the decision of whether to disclose the information to one’s child.

Objectives: The current study investigated the lived experiences of autistics who were not informed of their autism diagnosis for at least one year after parents were informed of the outcome of assessment.
Methods: A qualitative methodology was implemented utilizing semi-structured interviews. Interpretive phenomenological analysis was conducted to understand autistics’ perceptions, experiences, and opinions on nondisclosure of their autism diagnosis.

Results: Six North American participants between the ages of 22 to 27 took part in semi-structured interviews. Six group experiential themes (Misleading Perceptions; I Did Not Know I Was Autistic; Negative Outcomes of Nondisclosure; Wait, I have Autism?; Now I know, Now I Can; and Earlier the Better) emerged from cross-case analysis of individual themes. Each group experiential theme highlights first-person perspectives regarding the difficulties of diagnostic nondisclosure and benefits of receiving information.

Conclusions: The current study appears to be the first to give voice to autistics regarding a highly debated decision of whether to disclose or not disclose an autism diagnosis through investigating their lived experiences of nondisclosure of their diagnosis. This study generated new knowledge surrounding ethical considerations diagnosticians should be wary of in diagnostic assessment feedback and the interplay of guardians as translators of information leading to false hope and belief.

423.235 (Poster) “I Am My Child’s Voice”: Exploring Parents’ Advocate Roles As They Navigate School-Based Services for Their Autistic Child
I. Hastedt, S. Yang, A. Eisenhower and A. S. Carter, Department of Psychology, University of Massachusetts Boston, Boston, MA

Background: In the U.S., many parents of autistic children that receive school-based services are heavily involved in their child’s education (Wagner et al., 2012). Unfortunately, many parents report not receiving the school-based services they feel their child needs (Suhrheinrich et al., 2021) or experiencing a lack of communication with school providers (Tucker & Schwarz, 2013). Further, families with marginalized identities (e.g., immigration status, socioeconomic status) face barriers in accessing interventions for their autistic child (Bishop-Fitzpatrick & Kind, 2017; Zuckerman et al., 2017). A need therefore exists to examine how the parents of autistic children—especially those with marginalized identities—navigate the transition to school-based services in the U.S.

Objectives: To explore parents’ goals and motivations as they navigate the transition from early intervention (EI) to school-based services for their autistic child. We explore these in a sample of parents in Boston, Massachusetts, most of whom are first-generation immigrants, non-native English speakers, and/or living at/below the state poverty line.

Methods: Participants were parents (N=22) of three-year-old children diagnosed with autism through an EI-based, multistage screening study. Parents were mostly women (n=18), first-generation immigrants (n=13), non-native English speakers (n=13), and/or living at/below 185% of the Massachusetts state poverty line (n=16). Parents completed follow-up interviews about their children’s services at age 39 months and completed a two-session motivational interviewing (MI) intervention focused on parent-school engagement, in which parents and their MI clinician co-constructed action plans that outlined the parents’ goals and reasons for these goals. In a mixed-methods approach, we analyzed the parent action plans using Braun and Clarke’s six-step thematic analysis approach (Braun & Clarke, 2022) and examined parents’ service satisfaction using descriptive statistics.

Results: Results are based on data from 14 participants (analyses for others are underway). In rating their child's school services, 64% of parents were satisfied or very satisfied with school services; 50% were satisfied with school communication. However, qualitative results suggest that all parents, regardless of satisfaction level, identified multiple areas for improvement. Emerging themes (italicized) showed that in navigating school-based services for their autistic three-year-old children, parents wanted more communication and collaboration with school-based providers and identified wide-ranging, daunting goals and shortcomings regarding their child’s services. Some parents’ goals were motivated by a desire for progress in their child’s development, and others by a desire for their child to have a happy, meaningful, and autonomous life. Overarching themes highlight parents’ view of themselves as advocates or champions for their child.

Conclusions: Our research highlights the tremendous role that parents of autistic children take on in navigating school-based services in the U.S. Even in the context of parent-reported satisfaction with children’s school services, parents described carrying out intensive roles in advocating for and ensuring these services. Further, in this sample of predominantly multiply-marginalized families, our findings highlight the need for better parent-school communication and support for parents of autistic children as they navigate the transition into school-based special education services. This need may be particularly relevant for parents with marginalized identities who already face barriers to accessing care.

423.236 (Poster) “I Think of It As a Curse Gift”: Predictors of Autism Understanding in Autistic Teenagers

Background: Parents may wait to tell a child they are autistic until they feel the child is “ready,” leading some autistic people to learn they are autistic years after their diagnosis (Smith et al., 2018). Parents often express concerns that their child will not understand the diagnosis, that it could confer stigma, and/or harm their child’s mental health. However, learning one is autistic earlier is associated with better mental
health in adulthood (Oredipe et al., 2022) as talking openly with children about autism promotes self-understanding and coping (Crane et al., 2021). Indeed, autistic adolescents whose parents talked to them openly about being autistic tended to describe themselves and autism more positively than peers whose parents had not voluntarily told them they were autistic (Riccio et al., 2020a). While emerging research has begun to outline clear benefits of talking openly with children about autism, little remains known about how characteristics of autistic youth may help shape their understanding of autism.

Objectives: To examine if the following factors, identified by the autistic lead author as likely predictors of autism understanding, are associated with heightened autism understanding: a) parental disclosure of autism; b) cognitive skills (fluid intelligence, perceptual abilities, and verbal reasoning; because youth may use these skills to determine if they have autism and what it means); c) self-determination; and d) age.

Methods: Autistic youth (N = 37) in a game design workshop completed the Self-Determination Inventory-Student Report (Shogren et al., 2018), game-based cognitive assessments (Cambridge Brain Sciences) and answered interview questions, including: “What is autism?” and “What do you think autistic people like and do not like about being autistic?” Parent surveys included the question, “What have you told your child about their diagnosis/diagnoses?” After obtaining inter-rater reliability, coders coded open-ended responses.

Results:

Greater deductive reasoning was associated with greater likelihood of stating one is autistic when asked what autism is, \( r(34) = .34, p = .045 \). Youth whose parents had disclosed to them were less likely less likely to struggle defining autism, \( r(27) = -.44, p = .02 \), and older, \( r(30) = .48, p = .006 \). Higher self-determination was associated with less difficulty defining autism, \( r(34) = -.33, p = .046 \), but greater likelihood of misconceptions, \( r(35) = .36, p = .03 \).

Autistic students with ADHD had less difficulty defining autism, \( r(24) = .56, p = .003 \), but more often described challenges, \( r(25) = .47, p = .01 \).

In their descriptions of what autistic people like and do not like about being autistic, students commonly described autism as a difference that could lead to discrimination (Figure 1).

Conclusions: How autistic people come to understand autism is shaped by the interplay between individual differences and how others talk to them about autism. Autistic adolescents are acutely aware that autism is a difference from others, though how they interpret this difference varies greatly. Future research should evaluate individually and culturally-adapted strategies to help autistic youth understand autism.

423.237 (Poster) “Let Them Show What They Can Do”: Parents’ Perspectives on Strength-Based Practices for Autistic High School Students

**J. White**, M. H. Black**, P. J. Williams** and S. McGarry, (1)School of Education, Curtin University and Autism CRC, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)Center for Neurodevelopmental Disorders at Karolinska Institute (KIND), Center for Psychiatry Research, Dept. of Women's & Children's Health, Child and Adolescent Psychiatry, Stockholm, Sweden, (4)Curtin School of Allied Health, Curtin University, Perth, Western Australia, Australia, (5)School of Education, Curtin University, Perth, Western Australia, Australia

Background: Although there is emerging evidence to support leveraging the strengths and interests of autistic students, there is a lack of research on utilising strength-based practices to support autistic students in the school environment. The experiences of parents supporting their autistic child navigating through their educational journey have been underrepresented in the research. There is a need to understand the lived experiences of parents to facilitate the development of strategies to provide positive educational journeys for autistic individuals.

Objectives: This study aimed to explore the experiences of parents of autistic adolescents regarding strength-based practices in secondary schools.

Methods: A phenomenological research methodology was chosen to address the objective of this study. Semi-structured interviews were conducted with 23 parents (21 mothers and 2 fathers) of autistic adolescents (21 males and 2 females) who were either in secondary school (N=18) or had completed secondary school within the last five years (N=5) at the time of the interview. The interview examined the overall experience of parents in supporting autistic adolescents in their schooling and specifically explored strength-based practices. Interviews included probing questions exploring participants’ perceptions, thoughts, and feelings. Transcripts were analysed following seven-steps proposed by Coliazi for phenomenological analysis.

Results: Analysis of interview transcripts revealed that parents perceived a limited use of strength-based practices for autistic adolescents in secondary schools. Parents experienced challenges and sought resources and support in navigating through the system with their autistic
Background: In England majority of students with special needs could not attend school during the pandemic. School closures were difficult for all, but especially for autistic children who likely rely on routines. With the closure of schools, caregivers did not voluntarily choose homeschooling and many children were out of education. The Covid-19 pandemic offered a unique opportunity to understand the schools' support level for home learning and to understand how we can improve the homeschooling experiences for the children and their caregivers. Most of the research available was carried out with a quantitative approach. There are limited qualitative studies focusing on the experiences of caregivers regarding their children's homeschooling experiences.

Methods: A qualitative approach is adopted in this study. An online open-ended questionnaire was conducted so that the parents can type their own words whenever they want without time limitation. Photographs reflecting homeschooling experiences were collected as secondary data. Nine parents of twelve school age autistic children who live in England (6 mothers and 3 fathers) participated in the study. The questionnaire included demographic questions and 15 open-ended questions. The online questionnaire was available from January to March 2021. The responses to these open-ended questions were analysed by thematic analysis.

Results: A total of four themes, comprising 10 subthemes were identified. The primary themes were a) resources and support (received resources and support from school, external support and resources, quality of support and resources, support need areas), b) homeschooling experiences (caregivers’ experiences, children’s experiences), c) impact of Covid-19 pandemic on outcomes of autistic children (academic skills, speech, language and communication skills, mental health and motor development) and d) strategies of caregivers to support autistic children. Caregivers stated that the resources and support provided by schools were available during the homeschooling process but were either not appropriate or not sufficient. 8 of 9 participants emphasized that their experiences were difficult by using the word “terrible”, and they felt incompetent. Moreover, changes in academic, social, communication and mental health of children were stated.

Conclusions: It is important to examine this issue in order to discover how adequate the existing educational services are for autistic children and to help develop the support and programmes to be provided in the future period of homeschooling. This study provides insight into areas of need for overcoming inequalities in education and highlights negative effects on these caregivers’ wellbeing and autistic children's outcomes as well as gaps in the supports that were available. More useful support is essential from a variety of sources for caregivers to support their wellbeing and be able to support their children at home. Also, schools should be empowered to meet needs of autistic children.
Objectives: To address this limitation, the current study aimed to deliver a qualitative study asking autistic children how they perceive a social robot, JD.

Methods: This exploratory study was the second phase of a larger project titled ‘Evaluating the Usability of Social Robots for use in Learning Emotion Recognition in Autism Therapy with Children.’ The first phase involved developing several games with the aim of gamifying emotion recognition support with the small humanoid robot, ‘JD’. Focus groups were held with 14 autistic children across various settings in regional and metro areas in Western Australia to capture their opinions of JD. Participants’ age ranged from 7 to 12 years (M = 10.07; SD = 1.82), with 12 participants identifying themselves as male and 2 as female. All participants had previously received an autism diagnosis. The focus group questions were developed to capture the opinions of autistic children about their initial impressions of robots and JD, JD’s physical characteristics (appearance and operation), and preferred games and stories when interacting with JD. Several prompts tailored to each child were provided during the session. The researchers ensured they avoided leading responses or prompts to support the participants while enabling them to answer the questions in their own time. The focus group sessions were audio recorded and then transcribed verbatim. Data was analysed via NVivo® 20 and guided by the Thematic Analysis Approach suggested by Braun and Clarke (2007).

Results: Through thematic analysis, two main categories emerged, child-related and JD-related. The child-related category was informed by the children’s prior personal experiences with robots, including initial impressions, involvement preference in robot-related stories and narratives and their interest in technology (e.g., gaming, computing, and coding). JD-related category captured the children’s impressions and interactions with JD during the focus group session, including its aesthetic appeal, physical operation and movements, robotic technology as an assistive tool, children’s willingness to directly interact with JD, and its utility across therapy, school, and other contexts.

Conclusions: Along with informing future improvements for JD, the findings of this study indicated that to develop a robot that maximises engagement with autistic children, developers should consider children’s previous experiences and their favoured features of robots. Future research would benefit from exploring autistic children’s experience of robots when used within a therapy context.

423.240 (Poster) “You Need to Meet People Where They Are”: Autistic Adults’ Mental Health Therapy Experiences

M. O. Mazurek1, J. E. Pappagianopoulos2, S. M. Brunt3, E. Sadikova3, R. E. Nevill1, M. Menezes1 and C. Harkins1, (1)University of Virginia, Charlottesville, VA, (2)Clinical and School Psychology, School of Education and Human Development, University of Virginia, Charlottesville, VA, (3)Curry School of Education and Human Development, University of Virginia, Charlottesville, VA

Background:

Autistic adults commonly experience significant co-occurring mental health problems, including depression, anxiety, and suicidality. As such, there is an urgent need for effective mental healthcare for this population. Although outpatient psychotherapy is considered a first-line treatment for depression and anxiety, few studies have explored autistic adults’ personal experiences with mental health therapy. Understanding the perspectives of autistic adults is essential for gaining insight into the factors that may facilitate a positive therapeutic experience.

Objectives:

This study explored the perspectives of autistic adults regarding their overall mental health therapy experiences. A qualitative approach was selected to reveal unanticipated insights into the aspects of therapy that are most and least helpful for autistic adults.

Methods:

Autistic adults (n=303, ages 21-77) completed an online survey of their mental health therapy experiences. Participants were recruited through the Simons Foundation Powering Autism Research for Knowledge (SPARK) Research Match process. Items assessed prior mental health diagnoses, experiences with therapy, and therapist characteristics. Those with therapy experience responded to two open-ended questions: “What have you found to be most helpful in therapy?” and “What have you found to be least helpful in therapy?” Descriptive statistics were calculated for key variables. An iterative qualitative content analysis approach was used to analyze open-ended responses.

Results:

Most participants (89.1%) had been diagnosed with a mental health condition, with depression (74.9%) and anxiety (74.3%) being the most common. Most (88.8%) had previously participated in therapy for mental health issues and had worked with a psychologist (69.3%). Regarding how much their therapist knew about autism, mean ratings across professional disciplines ranged from 3.07 to 3.41 (on a scale of 1 = no knowledge, to 5 = a great deal of knowledge). Most (66.5%) participants felt that it was “very important” (5 on a scale of 1 to 5) for their therapist to know a lot about autism. Regarding overall therapy experiences, qualitative analyses revealed 4 primary themes and 9 subthemes. Autistic participants reported that therapist acceptance and understanding are critical for therapy success (Theme 1), and many noted that therapy has offered them tools for personal growth (Theme 2). However, communicating in session (including expectations for
talking about feelings) can be challenging for many autistic adults (Theme 3), and aspects of the session format (such as structure, organization, and alternative activities) can help or hinder their progress (Theme 4).

Conclusions:

The results of this study indicate that factors related to the therapist, the autistic client, and the therapeutic approach likely interact to influence therapeutic outcomes. Many autistic adults found therapy to be helpful for personal growth, particularly in helping them to process issues, gain new perspectives, and develop greater self-understanding. Notably, it was especially important to participants that their therapists understand autism and work to create an accepting and validating therapeutic relationship. The results also revealed the importance of ensuring that therapy sessions are individualized to accommodate the communication, information processing, and sensory needs and preferences of autistic clients.

423.241 (Poster) A Systematic Review and Meta-Analysis of Associations between Primarily Non-Autistic People’s Characteristics and Attitudes Toward Autistic People

S. Y. Kim, D. Y. Song, K. Bottema-Beutel, K. Gillespie-Lynch and E. Cage, (1)Dukung Women’s University, Seoul, Korea, Republic of (South), (2)Department of Psychiatry, Seoul National University, Seoul, MD, Korea, Republic of (South), (3)Lynch School of Education and Human Development, Boston College, Chestnut Hill, MA, (4)Department of Psychology, CUNY Graduate Center, Staten Island, NY, (5)Department of Psychology, University of Stirling, Stirling, United Kingdom

Background: There has been increasing research on non-autistic people’s attitudes toward autistic people. Such research has often focused on identifying characteristics associated with their attitudes, purportedly to facilitate the development of effective autism trainings. The degree to which such research is rooted in theory and measurement practices for assessing rater characteristics may impact the utility of previous studies as a foundation for trainings. However, no systematic review has synthesized prior literature on non-autistic people’s characteristics associated with attitudes toward autistic people.

Objectives: This systematic review consists of narrative synthesis and meta-analysis. The narrative synthesis aimed to understand which characteristics have been measured in relation to attitudes toward autistic people, focusing particularly on the theoretical frameworks used and the internal consistency of the instruments utilized to assess raters’ characteristics. The purpose of the meta-analysis was to identify whether raters’ age, gender, quality and quantity of contact with autistic people, autism knowledge, and autistic traits were associated with their attitudes about autistic people.

Methods: Peer-reviewed studies that were published in English after 1970 and reported quantitative associations between primarily (at least 90%) non-autistic samples’ self-reported attitudes toward autistic people and at least one characteristic of the participants were included in the narrative synthesis. Two independent coders extracted all relevant information, including the internal consistency of the instruments used to measure participants’ characteristics, and the theoretical frameworks the authors drew upon to motivate testing associations. Types of rater characteristics were inductively categorized into demographic characteristics, knowledge, contact, traits, and ‘other.’ Studies selected for the narrative synthesis were included in the meta-analysis if the authors supplied Pearson’s r between the variables of interest and attitudes and/or the means and standard deviations of attitudes by gender. We conducted unconditional meta-regressions to estimate the effect sizes for attitudes and each correlate using robust variance estimation.

Results: In the 47 studies included in the narrative synthesis, Western and White undergraduate students were surveyed most frequently. Demographic characteristics were the factors most frequently tested, followed by contact-related factors, autism knowledge, and participants’ traits. Internal consistency was not reported for some instruments, some had alpha levels lower than .70, and many characteristics of raters were measured using one-item measures. Moreover, theoretical motivations for investigating the rater characteristics were rarely provided (Table 1). Thirty-seven studies were included in the meta-analysis. Attitudes toward autistic people were associated with gender, autism knowledge, and quality and quantity of previous contact with autistic people, but not with age or autistic traits (Figure 1).

Conclusions: Research examining characteristics associated with primarily non-autistic people’s attitudes toward autistic people often utilized instruments with low reliability and unclearly operationalized constructs, and very few studies provided theoretical motivations for examining associations. Generalizability is limited by over-reliance on primarily western and white participants. These findings indicate a need for more studies that situate their investigation in a theoretical framework, focus on context-related characteristics (e.g., culture and institutional variables such as support/commitment to inclusion), and identify which specific aspects of contact and knowledge about autism improve people’s attitudes.

423.242 (Poster) Ready2Work: A User-Informed Employment Website for Autistic Job Seekers

P. Burnham Rosa, J. Phan, L. Whittingham, C. Bishop, N. Kenyeres, Q. Wan, W. Roberts, B. Di Rezze, N. Walker and J. Seymour, (1)Brock University, St. Catharines, ON, Canada, (2)isand, Toronto, ON, Canada, (3)School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, (4)York ASD Partnership, Toronto, ON, Canada
Background: Securing meaningful employment is a priority for autistic people in Canada and beyond. While people on the spectrum are motivated to obtain employment, unemployment and underemployment rates remain high. Throughout the existing literature, employment research has focused on individual and social characteristics that influence job-seeking. What remains missing is an empirical investigation of the resources that may support autistic job seekers in locating fulfilling work opportunities. Little is known about what job seekers on the autism spectrum need to locate, apply for, and secure meaningful employment.

Objectives: The purpose of this integrated knowledge translation research study was to 1) understand what autistic job seekers, caregivers, and employment professionals identify as important for job seekers on the spectrum to successfully enter the workforce (Phase 1) and to use these findings to develop and subsequently pilot an online employment platform (Phases 2 and 3).

Methods: In Phase 1, we conducted five focus groups with 29 participants, including seven autistic self-advocates, six caregivers of people on the spectrum, and 16 professionals from vocational and employment organizations about the employment needs of autistic job seekers. We used our findings from the thematic analysis to inform the subsequent employment website’s development (Phase 2) and refinement (Phase 3). After developing the initial beta version of the website (Phase 2), we recruited eight autistic self-advocates who interacted with the first website version and completed a survey containing open- and closed-ended questions about the website (e.g., usability, interface) during research sessions. In the final phase, we incorporated the Phase 2 usability feedback into redesigning the website and recruited 14 participants (n = 7 autistic self-advocates; n = 7 caregivers of autistic job seekers) to test the re-developed website to provide additional feedback. During Phases 2 and 3, we also gathered feedback from two community member consultants.

Results: Phase 1 focus group participants outlined a variety of barriers that autistic job seekers face. Participants provided several recommendations for an online employment site tailored to the needs of autistic people. Phase 2 participants rated the initial website iteration favourably (e.g., n = 7, 87.5% reported the website met or exceeded their expectations; n = 7, 87.5% reported that they would likely re-visit the website for employment resources). Phase 3 participants also reported generally positive ratings of the second iteration of the website (e.g., n = 14, 100% reported it was “easy” or “very easy” to navigate; n = 12, 85.7% reported that they would likely re-visit the website for employment resources).

Conclusions: Findings from our integrated knowledge translation study add to the dearth of information on empirically based resources that support autistic people in pursuing employment. This innovative, evidence-informed approach to developing an online employment resource focuses on engaging end-users and key stakeholders throughout the research process. We embedded community involvement into our model of developing the online platform throughout the study, an area that future researchers might consider when initiating projects intended to serve the needs of a particular community.

P. Burnham Riosa, S. Mills, J. Mindru, K. Yu, N. Walker, J. Seymour and L. E. Smith DaWalt, (1) Brock University, St. Catharines, ON, Canada, (2) York ASD Partnership, Toronto, ON, Canada, (3) University of Wisconsin-Madison Waisman Center, Madison, WI

Background: Transitioning to adulthood encompasses many developmental and institutional changes across many life areas. Developmental changes include the shift from childhood to adulthood; institutional changes include the transition from child to adult services. Unique challenges accompanying these changes may be even more pronounced for transition-aged youth on the autism spectrum compared to their neurotypical peers. From a family systems perspective, changes affect not only the autistic youth but also other family members transitioning alongside the teen, in addition to relational adjustments and changes between teens and their family members, namely caregivers. Transitioning Together (Da Walt Smith et al., 2012; Da Walt Smith et al., 2018) is one of the relatively few empirically based programs to support the transition experiences of youth on the spectrum and their families. This 8-week psychoeducational group program focuses on preparing autistic youth and their caregivers for the transition to adulthood. Studies examining the effectiveness of Transitioning Together have indicated promising evidence supporting its positive impact on parent and child outcomes. Further examination into the influence of Transitioning Together on parent-child relational outcomes merits further attention.

Objectives: The purpose of this study is to examine parent-reported relationship quality changes pre, post, and 1-month following participation in Transitioning Together.

Methods: The present study was a pre-post with a 1-month follow-up design delivered across four partnering community agencies involving 17 program facilitators. Twenty-six parent-child dyads completed the study. At study entry, most of our caregiver sample comprised mothers (88.5%; n = 23). Most autistic youth were male (84.6%; n = 22); with a mean age of 15.9 years (14-17; SD = 0.78), and an average Social Communication Questionnaire (Rutter et al., 2003) score of 19.8 (SD = 7.0). Among various parent (e.g., depressive symptoms) and youth (e.g., social functioning) outcomes measured at three time points, we asked parents to speak for five uninterrupted minutes about their child and their relationship with their child (i.e., Five Minute Speech Sample, FMSS; Magana et al., 1986).

Results: All data have been collected. Transcripts are being prepared and reformatted for linguistic analysis using the Linguistic Inquiry and Word Count (LIWC) software (Pennebaker et al., 2015). A repeated measures ANOVA will be used to examine changes in parent-child relationship quality over time with a focus on (1) positive (e.g., warmth, praise) and negative (e.g., criticism, overinvolvement)
relationship indicators, (i.e., past vs. present vs. future-focused narratives) regarding their relationship descriptions. Further, we will examine the relation between our FMSS data and parent and child outcome data.

Conclusions: Our findings will add to the existing literature on relational measures of parent-child functioning. The results may have implications for other family-focused programs during the transition to adulthood for autistic youth and beyond. We will discuss the importance of examining relational variables as a unit of analysis for future family-oriented research.

Background: Controversies regarding the neurodiversity movement (NDM) may be exacerbated by confusion over its meaning. Some critics and supporters of the NDM describe it as identical to the social model of disability (SM), whereas many NDM supporters assert that the NDM, unlike the SM, recognizes both biological and societal contributors to disability (Dwyer, 2022). Calls for the SM to better recognize the complexity of disability further complicate comparisons of the NDM and SM (Crow et al., 1996; Hughes & Patterson, 1997).

Objectives:
1. Compare perspectives on the NDM and SM among autistic and non-autistic stakeholders.
2. Relate beliefs about the NDM and SM to intervention goals.

Methods:
504 stakeholders (276 autistics), 236 family members (95 autistic), 120 professionals (33 autistic), and 100 researchers (41 autistic) provided valid data.

Quantitative measures of perceived appropriateness of intervention goals included the 35-item Autism Intervention Attitudes Scale (AIAS) and single items regarding goals for epilepsy, anxiety, and depression.

Open-ended responses about the meaning of neurodiversity, the NDM and SM, and similarities and differences between the NDM and SM were analyzed thematically; >80% inter-rater agreement.

Results: See Tables 1-2 for common themes. “Neurodiversity” was primarily understood as a factual term, though some understood it prescriptively. The NDM was overwhelmingly described as prescriptive. Autistic participants more often said the NDM promotes thriving and societal reform, while non-autistic participants more frequently saw it as celebrating differences. Most described the SM as attributing disability solely to society, though others spoke of societal-individual interactions.

Many said the NDM and SM share common goals and attitudes and similarly-valenced views of disability. Some said that they saw no difference between the NDM and SM. However, some said the NDM differs from the social model by recognizing medical needs or societal-individual interactions that cause disability.

SM supporters who described the SM as attributing disability to social-construction (n=164) remained open to individual-focused interventions. Their median AIAS ratings at least slightly supported interventions to teach adaptive skills (e.g., interpersonal skills) and cure depression and epilepsy. Moreover, their ratings were similar to those of SM supporters who described the SM as attributing disability only partly to society (n=70). However, those who described the SM as recognizing individual-societal interactions were less enthusiastic about creating more supportive/accessible environments than those who attributed disability solely to society, \( p=.003 \).

NDM supporters who said the NDM endorses, is identical to, or is based on the SM (n=91) and those who described the NDM as diverging from the SM by recognizing societal-individual interactions (n=33) did not generally differ in treatment preferences.

Conclusions: Autistic people, who have been at the NDM’s forefront, were more likely to describe the NDM in terms of substantive efforts to try to make autistic people's lives better, whereas non-autistic people were more likely to describe a more diluted construct, "celebrating diversity." However, participants who attributed disability solely to society in their theoretical perspectives often still pragmatically supported some individual-focused interventions. Thus, while important controversies remain, there may be greater room for agreement on various practical issues than theoretical debates imply.
Panel Discussion — Genetics

206 - Genetic Research in Autism: What Are the Implications and How Should We Involve the Autism Community?

Panel Chair: Tinca Polderman, Clinical Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Discussant: Sander Begeer, Clinical Developmental Psychology, Amsterdam, Netherlands

The goal of this symposium is first providing information on what is currently possible with genetic research in general and in autism specifically, second, providing examples on how to involve lived experience people in this type of research in a meaningful way, and third, providing information on how genetic findings could potentially be used in clinical practice.

206.001 (Panel Discussion) As a Parent of a Child with Autism, Why I Am Setting out to Do a PhD on the Genetics of Autism? M. Morgan and A. Ronald; (1)Birkbeck, University of London, London, United Kingdom, (2)Birkbeck College, London, UNITED KINGDOM

Background:

We are in the midst of a genomic revolution and genetic progress is bringing tangible benefits to many diverse conditions, disorders and diseases across biomedical science. At the same time, accurate understanding of what genetic information does and does not tell us is essential. The reasons for conducting genetic research in relation to each specific condition is essential to both understand and articulate clearly. As a parent of a child with autism, here I highlight why I am setting out to do a PhD on the genetics of autism and what I intend to focus on in order to derive maximum benefit for the autism community.

Objectives:

To outline the benefits that genetic research can bring to autism research specifically and to describe the priorities and aims of my PhD.

Methods:

In this talk, I outline the main benefits that genetic research can bring for the autism community. I explain core concepts and methods, with a focus on common genetic variation, genome-wide association studies, and the current autism polygenic score. I outline what I consider, as a parent of a child with autism as major priorities for the field.

Results:

Autism is a condition that is driven predominately by genetics and so understanding the genetic variance associated with autism is key to understanding what autism is, how to identify autism in its different forms and how to support autistic people in their lives.

The core methods of genetic investigation into autism include identifying genetic variance through genome wide association studies and using the variance identified to construct polygenic scores, identify biological pathways and compare that genetic variance with that discovered for other traits and conditions.

My PhD research priorities are to further develop existing genetic research into autism that suggests that the underlying traits that make up autism are present in everyone to different degrees. This finding supports the idea that the different presentations of autism form part of the natural differences in the neurodevelopment of individuals. By identifying the genetic variance associated with these differences we can better understand not only how and why autism develops in diverse ways in different people but most importantly how to tailor and target support for autistic people. Along with most other psychological traits and psychiatric conditions, autism is rarely the only part of a person’s psychological profile and instead forms a part of a patchwork with other traits and conditions, for example, ADHD. By investigating the genetics of this patchwork we can better understand the way that different traits and conditions combine to create unique individuals with their own strengths and areas where they need support.

Conclusions:
Autism genetics research can be a force for good in helping autistic people and their families and will help demonstrate that it is a natural form of individual difference to be accepted and welcomed by society as a whole.

206.002 (Panel Discussion) Foundations of Trust in Genetic Research: Themes from the Co-Design of the Spectrum 10K Consultation

K. L. Buckle, University of Manchester, Manchester, United Kingdom

**Background:** The Spectrum 10K project was initiated to conduct a Genome Wide Association Study to investigate the genetic and environmental factors contributing to autism and associated health conditions. Although the study was developed in consultation with a range of stakeholder groups, the study’s launch in the summer of 2021 evoked widespread opposition from autistic people. Much of the criticism revolved around fears that the data collected could be used to develop a pre-natal test for autism, leading to selective termination. In light of this response, the study was paused pending a wider public consultation.

**Objectives:** The consultation aims to engage effectively with autistic people throughout its design, delivery, and reporting, thereby answering concerns and determining what modifications may make the study feel safer. Throughout the consultation process, we aim to engage with the widest possible range of autistic people in terms of demographic and cultural diversity, expression of autism, and attitude towards genetic research.

**Methods:** The consultation is conducted by an independent consultancy and engagement organisation, Hopkins Van Mil. It is co-designed with autistic people and their families and consists of three phases: 1) Determine who should be involved, 2) Co-design the consultation; 3) Hold the consultation and make recommendations to the Spectrum 10K research team.

The consultation uses a qualitative participatory methodology. Engagement in the development and co-design process has involved multiple methods to meet a variety of communication needs. These include: live online workshops and individual interviews using video, voice, or text. Additionally, participants have engaged in asynchronous online activities, discussion and polls. The co-design has involved over 120 autistic people, selected from over 400 applicants to represent the widest diversity of demographics and views.

**Results:** The development and co-design of the Spectrum 10K consultation have raised some important themes and considerations for involvement in autism genetic research. Key themes include accessibility, genuine participation, and trust. Co-design participants emphasised that the consultation should be accessible to anyone who wants to participate, including those who don’t communicate in words, and those who are critical of the research. They also emphasised the importance of the consultation resulting in tangible changes in the study. A key outcome of phase 1 was that an autistic person should co-lead the process, which they felt gave credibility to claims of genuine co-production.

Most importantly, a well-conducted consultation builds trust. Trust is founded not only on the current project’s objectives and methods, but also on the perception of the researchers’ past actions. Trust also depends on transparency, which in turn requires clear and effective communication of complex topics to a lay audience.

**Conclusions:** The initial reaction to the launch of Spectrum 10K has demonstrated that genetic research needs to be handled with the utmost care and consideration for the views and priorities of autistic people. Extensive and public engagement and participation throughout the research life cycle are essential. Trust must be built and maintained on a foundation of transparency and genuine involvement of autistic people.

206.003 (Panel Discussion) How to Involve Lived Experience People in Genetic Research in Autism

T. J. Polderman, M. M. Wit and S. Begeer, (1)Clinical Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (2)Clinical, Neuro- and Developmental Psychology, VU Amsterdam, Amsterdam, Netherlands, (3)Clinical Developmental Psychology, Amsterdam, Netherlands

**Background:** In recent years, genetic research in autism has evoked negative voices from parts of the autism community. As a result, the ambitious genetic research project Spectrum 10K in the UK (2021) is currently paused. The basis for the negative responses seemed to relate to anxiety, suspicion, lack of communication and misunderstanding.

**Objectives:** To avoid a similar backlash, we aim to involve lived experienced people in genetic autism research and optimize communication about this research to the public and specifically to participants of the Netherlands Autism Register (NAR), where recently (March 2022) a genetic project has been launched.
Methods:

We use NAR newsletters, the magazine of the Dutch Association for Autism, and the NAR website to communicate as clear and transparent as possible about the goals and execution of the genetic research in the NAR. Also, we established a panel of (parents of) autistic people (N 3 males, 1 female, 1 binary gender, age range 25-55 years old). During biannual 3-hour panel meetings, we educate the panel members on methods and results of genetic research, and update them on new findings in the field. In addition, we ask for feedback and advice on the genetic research in the NAR, and on communication strategies towards the autistic community and the NAR participants specifically. We either implement the panel’s feedback, or clearly explain why implementing the feedback is not feasible. Panel members receive a volunteer fee for their contribution as well as full coverage of their travel costs, for which in turn we expect a 4-year commitment that includes preparation (e.g., read an article, provide feedback on a text) and being present in the biannual meetings, and in general having an active role in the panel.

Results:

NAR members have received the genetic project positively, and no negative voices from the autism community or general public have been heard so far. The response rate of eligible participants to participate in the genetic project is relatively good with ~40%. Members of the panel are positive about the meetings, the reception of their feedback, and they appreciate the educational part as it enhances providing informed feedback on the subject.

Conclusions:

Involving lived experienced people in genetic research and provide communication in a careful and thoughtful way may reduce negative responses such as anxiety, suspicion and misunderstanding of the goals and intentions of genetic research.

206.004 (Panel Discussion) Individual Return of Genomic Results: Ethical Aspects and Barriers to Implementation

J. Zinkstok, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands

Background:

Genomic research has made enormous progress in the past decades. In the field of psychiatric genetics large-scale genomic studies such as genome-wide association studies (GWAS) have provided important insights into the genetic architecture of psychiatric conditions. These large-scale genomic studies may generate primary or secondary findings that may be relevant to participants. Thus far, it is not common practice to consider return of individual research results to research participants.

Objectives:

We aim to provide an overview of current ethical and practical considerations with respect to returning individual genomics results in clinical practice. We will focus on individual return of polygenic scores (PGS) in general and for autism specifically, and will review existing literature and guidelines.

Methods:

Normative ethical analysis of ethical arguments and empirical data.

Results:

Studies exploring attitudes of participants, psychiatrists and researchers in the field of psychiatric genetics report growing support for the return of individual results. However, it is not current practice to return individual genomic research results and it is unclear what findings should be returned. Reasons not to share individual results include epidemiological (e.g., uncertainty regarding clinical validity of results), practical (e.g., limited capacity to provide clinical counseling by qualified staff in a research environment) and ethical considerations (e.g., concerns that communicating genetic results could increase stigma). While there are indeed good reasons to take a careful approach to sharing individual results, an overly restrictive policy also precludes valuable learning opportunities on how consent should be obtained, how genomic results such as PGS are best communicated and how these are perceived by recipients. In this session we will consider the possibility that studies investigating the return of individual PGS research results may provide a great opportunity to establish evidence-based practices on if and how to return individual PGS, in clinical practice in general and for autism specifically. This evidence may then guide further developments towards clinical use of PGS. Specific research gaps include exploring ways to communicate individual PGS data and understanding the short- and long-term consequences of return.

Conclusions:
Autism-Associated Transcriptional Regulators Target Shared Loci Proximal to Brain-Expressed Genes

S. J. Sanders, Department of Psychiatry, Weill Institute for Neuroscience, University of Oxford, San Francisco, CA, United Kingdom

Background: Hundreds of genes have been associated with ASD, mostly through the detection of rare loss-of-function variants that disrupt the function of one of the two copies of a gene. However, the mechanism by which disruption of these genes leads to ASD symptoms remains elusive. The majority of ASD-associated genes encode proteins that act as transcriptional regulators (TRs), influencing the expression of other genes; these include transcription factors (e.g., TBR1, FOXP1), histone modifiers (e.g., KMT5B), and chromatin remodelers (e.g., CHD8). The genomic targets of these regulatory genes and the transcriptomic consequences of their disruption remain largely uncharacterized, as do their functional relationship to other ASD-associated genes.

Objectives: To assess the extent of shared regulatory targets across ASD-associated genes.

Methods: We selected four TRs for further analysis, based on strong evidence for ASD association, expression during cortical development, evidence of direct binding to DNA, and the availability of reliable antibodies: ARID1B and BCL11A that are both DNA-binding subunits of the BAF (SWI/SWF) chromatin remodeling complex and FOXP1 and TBR1 that are transcription factors. We performed ChIP-seq using antibodies to the proteins encoded by these four genes in developing human cortex and mouse cortex at E15.5 and E18.5. Peaks were integrated ChIP-seq data for H3K27ac and H3K27me3 and ATAC-seq data from equivalent tissues.

Results: We observed substantial overlap in the binding sites of all four TRs, especially within open chromatin regions. The binding of all four ASD-associated TRs within a promoter region was highly predictive of genes with high brain RNA expression and this signature was observed at 96 out of 102 ASD-associated genes. Motif analysis of the shared loci implicated other genes associated with ASD and neurodevelopmental delay, including RFX3 and YY1. Physical interactions between the TRs could underlie the shared binding sites; proximal ligation assays support such interactions between TBR1 and ARID1B, BCL11A, and FOXP1 in the developing mouse cortex. To assess downstream convergent biology, CRISPRi knockdown of ARID1B and TBR1 was performed in cells from mouse cortex. After eight days of culture, neuronal markers were decreased, non-neuronal markers were increased, and transcriptomic signatures correlated with those seen in postmortem brain samples from individuals with ASD.

Conclusions: Analysis of four ASD-associated transcription regulators leads to a model in which their encoded proteins act as components of molecular mechanisms titrated to control gene expression in developing neuronal lineage cells. Like a clock mechanism, many components are essential, and failure of any individual component can impact overall function. Under this model, disruption of any of multiple ASD-associated transcriptional regulator genes leads to a common neurodevelopmental outcome through shared genomic targets, while specificity to ASD and developmental delay is due to a combination of haploinsufficiency and high neuronal expression of ASD-associated target genes during neurodevelopment, making them the most vulnerable to small perturbations in expression.
220.002 (Panel Discussion) Korean ASD-WGS Cohort: Potential Phenotypes for Genetic Studies

H. Yoo\(^1,2\), I. B. Kim\(^3\), T. Lee\(^4\), J. Y. An\(^5\), E. Kim\(^6\), J. K. Cho\(^7\), J. H. Lee\(^8\), D. Y. Song\(^2,11\) and G. Bong\(^1\), (1)Psychiatry, Seoul National Univ Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Psychiatry, Seoul National University College of Medicine, Seoul, Korea, Republic of (South), (3)Psychiatry, Hanyang University Guri Hospital, Guri, Korea, Republic of (South), (4)Psychiatry, Asan Medical Center, Seoul, Korea, Republic of (South), (5)Korea Institute of Science and Technology Information, Daejeon, Korea, Republic of (South), (6)School of Biosystem & Biomedical Science, Korea University, Seoul, Korea, Republic of (South), (7)Biological Sciences, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of (South), (8)Center for Synaptic Brain Dysfunctions, Institute for Basic Science, Daejeon, Korea, Republic of (South), (9)Bio and Brain Engineering, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of (South), (10)Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of (South), (11)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South)

Background:

Genetic studies of autism spectrum disorder (ASD) in the Asian population have been relatively under-explored. Understanding the genetic landscape, as well as the phenotypic structure of diverse ethnicity, might contribute to understanding the underlying mechanisms of ASD.

Objectives:

This presentation aims to demonstrate the neural and behavioral phenotypes that could potentially contribute to the genetic architecture of ASD in the context of whole genome sequencing (WGS) from Korean ASD family cohorts.

Methods:

1. Individuals with ASD, their siblings, and their biological parents are comprehensively evaluated using the standard diagnostic instruments (ADOS-2 & ADI-R) and various measurements for intelligence, nonverbal intelligence, adaptive functioning, executive functions, and emotional/behavioral symptoms.
2. In our first WGS study with Korean ASD simplex families, a total of 813 individuals from 242 families were sequenced. Induced pluripotent stem cell (hiPSC) models were generated from two ASD families for functional characterization of regulatory non-coding \textit{de novo} mutations (DNMs) in regard to three-dimensional chromatic interactions.

Results:

1. A total of 1,220 families (1,220 individuals with ASD, 441 siblings, 2,440 biological parents, mean age of probands 6.82 years, 4.71 SD, 15.7% female, 1,056 simplex and 164 multiplex with typical or broad autism phenotype in more than two family members) have been ascertained for the study.
2. Our previous studies on clinical variables have demonstrated the importance of exploring comorbid conditions and behavioral/cognitive characteristics as phenotypes in genetic studies. 1) Up to 40% of the individuals with ASD reported having motor or vocal tics, and these participants had greater severity in autistic traits and higher IQ than those without tics. 2) Heightened anxiety is correlated with repetitive behaviors, depressive symptoms, compulsion, and adherence in adolescents with ASD (Kim et al., 2021). 3) Distinct visuospatial processing patterns were found in children with ASD, their siblings, and typically developing children (Kim et al., 2021). 4) Savant skills, one of the under-explored phenomena, were found in 21.9% of the individuals with ASD, in which skills related to memory, reading, and visuospatial were most common.
3. In the study by Kim et al. (2022), we observed that non-coding DNMs in chromatin interactions alter the expression of target genes during early neural developmental stages in primitive neural stem cells (pNSCs) derived from hiPSCs. Low intelligence quotient (IQ) levels in ASD might be one of the most specifiable phenotypes, given that non-coding DNMs in chromatin interactions notably contributed to IQ levels in ASD probands.
4. Parental mental health problems were highly represented in our multiplex family samples (70.1% in mothers, 56.8% in fathers). Mental health concerns were not associated with the multiplicity of diagnosis, symptom severity, age, and gender of their offspring but rather with pragmatic language deficits in their spouse ($F(1,178)=7.76$, $p=0.006$).

Conclusions:

A novel cohort for genomic research, based on a rich and deep collection of phenotype information, is actively being collected for ASD simplex and multiplex families. We expect that WGS studies with distinct ethnicity, as well as cultural/linguistic backgrounds, will enhance the diversity of ASD research.

220.003 (Panel Discussion) Whole Genome Sequencing Analysis Identifies Genetic Architecture Underlying Female Protective Effect in Autism Spectrum Disorder
Background:

Sexual dimorphism of autism spectrum disorder (ASD) is well recognized: about 4 times higher prevalence in males and more severe phenotypes in female cases. A female protective effect (FPE) has been suggested, which assumes that females have a higher liability threshold for being ascertained as ASD, thus largely protected from ASD risk. However, the existing genetic architecture of ASD has failed to capture FPE robustly. Immunological studies have implicated the evidence of sex-biased immune dysregulations in ASD etiology. Incorporating polygenic risk for immune marker into genetic risk of ASD may provide a finer resolution for sex differences in ASD to unravel the genetic mechanism underlying FPE.

Objectives:

Our study aims to evaluate the combined effects of rare variants and polygenic risk of ASD-associated variants and how they correlate with each other and with clinical phenotypes sex-differentially. We further explore polygenic risk for inflammation and immune related markers and its interaction with clinical phenotypes in ASD males and females.

Methods: We analyzed whole genome sequencing (WGS) of Korean ASD-WGS cohort (657 families; 2,186 individuals) for rare and common variants. We prioritized gene-disruptive variants including loss of function (LoF) and damaging missense (MIS) for de novo (dnDIS) and rare inherited variants (inhDIS) and measured enrichment of these variants for ASD status and sex. We computed polygenic score (PS) for ASD- and immune-associated markers for Korean ASD-WGS cohort as well as ancestry-matching general population obtained from the Korean Variant Archive (KOVA) v2 WGS cohort (n=1,891). For Korean ASD-WGS, we calculated a polygenic transmission disequilibrium test (pTDT) score for PS_{ASD} and PS_{MM} and computed a composite rare variant risk score (RVRS) with dnDIS and inhDIS, and PS for pTDT_{ASD} and pTDT_{MM}. Finally, we assessed the correlation between the genetic factors of RVRS and PS and between all genetic factors and clinical phenotypes in males and females.

Results: Our WGS study found significant enrichment of de novo LoF (dnLoF) and PS_{ASD} for ASD cases. ASD females showed higher burden for dnLoF and PS_{ASD} compared to ASD males. Similarly, maternal transmission of inhDIS was significantly enriched for ASD males, suggesting greater genetic burden in female. While ASD-associated variants were enriched in females, PS_{MM} was shown to be higher in ASD males. This sex difference was not found in control siblings or general population. Comparing with phenotypic and behavioral traits, we did not find any sex-specific enrichment for dnLoF or PS_{ASD}. However, PS_{MM} showed a female-biased negative correlation with RVRS but male-biased positive correlations with core ASD symptoms.

Conclusions:

Our result supports FPE and demonstrates that sex-differential genetic architecture confers a distinct susceptibility towards a wide spectrum of ASD phenotypes. We also show that polygenic risk of immune traits can improve the interpretation of FPE model in ASD.

220.004 (Panel Discussion) Novel Bioinformatic Techniques Reveal Link between Sex-Specific Genome Regulation in the Developing Human Brain and Developmental Delay-Associated Genes in an Ancestrally Diverse Population

J. Lalli,1 D. Liang,1 J. Y. Arr, N. Sestani, S. J. Sanders, and D. M. Werling,1 (1)University of Wisconsin-Madison, Madison, WI, (2)Yale School of Medicine, New Haven, CT, (3)Department of Biosystems and Biomedical Sciences, Korea University, Seoul, CA, Korea, Republic of (South), (4)Department of Psychiatry, Weill Institute for Neuroscience, University of Oxford, San Francisco, CA, United Kingdom, (5)Laboratory of Genetics, University of Wisconsin-Madison, Madison, WI

Background:

Autism spectrum disorder (ASD) is 3-4X more commonly diagnosed in males than females, a fact that is currently unexplained. While cultural differences in how ASD is perceived in males and females likely influence diagnostic rates, multiple lines of evidence suggest that individuals with comparable genetic liability are less likely to develop ASD phenotypes if they are female. Sex differences in genome
function, including gene expression and splicing, may contribute to this female neuroprotective effect, but mechanistic understanding is hampered by limited knowledge of how sex affects gene regulation during neurodevelopment.

Objectives:

We aimed to identify genomic loci associated with sex-differential gene expression or splicing (expression or splicing quantitative trait loci, xQTLs) in developing human cortex tissue, and to assess identified loci and genes for association with ASD. We also aimed to improve both the resolution and patient relevance of xQTL discovery by utilizing an ancestrally diverse pangenomic reference for variant calling and personalized reference genomes for allele-specific expression estimates.

Methods:

We utilized a previously published dataset of bulk RNA-seq and whole genome DNA sequences (WGS) from the dorsolateral prefrontal cortices (DLPFCs) of 81 human donors (38 male, 43 female; 14-21 post-conception weeks). To account for samples’ diverse ancestries, we mapped WGS short reads to the draft human pangenome, identified common structural variants and short tandem repeats (PanGenie and ExpansionHunter), and phased variant calls (ShapeIt4, 1000G reference). We then generated personalized diploid reference genomes for each individual to quantify allele-specific expression and splice site utilization.

We performed a standard cis-xQTL analysis to identify structural variants, short tandem repeats, indels and SNPs nominally associated with gene expression and/or splice site usage, including sex as an interaction variable. We used the SuSiE finemapping algorithm to identify variants most likely to be causally associated with sex-specific changes in expression or splicing. We performed gene ontology enrichment analyses to identify common functions underlying sex-differentially regulated genes.

Results:

Employing a pangenomic reference increased both average sequencing depth (31.5X -> 37.1X) and coverage (94.1% -> 99.4%), with notable improvement in African American donors (30.7X -> 37.8X). Personalized transcriptome alignments further yielded a 18.7 percentage point increase in proportion of reads aligned to genes (African Americans: 26.0 percentage point increase). These improvements reduce expression variability and increase the number of sex-by-genotype interactions discovered. We observed extensive evidence of allele specific expression in our dataset, including in ASD-associated genes. We identified 139 genes regulated by genetic variants in a sex-specific manner (purity >0.95). These differentially regulated genes are significantly associated with global developmental delay (p=3.12x10⁻³) and abnormal central motor function (p=9.14x10⁻⁴, 2.18x10⁻⁴), which are critical for neural progenitor proliferation and brain plasticity, respectively.

Conclusions:

Our work suggests that utilizing a pangenomic personalized transcriptome alignment strategy improves the detection of regions involved in gene regulation via QTLs. Additionally, we observe that genes important for neurodevelopment are differentially regulated in male and female DLPFCs during mid-gestation, providing a potential mechanism contributing to the sex-biased prevalence of some neurodevelopmental disorders.

ORAL SESSION — GENETICS

314 - The effect of CHD8 & Other Rare Variants on the Brain & Behavior in Mice & Humans

Moderator: Natasha Marrus, Washington University in St. Louis, St. Louis, MO

314.001 (Oral) Behavioral Features in Children and Adolescents with Rare Variants in ASD-Associated Genes: Phenotype & Developmental Insights

Background: Autism is associated with high rates of co-occurring mental health symptoms, yet we know little about psychiatric phenotypes of rare variants in high-confidence ASD genes. Understanding behavioral features of these variants can identify shared versus specific phenotypic features across gene groups, enable mechanistic understanding, and provide prognostic insights to inform clinical practice.
Objectives: We evaluate behavioral features within three gene groups associated with ASD – ADNP, CHD8, and DYRK1A – with two aims: (1) Characterize phenotype across behavioral domains of anxiety, depression, ADHD, and challenging behavior. (2) Understand whether early developmental milestones provide prognostic information.

Methods: Families with rare pathogenic variants in ADNP (n=21), CHD8 (n=19), or DYRK1A (n=25) completed extensive clinical phenotyping through in-person, in-home, and/or virtual methods, yielding data for 65 children and adolescents (27 female; mean age=8.84 years, range 3.9 to 18.7 years) with ongoing enrollment. Groups did not differ on verbal or nonverbal IQ, based on a subset with available IQ data (verbal IQ, \(F(2,44)=8.88, p=.002\); nonverbal IQ, \(F(2,45)=1.17, p=.32\)). Behavioral features were assessed through caregiver report with the Child Behavior Checklist (Achenbach, 1991), yielding age- and sex-normed T-scores for anxiety, affective (depression), attention/hyperactivity, and oppositional symptoms. Developmental milestones related to motor skills and language acquisition, as well as developmental regression (loss of motor, communication, or social skills), were assessed through structured caregiver interview (Autism Diagnostic Interview, Revised; Lord, Rutter, & Le Couteur, 1994).

Results: Patterns of behavioral features differed across gene groups (\(F(6,186)=4.1, p<.001\)), such that internalizing symptoms were most prominent for the CHD8 group (\(F(3,54)=12.2, p<.001\)). In contrast, ADNP was associated with elevated oppositional behavior relative to the other groups (\(F(2,62)=6.61, p=.003\)). These features were less prominent in DYRK1A, for whom attentional concerns were most common (\(F(3,72)=8.1, p<.001\)). In many cases, effects included both continuous symptoms measures, as well as likelihood of clinically significant elevations. With regard to developmental factors, correlations indicated that elevations in anxiety became more marked with increasing age, particularly for the ADNP (\(r=.63, p=.002\)) and CHD8 (\(r=.50, p=.029\)) groups. The predictive value of developmental milestones differed across gene groups, with delays in the acquisition of single words corresponding to fewer oppositional behavior in ADNP (\(F(2,56)=3.05, p=.05\)). Loss of developmental skills was more broadly relevant but differed in effect across the groups, such that skill loss was associated with less anxiety and oppositional behavior for those in the ADNP group, but more difficulties for those in the DYRK1A and CHD8 groups (anxiety, \(F(5,57)=3.4, p=.009\); oppositional, \(F(5,57)=4.3, p=.002\)). See Figure 1.

Conclusions: Findings suggest meaningful differentiation between groups with rare variants in these three high-confidence ASD genes, with anxiety and oppositional behavior as frequent areas of divergence between the groups. Anxiety may become particularly problematic for youth in these groups as they age. Developmental milestones related to language development may carry prognostic value as well, and loss of attained skills may be especially informative for later psychopathology. These findings may inform mechanistic models of gene effects moving forward, and carry implications for clinical screening and supports for affected youth and families.

314.002 (Oral) Delineation of Functionally Important Protein Domains of CHD8 for Assessment of Variants Linked to ASD

Background: Autism spectrum disorder (ASD) is an early-onset etiologically complex disorder with a broad clinical presentation. While a wide range of genetic and environmental factors are known to contribute to ASD, subsets of individuals carrying deleterious variations in the same gene exhibit common co-morbidities in addition to an ASD diagnosis. One such gene is CHD8, a high confidence ASD gene based on the identification and statistical enrichment of de novo likely gene-disruptive variants in individuals with a primary diagnosis of ASD. CHD8 has since been shown to be responsible for an associated neurodevelopmental syndrome in which affected individuals frequently present not only with ASD, but also intellectual disability, overgrowth, sleep disturbances, gastrointestinal problems, and dysmorphic features. However, it remains unclear what, if any, correlation there may be between the type and location of genetic variation affecting CHD8 and any specific phenotype known to be associated with mutations in this gene.

Objectives: We sought to further delineate the genetic and phenotypic characteristics of CHD8-associated syndrome by utilizing the richly detailed genetic data curated in the Human Gene module of AutDB, our online genetic database (http://autism.mindspec.org/autdb/Welcome.do), in an attempt to identify functionally important protein domains by using a large set of CHD8 variants associated with ASD and/or other neurodevelopmental disorders (NDD).

Methods: Rare genetic variations in CHD8 identified in individuals diagnosed with ASD or NDD were extracted from peer-reviewed scientific literature and annotated for inclusion in AutDB. The standardized variants were mapped to the canonical transcript as well as on the protein domain architecture of CHD8. A comprehensive set of variants distributed across CHD8 were used for the subsequent analysis. Randomization across protein domains was performed on the standardized CHD8 rare variant dataset, as well as on a dataset of CHD8 variants from gnomAD, to identify protein domains statistically enriched for variations linked to ASD. Additionally, detailed phenotypic information for individuals with CHD8 variations were extracted and standardized using Human Phenotype Ontology (HPO).

Results: A total of 204 individuals with rare variants in CHD8, 144 of whom were reported to have a diagnosis of ASD, were included for analysis. While disease-associated variants were distributed across the entire length of the CHD8 protein, randomization analysis demonstrated that the helicase ATP-binding domain displayed a statistically significant enrichment for ASD-associated variants, while a trend towards significance was observed for ASD-associated variants in both the chromo 2 domain and the helicase C-terminal domain of the protein. In contrast, neither NDD patients or controls from gnomAD showed a comparable enrichment for CHD8 variants in any protein domain in our analysis. The phenotypic profile of ASD individuals with variants in protein domains identified by randomization analysis
with at least a trend towards significance exhibit subtle differences in the frequencies of recurrent phenotypes observed in CHD8-associated syndrome, suggesting that variant location may influence phenotype.

Conclusions: Our approach of protein domain-based enrichment of variants associated with ASD improves understanding of functional consequences of CHD8 variations. Importantly, protein-domain map will facilitate interpretation of new CHD8 variants reported in large-scale genetic studies.

314.003  (Oral) Chd8 Haploinsufficient Mice Exhibit Reduced Novelty Induced Hyperactivity and Decreased Exploratory Behavior
D. Rivas, S. Dhanani, M. Begum, Y. K. Kim and R. A. Muhle, (1)Psychiatry, Columbia University, New York, NY, (2)Barnard University, New York, NY

Background:
Autism Spectrum Disorder (ASD) is characterized by repetitive behaviors, restricted interests, and altered social communication. Advances in sequencing technologies have established the association between mutations in specific genes and regions with an increased likelihood of ASD. Mutations in the gene Chromodomain Helicase DNA Binding Protein 8 (CHD8) are frequently associated with an ASD diagnosis, and understanding how loss of CHD8 impacts neurodevelopmental pathways across the lifespan holds the potential for improved clinical care. By using mouse models that recapitulate the genetic changes in CHD8 found in patients, we can implicate certain brain regions and neurochemical pathways for further study by using behavioral assays tied to these brain circuits. We are using Chd8+/− haploinsufficient mice to assess the effect of CHD8 loss on social, emotion regulation, locomotor, and repetitive behaviors.

Objectives:
This study assessed the effects of Chd8 gene disruption on anxiety-like, repetitive, and social behaviors using a mouse model of CHD8 haploinsufficiency. These behavioral readouts provide insight into brain regions and functional circuits affected by CHD8 loss, Chd8+/−.

Methods:
Behavioral assessments were performed with 40 mice (20 wildtype, 20 Chd8+/−, with equal sex distribution and similar age). The order of assays was: open field, marble burying, nestlet shredding, Y-maze spontaneous alternation, self-grooming & spray test, 3-chamber socialization, rotarod. Data was analyzed using 2-way repeated measures ANOVA (including sex and genotype as variables) unless noted. Average values per group are presented.

Results:
In the open field, Chd8+/− mice travelled significantly less distance (5419cm vs 4376cm, p <0.0001), and spent less time in the center of the arena (1007sec vs 714.2sec, p <0.0001). All mice showed novelty-induced hyperactivity in the first 10 minutes, but Chd8+/− mice showed a significant decrease in rearing throughout the assay (489.8 rears vs 264.1 rears, p <0.0001). We found no difference in the latency to fall from an accelerating rotarod. In tests of repetitive and stereotyped behavior (marble burying, nestlet shredding, self-grooming & spray tests) we found no difference between genotype or sex. In the Y-maze test, we found no difference in the proportion of arms entered (percent alternation) but found a significant decrease in the number of arm entries in Chd8−− females (65.3 v 42.6 avg. entries, p <0.0001 by unpaired, 2-tailed t-test). In the 3-chamber assay for social preference, we found no difference by genotype in the preference for stranger mice over objects, and no preference for a novel mouse over the first mouse.

Conclusions:
Chd8+/− mice show increased anxiety-like behaviors as shown by reduced novelty-induced hyperactivity, reduced rearing, and reduced time in the center of the open field. This did not differ by sex, but there was a deficit in number of arm entries in the Y-maze in females but not males. Chd8−− mice exhibit novelty induced hyperactivity, but to a lesser degree than wildtype mice, suggesting a motor pathway deficit. We found no difference in latency to fall from a rotarod, suggesting no underlying motor deficit is responsible for the reduced movement of Chd8−− mice, and implicating higher order brain structures.

314.004  (Oral) Cell-Type and Region-Specific Impacts of Chd8 Haploinsufficiency in Mouse Brain
S. Lozano, C. P. Canales and A. S. Nord, (1)Center for Neuroscience, University of California Davis, Davis, CA, (2)Center for Neuroscience, Department of Neurobiology, Physiology, & Behavior, UC Davis, Davis, CA
Background: CHD8 is among the top causal genes to be identified via ASD case sequencing studies, yet little remains known about the cellular and molecular mechanisms linking CHD8 haploinsufficiency and neurodevelopmental disorders. Similarly, comparative studies of the effects of CHD8 haploinsufficiency across brain regions are lacking.

Objectives: We sought to identify the transcriptional changes across cortical cell types and between cortex, hippocampus, and cerebellum in heterozygous constitutive germline Chd8 mutant mice. The goal of this work is to evaluate brain regions, cells, and biological pathways for a role in NDD pathology.

Methods: We generated bulk RNA-seq data from adult brain regions and analyzed for differential gene expression and network level signatures with WGCNA. We generated single nuclei RNA-seq prepared from age-matched adult cerebral cortex and tested for altered cell populations and cell-type specific gene expression changes.

Results: We identified both region-specific and shared differential gene expression signatures, with some differences between male and female Chd8 mutant mice. Major pathways effects includes upregulation of metabolic and energetic genes and downregulation of synaptic and neuronal gene sets. For single nuclei data, we mapped differentially expressed genes from bulk analysis to cell type and further identified cell-type specific signatures in neuronal and non-neuronal cell types. Validation and follow up analysis are ongoing.

Conclusions: Our results reveal diverse cellular and molecular phenotypes in the adult Chd8 heterozygous mutant mouse brain, with stronger effects identified in cortex and cerebellum. Both neuronal and non-neuronal cell populations exhibit altered gene expression, with stronger effects in specific sub-populations. Most changes in gene expression are subtle, both at the bulk and cell-type specific level, but implicate specific gene sets and pathways for further investigation.

POSTER SESSION — GENETICS

414 - Genetics

414.226 (Poster) A Systematic Review and Meta-Analysis of Research Using the Autism Polygenic Score

Background: Autism is a highly heritable, common neurodevelopmental diagnosis characterized by a very heterogeneous pattern of behaviors. It often co-occurs with other diagnoses. Recent genome-wide association studies (GWAS) revealed the polygenic nature of autism. Polygenic scores (PGS) are based on genetic effect estimates from these GWAS and reflects an individual’s inherited propensity towards autism. PGS are considered tools with great potential for research, which has resulted in an increasing number of studies that use the autism PGS to assess its relation with autism and other phenotypes.

Objectives: Here, we systematically reviewed and meta-analyzed all published associations between the autism PGS and autism diagnostic status, autistic traits, and other behavioral and neurobiological phenotypes that have been investigated.

Methods: We limited the literature search to PGS analyses that were based on the latest autism GWAS (Grove et al. 2019). All included studies underwent a thorough quality assessment. We grouped our outcome variables into meaningful categories.

Results: In total, 58 studies met our inclusion criteria and these examined a wide range of outcome variables. Eligible studies were published between 2019 and 2022. The vast majority of the included studies was of good quality. Here, we describe the systematic review and meta-analysis results of four of the twelve categories of outcome variables.

Autism Diagnosis and traits

In sum, for the association of the autism PGS with autism diagnosis, two out of three studies reported a significant association. For autistic traits, two studies reported a statistically significant association, two studies observed no association, and three reported mixed results depending on the scale used as the outcome measure. Meta-analysis showed a significant association between autism PGS and autism diagnosis ($r = .19$ [95% BI .08 - .30], $p < .01$) and autistic traits ($r = .04$ [95% BI .02 - .05], $p < .01$).

General psychopathology and specific psychiatric classifications
For general psychopathology ($p$ factor), only one of the four studies found an association between the autism PGS and general psychopathology. Seven studies reported mixed results between the autism PGS and specific psychiatric classifications (i.e. bipolar disorder and psychotic experiences), and four studies reported no association (i.e. cannabis use disorder, nocturnal enuresis). Meta-analysis showed a small significant association between autism PGS and specific psychiatric classifications ($r = .03 [95\% BI .01 -.04], p < .01$) but not with general psychopathology ($r = .02 [95\% BI .00 - .04], p < .01$).

Conclusions: In conclusion, the latest autism GWAS has stimulated a range of studies assessing the relation between autism PGS and a myriad of outcome variables. So far, results of associations with autism diagnosis and traits, co-occurring psychiatric classifications and general psychopathology are mixed. Meta-analysis revealed a significant association between autism PGS and autism diagnosis, autistic traits and other specific psychiatric classifications, but the effect sizes were generally small. We will discuss the results of our full systematic review and meta-analyses and potential explanations of our findings.

### 414.227 (Poster) An Association Study of Aberrant Brain Morphology-Naip Copy Number Variation with Social Deficits in Autism Spectrum Disorder

**C. H. Tsai**, Y. C. Chen and S. S. F. Gau, (1)National Taiwan University, Taipei, Taiwan, (2)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan

**Background:** Autism spectrum disorder (ASD) describes an umbrella of early-onset neurodevelopmental conditions characterized by persistent deficits in social communication and reciprocal interaction and repetitive and stereotyped behaviors and interests. Given that this prevalent highly heritable disorder possesses heterogeneous characteristics in both clinical and genetic aspects, recent studies have proposed that the genetic variations may contribute to the neural developmental processing of ASD and individual differences. Moreover, evidence supported that the genes involved in apoptotic mechanisms may also partially contribute to ASD traits. *NAIP*, NLR family apoptosis inhibitory gene, encodes an anti-apoptotic protein. *NAIP* is expressed throughout brain regions. Alterations of *NAIP* may be associated with alteration of the size and shape of the brain and dysregulation of the proper wiring of the neuronal network. Therefore, we hypothesized that both deletion and duplication of *NAIP* were associated with atypical brain volume and affected the social behaviors of ASD. However, little is known about how apoptosis-related gene variations participate in the pathogenesis of ASD.

**Objectives:** Herein, we aim to investigate the underlying associations among apoptosis-related ASD susceptibility gene variations, brain volume, and behavioral problems.

**Methods:** Experimental data were collected from ASD patients (n = 40, ASD), their unaffected siblings (n = 40, SIB), and typically developing controls (n = 54, TDC) of the Taiwanese Han population. Along with clinical measures of the Social Responsiveness Scale (SRS) and Child Behavior Checklist (CBCL), all participants also received exome sequencing targeted at the 525 ASD susceptibility genes reported by Autism Gene Database (AutDB). Targeted exome gene sequencing procedures were performed with 100M reads per sample on the Illumina Miseq system. Data analyses were implemented on the Galaxy platform. Further, we acquired T1(MPRAGE; 3T Siemens trio) images from all subjects, and Freesurfer (Version 6.0) was used for our imaging preprocessing. All brain regions were derived from parcellations based on Desikan-Killiany-Tourville (DKT) atlas. We used linear regression models controlling for sex and age to examine the associations among *NAIP* CNV via reads ratio, the extent to which the copy number deviates from the non-carriers, brain volume, and clinical measures, with the significance level at p-value <0.05.

**Results:** Greater volume in the superior temporal sulcus, anterior occipital sulcus, and posterior limit of the orbitofrontal cortex, which was correlated with the higher reads ratio of *NAIP*, was found in ASD than SIB and TDC. Further, there was a positive correlation of *NAIP* CNV with the social emotion subscale and total score of SRS. In addition, there were positive correlations between *NAIP* CNV and both anxiety-depression and social problems subscales on the CBCL. Overall, we found positive associations among the brain volume, *NAIP* CNV, and clinical symptoms (social and behavioral deficits) only in the ASD group. However, none of these findings was observed in SIB or TDC.

**Conclusions:** Our findings of *NAIP* CNVs-brain structure-behaviors relationships support the concept that apoptosis-related genes may contribute to the brain morphology and behavioral deficits of ASD.

### 414.228 (Poster) Assessment of Gene-Environment Interactions in ASD through Four-Generation Artificial Neural Network: A Pilot Study

**A. Stoccoro**, R. Gallo, S. Calderoni, R. Cagiano, R. Battini, F. Muratori, E. Grossi, L. Migliore and F. Coppedè, (1)Dept of Translational Research and of New Surgical and Medical Technologies, University of Pisa, Pisa, Italy, (2)IRCCS Fondazione Stella Maris, Calambrone (Pisa), Italy, (3)IRCCS Stella Maris Foundation, Pisa, Italy, (4)Autism Research Unit, Villa Santa Maria SCS, Tavernello, Italy

**Background:**
Autism spectrum disorder (ASD) is a genetically heterogeneous disorder and may be caused by both inherited and de novo gene variants. Increasing evidence points to a contribution of environmental and epigenetic factors in ASD, but their connections are still largely unexplored.

Objectives:

Aim of the present pilot study was to apply the Auto Contractive Map algorithm (Auto CM), a special kind of Artificial Neural Networks to link various ASD maternal risk factors to the DNA methylation levels of selected genes, sex, and symptoms severity (ADOS 2 score) of their children diagnosed with an ASD.

Methods:

A total of 58 ASD children aged less than 8 years (mean age 4.35 ± 1.79 years) were recruited, including 23 males and 35 females. Blood DNA methylation levels of MECP 2, BDNF, OXTR, RELN, BCL 2, EN 2, and HTR 1 A, were measured by means of MS HRM technique. Mothers filled in a detailed questionnaire on various environmental factors during pregnancy. We also investigated the methylation levels of miRNA encoding genes (miR-30e, miR-23/27a, miR 28 miR 92 a 1 miR 92 a 2 miR 21) in DNA extracted from saliva of 11 idiopathic ASD and 13 typically developing preschool aged girls. To graphically show the most important connections among variables we used a four generation artificial neural network called Auto-CM, that develops weights that are proportional to the strength of the associations of all variables each other. The weights are then transformed in physical distances so that couples of variables whose connection weights are higher become nearer and vice versa. After the training phase, the weights matrix of the Auto-CM represents the warped landscape of the dataset. Subsequently, a minimum spanning tree filter was applied to the weights matrix of the Auto-CM system to obtain a map of the main connections between the variables of the dataset and the basic semantic of their similarities, defined connectivity map (figure 1).

Results:

Sex differences were observed in blood DNA methylation levels of the studied genes, and ANNs revealed sex-specific connections among maternal risk factors and gene methylation. Furthermore, ANNs selected a set of variables allowing discriminating between high and low-moderate ADOS-2 scores with 86.8% overall accuracy. Particularly, high gestational weight gain, lack of folic acid supplements, advanced maternal age, pre-term birth, low birthweight, and living in rural context were the best predictors of high ADOS-2 score. Moreover, the analysis of saliva DNA samples revealed that Mir-28 methylation levels could represent a biomarker of disease severity in ASD children.

Conclusions:

ANNs revealed links among ASD maternal risk factors, symptoms severity and gene methylation levels, as well as sex differences in gene methylation levels that warrant further investigation in ASD.

414.229 (Poster) Autscore – an Integrative Scoring Approach for Prioritization of Ultra-Rare Candidate ASD Genetic Variants from Whole Exome Sequencing Data

A. Shil1,2, N. Arava1, N. Sadigurschi1,3, H. Abu-Kaf2, G. Meiri4, A. Michaelovski1, Y. Tsadaka1, A. Aran3, I. Dinstein2,3, I. Background:

Identification of susceptibility genetic variants of autism spectrum disorder (ASD) in whole-exome sequencing (WES) data is a complex task. Existing bioinformatics tools to identify clinically relevant genetic variants in WES data are not specific to ASD. Thus, there is a need for automatic in-silico tools to facilitate the detection of ASD susceptibility variants in WES data.

Objectives:
We developed ‘AutScore’, an integrative scoring approach to prioritize ultra-rare candidate ASD genetic variants from whole exome sequencing data and assessed its performance to identify clinically relevant genetic variants of ASD.

Methods:

AutScore was applied to a joint variant calling format (vcf) file of 219 ASD probands and their parents registered at the database of the Azrieli National Center for Autism and Neurodevelopment Research. First, rare (allele frequency <1%) and poor-quality variants were removed from the data. Then, we used the pedigree structure of the families to select only proband-specific genotypes (i.e., de-novo, sex-linked, and recessive). Finally, we used a range of in-silico tools to prioritize the remaining variants according to their pathogenicity, clinical relevance, gene-disease association, and inheritance pattern. Variants in the upper quartile of AutScore were evaluated by clinical experts that visually inspected them with the IGV tool to detect potential false-positive variants and rated them on a 1-5 scale according to their clinical relevance to the affected probands.

Results:

Overall, 275 ultra-rare variants distributed in 226 genes in 142 probands were evaluated by AutScore and their scores ranged from -4 to 21 with a median=4 and IQR=6 (Figure 1). A total of 15 of the 60 top-rated variants (25%) were suspected as false positives and were removed from further analysis. Of the remaining variants, 26 (in 24 probands) were ranked by the clinical experts to be “highly relevant” or “relevant” to ASD, resulting in a detection yield of 11%. Of these, 18 variants (69.2%) were found in 17 genes ranked by the SFARI database as high-confidence ASD genes (Score 1) and another 3 variants (11.5%) in 3 lower-ranked SFARI genes (Scores 2 or 3). Interestingly, five variants with AutScores ranging from 11 to 14, were detected in five ASD novel genes. Comparing AutScore and the clinical expert rankings revealed that AutScore cutoffs of ≥ 11 or ≥ 12 had the best performance in detecting ASD susceptibility variants with a detection accuracy of 93.4% and 93.8% and a detection yield of 11% and 10.5% respectively (Figure 2).

Conclusions:

AutScore is an efficient automatic tool for prioritizing candidate ASD genetic variants in WES data. Important extensions of this tool should include analyses of copy-number variants, compound heterozygote variants, and partially penetrant variants.

414.230 (Poster) Concentration of Placenta Folate Metabolites in a High-Risk Autism Cohort Is Associated with DNA Methylation in Genomic Regions Involved in Neurodevelopment.

L. A. Williams, Y. Zhu, O. V. Malysheva, M. A. Caudill, J. M. LaSalle and R. J. Schmidt; (1)Medical Microbiology and Immunology, University of California, Davis, Davis, CA, (2)University of California, Davis, Davis, CA, (3)Division of Nutritional Sciences, College of Agriculture and Life Sciences, Cornell University, Ithaca, NY, (4)Medical Microbiology and Immunology, University of California at Davis, Davis, CA, (5)Department of Public Health Sciences, University of California Davis, Davis, CA

Background: While the etiology of autism spectrum disorder (ASD) is partially genetic, numerous environmental exposures have been associated with ASD risk. Prior studies have highlighted prenatal folic acid levels as one such potential ASD-associated environmental exposure, with disruptions to folate metabolism potentially inducing downstream epigenetic dysregulation as detected by DNA methylation. Nonetheless, few studies have attempted to directly identify associations between folate metabolite levels and placental DNA methylation genome-wide. Identifying signatures of DNA methylation associated with ASD-implicated environmental exposures may help illuminate the mechanisms by which folate metabolism converges with ASD development.

Objectives: By identifying differential methylation patterns associated with both placental folate metabolite levels and placenta DNA methylation in a high-risk ASD cohort, this study aimed to highlight the gene networks associated with folate metabolites in order to gain insights into folate's protective role in the molecular etiology of ASD.

Methods: Whole genome bisulfite sequencing (WGBS) was performed on DNA from 95 placentas from the MARBLES high-risk prospective ASD cohort. Concentrations of folate metabolites tetrahydrofolic acid (THF), 5-formyl-tetrahydrofolate (5-Fo-THF), 5-methyl-tetrahydrofolate (5-Me-THF), and folic acid (FA) from those same placentas were measured using a LC-MS/MS. WGBS data from the placenta samples were then used to generate comethylation networks via the Comethyl R package. The associations between comethylation modules and various sample traits, including placenta folate metabolite levels and child ASD diagnoses, were then tested, with comethylation modules showing significant associations with either trait annotated to investigate genomic membership.

Results: None of the comethylation modules found to be significantly associated with maternal use of folate-containing vitamin supplements were also associated with measured placenta folate-related metabolite levels. No significant associations were identified between placenta 5-Me-THF and placenta THF levels. Placenta 5-Fo-THF and placenta FA levels each were associated with one comethylation module (salmon and yellow modules, respectively). Hypermethylation of the salmon comethylation module was associated with increased placenta 5-Fo-THF levels, and salmon module hypomethylation was associated with increased ADOS score and increased...
likelihood of ASD diagnosis. Upon annotation, the salmon module was observed to contain the genes \textit{PLCB1} and \textit{PLCB4}, both of which are implicated in reproduction and immune pathways. Hypomethylation of the yellow comethylation module was associated with increased placenta FA levels and with higher child Mullens Scores. The yellow module contained \textit{AUTS2}, a protein-coding gene involved in neurodevelopment and implicated in multiple neurological disorders, including ASD.

Conclusions: This study identified two comethylated gene networks associated with placental folate metabolite concentrations and neurodevelopmental outcomes. Further investigation will be required to determine whether placenta folate metabolites are directly altering placenta DNA methylation in gene pathways relevant to neurodevelopmental outcomes.

414.231 (Poster) De Novo Mutations in DLL1 Gene Revealed b By Whole-Exome Sequencing in Three Libyan Siblings with Autism Spectrum Disorder
A. M. Zeglam, Pediatric Neurology, Faculty of Medicine, Tripoli University, Tripoli, Libya

Background: Autism spectrum disorder (ASD) is a clinically heterogeneous neurodevelopmental disorder with various genetic backgrounds characterized by impaired social interaction and communication, and stereotyped behaviors and interests. It is a highly prevalent disorder. According to CDC, one in 58 children are identified as having ASD. Presently, a number of genetic syndromes are known to be related to ASD.

Objectives: Here, we report a novel mutation in DELL1 gene revealed by whole-exome sequencing (WES) in three Libyan siblings (brother and two sisters) with ASD and intellectual disability. The father of the children signed the informed consent form.

Methods: Whole exome sequencing was performed in an accredited commercial laboratory (BIOSCIENTIA International-Germany). WES identified the heterozygous variant c.362_365del p. (Ser121*) in DLL1 (OMIM:606582) which leads to a frameshift, resulting in a premature stop codon, and subsequent mRNA degradation (nonsense-mediated decay) or truncation of the protein. Parallel analysis of the WES data also found the same DLL1 variant in the affected sister and brother of the index.

Results: To the best of our knowledge the variant has not been described in the literature so far (HGMD 2020.1); although several other loss of function variants in DLL1 have been reported in similarly affected patients (PMID:31353024). Allele frequency of this variant in the general population has not been documented.

Conclusions: The DLL1 gene encodes a Notch ligand. Notch signaling is essential for appropriate cell differentiation and cell fate decisions, and plays a role in developmental, homeostatic, and disease processes. DLL1 is a human homolog of the Drosophila Notch ligand Delta, and plays an important role in the developing nervous system and somites.

Pathogenic variant in DLL1 cause autosomal dominant neurodevelopmental disorder with nonspecific brain abnormalities and with or without seizures (NEDBAS; OMIM:618709).

Therefore, its loss-of-function or pathogenic missense mutations are likely to be responsible for the clinical features of the children and needs further studies and deserves consideration when dealing with families who have more than one child with ASD.

414.232 (Poster) De Novo Variants in Three-Generation ASD Families
Background: Autism Spectrum Disorder (ASD) risk has been positively correlated with advanced paternal age, which partially explains the high proportion of de novo variants (DNVs) in ASD probands. DNVs analysis has also proven to be a powerful approach to gene discovery in ASD, which has not yet been shown in a Brazilian ASD cohort.

Objectives: We hypothesized that three-generation analyses of DNVs could provide new insights into the relevance of variants that have arisen de novo across generations.

Methods: To accomplish this goal, we performed whole-exome sequencing of 33 septets families composed of probands, parents, and grandparents (n = 231 individuals), and compared these DNV rates (DNVr) with those from two control cohorts.

Results: The DNVr in the probands (DNVr = 1.22) was higher than in parents (DNVr = 0.62; p=0.04), and in controls (DNVr = 0.68; p=0.02, congenital heart disorder and DNVr = 0.70; p=0.02, unaffected ASD siblings). Moreover, for the DNVs whose origin could be assessed, the vast majority were found to have paternal origin in both generations (84.6%). Finally, we observed that 43% (6/14) of the DNVs in parents transmitted for probands are in ASD or ASD candidate genes, representing recently emerged risk variants to ASD in their families and suggest ZNF536, MSL2 and HDAC9, as ASD candidate genes.

Conclusions: In conclusion, our study showed that the analysis of three-generations presents a promising strategy to investigate the effect of de novo and inherited risk variants in ASD, with a better cost-effective effect than extreme large population studies.
To conclude, the identified results may bear important new insights into altered oxytocinergic signaling in ASD, which may aid in establishing relevant biomarkers for diagnostic and/or treatment evaluation purposes, as well as for the development of new treatment approaches for targeting the oxytocinergic system in ASD.

414.234 (Poster) Examining Symptoms of Autism Spectrum Disorder and Behavioral Phenotypes in Young Children with CLN2 Disease

J. F. Scherr, C. M. Albright and E. D. L. Reyes MD, (1)Behavioral Health, Nationwide Children's Hospital, Columbus, OH, (2)Developmental Assessment Program, Nationwide Children's Hospital, Columbus, OH, (3)Nationwide Children's Hospital, Columbus, OH

Background: CLN2 disease (neuronal ceroid lipofuscinosis type 2) is caused by a deficiency in the enzyme, tripeptidyl peptidase 1 (TPP1) and is a rare, fatal, neurodegenerative lysosomal storage disease (Mole et al., 2020). CLN2 disease is an autosomal recessive disorder and symptoms emerge early, usually by 3 years of age, and progress rapidly with seizure onset and the loss of motor and vision functioning (Williams et al., 2017). Children with CLN2 disease may also have behavioral challenges and 80% present early language delays (Nickel et al., 2018), which are also characteristic symptoms of Autism Spectrum Disorder (ASD; American Psychiatric Association, 2013). Little research has examined ASD symptomology in younger children with CLN2 disease. It is important to identify behavioral phenotypes associated with CLN2 disease to inform diagnostic and treatment practices.

Objectives: The present study aims to examine symptoms of ASD, behavioral, and developmental profiles in children with CLN2 disease with and without a clinical diagnosis of ASD.

Methods: Data was collected as part of an ongoing, longitudinal, clinical study. Participants in the current study included 20 children (12 females) between the ages of 1-5 years with a diagnosis of CLN2 disease. This sample was characterized to include children with CLN2 disease that received a clinical diagnosis of ASD (N = 6; 30%) and children without a diagnosis of ASD (N = 14; 70%). Symptoms of ASD and behavioral functioning were assessed using T-scores from scales on the Child Behavior Checklist (CBCL) via caregiver report. Developmental functioning was measured by raw scores and age equivalencies on the Mullen Scales of Early Learning (MSEL) across visual reception, fine motor, receptive language, and expressive language scales.

Results: Statistically significant group differences across T-scores are present on CBCL scales assessing attention (t (18) = 3.7, p <.01), aggressive behavior (t (18) = 2.9, p <.01), externalizing problems (t (18) = 3.3, p <.01), total problems (t (18) = 2.4, p <.05), as well as CBCL DSM-5 scales assessing ADHD problems (t (18) = 4.4, p < .01), and anxiety problems (t (18) = 2.2, p <.05). Children with CLN2 disease and ASD were reported to demonstrate more problems in comparison to children with CLN2 disease without ASD. There were no statistically significant differences (p >.05) on measures of chronological age across groups. There were no differences on measures of developmental functioning across scales on the MSEL.

Conclusions: Results suggest that young children with CLN2 disease may be at higher risk for ASD and children with CLN2 disease and ASD have increased behavioral challenges such aggression, externalizing problems, anxiety, and symptoms of ADHD. Limitations of the present study include a small sample size, cross-sectional study, and lack of ASD-specific measures. Future research should further evaluate how behavioral symptoms present and change over time in children with CLN2 disease to inform diagnostic decisions and treatment efforts. Behavioral intervention, such as Applied Behavioral Analysis (ABA), may help improve quality of life by addressing behavioral challenges and teaching functional communication.

414.235 (Poster) FMR1 Cgg Repeat Length Interacts with Adverse Childhood Experiences to Influence Expression of the Broad Autism Phenotype

J. Klusek and E. Berry-Kravis, (1)Communication Sciences and Disorders, University of South Carolina, Columbia, SC, (2)Pediatrics, Neurological Sciences, & Biochemistry, Rush University Medical Center, Chicago, IL

Background: The FMR1 gene plays a major role in genetic susceptibility to autism, with one-third to one-half of autism susceptibility genes regulated by FMR1 protein (Darnell et al., 2011). The length of the FMR1 trinucleotide CGG sequence varies in the normal population, with 6-45 considered “normal” but with ~30 repeats reflecting the population mode. New research has linked lower-than-typical numbers of CGG repeats with a variety of adverse phenotypes, including reduced well-being, motor, and cognitive function (Klusek et al., 2022; Mailick et al. 2014). Yet, despite strong evidence that FMR1 contributes to autism susceptibility, there has been little research into how variation in FMR1 CGG length may relate to the expression of autism or broader autism phenotype (BAP) traits in the population.

Objectives: In this study we investigated the relationship between CGG length and the expression of BAP traits in healthy adult women. We focused on women because they are more likely than men to carry lower-than-typical CGG repeat lengths (Kraan et al., 2018). Consistent with emerging evidence of FMR1 gene-environment interactions (Mailick et al., 2020, we also tested interactions with adverse childhood experiences (ACEs), a major environmental stressor associated with increased psychiatric risk.
Methods: Participants were 82 women who had no immediate family history of autism and were biological mothers of typically developing children (M age=47; range 27-73). The women completed the Broad Autism Phenotype Questionnaire (BAPQ; Hurley et al., 2007), a well-validated self-report questionnaire that measures the expression of BAP traits, and the ACE questionnaire (Felitti et al., 1998), which inquires about the presence of 10 types of childhood traumas (e.g., abuse, neglect) and yields a total score reflecting childhood adversity. Buccal swabs were collected and CGG repeat analysis conducted using the Asuragen® assay. General linear models tested CGG length on the shorter allele, ACE score, and their interaction, as predictors of the BAPQ scores, while controlling for the CGG repeat length on the other allele. Age and education were tested as covariates but were not retained (p’s>.253).

Results: Consistent with a gene-environment interaction, the interaction between ACES and CGG length accounted for significant variance in overall expression of BAP traits (p=.035, η²=.057). High ACES were associated with increased expression of BAP traits only among women who also carried lower-than-typical CGG lengths. Similar gene-by-environment interactions were observed for the models predicting the aloof (p=.012, η²=.08) and rigid (p=.036, η²=.06) subscales of the BAPQ, but not for pragmatics (p=.988, η²<.01).

Conclusions: Lower-than-typical numbers of FMR1 CGG repeats increased vulnerability to the BAP among women who had also experienced significant environmental stressors in the form of ACES. Thus, findings suggest that variation in FMR1 CGG repeats contributes to BAP expression in the population, with environmental stress exposure moderating this relationship. Follow-up in a larger epidemiological sample, including men, or in those with elevated autism risk, will better inform relationships. One-third of women and one-fifth of men in the US carry lower-than-typical numbers of CGG repeats (e.g., the “low zone” FMR1 genotype), highlighting broad implications for population health.

414.236 (Poster) Forebrain Organoids Model the Impact of Autism-Associated De Novo Mutations in TBR1

H. C. Rudolph, F. N. Sullivan, A. B. Mar, R. M. Mulqueen, B. DeRosa, M. Co, A. C. Adey and B. J. O’Roak; (1)Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR, (2)John P. Hussman Institute for Human Genomics, Miami, FL, (3)Knight Cardiovascular Institute, Oregon Health & Science University, Portland, OR

Background:

The in vitro differentiation of forebrain-like organoids from induced pluripotent stem cells (iPSCs) has been shown to recapitulate many early neurodevelopmental processes in vivo. This time period is critical for many autism risk genes, especially in deep layer neurons. Recent work from our lab has identified changes in cortical layer formation of patient-specific Thr1 mutant mice, particularly K228E homozygotes (Co et al., 2022). Exploring if these differences can be recapitulated in patient-derived organoids is an essential step in validating these results in human cells.

Objectives:

Here, we perform an intensive genomic characterization of these forebrain organoid models using immunohistochemistry and single-cell genomics to better understand the effects of de novo mutations (DNMs) in TBR1, a key transcriptional regulator of deep layer neuronal fate. We then compare changes in expression and layer morphology of K228E mouse and human models to identify commonalities and validate these as in vivo and in vitro models of autism.

Methods:

Using CRISPR-Cas9, isogenic pairs of a control iPSC line were edited to contain DNMs in TBR1. Forebrain-like organoids were generated over 90 days in vitro (Qian et al., 2018). IHC was utilized to characterize the cell-types and quality of each differentiation. Dynamic changes in epigenetic state during organoid differentiation were assessed using single-cell combinatorial indexing (sci) ATAC-seq (Mulqueen et al., 2019). Single-cell profiles were collapsed into groups using cisTopic then analyzed for enrichment of specific transcription factor binding motifs. Pseudotemporal analysis was performed to uncover the succession of putative transcription factor activity.

Results:

To ensure reproducibility and test epigenome correlation to primary samples of neurodevelopment, we performed IHC and single-cell ATAC-seq on a control iPSC line. From the sci-ATAC assays, we generated 31,280 cells with 183,391 open regions of chromatin passing quality control from 16 organoids and two independent differentiations. Across differentiation time points, we observed clear shifts in cell-type populations and epigenomic reconfiguration consistent with waves of transcriptional regulatory activity controlling differentiation and neurogenesis. New primary fetal tissue data sets revealed correlating chromatin signatures of cell cycle stages and improved our differentiation trajectory through chromatin dynamics of differentiation.
Additionally, we are currently generating organoids from isogenic pairs with or without the TBR1-K228E mutation. Data from these models will be used to validate the expression and cortical layer abnormalities noted in mice with an analogous mutation, including TBR1 upregulation and layering defects. This will involve the same organoid differentiation and characterization process, which will be analyzed prior to the meeting.

Conclusions:

In vitro modeling allows us to study the impact of specific DNMs on early human brain development. Our control line data demonstrates these models recapitulated the transcriptional waves of activity that control cell-fate during corticogenesis. Our current experiments are poised to inform the translational efficacy of in vivo cortical layer aberrations in K228E mice using human cells in 3D culture. Ultimately, we believe this system will be a powerful model for discovering the molecular and cellular impacts of autism-associated DNMs; specifically, in transcriptional regulators like TBR1.

414.237 (Poster) Functional Analysis of Genetic Variations Found in Clinical Exomes of ASD/ID Patients
A. Bhattacharya, P. Parlanti, L. Cavallo, E. Farrow, T. M. Spivey, A. Renieri, F. Mari and C. Manzini, (1)Neuroscience and Cell Biology, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, (2)Pharmacology and Physiology, School of Medicine and Health Sciences, George Washington University, DC, DC, (3)Medical Genetics, University of Siena, Siena, Italy

Background: Autism Spectrum Disorder (ASD) is a clinically heterogeneous neurodevelopmental disorder diagnosed by restrictive, repetitive behaviors paired with persistent social communication deficits. ASD imposes a significant disease burden: every 1 in 100 children in the world is autistic (1 in 54 in the US). Median estimates suggest 33% of these children also have Intellectual Disability (ID), defined as moderate to severe cognitive impairment. ASD/ID have a complex genetic architecture. There are more than a hundred genes involved, with highly penetrant, rare loss of function (LoF) mutations implicated in the disease, but most of them are restricted to a small subset of patients. Clinical exome sequencing has contributed to the discovery of missense variants in known genes; however, there exists a wide gap in functionally annotating them to inform clinical decisions. Often variants in a known ASD/ID gene are classified as variants of uncertain significance (VUS).

Objectives: We sought to develop a framework to characterize VUS in Coiled-coil and C2 domain containing 1A (CC2D1A; MIM *610055, UniProtKB Q24K25), a gene leading to moderate to severe autosomal recessive ID with comorbid ASD in 40% of cases.

Methods: Variants were cloned and overexpressed either individually or in patient combination in HEK293 cells. Luciferase reporter assay was used to test their effect on CREB activation, a downstream effector of CC2D1A. Competitive ELISA was performed to measure cAMP levels. To test phosphodiesterase 4D5 (PDE4D5) interaction, cells were co-transfected with PDE4D5-Myc and HA-tagged mutant (or wild type, WT) CC2D1A, followed by immunoprecipitation with anti-Myc antibody and quantification of CC2D1A on a western blot.

Results: We report four cases (three males, one female) with compound heterozygous missense variants [c.980C>T(p.Ser327Leu)/c.1345G>A(p.Val449Met), c.980C>T(p.Ser327Leu)/c.1322G>T(p.Gly441Val), c.956C>T(p.Pro319Leu)/ c.2728G>A(p.Glu910Lys), c.1739C>T(p.Thr580Ile)/c.2675G>A,T(p.Arg886His)] (Table 1). Overexpression of each CC2D1A VUS neither affected protein stability nor the survival of the transfected cells. CC2D1A is a signaling scaffold which modulates protein kinase A (PKA)/CREB activity by repressing PDE4D. This interaction is likely mediated by its unique DM14 domains while its C2 domain tethers the signaling complex to the plasma membrane. We hypothesized that missense DM14 variants (S327L, G441V, V449M, P319L and T580I) disrupt binding and release PDE4D repression, increasing cAMP degradation and reducing CREB activation. We quantified CREB activation 24hrs after transfection, following a 6hrs forskolin treatment to activate this pathway. Compared to the WT, four DM14 variants G441V, V449M, P319L and T580I lead to blunted response to forskolin induced CREB activation (p=0.0313, N=6-7, Wilcoxon matched pairs signed rank test), suggesting these are most likely LoF (Figure 1). S327L, V449M, P319L, T580I and R886I also have a concomitant reduction in cAMP levels (p<0.05, N=6, Wilcoxon matched pairs signed rank test). We are currently testing the effect of each variant on PDE4D5 binding and our preliminary results show that a few DM14 mutants reduce CC2D1A binding.

Conclusions: Our data suggest DM14 mutations affect CC2D1A binding to PDE4D to disrupt PKA/CREB signaling. CREB activation and cAMP degradation assays can be used for functional validation of VUSs. Variants disrupting this pathway may be amenable to treatment with PDE4D inhibitors.

414.238 (Poster) Genetic Variations Associated with Ultrasonography Fetal Anomalies in Children with Autism Spectrum Disorder
O. Regev, A. Shil, T. Bronshtein, A. Hadar, G. Meir, H. Flusser, A. Michaelovski, I. Dinstein, R. Hershkovitch and I. Menashe, (1)Ben Gurion University, Beer Sheva, Israel, (2)Department of Epidemiology, Biostatistics, and Community Health Sciences, Ben Gurion University, Beer-Sheva, Israel, (3)Ben-Gurion University, Beer-Sheva, Israel, (4)Soroka University Medical Center, Beer Sheva, Israel, (5)26 YA’ARA ST., Beer-Sheva, Israel, (6)Azrieli National Centre for Autism and Neurodevelopment Research, Ben-Gurion University of the Negev, Beer-Sheva, Israel, (7)Cognitive and Brain Sciences Department, Ben Gurion University, Beer Sheva, Israel, (8)Department of Epidemiology, Biostatistics, and Community Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel
Background:

Recently, we reported that ultrasonography fetal anomalies (UFAs) during mid-gestation are detected in ~30% of fetuses later diagnosed with autism spectrum disorder. Given the significant genetic contribution to both ASD and prenatal UFAs we hypothesized that shared genetic mechanisms underlie the comorbidity of ASD and UFAs.

Objectives:

To identify genetic mutations associated with UFAs in children with ASD.

Methods:

We conducted a cross-sectional study of all children diagnosed with ASD registered at the Azrieli National Centre for Autism and Neurodevelopment (ANCAN) who have both fetal ultrasound and WES data. We used an integrative in-house bioinformatics pipeline specifically designated to identify gene-disrupting variants (GDVs) in a panel of >1200 genes associated with ASD according to SFARI gene database. We compared the prevalence of identified GDVs between children with and without UFAs.

Results:

UFAs were found in 49 of the 115 (42.6%) children who had both prenatal ultrasound and WES data at the ANCAN database. Children with and without UFAs did not differ in their sociodemographic and clinical characteristics except for a significantly higher proportion of females in the UFA group (36.6% vs. 15.2%, respectively; p=0.011). Notably, children with UFAs were more likely to have GDVs in ASD genes than their counterparts even after adjustment to the sex differences between the groups (aOR=2.27, 95%CI: 1.05-4.93), and this association was the most prominent with GDVs in high-confidence ASD genes (i.e., those with SFARI gene score=1). Similarly, GDVs in ASD genes were significantly associated with specific fetal anomalies (Figure 1) with abnormal fetal size (either small/large for gestational age) and UFAs in the head&brain being the most prominent ones (OR=10.44 95% CI=1.26-86.42, and OR=3.87 95% CI=0.99-15.12 respectively). Finally, a moderate but significant correlation was found between the numbers of GDVs and UFAs found in the study sample (r=0.20, p=0.035).

Conclusions:

Our findings suggest distinct genetic mechanisms of UFAs predisposing ASD diagnosis. These findings may form a basis for future prenatal screening approaches for ASD using both ultrasound and genetic testing.

Background: We have established the Genomics of Autism in Latinx Ancestries (GALA) Consortium to develop a large prospective cohort to examine the role of genetic and environmental factors in autism across ancestral backgrounds and collect, genotype and sequence genetic materials for large-scale analyses. This abstract is presented on behalf of the GALA Consortium and the Autism Sequencing Consortium (ASC).

Objectives: Despite the success of large-scale genetic analyses for autism, the question of whether its genetic architecture differs across ancestral populations remains. Notably, there has been no systematic effort to investigate this in Latinx populations, the largest minority population in the United States currently totaling ~60 million individuals and 18% of the total population. GALA was developed to help address this gap.

Methods: GALA was first assembled ad hoc to enhance genomic diversity in the ASC and comprised of sites within the USA (Seaver Autism Center, University of Miami, University of California, Davis), Brazil (Universidad De São Paulo), Colombia (Universidad de los Andes) and Peru (Centro AnnSullivan del Perú). GALA has recruited over 900 Latinx individuals (mostly trios) diagnosed with autism.
Samples were genotyped and sequenced and incorporated into the ASC and the Psychiatric Genomics Consortium. GALA has recently received NIMH support to recruit, sequence and analyze an additional 1600 Latinx trios focusing on rare genetic variation.

Results: We analyzed de novo mutation rates as a function of ancestry in the most recent study of the ASC (Fu et al. 2022). We observed that the signal is overwhelmingly found in the most conserved genes, irrespective of ancestry.

We are now analyzing data from the existing and emerging GALA samples, focusing on de novo variation. The top 10 genes in the analyses to date are SYNGAP1, SHANK3, DYNCH1, PTEN, CHD8, CACNA1D, RERE, MED13, and SCN2A. The findings implicate known autism genes, consistent with the molecular risk architecture being shared across ancestries.

Conclusions: Admixed populations (where ancestral components from 2+ major groups are represented) present unique challenges in genetics, since the ‘local’ genomic context, i.e., ancestry at the specific chromosomal location, should be considered. The vast majority of minority populations in the USA are admixed (e.g., African American, Latinx), and there is a pressing need to include admixed populations in genomics. Latinx populations include ancestral components from 3 (or more) groups (African, European, and indigenous Americans) and are hence one of the most interesting and challenging examples of recently admixed groups. Our analyses are consistent with the hypothesis that the rare mutational burden for autism does not differ across ancestries and that there is extensive overlap between genes identified. Our results support continued autism gene discovery across populations. Biology, here reflected as genes that are intolerant to deleterious variation due to critical function and dosage sensitivity, is universal and not impacted by “local” genetic processes. Incorporating rare and common standing variation is more challenging, but we and others are working on such approaches.

414.240 (Poster) Identifying Gene-Gene Interactions Associated with Protective Effects in ASD Males and Females

W. Baskett, C. R. Shyu and D. Q. Beversdorf, (1)Bioinformatics, University of Missouri, Columbia, MO, (2)Institute for Data Science and Informatics, University of Missouri - Columbia, Columbia, MO, (3)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, Columbia, MO

Background:

Many genetic variants have been linked with the development of ASD, but less attention has been given to variants associated with a reduced risk of developing ASD, which is more prevalent in males than in females. Examining how patterns of potentially protective variants differ in effect between males and females may help us understand the reasons for the sex difference in ASD presentation. Understanding the protective mechanisms may also provide targets for intervention.

Objectives:

We aim to identify patterns of genetic variants linked to reduced risk of ASD. We plan to separately analyze these patterns in both male and female populations with the goal of better understanding how the interaction of protective variants differ between the two.

Methods: We used the SFARI SPARK dataset consisting whole exome data of 59,819 individuals, 31,139 of which were diagnosed with ASD. 10,600 high significance genetic variants were selected from the SPARK data using an FDR adjusted Chi-Square GWAS to identify variants which occurred at significantly higher or lower frequencies between the ASD and non-ASD populations. A modified version of the STUCCO contrast set mining algorithm was applied to identify patterns of variants disproportionately associated with ASD non-diagnosis. Contrast mining was run on both male and female populations separately. The relationships observed within high significance patterns were then aggregated into a network representation.

Results:

Figure 1 and Figure 2 show relationships observed in highly significant patterns in both male and female populations with orange connections showing relationships which appear in both populations. Less significant relationships were excluded for readability. DUSP15, which has previously been linked to ASD, and OSBP2 are prominent genes in both networks, but other relationships had specificity for males or females. The male network shows significantly fewer relationships which are entirely absent from the female network, such as in the relationships of DUSP15 and OSBP2 to GUCY2C/C12orf60. In contrast, the strong relationship between DUSP15 and SEMA3F is present, but dramatically weaker in the male population as compared to the female population.

Conclusions:

We observe differences in how genetic variants appear to interact between males and females to produce an effect which is associated with reduced risk of ASD. These differences in the male and female networks may help to explain ASD sex differences. This may also allow exploration of novel targets for intervention.
Impact of Selected Single Nucleotide Polymorphisms in OXTR and AVPR1a Genes on Their Expression in Persons with ASD.

K. M. Wilczyński, A. Auguściak-Duma, A. Stasiak, L. Cichoń and M. Janas-Kozik, (1)Department of Psychiatry and Psychotherapy of Developmental Age, Medical University of Silesia, Katowice, Poland, (2)John Paul II Paediatric Center in Sosnowiec, Sosnowiec, Poland, (3)Department of Molecular Biology, Medical University of Silesia, Katowice, Poland

Background:

Autism spectrum disorder is a heterogeneous group of disorders that affects virtually every population, regardless of their ethnic or socioeconomic origin. In recent years, the attention of researchers has been drawn to the participation of the oxytocinergic and vasopressinergic systems in the development of autism spectrum disorders. A relatively large number of studies have investigated the association of SNPs in these genes with the development of ASD, however, there is a lack of studies in the literature focusing on their actual effect on expression and on the effect of their expression on the risk of ASD.

Objectives:

The aim of this study was to assess the levels of expression of OXTR and AVPR1a genes and evaluate their links with both risk of ASD and genotypes of the most studied polymorphisms.

Methods:

The study included 132 people, 77.5% of whom were male (n = 100). 113 participants (85.6%) were diagnosed with autism spectrum disorders confirmed by the ADOS-2 test conducted by a certified diagnostician. In this group, men constituted 76.1% of the population (n = 77). The remaining 28 people did not have a diagnosis of autism spectrum disorders, and in the ADOS-2 study they obtained the result below the cut-off level. The mean age in the whole group was 14.4 years (95% CI: 13.92-14.93).

Results:

Results: Significant decrease in expression of the OXTR gene was found in case of rs53576 where presence of the alternative allele (G) was linked to the 20% decrease in expression (2^(-ΔΔCt) = 0.8). In case of AVPR1a alternative allele (T) of SNP rs10877969 was linked to the 20% increase in the gene expression(2^(-ΔΔCt) = 1.197). SNPs rs2254298 (2^(-ΔΔCt) = 0.97) and rs7294536 (2^(-ΔΔCt) = 0.97) did not influence expression of the appropriate genes in significant way. In comparison between the test and control group in participants with confirmed diagnosis of ASD 13% lower expression of AVPR1a was found (2^(-ΔΔCt) = 0.87).

Conclusions:

Genotype of SNPs rs53576 and rs10877969 significantly influenced the levels of expression of the genes OXTR and AVPR1a respectively. In case of rs2254298 and rs7294536 observed effects were negligible. Presence of ASD diagnosis was linked to the 13% lower expression of AVPR1a. Abnormalities in AVPR1a expression seem to be more important for the development of autistic traits than the more attention-grabbing gene abnormalities for the oxytocinergic system.

Inducible Calling Cards: A Mouse Reagent for Temporally Controlled Recording of Neural Activity and Activity-Dependent Gene Expression

S. Sarafinovska, A. Yen, A. Venkatesan, R. Mitra and J. Dougherty, (1)Washington University in St. Louis, St. Louis, MO, (2)Washington University in St. Louis, Saint Louis, MO, (3)Genetics, Washington University in St. Louis, St. Louis, MO, (4)Genetics, Washington University School of Medicine, St. Louis, MO

Background: Genetically identical rodents often display individual behavioral responses to the same manipulation. For instance, identically reared mice demonstrate differential levels of social motivation and learning for an age- and sex-matched stimulus. Identifying the molecular landscapes and neural circuits that mediate these individual differences may help elucidate underpinnings of social motivation. However, to identify pre-existing factors that underlie individual differences, molecular states need to be recorded or preserved before phenotypic read-out in the same animal. Current techniques for molecular read-out require prematurely sacrificing the animal, while phenotypic read-out destroys the molecular state from before the manipulation.

Objectives: Here, we introduce mJun-iCC, a novel transgenic mouse tool to nondestructively record molecular states in the live mouse for later read-out. With mJun-iCC, we will be able to 1) fluorescently tag transiently active neurons and 2) record their activity-dependent gene expression for post-mortem read-out.
Methods: mJun-iCC introduces temporal control to Calling Cards, a recently published method to record transcription factor-DNA interactions nondestructively in the live mouse brain. To enable temporal control, mJun-iCC contains a tamoxifen-inducible domain, which allows specification of time windows for fluorescent tagging and recording. We use both fluorescent reporters and next-generation sequencing in vitro and in vivo to evaluate the efficacy of mJun-iCC.

Results: We demonstrate proof-of-principle in the mouse brain that mJun-iCC only records under control of tamoxifen and requires induction by neural activity. Next, to validate the broad applicability of mJun-iCC, we show that mJun-iCC records activity-dependent gene expression in response to behavioral stimulus in relevant brain regions. Finally, we benchmark the mJun-iCC transgenic reagents and characterize efficacy, general health, and behavior of these animals.

Conclusions: Our results indicate mJun-iCC may uniquely allow retroactive, temporally controlled analysis of molecular landscapes and neural activity prior to environmental manipulation. We anticipate mJun-iCC will have broad applications with epigenetic and circuit mapping and enable significant advancements for research into social motivation, early-life adversity, and autism models.

414.243 (Poster) Interaction between Maternal and Progeny Glutathione S-Transferase Genes in Relation with Autism Spectrum Disorder in Jamaican Children

D. Calver, M. E. Samms-Vaughan, L. E. Mitchell, J. Bressler, S. Saroukhani, Y. Zhao, M. Hessabi, M. L. Grove, S. Pellington, K. A. Loveland and M. H. Rahbar, (1) The University of Texas Health Science Center at Houston, Houston, TX, United States, Houston, TX, (2) Department of Child & Adolescent Health, The University of the West Indies, Mona Campus, Kingston, JAMAICA, (3) Department of Epidemiology, Human Genetics and Environmental Sciences, The University of Texas Health Science Center at Houston, Houston, TX, United States, Houston, TX, (4) Human Genetics Center, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (5) Department of Epidemiology, Human Genetics, and Environmental Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (6) Biostatistics/Epidemiology/Research Design (BERD) core, Center for Clinical and Translational Sciences (CCTS), The University of Texas Health Science Center at Houston, Houston, TX, (7) Division of Clinical and Translational Sciences, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, (8) Department of Biostatistics & Data Science, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, United States, Houston, TX, (9) Department of Child & Adolescent Health, The University of the West Indies, Mona Campus, Kingston, Jamaica, (10) Louis A. Faillace, MD, Department of Psychiatry and Behavioral Sciences, McGovern Medical School, University of Texas McGovern Medical School, Houston, TX

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder. Although the etiology of ASD is not completely known, it is believed to involve complex interactions between/among genes or gene-environment interaction.

Objectives: In this research we investigated the association of genotypes for three metabolic glutathione S-transferase (GST) genes (GSTM1, GSTT1, and GSTP1) in both mothers and their progeny with ASD case status in the children, and with ASD severity only in the children with ASD.

Methods: We used data from 68 pairs (n=136) of Jamaican children (2-8 years old) with ASD and their 1:1 sex-and age-matched typically developing (TD) controls who were enrolled in the Epidemiological Research on Autism in Jamaica (ERAJ) study. The genotypes for GST genes were also evaluated in mothers of the enrolled children. We applied univariable and multivariable Conditional Logistic Regression (CLR) models to explore additive and interactive effects of GST genotypes in mothers and their progeny in relation to ASD status, as well as ASD severity as measured by the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) total comparison score in children with ASD.

Results: In univariable analyses, we did not find any significant associations of the maternal GST genes with ASD in children (all \( P > 0.3 \)). However, we found that the odds of ASD in children who were homozygous for the GSTT1 deletion allele (DD) was 5.5 times greater than in those with at least one active GSTT1 allele (I/*) [Matched odds ratio (MOR) (95% confidence interval (CI)) = 5.5 (1.9, 16.0); \( P = 0.0017 \)]. In the interactive multivariable models, although we did not identify a significant interaction between progeny and maternal GST genes in relation to ASD (all \( P \geq 0.06 \)), we found significant associations between children’s genotype for GSTT1 and ASD only among children whose mothers had certain genotypes for GSTT1 and GSTP1. Specifically, among children whose mothers had GSTT1 DD genotype, the odds of ASD in those with GSTT1 DD genotype was 19.8 times that in children with GSTT1 I/* [MOR (95% CI) = 19.8 (2.5, 157.6); \( P = 0.0048 \)]. Additionally, we found that among children whose mothers were homozygous Val/Val for the GSTP1 Ile105Val polymorphism, the odds of ASD in children with GSTT1 DD genotype was 14.3 times greater than in children with GSTT1 I/* [MOR (95% CI) = 14.26 (1.294, 157.1); \( P = 0.030 \)]. Furthermore, we identified a significant interaction between maternal and children’s GSTM1 genotypes in relation to ASD severity (Interaction \( P = 0.02 \)). Specifically, among children whose mother had I/* genotype for GSTM1, those with GSTM1 DD genotype had less severe ASD than those with GSTM1 I/* genotype [OR (95% CI) = 4.17 (1.39, 12.5); \( P = 0.01 \)].

Conclusions: Multiple significant associations were found with ASD case status or ASD severity when gene-gene interactions for the GST genes were investigated. Such findings indicate that no single gene affects the association with ASD outcome status or severity, but rather the presence of multiple factors may have significant associations with increased odds of ASD outcomes and/or increased severity of ASD.
Background: While the diagnostic yield of genetic testing in autism is approximately 20%, the clinical utility of genetic testing to help understand longitudinal health outcomes and service needs for autistic children and youth remains unclear.

Objectives: The objectives of this study were to (1) demonstrate the feasibility and potential of linking clinical, genomic, and administrative health data and (2) to better characterize the clinical impact and utility of having a genetic diagnosis for autistic children and youth. To meet these objectives, we conducted an analysis to determine whether carrying an underlying genetic variant is associated with differences in health system utilization among a cohort of children with a confirmed diagnosis of ASD. We hypothesized that a genetic diagnosis in autism would be associated with higher health system utilization, including higher overall health care costs.

Methods: The study population consisted of 415 autistic children and youth (mean age 9 years) who underwent whole genome sequencing through a translational neuroscience program (Province of Ontario Neurodevelopmental Disorders Network- POND). Genome sequencing data were used to identify children carrying pathogenic variants (copy number and single nucleotide variants) in 74 known genes with developmental impact. Participants’ research and genetic data were linked to their longitudinal health service utilization using Ontario health administrative databases. Physician, specialist, hospital visits, and total healthcare costs during a 3-year look-back window from POND recruitment were examined and compared between autistic children and youth with and without an underlying genetic variant.

Results: A total of 83 (20%) of participants carried a pathogenic or likely pathogenic genetic variant. Clinical, and demographic characteristics were similar between both groups. Health system utilization was comparable between both groups as well, except for visits for mental health concerns. Children with a genetic variant were less likely to seek psychiatric care (including psychiatrist visits: 19.3% vs. 34.3%, p = 0.008; and outpatient mental health visit with any physician 66.3% vs. 77.1%, p = 0.04), than those without a variant.

Conclusions: This preliminary analysis highlights the feasibility and potential of genomic and health system data linkage, as well as the possible clinical utility of using genetic data to predict mental health care needs in patients with neurodevelopmental conditions.

Background: Phelan-McDermid syndrome (PMS) is a rare genetic condition primarily caused by a 22q13.3 deletion or pathogenic variant of SHANK3. The clinical presentation is heterogeneous and comprises global developmental delay/intellectual disability, marked speech impairment and other features like hypotonia, medical comorbidities, hyperactivity and autism spectrum disorder (ASD).

Developmental stagnation/regression is not uncommon, and behavioral changes may be notable as individuals age. Some studies report data on psychiatric comorbidities and decompensation in adolescents and adults. Nevertheless, longitudinal evaluations are scarce and our ability to establish developmental trajectories remains limited.

Objectives: Our main objective is to describe the behavioral and autistic symptomatology course of a sample of participants with PMS evaluated at two time points. We used standardized tools for the assessment of ASD, global adaptive functioning and repetitive or otherwise altered behaviors.

Methods: Fifty-three participants (88%) from the cohort of Burdeus et al. (2021) consented to participate in a follow-up evaluation, ~4 years after visit 1 (V1). We repeated the assessments, which consisted of the evaluation of autistic symptoms using the ADOS-2 and several scales measuring altered behavior (ABC-C, RBS-R) and adaptive behavior (Vineland-3). We present longitudinal variations in a descriptive fashion, informing of mean score changes and percentage of individuals showing no change, increases or decreases in the mentioned tools. Evaluations are ongoing; once the final sample is available, we will analyze the significance of these changes.

Results: Preliminary results of 31 participants (48% female) are available, with a mean age at V2 of 12.29 years (SD=5y). The average time lapse between V1 and V2 was 46 months (SD=5m). Regarding adaptive behavior, mean standard scores for all domains showed a global
decrease; however, around 50-60% of the participants showed equal or increased scores in the “Communication” and “Socialization” domains. Autistic severity measured with ADOS-2 CSS appeared to increase with age, with around half of the participants scoring higher at V2, especially in the “Total” and “Social affect” domains. At V2, six out of 8 participants stayed under the cut-off score relative to V1, while 3 previously above the ASD cut-off lowered their score.

Concerning repetitive behaviors, stereotypic and insistence in sameness showed a decreasing tendency in over half of the sample, while compulsive and restrictive behaviors appeared stable or increased. Agitation or irritability, as well as hyperactivity, also appeared decreased, with around 75% of participants scoring lower on V2.

Conclusions: Preliminary results of behavioral change in several domains are variable. The informed decrease in adaptive behavior is unsurprising, consistent with the phenomenon of “growing into deficit”. ADOS-2 CSS scores hint to a slight increase in autistic severity, however, significance of this finding must be explored. Five individuals (26%) differed in their ADOS-2 classification, both due to increases and decreases in their scores. Irritability and hyperactivity appeared to drop with age, and so did insistence in sameness. Stratification based on genetic information, as well as clinical or demographic characteristics, such as verbal ability or sex, may provide more details on the differential clinical courses of individuals with PMS.

414.246 (Poster) Mass-Spectrometry Based Metabolomic Profiling of Twin Pairs from the Roots of Autism and ADHD Twin Study in Sweden (RATSS)

A. Arora1,2,3, S. Bolte1,4 and K. Tammimies1,2. (1)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (2)Center for Psychiatry Research, Region Stockholm, Stockholm, Sweden, (3)Astrid Lindgren Children’s Hospital, Karolinska University Hospital, Region Stockholm, Stockholm, Sweden, (4)Curtin Autism Research Group, Curtin School of Allied Health, Curtin University, Perth, Australia

Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition with a heterogeneous clinical presentation that affects between 1-2% of the world population. Although many genes and genetic variants have been found to underlie ASD, additional biomarkers are required for aiding diagnoses and identifying clinical subgroups. Recent studies have suggested an association of several metabolites with ASD that could potentially find application as biomarkers. However, more data are required to identify any robust associations. Twin studies are a suitable approach to analyse the contribution of environmental and genetic factors in metabolic profiles. It is especially valuable to analyse differences between monozygotic (MZ) twins that are discordant for ASD to tease out the genetic contributions.

Objectives: We utilized a rare twin sample, the Roots of Autism and ADHD in Sweden (RATSS), enriched for MZ twins who are discordant for ASD, and their urine sample-based metabolomics to search and validate potential metabolite biomarkers.

Methods: In this study, individuals (N=100) of 50 twin pairs were selected from the RATSS study for mass spectrometry-based metabolomics. The participants have a median age of 16, where 39 are female and 37 have a clinical diagnosis for ASD. Metabolites were extracted from collected urine samples and processed using ultra-high performance liquid chromatography (UHPLC; Ultimate 3000, Thermo Scientific) coupled with a mass spectrometer (Q Exactive Hybrid Quadrupole Orbitrap, Thermo Scientific). Differential metabolomic analysis for 208 metabolites was performed using the drgee package in R, for overall effects using a generalised estimating equations model (GEE) and twin-pair effects using a modified GEE model, with suitable covariates. Metabolomics pathway-level predictions were made in R using annotations from the Kyoto Encyclopaedia of Genes and Genomes (KEGG) pathway database.

Results: Following an unbiased approach, 208 metabolites were detected in urine samples from the study cohort, representing several classes of metabolites such as organic acids, carbohydrates, amino acids, lipids, and nucleic acids. None of the metabolites reach significance after adjusting for the number of tests performed. However, nominal significance was detected for four metabolites in the comparison between the non-ASD and ASD groups. Increased levels were recorded for allantoin (p=0.047), and decreased levels were detected for carnitine (p=0.031), guanidoacetic acid (p=0.23), and pantothenate (p=0.027). Within twin pairs, differences with nominal significance were identified for four metabolites: indole (p=0.038), guanidoacetic acid (p=0.031), uric acid (p=0.029) and xanthine (p=0.045). All these metabolites have been previously indicated in ASD. The effects on pathway level changes are being evaluated.

Conclusions: Only small differences in the metabolite profiles were identified between ASD and non-ASD twins, however the metabolites with nominal significance have been previously reported in other ASD cohorts. These metabolites can be further investigated in larger cohorts which will support the development of diagnostic biomarkers for ASD.

414.247 (Poster) Tuberous Sclerosis Associated Autistic Features – a Retrospective Analysis

S. Gulati1, R. Triwari2, G. Kamila3, A. Wander4, P. K. Choudhary5, P. Jauhari6 and B. Chakrabarty7. (1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (2)Child Neurology Division, All India Institute of Medical Sciences, New Delhi, India, (3)All India Institute of Medical Sciences, New Delhi, New Delhi, India, (4)All India Institute of Medical Sciences, New Delhi, India, (5)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (6)Pediatrics, All India Institute of medical sciences, New Delhi, India, NEW DELHI, India
Background: Tuberous sclerosis complex (TSC) is a rare autosomal dominant inherited neurocutaneous disorder. It results from mutations in the genes TSC1 and TSC2 and has multisystem involvement and wide repertoire of presentations including prenatally detected cardiac rhabdomyomas and cortical tubers, other lesions are detected later in life like osseous, renal, or pulmonary lesions. Skin manifestations include hypomelanotic macules, ungual and facial angiofibroma’s and other less common lesions. TSC - associated neuropsychiatric disorders (TAND) are of significant concern and studies quote upto 90% of individuals with tuberous sclerosis complex will have some of these difficulties. Children with TSC are at high risk of Autism Spectrum Disorder (ASD) which consist of problems pertaining to social communication and interaction and restricted or repetitive behaviours or interests.

Objectives: Our objective was to analyse the incidence of TAND and autistic features in children with Tuberous Sclerosis Complex

Methods: Retrospective data from a tertiary care center, with pediatric neurology and Autism specialty clinics was studied via available records during the period of Jan 2018 to September 2022. Twenty-six children with tuberous sclerosis complex were identified, and their clinical data were analysed.

Results: All assessed children (N=26) had one or more difficulties as per the TAND checklist. 18 of the 26 children, fulfilled Diagnostic and Statistical Manual -5th edition (DSM-V) criteria for ASD. There were 10 males and 8 females in the group. Skin manifestations in form of hypomelanotic macules were seen in all the children (100%) and other features like adenoma sebaceum were seen in 10/18 (56%), shagreen patch in 7 (40%), ungual fibromas in 2 (11%). Of these 18 children with ASD – 17/18 (94%) of had had drug refractory epilepsy and with minimum age of onset of seizures being 9 months. 7 (40%) of them required more than three anti-seizure medications, 2 (11%) were on dietary therapy. 3 (17%) children were on mTOR inhibitors (Everolimus). Baseline average CARS-2 (Childhood Autism Rating Scale-edition 2) score was 40 (range 34-48). Most common co-morbidity apart from epilepsy was hyperactivity and impulsivity (12/18; 67%), followed by sleep related problems including increased latency, frequent awakenings, and reduced sleep duration (7/18; 39%).

Conclusions: TAND especially syndromic ASD represents a large burden of neurological disease in children with TSC. Poorly controlled epilepsy may be a major contributor to these manifestations. Apart from the other multidisciplinary care, ASD in these children requires early referral for ABA therapy (Applied Behaviour Analysis) and medications, for optimal outcome. Early screening using TAND checklist and thorough evaluation of the high-risk population should be instituted timely in disease course.

414.248 (Poster) The Variability of the ASD Phenotype in Monogenic Disorders: A Study in Neurofibromatosis Type 1

Background: The DSM-5 classification Autism spectrum disorder (ASD) covers a heterogeneous spectrum of phenotypes. It has a strong genetic component, which, insofar it can be pinpointed in individuals, is also very heterogeneous. The genetic component can be a monogenic disorder with a high impact on the behavioural phenotype, a rare variant increasing the likelihood of developing ASD, or a less traceable polygenic mechanism. Whether the genetic diversity regarding the etiology of ASD also accounts for the phenotypical variation is unclear. Persons with neurofibromatosis type 1 (NF1), a monogenic disorder, often have neurodevelopmental issues, including ASD. This suggests that the NF1 mutation is involved in the development of ASD, making NF1 an interesting model to study the influence of a specific genetic mutation on the variability of the ASD phenotype. Earlier research indicated a general shift towards ASD traits in the NF1-population, as well as a higher prevalence of an ASD diagnosis.

Objectives: We study the developmental phenotype of NF1 into more detail, and ASD traits in particular, in a population of NF1-children, regardless of prior suspicion of ASD. We consider the variability of the ASD phenotype and assess how several validated instruments measuring ASD traits relate to categorical ASD diagnoses in a specific genetic condition.

Methods: We compared 70 patients with molecularly confirmed NF1 (aged 3 to 16 years) to peers with idiopathic ASD, using questionnaires pertaining to various developmental domains, a diagnostic interview (the Diagnostic Interview for Social and Communication disorders, DISCO), and a standardized observation (the Autism Diagnostic Observation Schedule, second edition, ADOS-2).

Results: We observe a marked variability on most developmental domains in the NF1 group, and this finding also applies to ASD phenotype, even when comparing to idiopathic ASD. Furthermore, in the NF1 group we found poor diagnostic agreement between several instruments, of which some are commonly used to study ASD in monogenic syndromes. Both the SRS and the ADOS estimate the ASD prevalence in our NF1 sample to be around 40%, but when classifying individual participants they agree on only 48.2% of the participants. According to the DISCO on the other hand, only 7.7% of the NF1 sample receive an ASD classification.

Conclusions: Our findings in children and adolescents with NF1 do not support the hypothesis that more homogeneity in the genetic factors leading to an increased likelihood of ASD results in a significantly less variable ASD phenotype. In addition, our findings urge us to adopt a critical approach of ASD research in NF1 and other monogenic disorders.
414.249  (Poster) Role of FMRP in Regulating the Ribosomal 2’O Methylation in Human Embryonic Stem Cell and Its Differentiation
N. K. C. Gowda¹, M. N. Dsouza², N. Hariharan³, D. Palakodeti⁴ and R. S. Muddashetty⁵, (1)Molecular Medicine, CARE-ADD, St. John’s National Academy of Health Sciences, Bangalore, India, Bangalore, India, (2)Institute for stem cell science and regenerative medicine, Bengaluru, India, (3)Institute for Stem Cell Science and Regenerative Medicine, Bangalore, India, (4)Institute for Stem Cell Science and Regenerative Medicine, Bengaluru, India, (5)Centre for Brain Research, Bengaluru, India

Background:

Ribosomes are macromolecules present in the cell and are an integral part of the translation machinery. There are many reports suggesting ribosomes are heterogeneous. Factors contributing to this may arise from both rRNA and proteins. FMRP is a RNA binding protein and loss of which causes the Fragile X syndrome (FXS). Previously we showed that FMRP interacts with C/D box snoRNA and regulate 2’O methylation of ribosomal RNA.

Objectives:

We studied how the absence of FMRP brings the changes in the 2’O methylation in human embryonic stem cells (ESCs) and their differentiation

Methods:

To understand the differential methylation of rRNA during differentiation along the neuronal lineage, we differentiated the human embryonic stem cells into neuronal stem cells and then to cortical neurons. Total RNA was alkaline digested and 2’O methylation positions are mapped by ribometh sequencing

Results:

Interestingly, we found more heterogeneity in the 2’O methylation in the embryonic stem cells (pluripotent state) than in the neuronal state (terminally differentiated). This data provides new insight into how rRNA 2’O methylation can contribute to defining the pluripotent nature of embryonic stem cells. Maps of 2’O methylation residues across the 80S ribosome suggests that they position around key sites that interact with RNA binding proteins for possible translation regulation. We have also observed the major difference in methylation pattern in wildtype and Fmr1 KO in stem cell state rather than at neuronal state.

Conclusions:

We hypothesize that the presence of FMRP brings more heterogeneity in the stem cell state in comparison to neuronal stem cells which may influence the rate and timing of neuronal differentiation. Overall this study brings a new concept of ribosome heterogeneity and defines the role of FMRP in embryonic stem cells and their differentiation.

414.250  (Poster) SLC6A4 and BDNF Polymorphisms Modulate Acquisition of Adaptive Behavior Skills in Children with Autism
A. Aitken¹, E. J. Marco², N. Hattangadi³ and K. A. Shapiro⁴, (1)Cortica, San Diego, CA, (2)Cortica Healthcare, San Rafael, CA, (3)Cortica Healthcare, San Diego, CA, (4)Cortica, Westlake Village, CA

Background:

Children with autism demonstrate a range of neurodevelopmental differences which often result in challenges with adaptive skills. Adaptive functioning is assessed routinely in clinical practice as a measure of severity of symptoms, and improvements are assumed to reflect response to treatments over time. However, genetic factors may also moderate the response to medical and behavioral intervention, and thus may influence adaptive behavior outcomes. Among the common genetic variants demonstrated to affect response to environmental influences are changes in the promoter region of the serotonin transporter protein SLC6A4 (5HTTLPR); specifically, the short (S) allele has been associated with increased susceptibility to cognitive and behavioral stress. Similarly, brain-derived neurotrophic factor (BDNF) variants may affect neuronal plasticity, which is implicated in the pathogenesis of autism.

Objectives:

The primary aim of this study was to examine longitudinal adaptive behavior outcomes in children with autism currently receiving clinical care, including applied behavior analysis (ABA) therapy and medical treatment. The second aim of this study was to evaluate differential change in adaptive behaviors based on single gene polymorphisms (SNPs) hypothesized to affect cognition and behavior, specifically SLC6A4 5HTTLPR and BDNF Val66Met.
Methods:

Children with a diagnosis of autism who had clinically undergone pharmacogenomic testing (N = 157) were evaluated with the Vineland Adaptive Behavior Scales up to 7 times between the ages of 20-90 months. We constructed multilevel models to characterize growth curves within each adaptive behavior domain including Adaptive Behavior Composite (ABC), Communication, Socialization, and Daily Living Skills (DLS). We included a Time × SLC6A4 5HTTLPR and Time × BDNF Val66Met interaction term (in separate models) to compare relative rates of growth based on genetic background.

Results:

Multilevel models showed a main effect of time, such that there was an improvement in adaptive behaviors over the course of treatment for both cohorts in all domains (p<0.02). There was a significant SLC6A4 5HTTLPR × Time interaction for Communication (p=0.04) and Daily Living Skills (p=0.03) sub-scores but not ABC or Socialization. The significant interaction showed that dosage of the S allele predicted slower or null rates of improvement in adaptive behaviors. Further, results showed a significant BDNF Val66Met × Time interaction on the ABC score (p=0.05), Socialization (p=0.0001), and DLS (p=0.02), but not Communication. The interaction demonstrated more rapid improvement in scores for Val/Val homozygous individuals compared to Met/Met homozygous or Val/Met heterozygous genotypes.

Conclusions:

These results indicate that genetic background influences the rate of change in adaptive behaviors in children with autism. Dosage of the S allele of SLC6A4 5HTTLPR predicted poorer improvement in adaptive behaviors. This may indicate that susceptibility to environmental stress modulates developmental trajectories in children with autism. Similarly, the Val/Val homozygous genotype in BDNF Val66Met predicted greater improvement in adaptive behaviors relative to Met/Met or Val/Met. Results demonstrate the potential utility of screening for common genetic polymorphisms to help predict clinical outcomes and potentially to guide individualized treatment plans.

**414.251** (Poster) Sex-Differentially Expressed Genes in the Developing and ASD Cortex Implicate Glial Function in Sex-Differential ASD Risk

Background: Autism spectrum disorder (ASD) has a consistent 4:1 male prevalence, suggesting a role for sex-differential biology in risk. Defining molecular differences between males and females in the brain will advance understanding of how sex impacts neurodevelopment and disorder risk. Previous studies of human adult cortex show subtle male-skewed expression of glial-associated genes that are coordinately elevated in the ASD brain, but it is unknown whether this sex-differential pattern emerges in early cortical development or is preserved in ASD brain.

Objectives: We sought to quantify sex-differential gene expression in two under-studied biological contexts relevant to ASD: neurotypical prenatal development, and in ASD cases. By comparing sex-differentially expressed genes (sex-DEGs) with ASD risk genes and affected molecular pathways, we aimed to identify putative mechanisms involved in sex-differential ASD risk.

Methods: We analyzed sex-differential expression and co-expression patterns in prenatal dorsolateral prefrontal cortex (dIPFC) from BrainVar (14-21 post-conception weeks, PCW; 39 male, 46 female) and in cortical tissue from an independent, published data set generated at UCLA (14-21 PCW; 101 male, 85 female). We tested sex-DEGs for enrichment of risk genes for ASD and other diagnoses, ASD-associated expression changes, and cell type marker genes. To identify sex differences preserved or altered in ASD, we also quantified sex-differential expression in published RNA-seq data from frontal cortex of ASD (34 male, 9 female) and control individuals (37 male, 8 female).

Results: In BrainVar, we observe 69 significant sex-DEGs at FDR≤0.1 (30 X chr, 19 Y chr, 20 autosomal) and an extended set of 227 sex-DEGs at p≤0.05 and fold change >1.2. ASD risk genes from exome sequencing are not enriched among either set of sex-DEGs, but the extended set of male-skewed genes are enriched for ASD-upregulated, microglial- and immune-associated CTX.M19 (OR=6.75, p=0.01; Fisher’s exact test) and CD11 (OR=5.5, p=0.008) modules. Three co-expression modules evident in both sexes are enriched for both ASD risk genes and either vascular or neuronal cell markers, while sex-specific modules are not enriched for ASD risk genes. Similar to BrainVar, sex-DEGs from the UCLA data set do not overlap with ASD risk genes, while male-biased DEGs show trending enrichment for the CTX.M19 module (OR=3.86, unadjusted p=0.05), implicating elevated expression of CTX.M19 genes in both ASD pathology and male-typical cortical neurodevelopment.
Background: The underlying molecular mechanisms responsible for the etiology of autism and its sex-biased prevalence remain largely elusive. We have previously shown that children with non-syndromic low-functioning autism exhibit a sexually dimorphic pattern of relative telomere length (RTL) with autistic male children having significantly shorter RTL than autistic females, healthy controls, and paired siblings.

Objectives: The main goal of the current study was to examine the levels of telomeric oxidized base lesions among male and female autistic children and compare them to those in sex-, age-, and geographical location-matched healthy controls and paired siblings. We also wanted to find out if the levels of telomeric oxidized bases associate with the sexually-dimorphic nature of RTL among autistic children.

Methods: Levels of telomeric oxidized base lesions were measured by extracting genomic DNA from saliva samples and employing a quantitative PCR (qPCR)-based method previously described by Nathan O’Callaghan and colleagues (O’Callaghan et al., 2011).

Results: Our data show that both male and female children with autism exhibit substantially higher levels of oxidative base lesions at their telomeres than healthy controls and paired siblings. These elevated levels of telomeric oxidized bases show a direct correlation with RTL values in autistic children, with a significant impact coming from the male children with autism despite having shorter telomeres. There is no association between the levels of telomeric oxidized bases and age in either the autistic children or healthy controls, hinting that these oxidized bases are established early during development.

Conclusions: These findings open a fresh angle into autism spectrum disorders (ASD), raise new questions and lay the foundation for further research into the underlying molecular mechanisms involved in ASD. Telomeric oxidized bases may serve as new biomarkers for childhood autism.

Background: Among individuals with autism spectrum disorders (ASD) about 20% of cases are due to known genetic disorders, so-called syndromic ASD. Prader-Willi syndrome (PWS), a rare genetic disorder that results from lack of expression of paternally-derived genes on chromosome 15q11-13, is an example of syndromic ASD since 30% of patients have also an ASD diagnosis. Better understanding of the neural basis of PWS could help elucidate shared mechanisms underlying social cognition impairments in these disorders.

Objectives: No studies have investigated brain perfusion abnormalities in infants with PWS. Thus, the aim of this work was to investigate putative brain perfusion abnormalities in babies with PWS using arterial spin labelling magnetic resonance imaging (ASL-MRI).

Methods: This study included 10 babies with PWS (5 males, age = 11 ± 3 weeks) and a group of 7 age matched controls (3 males, age = 13 ± 3 weeks). All infants underwent ASL-MRI sequence during natural sleep on a General Electric 3T MRI scanner at Necker Hospital, Paris. Using a voxel-wise analysis, we compared whole brain rest cerebral blood flow (CBF) between patients with PWS and controls. The statistical analyses were conducted within the framework of general linear model (GLM) in SPM12 software, on normalized and smoothed CBF images, using age as a covariate.

Results: Compared to controls, in infants with PWS the voxel-wise whole brain analysis showed a significant increase of rest CBF mainly in the left superior temporal gyrus (corrected for cluster FWE; p < 0.001), but also in the right pallidum (family wise error corrected for
Background: Cortisol, a physiological marker of stress, is positively attuned in neurotypical (NT) mother-child dyads (e.g., maternal cortisol predicting child cortisol), but this attunement is moderated by maternal characteristics (DePasquale, 2020). Preliminary evidence suggests that maternal-child cortisol attunement is weaker in autistic children (Saxbe et al., 2017), yet little is known regarding moderation of cortisol attunement in neurodevelopmental populations. Parent-reported stress is elevated in mothers of children with Autism Spectrum Disorder (ASD) and Fragile X Syndrome (FXS; Baker-Ericzén et al., 2005; Potter et al., 2022) and may be an important moderator of maternal-child cortisol attunement. Determining parental stress’ impact on cortisol attunement may inform interventions and will broaden the field’s understanding of how behavioral and physiological indices of stress interact in neurodevelopmental groups.

Objectives: To determine how maternal-child cortisol attunement (maternal cortisol predicting child cortisol) is moderated by parental stress in FXS, ASD, and NT.

Methods: Salivary cortisol was collected from 84 mother-child dyads ($n_{ASD}=27$, $M_{ASD}=45.08$ months; $n_{NT}=28$, $M_{NT}=43.32$ months) before assessments. Cortisol values were natural log transformed (Hanrahan et al., 2006; Adam & Kumari, 2009). The Parent Stress Index (Abidin, 1995) measured parental stress and is comprised of three subscales (Parent-Child Dysfunctional Interaction (P-CDI), Difficult Child, and Parental Distress) and a total score, where higher scores indicate more stress. Per group, linear models with interactions assessed how parental stress moderated the effect of maternal cortisol on child cortisol, controlling for nonverbal IQ, time of saliva collection, and child age.

Results: P-CDI and Difficult Child did not moderate maternal-child cortisol attunement for any group ($p>0.05$). For NT children only, less Parental Distress resulted in stronger maternal-child cortisol attunement ($b=-0.053$, $p=0.046$; Figure1A). For the ASD and FXS groups, Parental Distress was not associated with stronger or weaker maternal-child attunement; when mothers had elevated cortisol (>mean), child cortisol did not substantially differ by Parental Distress levels (ASD: $M_{ASD}=1.84\mu g/dl$ vs. $M_{ASD}=-1.54\mu g/dl$; FXS: $M_{FXS}=1.48\mu g/dl$ vs. $M_{FXS}=-1.65\mu g/dl$). For NT children only, less Total Stress resulted in stronger maternal-child cortisol attunement at a trend level ($b=-0.025$, $p=0.058$; Figure1B).

Conclusions: Parental stress did not moderate maternal-child cortisol attunement in children with ASD or FXS. For NT children, however, maternal-child cortisol attunement was stronger when mothers reported less stress, suggesting that mothers who are less stressed may be more available to attend to their children, facilitating stronger attunement. This aligns with evidence showing that mothers with more stress engage in fewer mother-child interactions (Clowits et al., 2016) and are less sensitive to their children (B.T. Dau et al., 2019), where less sensitivity minimizes maternal-child attunement (Atkinson et al., 2013). Further, the strongest moderation effect occurred with Parental Distress, indicating that perceived parental efficacy (not parent-child interactions, perceptions of how challenging a child is, or composite stress) may drive attunement. These results suggest that parental stress may make NT children, but not those with neurodevelopmental disorders, vulnerable to decreased attunement and could serve as intervention targets. Future work should continue to probe the impact of parental stress on maternal-child cortisol attunement in larger samples across development.

Background: Communication, impaired social interactions and repetitive behaviors. Genetic studies have pointed to hundreds of presumptive causative or...
susceptibility variants in ASD, making it difficult to find common underlying pathogenic mechanisms and suggesting that multiple
different genetic etiologies for ASDs influence a continuum of traits. Smith–Magenis syndrome is a rare genetic disorder that results from
an interstitial deletion of 17p11.2 and, in rare cases, from a retinoic acid induced 1 (RAI1) gene variant. The prevalence is estimated to be
1/15,000–25,000. Haploinsufficiency of RAI1 is the primary cause of the neurobehavioral and metabolic phenotype in SMS. Individuals
with SMS present with a distinct pattern of mild to moderate intellectual disability, delayed speech and language skills, distinctive
craniofacial and skeletal abnormalities, behavioral disturbances, and, almost uniformly, significant sleep disturbances. Alterations in RAI1
copy number has been also linked to a number of neurodevelopmental disorders including ASD.

Objectives:

We conducted a large-scale association analysis of the ASD MSSNG whole genome sequencing data to elucidate the
prevalence of RAI1 SNVs and CNVs in the ASD population.

Methods:

We accessed the MSSNG database hosting over 11,000 genomes (6080 probands) and queried both SNVs and CNVs. Specifically,
we focused on the prevalence of the classic deletions, microdeletions of (exon 3) and of the causative variants.

Results:

We report a 2.5x enrichment of the major deletion and a >5x enrichment of the frameshift variants as compared to the known prevalence of SMS 1/15,000. Additionally, we report a significant enrichment of RAI1 rare missense variants in comparison to super controls (54/6080 versus 6/2541 P-value<0.002, OR 3.78 CI 1.62-8-81).

Conclusions:

Both ASD patients and SMS patients suffer from sleep disturbances. In this population of individuals with ASD, we report here an
enrichment of variants known to cause SMS. We estimate the enrichment to be at least 2.5-fold and potentially higher than 10-fold
enrichment, considering the types of variants observed in the population. Currently, the prevailing theory is that there is an underlying
circadian pathophysiology causing sleep disturbances in SMS associated with RAI1 haploinsufficiency, as these patients exhibit low
overall melatonin concentrations and abnormal timing of peak plasma melatonin concentrations. This abnormal inverted circadian rhythm
is estimated to occur in 95% of individuals with SMS. The sleep disturbance seen in individuals with SMS may be also the underlying
mechanism in at least a subset of individuals with ASD, especially in those individuals with consequential variants in the RAI1 gene.
Further studies will help delineate the role of RAI1 variants in sleep physiology.

414.256 (Poster) NBS-Ndd Task Force: Landscape Analysis of Neurodevelopmental Comorbidities in Newborn Screening Conditions
Z. Talebizadeh1, J. Taylor2 and A. Brower2, (1)NBSTRN, American College of Medical Genetics and Genomics (ACMG), Bethesda, MD,
(2)NBSTRN, ACMG, Bethesda, MD

Background: Newborn screening (NBS) is the largest public health genetic program in the US with 3.8 million newborns screened for up to
81 genetic conditions each year. Many of these conditions have comorbidities, including autism, neurodevelopmental disorders (NDD),
intellectual/developmental disabilities (IDD), and these comorbidities impact health outcomes across the lifespan. The majority of screened
conditions are inborn errors of metabolism (IEM). PKU, the first condition identified by NBS, is an inherited metabolic disorder that can cause developmental delays and IDD if not treated.

The Newborn Screening Translational Research Network (NBSTRN), a program funded by NICHD since 2008, is charged with developing, maintaining, and enhancing tools, resources, and expertise in support of NBS research. One of the tasks led by NBSTRN is to provide direction for developing question/answer sets used in the Longitudinal Pediatric Data Resource (LPDR) to create consensus-based, and standardized common data elements (CDEs) for NBS conditions. LPDR is a web-based application designed to enable the collection, analysis, sharing, and reporting of longitudinal laboratory and clinical data on newborn-screened individuals. Based on feedback received from the NBS stakeholders, the following needs have been identified: 1) evaluate the feasibility of the existing LPDR data to comprehend neurodevelopmental trajectories, and to 2) identify, refine, and/or develop CDEs for collecting longitudinal NDD data based on the evidence-based evaluation. The NBS-NDD Task Force has been formed to address these needs by conducting a systematic landscape analysis.

Objectives: The overarching goal is to develop a strategy roadmap for utilizing the NBS system to understand neurodevelopmental outcomes.

Methods: A mixed methods approach (data mining, community-based participatory approach, focus group, and systematic reviews) was used to conduct a feasibility assessment, including identification of needs and priorities. Data mining included examining health information from a completed, 10-year natural history study of IEMs, called Inborn Errors of Metabolism Collaborative (IBEMC).

Results: 44 IEM conditions are currently included in the Recommended Uniform Screening Panel. De-identified data from the IBEMC projects are available for secondary data analysis in LPDR. One of the IEM conditions included is MCAD (Medium-chain acyl-CoA dehydrogenase deficiency). The IBEMC enrolled 381 subjects with MCAD, of which 69% had longitudinal data (2 or more visits after the initial intake). Developmental assessment was done for 74% of MCAD subjects at visit 1, but the rate did not remain constant in subsequent visits. Furthermore, Ingenuity Pathway Analysis (IPA) was conducted to explore the genetic overlap between IEMs and NDD. The IPA analysis could be used to prioritize NBS conditions for NDD assessments.

Conclusions: The expected outcome is to identify NDD question/answer sets that can be incorporated into the LPDR and disseminated to the NBS research community for inclusion in research projects of conditions that are part of or candidate for NBS. Findings from this landscape analysis can inform future efforts toward advancing research infrastructure for this established public health program. The renewed awareness of the risk of autism/NDD/IDD after a positive NBS and diagnosis could lead to improving treatment guidelines for mental health conditions.

414.257  (Poster) NBS-Ndd Task Force: Landscape Analysis of Neurodevelopmental Co-Morbidities in Newborn Screening Conditions

Z. Talebizadeh, J. Taylor and A. Brower, (1)NBSTRN, American College of Medical Genetics and Genomics (ACMG), Bethesda, MD, (2)NBSTRN, ACMG, Bethesda, MD

Background: Newborn screening (NBS) is the largest public health genetic program in the US with 3.8 million newborns screened for up to 81 genetic conditions each year. Many of these conditions have co-morbidities, including autism, neurodevelopmental disorders (NDD), intellectual/developmental disabilities (IDD), and these co-morbidities impact health outcomes across the lifespan. The majority of screened conditions are inborn errors of metabolism (IEM). PKU, the first condition identified by NBS, is an inherited metabolic disorder that can cause developmental delays and IDD if not treated.

The Newborn Screening Translational Research Network (NBSTRN), a program funded by NICHD since 2008, is charged with developing, maintaining, and enhancing tools, resources, and expertise in support of NBS research. One of the tasks led by NBSTRN is to provide direction for developing question/answer sets used in the Longitudinal Pediatric Data Resource (LPDR) to create consensus-based, and standardized common data elements (CDEs) for NBS conditions. LPDR is a web-based application designed to enable the collection, analysis, sharing, and reporting of longitudinal laboratory and clinical data on newborn-screened individuals. Based on feedback received from the NBS stakeholders, the following needs have been identified: 1) evaluate the feasibility of the existing LPDR data to comprehend neurodevelopmental trajectories, and to 2) identify, refine, and/or develop CDEs for collecting longitudinal NDD data based on the evidence-based evaluation. The NBS-NDD Task Force has been formed to address these needs by conducting a systematic landscape analysis.

Objectives: The overarching goal is to develop a strategy roadmap for utilizing the NBS system to understand neurodevelopmental outcomes.

Methods: A mixed methods approach (data mining, community-based participatory approach, focus group, and systematic reviews) was used to conduct a feasibility assessment, including identification of needs and priorities. Data mining included examining health information from a completed, 10-year natural history study of IEMs, called Inborn Errors of Metabolism Collaborative (IBEMC).
Results: 44 IEM conditions are currently included in the Recommended Uniform Screening Panel. De-identified data from the IBEMC projects are available for secondary data analysis in LPDR. One of the IEM conditions included is MCAD (Medium-chain acyl-CoA dehydrogenase deficiency). The IBEMC enrolled 381 subjects with MCAD, of which 69% had longitudinal data (2 or more visits after the initial intake). Conclusions: The expected outcome is to identify NDD question/answer sets that can be incorporated into the LPDR and disseminated to the NBS research community for inclusion in research projects of conditions that are part of or candidate for NBS. Findings from this landscape analysis can inform future efforts toward advancing research infrastructure for this established public health program. The renewed awareness of the risk of autism/NDD/IDD after a positive NBS and diagnosis could lead to improving treatment guidelines for mental health conditions.

International and Cross-Cultural Perspectives

PANEL DISCUSSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

212 - International Adaptations and Applications of a System to Improve Program Quality and Use of Evidence-Based Practices

Panel Chair: Samuel Odom, Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA

Discussant: Ann Sam, Frank Porter Graham Child Development Institute, Carrboro, NC

Providing high quality programs that support the learning and development of autistic children and youth is an international issue. Research has yielded substantial empirical information about assessment approaches and practices. This research, however, exists in academic journals and often originates in the United States. The emergence of the iSciences (e.g., implementation science, improvement science, information science, dissemination science) has raised awareness that empirical findings have to be converted into practical information and communicated in culturally responsive ways if they are to be utilized by practitioners. In the US, the National Professional Development Center on Autism (NPDC) designed an assessment of autism program quality (Odom et al., 2018), identified through systematic reviews a set of evidence-based practices (Steinbrenner et al., 2020), and demonstrated the efficacy of the program model (Odom et al., 2013; Sam et al., 2021). Also, NPDC developed free online learning modules for each EBP, which has been accessed by over 275,000 practitioners world-wide. However, utilizing the practices within the US and other countries requires cultural adaptation to fit the specific domestic and international contexts. The purpose of this panel is to describe the cultural adaptation and use of features of the NPDC model in four different international contexts.

212.001 (Panel Discussion) Cultural Adaptation, Content Validity, and Assessment of Autism Program Quality in Swedish Schools

H. Bejnö, K. Wenneborg, S. Bolte and L. Roll-Pettersson, (1)Stockholm University, Stockholm, Sweden, (2)Stockholm University, Stockholm, Sweden, (3)Center for Neurodevelopmental Disorders at Karolinska Institutet (KIND), Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (4)Department of Special Education, Stockholm University, Nyköping, Sweden

Background: The prevalence of children diagnosed with autism in Sweden has increased placing greater demands on schools to provide high-quality programs for autistic learners. Previous research indicates lack of knowledge among educators about autism, how to promote inclusion, and what constitutes high-quality learning environments. In the U.S. the Autism Program Environment Rating Scale (APERS) has been developed to assess and improve program quality for autistic students in educational setting. APERS has been successfully used in the U.S. as well as in Swedish preschools. However, there are no comprehensive rating scales to assess program quality for autistic children in Swedish elementary school.

Objectives: The aim of this presentation is twofold: 1) describe the process and outcomes of culturally adapting and evaluating content validity and inter-rater reliability of the Swedish elementary school APERS (APERS-Fk/L-SE), and 2) present APERS assessment data on 22 kindergarten and 1-3rd grade classrooms participating in an ongoing study in the Stockholm region.

Methods: To cross-culturally adapt and validate APERS-Fk/L-SE, a step-wise procedure was followed. First, the instrument was translated by a PhD with expertise in autism and psychometrics. Second, our research group provided internal feedback on wording, contents and adaptations. Third, a total of 14 external experts with expertise in autism, habilitation, special education, and psychology were recruited to rate the clarity, completeness and relevance of individual items as well as domains and the scale in its entirety. Fourth, four interviews were conducted with a subset of expert raters to provide qualitative information on potential improvements. Fifth, this version of APERS-Fk/L-SE was tested in 10 classrooms within a pilot study on program quality improvement. Finally, follow-up interviews with school staff
provided further information on potential adjustments of the scale. The final version of APERS-Fk/L-SE was then used in 12 additional classrooms to assess autism program quality. Inter-rater reliability was assessed for a subset (10) of the 22 rated classrooms.

Results: Substantial modifications were needed to adapt the scale to the Swedish kindergarten to 3rd grade context. Three items were omitted and two added reflecting relevant quality features specific to the Swedish context. Furthermore, appropriate items were revised, original examples were modified or new clarifications added. Overall, the expert raters assessed APERS-Fk/L-SE as having a high level of content validity (content validity index [CVI] > 80), and ratings on general impressions of the instrument indicated that the APERS is a much needed albeit time consuming scale to administer. Mean single-measure intraclass correlations among raters was .75 (p < 0.001 95% CI [.71, .79]). Data from the 22 APERS ratings of classrooms indicated poor to moderate program quality, with Learning Environment and Positive Climate the highest and domains reflecting intervention practices (e.g., Communication) the lowest.

Conclusions: APERS-Fk/L-SE has a high level of cross-cultural content validity as well as acceptable inter-rater reliability. However, adaptations were needed to assure relevance within the Swedish context. Current APERS assessment data indicate a need to improve program quality for autistic students in inclusive elementary school classrooms, with specific emphasis on supporting students independence and communication skills.

212.002 (Panel Discussion) Translation, Adaptation and Dissemination of AFIRM in China
Y. Fan, X. He and L. Yu, (1)Center for Autism Research, School of Education, Guangzhou University, Guangzhou, China, (2)South China Normal University Autism Research Center, Guangzhou, China, (3)Center for Autism Research, School of Education, Guangzhou University, Guangzhou, MN, China

Background: In China, there are over 2.5 million children and teenagers with ASD. Reports showed that for the 300,000 therapists and teachers in China there has been a lack of training related to autism (Wang, 2022; Wen, 2015). Results from a survey of service providers showed that only 37% used established interventions (Sun, 2017). Thus, an efficient model of promoting the usage of evidence-based practices (EBPs) nationwide is in need. The Autism Focused Intervention Resources & Modules (AFIRM), developed by the National Professional Development Center on Autism (NPDC), provided free online public access of practical materials of EBPs. The disseminating study of AFIRM reported a promising result of reaching users in US and abroad (Sam et al., 2019). It shed insight on a cost-effective way to improve the situation in China as aforementioned. However, due to the differences between the two countries in culture and other perspectives, adaptations in translation and dissemination are necessary.

Objectives: This study aims to explore the process of translation, adaptation and dissemination of AFIRM for Chinese users.

Methods: EBP Brief Packets from the AFIRM program that contain all the materials and resources for each of the 27 EBPs were translated to Chinese by four postgraduates who are majored in psychology and have experiences in autistic research and practices. The first draft was then reviewed, edited, and proofread by the authors. A focus group of 6 experienced clinicians provided suggestions on cultural adaptation and dissemination. Modifications were made accordingly and the translation was then finalized. An intern on the spectrum worked with an IT colleague on format editing and constructing the website.

Results: Cultural adaptations were made in the materials of 5 EBPs. Unfamiliar items to children in China (like food, TV shows, toys, games) were substituted, for example ‘Pretzels’ was changed to ‘旺旺仙贝’ (a popular crispy snack). U. S. Council for Exceptional Children standards were omitted since they are not applied in China. A dissemination model was designed and adapted to habits of using digital devices among people in China. It contains 1) An WeChat official account for promotion and provision of easy access to the website, 2) The website for free access to all the translated materials, 3) Promotion in conferences and workshops. From December 18, 2021 to October 23, 2022, there were 3,544 followers of the WeChat official account. According to Baidu analytics, the website was visited 23,422 times by 4,702 users from all provinces except Qinghai and Xizang. Introduction to EBPs was presented in 5 research conferences, and there were around 60,000 visits of participants (online and offline). Evaluations gathered through online conferences and WeChat official accounts documented positively the acceptability and useability of the information.

Conclusions: Translation, adaptation and dissemination of materials from AFIRM facilitated the understanding and usage of EBPs in China. The adapted AFIRM information appears to be a valuable tool for supporting teachers’, clinicians’, and therapists’ use of EBPs in China.

212.003 (Panel Discussion) Perceived Social Validity and Attitude Towards Evidence-Based Practice Following the Implementation of the National Professional Development Center on ASD (NPDC) Model in Therapeutic Preschools
A. Waligorska, M. Waligorski; K. Kunczewicz-Sosnowska; K. Paluba; M. Andrezjewska and M. Rupinska, (1)The Maria Grzegorzewska University, Warsaw, Poland, (2)The SOTIS Autism Therapy Center, Warsaw, Poland, (3)The SWPS University, Warsaw, Poland

Background: One of the factors affecting implementation of EBPs in clinical or educational settings is their social validity (NeNeill, 2019). NPDC was developed in the United States. In Poland, there are therapeutic preschool programs similar to the U.S. However, the
social validity of the NPDC model when implemented a novel context such as Poland, has not yet been tested. Such implementation may be affected by perceptions of feasibility of the program and staff attitudes.

**Objectives:** To examine the social validity of the NPDC ASD intervention model and related factors, such as experience and attitudes towards EBP, as part of the 4-year pilot implementation of the NPDC model in 5 therapeutic preschools in Poland.

**Methods:** Two studies were conducted. In the first, participants were 31 therapists and teachers working in 11 preschool groups in the middle of a pilot NPDC model implementation. Experience working with EBPs, attitude towards EBP (EBP2Q, Panczyk et al., 2015 and EBP fidelity were assessed. In the second, 8 supervisors of 5 preschools implementing the NPDC model assessed social validity of the NPDC intervention model (rating of feasibility) and the NPDC quality assessment tool APERS. The form of the APERS measure originated from the parallel Swedish implementation study (Bejnö et al., 2019).

**Results:** In Study 1, both self-assessment and external evaluation (APERS-PE) indicated a high EBP implementation/intervention quality (over 80% of the maximum score). The team members’ attitude towards EBPs were similarly positive. The analysis of variance indicated that contrary to expectations attitude towards EBP was unrelated to the EBP implementation/intervention quality, however there was a high positive relationship between APERS-PE scores and the years of employment in the preschool using EBPs (for external evaluation F(1.27) = 4.91, p = 0.03, eta2 = 0.15; for self-assessment F(1.27) = 6.65, p = 0.02, eta2 = 0.20). In the second study, the social validity ratings of the APERS-PE domains were high, averaging over 93% of the maximum score. The highest scores were obtained for relevance, need for use and lack of an equivalent instrument. The lowest score (79% of the maximum) was obtained for “realistic use in practice”. The whole NPDC model was similarly rated; the mean score of the social validity domains was above 83%. The supervisors rated highest their preference to use the model. The lowest rated domain was realistic use in practice in the Polish context (61% of the maximum score).

**Conclusions:** These preliminary results support the notion that introducing the NPDC intervention in the novel cultural context such as Poland is challenging, as seen in the lowest assessment of the “realism of use” of NPDC model and related assessment tool, APERS-PE. Despite the challenge, the overall social validity assessment suggests the feasibility of introducing the EB NPDC model. Experience of the team members with the NPDC practices in their preschools (but not attitudes towards EBP) related to implementation success/intervention quality. It suggests that having “hand-on” experience may be the most promising factor for supporting the implementation of the NPDC model in the Polish context.

**212.004 (Panel Discussion) Enhancing Capacity for Implementation of Evidence-Based Practice for Autism: California Autism Professional Training and Information Network (CAPTAIN)**

Background: The California Autism Professional Training and Information Network (CAPTAIN) is a multi-agency collaboration focused on dissemination and implementation of autism evidence-based practices (EBPs) across educational, developmental disability and family support sectors in California (Suhrheinrich et al., 2020). Employing the interactive systems framework (Wandersman et al., 2008), we highlight collaboration between a translation system (i.e. National Professional Development Center (NPDC)), a support system (i.e.CAPTAIN), and a delivery system (i.e. providers) as necessary for successful implementation. CAPTAIN supports its network of providers with development of resources and skills to effectively disseminate and implement EBP with fidelity. CAPTAIN uses AFIRM and has recently adapted the NPDC-ASD model and resources to fit the diverse needs and context of California’s system of care.

**Objectives:** The present study examined CAPTAIN provider training, coaching outcomes, and reported needs for additional resources and adaptations to current resources (AFIRM materials and CAPTAIN supports).

**Methods:** CAPTAIN members use of NPDC-ASD resources and the impact of CAPTAIN efforts have been tracked through annual quality improvement data collection and targeted research evaluation. CAPTAIN members (n=232) completed an online survey regarding dissemination and implementation activities and needed adaptations to the AFIRM materials.

**Results:** Data indicate CAPTAIN providers used NPDC resources (or adapted versions of the resources) on autism EBPs to support California providers and family members through training (n=14,334) received training) and coaching (see Table 1). Respondents indicated AFIRM materials were their most used resource, followed by the EBP matrix and definitions. California has the highest number of registered AFIRM users (n=50,201) as compared to all other US states. Table 2 presents a summary of indicated needs. These include resources to support inclusion of EBPs in services for more diverse populations (i.e. adults with autism, English learners) and more accessible resources for families. Based on these data, targeted resources were developed to address identified needs. For example, AFIRM training modules were adapted for use by providers of autistic adults. Additionally, EBPs for autism were aligned with best practices for supporting English learners with disabilities to support integration of strategies.
Conclusions: Providers with direct experience in the field offer useful perspectives on barriers to practice implementation. NPDC resources have been consistently used by CAPTAIN for over 10 years, and more recently have been adapted to meet the needs of providers across service systems as they serve a diverse population of autistic individuals and their families.

**Panel Chair:** Amber Angell, Mrs. T. H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA

**Discussant:** Daniella Florinéz, Mrs. T. H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA

Despite progress with addressing autism disparities in some contexts, gaps in our knowledge remain. In the U.S., we know little about Native American populations, who have been largely overlooked in autism research. Despite increased attention to girls in autism research, they remain relatively understudied; and there is a dearth of research about the ‘diagnostic odyssey’ of Latina girls, from both English- and Spanish-speaking families. The Latine population continues to face diagnostic disparities, but we know little about the complex role of stigma in autism knowledge, attitudes, and beliefs. Finally, the global narrative on autism is most often centered on research from high-income countries, and we know little about the autism ‘diagnostic odyssey’ in other contexts. In this panel, we aim to address these gaps by using qualitative and participatory methods with under-studied, under-served groups: 1) Diné (Navajo) in the southwestern U.S.; 2) Girls, including Latina girls in Los Angeles County; 3) Latine families in Portland, Oregon; and 4) Children, families, and healthcare providers in the Greater Accra Region of Ghana. This panel brings together researchers with diversity in neurotype (including a Latina autistic discussant), race/ethnicity, gender, institution/geography, discipline, and tenure status, providing a richness of perspectives on these critical topics.

**221.001 (Panel Discussion) A Qualitative Study on Factors Influencing Access to Autism Services for Diné (Navajo) Parents**

**O. J. Lindly**, D. E. Henderson, C. Vining, C. L. Running Bear, S. Nozadi and S. Bia, (1) Health Sciences, Northern Arizona University, Flagstaff, AZ, (2) Communication Sciences and Disorders, Northern Arizona University, Flagstaff, AZ, (3) A.T. Still University, Phoenix, AZ, (4) Northern Arizona University, Flagstaff, AZ, (5) University of New Mexico, Albuquerque, NM, (6) National University, San Diego, CA

Background: Autism spectrum disorder (autism) is a relatively prevalent, chronic neurodevelopmental condition that can be diagnosed in children who are less than two years old. Access to diagnostic and evidence-based treatment services (e.g., early intensive behavioral therapy) when children are young can help to optimize their health. Still persistent race and ethnicity-based inequities exist in access to autism diagnostic and treatment services for U.S. children. Little is known about inequities in service access specifically for Indigenous children with autism including those who identify as Diné (Navajo), which is the largest federated tribe in the U.S. This information may be useful in planning, implementing, and evaluating equity-focused policy and programs intended to increase autism services access in Indigenous communities.

Objectives: To describe the lived experiences of Diné parents raising children with autism including factors affecting their access to diagnostic and treatment services.

Methods: From June 2021 to June 2022, we conducted in-depth interviews with 15 Diné parents of children with autism ages < 13 years. All interviews were facilitated by a Diné study team member using telephone or videoconference. A brief survey was also verbally administered to gather demographic information. The interview guide was based on constructs from the Modified Sociocultural Framework for Autism Health Services Disparities. Once interview data were transcribed, we used a directed content analysis approach in NVivo to distill themes.

Results: We identified 12 overarching themes. **Themes about experiences accessing diagnostic services** were as follows: (1) for many Diné parents, the diagnostic process was stressful and emotionally fraught; (2) once parents understood that their child needed autism diagnostic services they commonly experienced wait times on the magnitude of months or even years; (3) when parents recognized their child had developmental issues and expressed these concerns to health professionals, clinician training and cultural humility often influenced parents’ subsequent access to autism diagnostic services; (4) protective factors helping Diné parents to access autism diagnostic services included adequate health insurance, Indian Health Service referrals, care coordination, financial aid to travel, an efficient evaluation process, and provider cultural humility. **Themes about experiences accessing treatment services** were as follows: (5) parent perceptions of how much or how little an autism service helped their child could affect access; (6) obtaining referrals and care coordination services affected autism treatment access; (7) social support from family and friends influenced autism treatment access; (8) availability of
and geographic proximity to services impacted autism treatment access; and (9) costs of affected autism treatment access. Themes about ways to improve the autism system of care for Diné families were as follows: (10) greater awareness and understanding of autism among Diné families could improve access to services; (11) some Diné families may benefit from autism support groups; and (12) access to autism services would be easier with increased availability and quality across and around the Navajo Nation.

Conclusions: Increased autism awareness, social support, and service availability and quality may help Diné children with autism and their families to access needed services and to ultimately advance health equity.

221.002 (Panel Discussion) How Do Girls Come to Get an Autism Diagnosis?: Experiences of English- and Spanish-Speaking Families in Los Angeles County

A. M. Angell, M. D. Franklin, J. Lopez, D. C. Florinéz, A. Rodríguez, E. Taylor, J. Rios and M. Guzman; (1)Mrs. T. H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Department of Population and Public Health Sciences, University of Southern California, Los Angeles, CA, (3)University of Southern California, Los Angeles, CA, (4)Mrs. T. H. Chan Division of Occupational Science and Occupational Therapy, Chan Division of Occupational Science at the University of Southern California, Los Angeles, CA

Background: In recent years, girls and women have gained attention as an understudied autism sub-group. Girls are generally under-identified with autism and may be more likely to be misdiagnosed; increasing numbers of women are recognizing in adulthood that they are autistic. Little is known, however, about the autism ‘diagnostic odyssey’ for girls who are diagnosed in childhood, including the barriers and facilitators to obtaining an autism diagnosis and services. Further, there is almost no research on autism diagnostic experiences of girls with intersectional identities, i.e., those from minoritized racial, ethnic, and linguistic groups. Although we know that, as a whole, Latine children face disparities in autism rates and age of identification, Latina girls, from both English- and Spanish- speaking families, have been largely ignored in research.

Objectives: To address this gap, this qualitative study aims to understand the diagnostic odyssey (i.e., pathway to a diagnosis and services) experienced by diverse families of autistic girls.

Methods: We recruited from a Los Angeles area Regional Center. Participants included 21 caregivers from 18 families of 19 autistic girls (one family had twin autistic girls) ages 3 to 11 living in Los Angeles County. We conducted semi-structured narrative interviews with the 21 caregivers via Zoom between September 2021 and April 2022. Ten families were interviewed in English; 8 were interviewed in Spanish. Twelve families identified as Latine/Latino/Hispanic; 5 as mixed racial/ethnic identities; and 1 as Asian. We used a narrative approach and Braun and Clarke’s (2006) thematic analysis to identify overarching themes; and descriptive statistics to characterize important points in families’ narratives (e.g., age at first concerns and diagnosis). All transcripts were coded in NVivo by at least two coders, including those with diverse racial, ethnic, and neurotype identities.

Results: In our sample of 19 autistic girls from minoritized racial/ethnic groups, the girls were largely identified with autism at an early age compared to national averages for underrepresented groups (mean age at diagnosis 34 months). This may be due to our recruitment pool of regional center clients, as all families came to a Los Angeles County regional center before their daughter was 3-years-old. Overarching themes included barriers and facilitators at multiple levels (individual, family, community, systems). The Spanish-language families faced some barriers that the other families did not: Language barriers resulted in confusion about services, and some reported that a documented autism diagnosis did not qualify their daughter for school services. The Spanish-language families generally identified first signs and received a diagnosis a few months later than the English-language families; but for all families, culture and extended family played an important role in how caregivers came to identify early signs and report them to a healthcare provider, and how families came to understand their autistic daughter.

Conclusions: These qualitative findings elucidate the experiences of diverse families of autistic girls with regards to the autism ‘diagnostic odyssey’ in Los Angeles County. They serve as a starting point for addressing autism disparities and improving care for these underserved groups.

221.003 (Panel Discussion) Characterizing Autism Stigma in the Latine Community: Impacts and Implications

M. M. Abdul-Chani, Y. Morales, A. Jaimes Rice, S. E. O’Kelley and K. Zuckerman; (1)Psychology, The University of Alabama at Birmingham, Birmingham, AL, (2)Pediatrics, Div of General Pediatrics, Oregon Health & Science University, Portland, OR, (3)University of Alabama at Birmingham, Birmingham, AL, (4)The University of Alabama at Birmingham, Birmingham, AL, (5)Division of General Pediatrics, Oregon Health & Science University, Portland, OR

Background: Significant disparities in autism diagnosis and treatment exist for Latine families with limited English proficiency in the U.S. Stigma is one of the most understudied barriers to autism care and varies across cultures. The Latine culture is considered collectivist, meaning it places high value on community perception and inclusion. As a result, social support for families of individuals with autism may vary because of the dual emphasis on helping one’s community but maintaining community norms and fitting in. No study has explored autism stigma as perpetuated by the Latine community, and its effect on families of individuals with autism.
Objectives: Explore the Latine community's beliefs about autism, attitudes towards autism, and potential effects of stigma on Latine individuals with autism and their families.

Methods: Twelve Latine parents of typically-developing children were recruited from a pediatrics clinic in Portland, Oregon. Parents completed an in-depth qualitative interview and demographics questionnaire in Spanish or English, depending on preference. Using a phenomenological approach, a coding framework was developed, and structural coding established a set of predetermined codes that characterized the data generally. An emergent coding approach was used to create new codes exploring each predetermined global characterization more precisely. Coding frameworks were reviewed by stakeholders (i.e., parent and provider) for triangulation. Interviews and coding ceased when thematic saturation was achieved.

Results: Qualitative analysis revealed several major themes and a connection between these themes. Participants endorsed a lack of resources about autism leading to a lack of knowledge and awareness of autism in the Latine public. This lack of knowledge and awareness resulted in misinformation and uncertainty (e.g., beliefs that autism was caused by vaccinations, blaming parenting). Participants described a link between the misinformation and uncertainty, stating that this led to people causing harm (i.e., “saying the wrong thing”) to families of individuals with autism. Consequently, a fear of causing harm was reported, which ultimately led to hesitation or resistance to help out of fear that the “help” would actually “harm.” Despite this, all participants reported a desire — rooted in their culture — to learn more in order to be able to provide assistance to the families in need. Other major themes included comparisons and conceptualizations of autism within a perspective rooted in limited information.

Conclusions: Previous research in autism stigma suggests several possibilities: 1.) stigma is not as high as perceived by parents of children with autism, 2.) those perpetuating stigma are not reporting it explicitly on quantitative measures, and/or 3.) those perpetuating stigma are not aware that these attitudes are stigmatizing. The current study provides evidence for the third possibility. Participants acknowledged potential damage that is caused by a lack of knowledge without explicitly stating these views are stigmatizing. Moreover, participants recognized the negative impact of these attitudes on providing social support. Results from the present study provide avenues for future research such as utilizing collectivistic culture in linguistically- and culturally-sensitive ways to spread knowledge of autism, provide social support for families, and increase inclusivity.

221.004 (Panel Discussion) The Autism ‘Diagnostic Odyssey’ in the Greater Accra Region of Ghana: Using Participatory Research to Identify Barriers and Facilitators to Obtaining an Autism Diagnosis and Services

J. N. S. Akrofi, Y. Nanaaama Brew and A. M. Angell, (1)OT, New York University, NY, NY, Ghana, (2)Child Health, Greater Accra Regional Hospital, Ghana, Accra, Ghana, (3)Mrs. F. H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA

Background: Despite the increasing global prevalence of autism spectrum disorders, there is limited information about the prevalence of autism in Africa. Existing research on autism in Africa shows that autistic children are diagnosed relatively late, or not at all, compared to autistic children from higher-income countries. This may be attributed to delays and challenges that are unique to this context.

Objectives: The purpose of this study was to understand the barriers to the autism ‘diagnostic odyssey’ in the Greater Accra Region of Ghana, and to engage key stakeholders to action plan steps to reduce the barriers.

Methods: We conducted a participatory study using semi-structured qualitative interviews, photo elicitation, and focus groups with 11 participants (4 parents and 7 health professionals) from public and private healthcare settings in the Greater Accra region. A key informant (second author), a neurodiversity advocate who heads a neuro-developmental clinic in a large hospital, engaged with recruitment and data collection. For the interview transcripts and focus group notes, we coded using NVivo. We followed Braun and Clarke’s (2006) thematic analysis, specifically utilizing 1) theoretical (guided by a-priori theoretical framework), 2) semantic (focusing on surface-level meanings), and 3) essentialist (theorizing meaning in a straightforward way) approaches. All transcripts were coded by at least two coders; we discussed and resolved all differences. The themes were presented to the key informant for member checking; and to the stakeholders during a final focus group, where we used nominal group technique to identify and prioritize major problems and possible solutions for improving early and accurate autism diagnosis in this community.

Results: Neuro-pediatricians reported that it takes 2 to 6 visits over 2 weeks to 2+ years to diagnose a child. Our thematic qualitative analysis yielded three overarching themes, with barriers and facilitators for each: 1) Systemic, 2) Community, and 3) Parent/Family factors that influence the diagnostic process. However, the action plan of our stakeholder focus group prioritized not increasing diagnosis rates, particularly because a diagnosis does not currently lead to publicly available services. Rather, the stakeholders emphasized that first, community education is critical to dispel myths and encourage autism acceptance within the Ghanaian community, making the context more accommodating to autistic children and their families.

Conclusions: Knowledge about the diagnostic odyssey can help facilitate early autism diagnosis in Ghanaian contexts. Importantly, however, the community did not prioritize increasing diagnosis rates until there was more culturally sensitive, strengths-based knowledge and education about autism.
Background: Although most children with developmental disabilities live in Low-Middle Income Countries (Olusanya et al., 2018), few have access to care. The World Health Organization (WHO) developed the Caregiver Skills Training (CST) programme to address this unmet need by equipping parents with skills to promote social communication, learning, and behaviour management in children with developmental disabilities (WHO, 2022; Salomone et al., 2019). Acknowledging the importance of culturally-informed intervention adaptations, the WHO recommends adapting the intervention to increase feasibility, acceptability, and potential impact (Szlambka et al., 2022). The WHO CST programme has undergone field trials in over 30 countries. The programme comprises nine group sessions and three individual home visits and is fully manualised, comprising participant booklets and facilitator guides. In separate studies, the programme was previously contextually adapted and pilot-tested in Ethiopia (Tekola et al., 2020) and Kenya. However, there is limited understanding of how intervention adaptations made for one context can inform the adaptation and implementation in others, and how to harmonise adaptations in cross-cultural investigations.

Objectives:

- To outline the process of adapting and harmonising previous Kenyan and Ethiopian adaptations of the WHO Caregiver Skills Training programme for use in a cross-cultural randomised controlled trial (RCT) being implemented in rural and urban contexts in Ethiopia and Kenya.
- To highlight key lessons learned in the adaptation and harmonisation process.

Methods:

We used a stepwise approach (Movsisyan et al., 2019) to further adapt and harmonise the WHO CST training materials for use in the multi-country RCT. We:

1. Outlined and compared differences between adaptation approaches and final adaptations of materials used in the previous pilots.
2. Engaged in cross-site harmonisation meetings with researchers, CST master trainers and non-specialistic facilitators, clinicians, and WHO staff to discuss noted differences and agree on a harmonised approach across contexts. The decision-making strategy adopted is presented in Table 1.
3. Analysed differences between the harmonised materials and the newly revised WHO materials to select critical revisions based on limitations noted during the country-specific pilot studies.

Results: We made content and procedural adaptations to the CST training materials, without changing the core components of the WHO intervention programme. Content adaptations included the addition of a discussion on physical punishment based on the high prevalence of the practice in both countries and its negative impact on children. Procedural adaptations included re-introducing writing components of the intervention into the Ethiopian context using implementation strategies from the Kenyan context. Some context-specific adaptations were retained. For example, the practice of calling to remind participants was deemed critical to ensuring attendance in Kenya but not in Ethiopia, where attendance without reminders was near 100% in the pilot. Finally, the team adopted, across both countries, revisions recommended by the WHO team, e.g. changes to the order of training content and the inclusion of more diverse illustrations.
Conclusions:

This proposal outlines a stepwise process by which culturally-specific adaptations can be applied cross-culturally while incorporating critical revisions. The findings and study approach may inform future efforts to adapt and implement interventions across contexts.

305.002 (Oral) Socioeconomic Status, Mental Health and Cognitive Outcomes in Autism: The Effect of Family Composition and Income across Three Multi-Country Studies

Background: Despite much research on socioeconomic status (SES) from global health perspectives, surprisingly little has focused on autistic individuals. As this gap is integral to address the cognitive and mental health vulnerability of the vast majority of autistic people living in middle-to-low income settings (Lord, Charman, Havdal et al., 2022), recent studies have finally started to pursue this direction (Carter Leno, Wright, Pickles et al., 2022; de Leeuw, Happé & Hoekstra, 2020).

Objectives: This project aims to expand insights of SES, mental health and cognitive outcomes in autism with globally representative data across Europe, South Africa and South Asia. In the Longitudinal European Autism Project (LEAP) and South African Safe Passage (SP), common variables of SES, autistic traits and mental health were collected, and therefore used to investigate their relationship across settings. In the Indian Eye-Tracking Assessment for Children with Autism (EIRA), diagnostic status, income range and cognitive outcomes of children whose access to diagnostic service may be influenced by SES was collected, and therefore investigated.

Methods: 764 participants contributed to LEAP (311 autistic; 230 females; age range 6-30 years), 100 to SP (non-autistic, screened for autism; 50 females; age range 6-11 years), 124 to EIRA (46 autistic; 41 females; age range 3-5 years). Multiple linear regression investigated the effect of factor scores of parental employment and education, home and family characteristics on internalising and externalising scores as measured with the Strength and Difficulties Questionnaire (SDQ), in interaction with autistic traits (LEAP, SP). Income range as an instrumental variable was used in two-stage least-square regression, predicting cognitive standardised scores (as measured with the Developmental-Profile 3, DP-3) and autism diagnosis (EIRA).

Results: LEAP and SP cohorts showed similar 4-factor structures (Child Characteristics, Family System, Parental, Material Resources; Fig. 1). “Family System” captured family size and maternal factors and was associated with SDQ change (LEAP: Coef. = -2.54, SE = 1.02, p-value = 0.01; SP: Coef. = 25.53, SE = 11.32, p-value = 0.03). High autistic traits reduced these effects (LEAP: Coef. = 0.03, SE = 0.01, p-value = 0.01; SP: Coef. = -1.58, SE = 0.71, p-value = 0.03).

For EIRA, income influenced the cognitive outcome via changing the likelihood of diagnosis, as shown by a significant and negative instrumental effect of income (Coef. = -31.80, SE = 7.40, p-value < 0.001). However, this negative effect became non-significant for the second highest income range (Coef. < 0.001), and positive for the highest range (Coef. = 40.67).

Conclusions: The composition of the family significantly relates to mental health, with a distinct association with autistic traits and setting, suggesting that size and complexity of support networks affect mental health of autistic people. Income level influenced cognitive outcome by means of changing the likelihood of diagnosis, although positive effect on cognition was only significant for the highest income. These insights form a complex picture, with SES across settings affecting the life of autistic people from diagnosis up to mental health and cognitive outcomes; next steps should start informing how these domains influence each other.

305.003 (Oral) Adaptation of the Who Caregivers Skills Training Program. Implementation in Two Latin American Countries

Background: Despite much research on socioeconomic status (SES) from global health perspectives, surprisingly little has focused on autistic individuals. As this gap is integral to address the cognitive and mental health vulnerability of the vast majority of autistic people living in middle-to-low income settings (Lord, Charman, Havdal et al., 2022), recent studies have finally started to pursue this direction (Carter Leno, Wright, Pickles et al., 2022; de Leeuw, Happé & Hoekstra, 2020).

Objectives: This project aims to expand insights of SES, mental health and cognitive outcomes in autism with globally representative data across Europe, South Africa and South Asia. In the Longitudinal European Autism Project (LEAP) and South African Safe Passage (SP), common variables of SES, autistic traits and mental health were collected, and therefore used to investigate their relationship across settings. In the Indian Eye-Tracking Assessment for Children with Autism (EIRA), diagnostic status, income range and cognitive outcomes of children whose access to diagnostic service may be influenced by SES was collected, and therefore investigated.

Methods: 764 participants contributed to LEAP (311 autistic; 230 females; age range 6-30 years), 100 to SP (non-autistic, screened for autism; 50 females; age range 6-11 years), 124 to EIRA (46 autistic; 41 females; age range 3-5 years). Multiple linear regression investigated the effect of factor scores of parental employment and education, home and family characteristics on internalising and externalising scores as measured with the Strength and Difficulties Questionnaire (SDQ), in interaction with autistic traits (LEAP, SP). Income range as an instrumental variable was used in two-stage least-square regression, predicting cognitive standardised scores (as measured with the Developmental-Profile 3, DP-3) and autism diagnosis (EIRA).

Results: LEAP and SP cohorts showed similar 4-factor structures (Child Characteristics, Family System, Parental, Material Resources; Fig. 1). “Family System” captured family size and maternal factors and was associated with SDQ change (LEAP: Coef. = -2.54, SE = 1.02, p-value = 0.01; SP: Coef. = 25.53, SE = 11.32, p-value = 0.03). High autistic traits reduced these effects (LEAP: Coef. = 0.03, SE = 0.01, p-value = 0.01; SP: Coef. = -1.58, SE = 0.71, p-value = 0.03).

For EIRA, income influenced the cognitive outcome via changing the likelihood of diagnosis, as shown by a significant and negative instrumental effect of income (Coef. = -31.80, SE = 7.40, p-value < 0.001). However, this negative effect became non-significant for the second highest income range (Coef. < 0.001), and positive for the highest range (Coef. = 40.67).

Conclusions: The composition of the family significantly relates to mental health, with a distinct association with autistic traits and setting, suggesting that size and complexity of support networks affect mental health of autistic people. Income level influenced cognitive outcome by means of changing the likelihood of diagnosis, although positive effect on cognition was only significant for the highest income. These insights form a complex picture, with SES across settings affecting the life of autistic people from diagnosis up to mental health and cognitive outcomes; next steps should start informing how these domains influence each other.

Background: As the prevalence of autism spectrum disorder (ASD) increases (Zeidan et al., 2022), so have the global demands for ASD-targeted interventions and services through regional and local program implementation (Black et al., 2017; Tekola et al., 2020; Sengueta et al., 2021). Despite the promising results from the Parent Mediated Interventions (PMI) literature, most studies on the effectiveness of such interventions have been conducted in High-Income Countries, with limited evidence about their efficacy in Low and Middle-Income Countries (LMIC). Furthermore, the current implementation of PMI in LMIC is done with little knowledge or guidance on their quality, acceptability, feasibility, and scalability (Dababnah et al., 2018; Bordini et al., 2020).

Objectives: explore the perceptions of Argentinian and Uruguayan caregivers about the feasibility and acceptability of implementing the WHO-CST program in their countries and identify whether cultural adaptations are needed for its successful implementation in this global region.

Methods: The WHO-CST program was implemented in a school setting in Argentina and in a child psychiatry facility in Uruguay, and focus groups with participant caregivers (Argentina, n=8, and Uruguay, n=6) were completed after its implementation. The study used a phenomenological framework design to analyze the participants’ responses to post-implementation focus group questions and extract commonalities and differences in each country. Focus groups were audio-recorded and transcribed verbatim in their original language, and applied thematic analysis was used to analyze the data. In addition, more attention was given to themes related to feasibility, acceptability, and suggestions to improve the program delivery and content, following the method used by Salomone et al. (2021).

Results: The thematic analysis of the caregivers' responses identified four main themes across the two countries: 1) Expectations on the program, 2) Content, 3.) Benefits and Achievements, and 4) Challenges. In addition, suggestions to improve the program were included. According to caregivers, the CST program met their expectations. It gave them new tools, ways of interacting and dealing with their children, knowledge, new habits, such as pausing and reflecting, and the development of new skills, such as observation. Caregivers also mentioned how CST brought a service where it was not otherwise offered. Several adaptations were proposed to decrease barriers to accessing serving: having group sessions every other week instead of weekly, including other family members, use of videos for demonstrations, options for conducting home visits, follow-up sessions, and information on how to navigate the school system, among others.

Conclusions: Our findings support the feasibility and acceptability of implementing the WHO-CST program with caregivers of autistic children in Argentina and Uruguay. Suggestions included changing the delivery frequency, follow-up sessions, and different options for home visits to avoid caregivers' stress or the sense of intrusion. As in other low-resourced areas, the WHO-CST program in Argentina and Uruguay requires ongoing cultural and linguistic adaptations while being scaled up and implemented in community settings scaling up and implementing it in community settings. These adaptations help close the treatment gap by addressing barriers to accessing timely, evidence-based interventions.

ORAL SESSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

311 - Standardizing Measures Across Cultures

Moderator: Mirko Uljarevic, Department of Psychiatry and Behavioral Sciences, School of Medicine, University of Melbourne, Stanford, CA

311.001 (Oral) Cross-Cultural Differences in the Interpretation of Autistic Traits
O. Fani, M. V. de Jonge and M. de Vries, (1)School of Psychology, University of Nottingham Malaysia, Semenyih, Malaysia, (2)Faculty of Social Science, Education and Child Studies, Clinical neuroscience and developmental disorders, Leiden University, Leiden, Netherlands, (3)University of Nottingham Malaysia Campus, Semenyih, Malaysia

Background:

The diagnosis of Autism Spectrum Disorder relies partly on the judgment of social behaviour. What is perceived as normal or abnormal (social) behaviour is influenced by culture, as culture shapes norms and beliefs about behaviour. Culture might hence influence the interpretation of autistic symptoms and the diagnostic process.
Objectives:

We aimed to study whether culture affects the interpretation and reporting of autistic traits, and how autism knowledge is associated with this. To do so, we investigated cross-cultural differences in the perception of the Autism Spectrum Quotient’ (AQ) items in self-report and social/cultural-report levels across Iran, Malaysia, Morocco, and the Netherlands. Additionally, we explored the relationship between self-reported, social/cultural-reported autistic traits and autism knowledge across the four countries.

Methods:

We recruited non-autistic adults in Iran, Malaysia, Morocco, and the Netherlands (N = 476) and administered the AQ and the ‘Culture-AQ’, to study whether culture influenced the interpretation of AQ items. The ‘Culture-AQ’, was developed to measure autistic traits on a social/cultural level. The Culture-AQ enquires whether the behavioural traits as measured with the AQ are common in one’s cultural society. Additionally, we measured autism knowledge, to explore its association with the AQ and ‘Culture-AQ’ across the four countries.

Results:

There was a significant difference in AQ scores between the four countries, $F(3, 472) = 34.01, p < .001$. Post-hoc tests revealed that Iran, Malaysia, and Morocco scored significantly higher than the Netherlands. Moreover, there was a significant difference in Culture-AQ scores between the four countries; $F(3, 472) = 66.03, p < .001$. Post hoc tests revealed that Iran, Malaysia, and Morocco scored significantly higher than the Netherlands on the Culture-AQ scores. Additionally, there was a significant difference in autism knowledge between the four countries, $F(3, 383) = 29.68, p < .001$. Post hoc tests revealed that the Netherlands scored significantly higher than Iran, Malaysia, and Morocco. Finally, we investigated the association between the AQ, ‘Culture-AQ’, and autism knowledge across the four countries. There was no significant regression equation in Iran, while significant regression equations were found in Malaysia ($F(2, 93) = 9.03, p < .001$), with $R^2$ of .16; AQ = 158.998 - .598 (autism knowledge), Morocco ($F(2, 91) = 11.07, p < .001$, with $R^2$ of .20; AQ = 132.090 - .477 (autism knowledge)), and the Netherlands ($F(2, 106) = 6.190, p = .003$), with $R^2$ of .105. AQ = 98.139 + .224 (Culture-AQ).

Conclusions:

The results indicated, consistent with previous studies, cross-cultural differences in both self-reported and social/cultural-reported autistic traits. Cross-cultural differences in reporting autistic traits showed that cultural background might affect the interpretation of autistic traits. Therefore, it is crucial to consider cultural differences when using autism measurements or interventions. However, there was not a straightforward relationship between self-reported and social/cultural-reported autistic traits. Hence, if autistic traits are more common on a social/cultural level, people do not necessarily score themselves higher in autistic traits too. Besides perceiving certain autistic behaviour more common, knowledge about autism seems to influence self-reported autistic traits in some countries.

311.002 (Oral) Cross-Cultural Investigation of the Autism Stigma and Knowledge Questionnaire (ASK-Q) Psychometrics

A. J. Harrison1, M. Madison2, N. Naqvi3, J. M. Campbell2 and L. Bradshaw2, (1)Educational Psychology, University of Georgia, Athens, GA; (2)University of Georgia, Athens, GA; (3)Mona College, New Rochelle, NY; (4)Psychology, Western Carolina University, Cullowhee, NC

Background:

Given that global disparities stem in part from variability in autism knowledge and associated stigmas (Stahmer et al., 2019; Ruparelia et al., 2016; Durkin et al., 2015), quantifying regions in need of interventions to increase knowledge is an important public health priority. Unfortunately, efforts to systematically identify low autism knowledge regions have been slowed by measurement concerns in the field. The Autism Stigma and Knowledge Questionnaire (ASK-Q) was developed and validated to assess cross-cultural variability in autism knowledge (Harrison, Bradshaw et al., 2017; Harrison et al., 2019). However, with increased international use, the ASK-Q has demonstrated variable reliability in different countries following translation.

Objectives:

The current study aims to use a large, international sample to examine and refine the ASK-Q items to ensure the reliability across cultural contexts of the total score and four subscales: i) diagnosis/symptoms, ii) etiology, iii) treatment, iv) stigma. Recommendations will be made for item removal and refinement to create a more universally psychometrically sound measure.

Methods:

The psychometric examination of the ASK-Q used a subset of data from a large sample (n = 6830) from 13 different countries. The analyses included responses from countries with samples of 500 participants or more (i.e., United States, China, Netherlands, Romania, and
Background: Autism Spectrum Disorder (ASD) is a complex condition associated with significant impairments in social, communication, and behavioral functioning. Low- and middle-income countries face great disparities in access to best practice care, including standardized diagnostic assessments. Deficits were only exacerbated with the onset of COVID-19. During the pandemic, standard administration of the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) was not possible, as telehealth administration and use of personal protective equipment rendered the test invalid. Thus, the Brief Observation of Symptoms of Autism (BOSA) was developed by Dr. Catherine Lord and colleagues at the University of California at Los Angeles to address this gap. The BOSA was translated into Spanish, but no validation study of the Spanish language BOSA has been completed.

Objectives: Validate the use of the BOSA with a Latin-American population and, in turn, potentially improve access to appropriate diagnostic services in the region. In addition, the project sought to train professionals remotely in best-practice care and establish a multicenter network for diagnosis and referral.

Methods: The clinician-researchers that participated in the study were part of the Extension for Community Healthcare Outcomes (ECHO) Autism: PROTECTEA network. This network consists of professionals who work in primary care settings and hospitals that assess individuals with neurodevelopmental differences. Only those professionals who had prior training in the ADOS-2 and could show proof of certification were allowed to take part in the training and subsequent validation study (56 clinicians from 24 centers across Argentina and Chile). All clinicians completed the UCLA training on the BOSA, presented at least two BOSA cases during the ECHO BOSA supervision credit on the ASK-Q across cultures. The introduction of measures designed with cross-cultural validity in mind can facilitate cross-cultural comparisons without requiring measurement adaptation.

Conclusions:

This study acknowledges the importance of cross-cultural variability and uses a diverse sample to provide recommendations for improving the validity of the ASK-Q across cultures. The introduction of measures designed with cross-cultural validity in mind can facilitate cross-cultural comparisons without requiring measurement adaptation.

Results: A total of 313 cases (16 months to 49 years). Receiver operator characteristic (ROC) curves were run for each module based on the algorithm total, resulting in good discrimination between ASD and non-spectrum control groups. When comparing optimal cutoff scores for each module with the UCLA suggested cutoff scores, the LATAM ROC curves resulted in slight differences for modules 1 and 3, with greater differences with modules 2 and 4. The suggested cutoff for the Toddler Module T remained the same (See Table 1).

Conclusions: The ECHO Autism framework was used to train and supervise a network of clinicians during the pandemic to complete a validation study of the Spanish-language BOSA. Results of the Latin American sample were similar to those found by the UCLA group, with high levels of sensitivity and specificity. Findings suggest that it may be a good resource for populations with poor access to
specialists in their communities to reduce disparities and increase access to appropriate diagnosis.

311.004 (Oral) Cross-Cultural Adaptation of Measures of Childhood Functioning in Low- and Middle-Income Countries: A Process Description in a Northern Indian Context

M. Kakra Abhilashi, G. Lal, S. Johri, S. Pandey, R. Roy, K. Leadbitter, D. Kumar, S. Gulati, M. Juneja, J. Green and G. Divan;
(1)Sangath India, New Delhi, India, (2)Sangath, New Delhi, India, (3)University of Manchester, Manchester, United Kingdom, (4)sangath, delhi, India, (5)sangath, Delhi, India, (6)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (7)Maulana Azad Medical College New Delhi India, New Delhi, India, (8)Child Development Group, Sangath, New Delhi, India

Background: Measures assessing childhood functioning are often developed in High income countries (HIC) with western cultures and need to be adapted for use within cultures in which constructs they measure might be irrelevant in their original form. Hence, cross-cultural adaptation is a robust and cost-effective solution which ensures measurement validity is maintained. This study describes the framework of cross-cultural adaptation of three measures, viz. Vineland Adaptive Behavior Scales-Third Edition (Vineland-3); Communication and Symbolic Behavior Scales-Developmental Profile (CSBS-DP) Caregiver Questionnaire and Child Health Utility-9D (CHU-9D), followed in the ‘Communication-centred Parent-mediated treatment for Autism Spectrum disorder in South Asia’ (COMPASS) Trial.

Objectives: The primary objective of the study was to adapt the three measures using a systematic framework while establishing semantic, idiomatic, conceptual, experiential, and technical equivalence between the original and adapted versions of the measures.

Methods: A stepwise process was followed for adaptation as is detailed in Figure 1. The various steps of the cultural adaptation process were carried out in rural Haryana and in the urban setting of the National Capital Territory (NCT) of Delhi in Northern India where most residents use Hindi language for communication.

(Insert Figure 1 here)

Results: Cross-cultural adaptation was done with the aim of achieving equivalence between source and target items. Equivalent meaning for each word in every item of the original measure from a culturally equivalent word or set of words in Hindi was found. The underlying construct that each item was trying to measure was retained. Contextual elaborations were also found for idioms used in the items. The adapted versions of the measures had grammar, punctuation, sentence structure, instructions, layout & format, and mode of administration as they were in the original measures.

Conclusions: Adaptation of measures is a rigorous process and involved various challenges. The adapted versions of the measures were best representative of the culture under study while they retained the required characteristics and the intent of the items of the original version. The systematic process described to achieve the same could act as a guiding framework for researchers who are new to this process.

POSTER SESSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

403 - International and Cross-Cultural Perspectives

403.170 (Poster) A Practical Guide to Reducing Bias in Autism Research
A. Ostrolenk, M. Sperduti and K. Kovarski;
(1)Department of Psychiatry, Université de Montréal - Laboratoire des troubles envahissants du développement, Montreal, QC, Canada, (2)Université Paris Cité, Paris, France, (3)LaPsyDÉ, Paris, FRANCE, (4)Sorbonne Université, Paris, France

Background: The past decades have seen dramatic increases in funding for autism research and in number of autism papers published. Researchers seeking to improve existing knowledge about autism must thus assess and interpret a vast, disparate, and rapidly growing literature. How well autism researchers evaluate this body of work, pose research questions based on it, and go on to design, conduct, and report their own research, all affect the progress of autism research and the wellbeing of autistic people. Biases may undermine research at any stage from its conception to its publication, and biases in published research risk being perpetuated and amplified by further research. Efforts to identify and reduce biases should thus be a priority across all stages of research.

Objectives: This investigation aims to review biases in autism research and to provide autism researchers with tools to acknowledge potential biases and practical recommendations to tend towards better research.
Methods: We performed an extensive literature search in the fields of cognitive science, psychology, and neuroscience. We focused on biases particularly relevant to autism research in the field of human cognition, although some of these considerations might be applied to other scientific domains or to other conditions. We have opted to present biases that individual researchers may be able to directly act on, as opposed to large systemic biases which would require much more complex interventions. We describe and categorize different types of bias and how they can affect the quality of autism research at different stages and propose recommendations on how to recognize and minimize these biases.

Results: The biases we identified were organized into three categories: i) conception and study design; ii) participant selection and recruitment; and iii) reporting results and publication. Each category calls for recommendations and discussion points. The main recommendations emerging in these three categories were to involve autistic people in research so that its topics are aligned with autistics’ needs, to design inclusive research protocols that allow for participation across the autism spectrum, and to be transparent in reporting results by acknowledging the biases than cannot be eliminated. Although the biases identified in this investigation are not all individually specific to autism, taken together they point to the challenges and specificity of autism research.

Conclusions: Although studies and commentaries have been published about biases in research, the impact of these biases specifically on the field of autism research has not been addressed. Here we propose a non-exhaustive list of biases and associated recommendations that altogether can help the reader increase the quality of their research. Increasing awareness to biases within the scientific community may contribute to the establishment of higher standards of quality in autism research and better ethical practices.

403.171 (Poster) A Qualitative Investigation on the Cross-Cultural Humility of Caregivers for Children with Autism in Nigeria and South Africa

O. A. Kehinde and O. J. Lindly1, (1)English, University of Zululand, KwaDlangezwa, South Africa, (2)Health Sciences, Northern Arizona University, Flagstaff, AZ

Background:

Culture may influence the perceived need for treatment, which treatments are viewed as acceptable, and treatment seeking behaviours in individuals with autism and their families. To effectively deliver services to and care for individuals with autism spectrum disorder (ASD; hereinafter autism) in multilingual and multicultural societies, including Nigeria and South Africa, an understanding of different cultures is critical for caregivers such as educators and health professionals. Nigeria for instance has Yoruba, Hausa, Igbo and other over 500 living languages, and diverse cultures such as those relating to health management, child's upbringing, belief system on disorders etc. Cross-cultural competence is commonly defined as an individual’s ability to relate and communicate effectively when the other individuals involved in the interaction do not share the same culture, ethnicity, and/or language. In Nigeria and South Africa, many children with autism have different linguistic and cultural backgrounds than their available caregivers. This dissonance can create scenarios in which caregivers—at times unknowingly—negate the cultural values and beliefs of individuals with autism and their families thereby delivering suboptimal care. No research has, however, examined the training and experiences related to cross-cultural competence among caregivers delivering services to children with autism in Nigeria and South Africa.

Objectives:

This study aimed to explore the professional training and experiences related to cross-cultural competence in caregivers for children with autism in Nigeria and South Africa. This study also investigated the implications of limited cross-cultural competence among these caregivers in their work with children with autism and their families.

Methods:

The study adopted a qualitative approach, and its protocol adhered to ethical considerations. Using purposive sampling, 15 caregivers were recruited from Lagos, 10 from Ibadan, and eight from Abuja in Nigeria. In South Africa, 12 caregivers were recruited from Johannesburg, six from Pretoria, and 10 from Durban. The primary eligibility criteria was that the caregivers needed to be currently delivering evidence based services to children with autism ages 18 months-12 years in Nigeria or South Africa. The data was collected using semi-structured interviews and analysed using thematic content analysis.

Results:

A total of 61 caregivers were interviewed and a majority of them (n = 47; 77%) had no professional training on cross-cultural competence. Many caregivers (n = 41; 67%) mentioned challenges addressing cross-cultural issues while providing services to individuals with autism. The caregivers (n=53; 87%) felt their limited cultural competence negatively affected the care rendered to individuals with autism. “It is difficult for many of us who are Yoruba to care for people with autism from northern, and eastern parts of Nigeria for instance, because we don’t understand their languages and many aspects of their cultures” (CGN12).
Conclusions:

Increased training on cross-cultural competence is essential for caregivers of individuals with autism in Nigeria and South Africa. The findings from many caregivers who participated in this study suggest that limited caregiver cross-cultural competence may adversely affect the effectiveness of services for individuals with autism in Nigeria and South Africa; hence, in-service training on cross-cultural competence is highly required.

403.172 (Poster) A Systematic Review of Global Public Knowledge and Attitudes of Autism

M. Zhang and G. Y. H. Lam, Department of Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background:

Autism has attracted increasing attention in academia and in different communities around the world. Compared with professionals and clinicians, laypersons have fewer opportunities to receive formal academic knowledge of autism from professional training and research. The lack of public awareness and knowledge of accurate information about autism may result in stigma and misunderstanding.

Objectives:

This systematic review aims to synthesize the current state of laypersons’ knowledge and attitudes toward autism worldwide based on English-language research articles.

Methods:

Empirical studies published from 2013 to 2022 were identified by searching six electronic databases and a hand search of the reference list. The search criteria and strategies were presented in Figure 1. Totally 39 papers were included and analyzed via a narrative approach to synthesize the following themes.

Results:

(1) The main way for laypersons acquiring knowledge was social media, such as internet and TV. Other sources encompassed personal contacts and professional ways (< 26%). (2) Although most participants (> 70%) identified autism as a neurodevelopmental disorder in two studies, participants in the other eight studies believed autism as a communication disorder (around 50%), a brain disorder (around 60%) or a mental disorder (> 60%). (3) The public showed extremely varied understanding of the etiology, treatment, and prognosis expectations of autism, as evidenced by the wide ranges of the percentage of people across studies who endorsed these knowledge items either correctly or incorrectly: Autism is caused by genetic/neurological factors (<1% - 89%); by environmental factors (7% - 59%); by other mental disorders (2.3% - 63%); skills-based interventions are effective (8.1% - 83%); and adults with autism can "outgrow" autism (19% - 62.3%). (4) Most participants (around 80%) could identify the core features of autism based on DSM-5 (e.g., communication problems and repetitive behaviors). However, many also believed that autism is characterized by learning difficulties, illusion, deafness, and the inability to make friends. (5) Social economic status, educational attainment, and prior contact with someone with autism predicted more knowledge and positive attitudes, while the effect of gender and age were inconsistent. Country was also found to be a significant factor affecting knowledge and social attitudes in international studies (e.g., knowledge accuracy in the USA is higher than the UK, which is higher than China). 6) Despite that most participants (> 80%) showed a great willingness to be friends or neighbors with people with autism, more negative attitudes towards other types of social relationships with autism and implicit biases were prevalent among the public.

Conclusions:

Generally, the public had a high awareness of autism. Nevertheless, they hold more consistent knowledge of symptoms than etiology, treatments, and prognosis expectations. This inconsistency may imply ambiguous knowledge and further impact how the public form implicit attitudes and keep a distance from people with autism. More community training programs and advocacy initiatives explicitly targeting these areas are recommended. Mental health professionals and media groups should work together to promote more accurate knowledge and culturally sensitive understanding of autism to reduce misconceptions.

403.173 (Poster) A Systematic Review of Interventions to Teach Functional Skills to Autistic Children in LMIC Contexts

G. Yakubova, M. Al-Dubayan, S. Gupta, V. Y. Kang, B. B. Chen, M. Defayette and A. L. Proulx, (1)Counseling, Higher Education, and Special Education, University of Maryland at College Park, College Park, MD, (2)University of Maryland, College Park, MD, (3)Special Education, Towson University, Towson, MD
Background: Research on effective interventions to teach a variety of functional skills to autistic children in LMIC contexts is scant. Overwhelming majority of autistic individuals live in LMIC settings, yet what we know about effective intervention strategies in teaching functional skills come from HICs.

Objectives: The purpose of this study was to systematically review the interventions used to teach functional skills to autistic children in LMICs and synthesize the evidence base in this area. The aims were to analyze the types of interventions used, the characteristics of interventions and studies that resulted in successful outcome for children, and demographic and geographic characteristics of these studies.

Methods: A systematic search of the literature using several electronic databases was conducted to identify relevant studies. A total of 708 studies were identified, and a total of 9 studies met the inclusion criteria. These studies were published between 2015 and 2021. They coded and synthesized studies for the participant and interventionist characteristics, including race/ethnicity/culture, LMIC context as defined by World Bank, types of interVENTions and trainings used, participant learning outcomes and methodological rigour.

Results: Overwhelming majority of intervention studies to teach functional skills to autistic children in LMICs were conducted in Turkey, followed by Sri Lanka, India, Pakistan, and Syria. Studies focused on a variety of functional skills and used various quantitative methodologies (RCT, single-case experimental design, mixed-methods design). Autistic children in these studies ranged from 18 months old to 9 years old. Seven of the studies had strong or adequate ratings on methodological rigour with two studies having weak ratings.

Conclusions: Intervention studies that address functional skills instruction for autistic children in LMICs are scarce and loosely spread across geographic regions. All included studies focused on young children. Addressing the needs of autistic children, adolescents, and young adults and teaching them functional skills to foster independent functioning in the society is critical. Future research efforts should aim to examine the adaptation and feasibility of evidence-based practice in different LMICs.

403.174 (Poster) An Ecocultural Exploration of Play in Children with Developmental Disabilities from Resource-Limited Communities: Perspectives of South African Caregivers

R. F. Small, L. Schlebusch and L. Nel, (1)Psychology, University of the free State, Bloemfontein, South Africa, (2)Centre for Autism Research in Africa, Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Psychology, University of the Free State, Bloemfontein, South Africa

Background: Children’s play is a universal concept and easily apparent to even the most casual observer but remains a natural and culturally embedded phenomenon – one through which children explore and make sense of their world, societal norms, and cultural expectations. While there is research available on the play of children with and without developmental disabilities, there is minimal research on the play of children with developmental disabilities living in culturally diverse, resource-limited settings. Contextualised research on children’s play in their natural environments and the toys and materials they play with is essential when developing and implementing early intervention programmes. A deeper understanding of play and play materials is even more critical when (a) developing and implementing interventions for children at risk of developmental delays or disabilities living in resource-limited communities and (b) using interventions that include play and play materials in their approaches.

Objectives: This study explored the play of Basotho children with developmental disabilities living in resource-limited communities in South Africa from their caregivers’ perspective. First, we explored the toys and play materials that these children can access (i.e., what they play with), and secondly, we delved deeper to understand why they play, how they play, and where they play. We specifically included the toys and play materials suggested by the World Health Organization Caregiver Skills Training (WHO CST) programme to explore the availability of their recommended items.

Methods: We used an exploratory and descriptive qualitative design with a social constructivist orientation. Twelve Basotho caregivers of children with developmental disabilities (including children with autism) were purposively selected to participate in two focus groups, which resulted in deep and rich conversations. Data were analysed through a hybrid process of thematic analysis, and results yielded themes incorporating ecocultural considerations of what, why, how, and where children play.

Results: Children do have access to a variety of play materials. Still, to have a deeper ecocultural understanding of their access, it is essential to consider (1) availability, (2) affordability, (3) accessibility, (4) acceptability, and (5) accommodation. Caregivers gave unique insights into why their children play (sensory stimulation, emotional regulation, and development), how their children play (the visibility of their disability, specific interests, and play partners), and where they play (mostly at their home).

Conclusions: As early interventions for children with developmental disabilities continue to gain global attention, it remains essential to consider the ecocultural contexts of children and their families. Understanding why, how, where, and with what children with developmental disabilities living in resource-limited communities play is not only imperative for the feasibility of interventions; it is of paramount importance in order to be respectful and culturally sensitive to the conditions and views of the communities where such programmes are implemented.
Figure 1. Five balloons represent the interconnected domains that determine the access that children with developmental disabilities have to toys and play materials.

Figure 2. The “Box Toy” represents the ecocultural considerations when exploring the play of Basotho children with developmental disabilities living in resource-limited communities.

403.175 (Poster) An International Evaluation of the Brick-By-Brick Programme in Kenya and Mexico
M. H. Laurie¹ and G. Gomez de la Cuesta²; (1)Play Included CIC, Duxford, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom

Background:

There is growing interest in the application of play-based interventions to support autistic children’s social development. The Brick-by-Brick programme is an advancement on LEGO-based therapy, and brings children together in small groups to build LEGO® models playfully facilitated by a trained adult to promote collaboration and inclusion. The sessions are known as Brick Clubs to children. Previous research has found that Brick Clubs can support social awareness, the initiation of social interactions, sharing and turn-taking, negotiation, all while children develop confidence, self-esteem, and have fun, and build friendships.

Objectives:

Evidence to date has only been gathered in high-income, and mostly Western, contexts. The current study will evaluate the Brick-by-Brick programme, and test feasibility, acceptability, and child outcomes, in two LMIC countries: Kenya and Mexico.

Methods:

In each country, 2-3 facilitators are trained to run Brick Clubs, and two Brick Clubs will run (with 3-4 primary-aged autistic children each, total n = 16). Feasibility and acceptability of the training and the programme will be assessed using bespoke surveys and interviews with the facilitators and children’s families. Fidelity will be captured using direct observation and a bespoke measurement tool specific to the Brick-by-Brick programme, and children will provide direct qualitative feedback through interviews with the research team.

Results:

Data collected so far, through facilitator training and interviews across both countries, has shown that the Brick-by-Brick programme is feasible and acceptable in both sites. Suggested cultural adaptations include increased diversity and representation in training materials and worked examples of playful facilitation, and ways to recruit and engage with families across different contexts and geographies. Facilitators predict that the programme will have a positive impact on autistic children, and contribute to social connectedness, friendships, and children’s wellbeing and development. Children in both contexts have shared that Brick Club is a fun and engaging programme to develop social skills.

Conclusions:

The Brick-by-Brick programme is feasible, acceptable, and effective across different settings and cultures, according to autistic young people, their families, and facilitators.

403.176 (Poster) An Intersectional Lens of Black Parents’ Experiences of Autism
E. Gemegah, University of Birmingham, Birmingham, United Kingdom

Background:

This research examined Black parents’ lived experience of the autism spectrum disorder (hereafter autism) in the UK, to address the intersectional factors that influence their psychological wellbeing. Unlike predominant research on autism, the focus is exclusively on Black (African/Afro-Caribbean) parents’ experiences because of the dearth of research on this topic. It posits that a multifaceted lens is necessary to understand minoritized groups, value their experiences and provide relevant support at individual, contextual and systemic levels. This study recognises that parents’ experiences are not fixed but ever changing and offers new interpretation of different contexts. Thus, begins to bridge the gap in knowledge and awareness of Black parents’ experiences and the intersectional factors that shape their experiences.
Objectives:

- Describe and explain how intersectionality as a framework exposits the individual factors and familial settings that shape Black parents’ perceptions and experiences of autism in the UK
- Describe the different contextual and systemic factors that influence Black parents’ lived experiences of autism
- Determine ways that contextual factors shape parents’ wellbeing
- Synthesise the intersectional factors that shape parents’ experience of autism

Methods:

A qualitative approach was adopted using in-depth interviews with participants (N=15) across England and a hermeneutic phenomenological method provided breadth and depth of findings on experiences from an often-marginalised group of people at the intersection of race, gender and disability.

Results:

An intersectional lens provided insight of how multiple identities converge in various contexts. The findings revealed that in addition to challenges associated with autism, Black parents experienced distinct and nuanced difficulties associated with race, culture, gender and socio-economic status. Parents’ multiple and intersecting identities shaped their experiences of autism and their psychological wellbeing in the face of racism, unequal division of labour and oppressions from structural barriers in the home, community and organisations in wider society.

The findings of the study showed that mothers’ primary caregiving role negatively affect their quality of life (isolation, financial hardship) and psychological wellbeing. Culture influenced gender roles and perception of autism, which impacted the family structure and subsystems. However, mothers recounted the valuable nature of their coping strategies including spiritual beliefs, cognitive appraisal and resilience.

Conclusions:

This study revealed the multi-level intersection of race, culture, gender and disability and provides relevant information for mental health and social practice, policy, and research. The findings from this study have implications for Black parents’ mental health and wellbeing, especially as seen through the lens of cultural/religious factors and contributes to debates about individual wellbeing within a broader social milieu.

403.177 (Poster) Assessing Autism Knowledge across the Global Landscape Using the ASK-Q

(1) Educational Psychology, University of Georgia, Athens, GA, (2) Iona College, New Rochelle, NY, (3) Accare UCKJP, Groningen, Netherlands, (4) University of Georgia, Athens, GA, (5) Department of Family Medicine, Faculty of Medicine, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia, (6) Psychology, Université du Québec à Montréal, Montreal, QC, Canada, (7) South China Normal University, Guangzhou, China, (8) Université de Paris, Boulogne-Billancourt, France, (9) Universiti Sains Malaysia, Penang, Malaysia, (10) Manggatal Health Clinic, Ministry of Health Malaysia, Sabah, Malaysia, (11) Department of Child and Adolescent Psychiatry & Accare Child Study Center, University Medical Center Groningen, Groningen, NETHERLANDS

Background:

Global disparities are related to the variability of knowledge about developmental disabilities, including autism (Stahmer et al., 2019; Ruparelia et al., 2016; Durkin et al., 2015) and the stigmas that accompany lower levels of autism knowledge. Low autism knowledge has been specifically identified in many low and middle income countries (Low et al., 2021; Handayani & Paramita 2020; Alyami, 2022; Bakare et al., 2022), but it is difficult to know how concerning these knowledge levels are without direct comparisons to other regions and it is difficult to know what population variables likely contribute to knowledge deficits. The autism stigma and knowledge questionnaire (ASK-Q; Harrison, Bradshaw et al., 2017) was developed as a cross-culturally sensitive, comprehensive assessment tool to measure the nature and extent of ASD knowledge across different groups and countries.

Objectives:

The current study uses the ASK-Q to quantify autism knowledge across different countries and demographics. First, we investigated differences across individual countries and then in terms of groupings by worldview and income. Second, we examined differences in autism knowledge between the different populations in relation to autism that comprised the samples. Third, we examined how different sociodemographic factors related to autism knowledge.
Methods:

The current study compiled data from 6830 participants collected using adapted versions of the ASK-Q administered in 13 different countries, representing four different continents. Data was recoded to develop common sociodemographic metrics. Gross domestic product (GDP) and the Hofstede Model were used to designate countries as high and low income, and collectivist and individualist, respectively.

Results:

Structural equation modeling was used to examine how autism knowledge varied across country and individual factors. Results revealed cross country variability with a large, 17-point difference between the countries with the highest knowledge (Canada) and the lowest knowledge (Lebanon). Post hoc analyses revealed a meaningful stepwise pattern of significant differences for most countries (see figure 1). Countries either with higher economies or an individualistic worldview had higher levels of knowledge (both \( p < .001 \)). We also documented sociodemographic differences. Teachers and health professionals (both \( p < .001 \)) had significantly less knowledge than family members of autistic persons or the lay public (both \( p < .001 \)). Additionally, women had more autism knowledge than men (\( p < .0001 \)), and more education was significantly related to more autism knowledge (\( p < .0001 \)). Finally, our SEM model revealed that middle aged, elderly and young adults all had comparable autism knowledge after controlling for country and study population, but that older adults (\( p = 0.006 \)) and college age students (\( p < 0.001 \)) had significantly lower knowledge.

Conclusions:

These results help identify specific regions and populations that might most need greater information about autism. This study provides information that is important to policy makers in formulating strategies and interventions to raise awareness of autism by targeting those groups who demonstrate the most meaningful deficits. Heightened public awareness among caregivers, teachers and other service providers, health care professionals is crucial for early diagnosis of autism as it leads to prompt treatment initiation and better outcomes.

403.178 (Poster) Translation and Cultural Adaptation of the Abas-3 in the Brazilian Context: A New Tool to Evaluate Adaptive Functioning in Children with ASD in Brazil

T. P. Mecca, T. Tafla, F. Valentini and M. C. Teixeira, (1)Mental Health Department, Santa Casa de São Paulo School of Medical Sciences, São Paulo, Brazil, (2)Mackenzie Presbterian University, Sao Paulo, Brazil, (3)Sao Francisco University, Campinas, Brazil, (4)Developmental Disorder Program, Mackenzie Presbterian University, Sao Paulo, Brazil

Background: In low- and middle-income countries there is a lack of screening tools to verify adaptive functioning in individuals with autism spectrum disorders (ASD). Adaptive functioning refers to a set of conceptual, social, and practical skills that are learned and performed to meet the demands of everyday life. In ASD, the assessment of adaptive behavior helps to specify the level of severity of the disorder. Assessing the adaptive functioning of individuals with ASD helps design intervention programs. An important instrument to assess adaptive functioning is the Adaptive Behavior Assessment System (ABAS-3). This instrument has different forms for use with children, adolescents, adults and the elderly. When translating an instrument, the idiomatic, linguistic, cultural, and contextual aspects related to its adaptation must be considered to demonstrate the semantic equivalence of the items in terms of the psychometric evidence of the adapted version.

Objectives: This study aimed to describe the process of translation and cultural adaptation of the ABAS-3 in the Brazilian context, as well as verify evidence of validity content.

Methods: This is a cross-sectional quantitative study. The study adopted the translation, cultural adaptation procedures based on 33 judges' criteria and evaluation by the target population (2 parents and 2 teachers), to facilitate the informants understanding. Instrument: ABAS-3 has five forms according to age, and the number of items and the skills area included. The forms of ABAS-3 for population between 0 and 21 years old are Parents/Primary Caregiver Form (0-5 years); Parent Form (5-21 years); Nursery/School Teacher Form (2-5 years); Teacher Form (2-5 years) and Adult Form (16-89 years).

Results: After the synthesis of the translations, the results of the evaluation by the committee of 33 experts showed that of the 1121 items of the five ABAS-3 forms, 82 (7.31%) needed revision. The criterion with the largest number of items for review was grammar/phrasing (48 items) and general criteria (45 items). Only three items showed a lack of agreement between the 33 experts in the item format criterion. Regarding the scales, the one that required the greatest revision of the items was health and safety (16 items), followed by the motor scale (14 items) and self-regulation (12 items). The leisure scale showed 100% agreement by the experts for all criteria, without any revision being necessary. The analysis of the items by target population showed no changes to the Parents/Primary Caregiver Form (0-5 years) and the Parents Form (5-21 years). The suggestions of the target population in the Teacher Form of the daycare/school (2-5 years old) resulted in two items being partially modified (Communication - item 18; Self-care - item 20) and in the Teacher Form (5-21 years old) one item was partially modified (Health and Safety – item 6).
Conclusions: This process resulted in good evidence of instrument content validity. After carrying out all the adaptation stages and establishing evidence of content validity, the instrument is ready to be used in future studies that investigate its accuracy and other types of validity evidence such as internal and external validity.

403.179 (Poster) Autism Research Conducted in Central Asia: Knowledge Gaps and Research Priorities
R. Zakirova Engstrand and G. Yakubova, (1)Stockholm University, Stockholm, Sweden, (2)Counseling, Higher Education, and Special Education, University of Maryland at College Park, College Park, MD

Background: Ninety-five percent of children with neurodevelopmental disabilities younger than 5 years old live in LMICs. Scarcity of autism research in LMICs – including countries located in Central Asia – present major obstacles in providing education, healthcare, and social services to autistic people.

Objectives: The purpose of this scoping review was to review and examine the scope and focus of the published peer-reviewed research studies in order to understand the extent of the published autism research that originated in five Central Asian countries – Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, and Uzbekistan. We examined: (a) topics and research areas represented in autism research in each country, (b) research designs of conducted studies, and (c) the rate, trajectory, and geographic representation of autism research conducted in the region. The study also aimed at analyzing knowledge gaps and research needs to guide future research in autism in the Central Asian region.

Methods: A systematic search of literature through electronic databases and hand searches (Academic Search Premier/Ultimate, ERIC], CINAHL, APA PsycINFO, and MEDLINE, and Web of Science) yielded 11 peer-reviewed research articles published between 2013–2021 that met the inclusion criteria for the study. We extracted data according to the three areas of analysis described in the objectives and analyzed the topics and research areas of the studies according to the IACC Strategic Plan.

Results: Eleven studies used a variety of research methods (qualitative, quantitative, and mixed-methods). There was a total of 878 participants with 66 of them being parents. Eleven studies were published during the years of 2013–2021 with only one study published in 2013 and 10 studies published between 2019 and 2021. Nine articles were published in English and two in Russian. Ten studies took place with participants in Kazakhstan and one in Uzbekistan. There was an increase in autism research publications in Kazakhstan over time – from 2013 to 2021. When analyzing the topics and research areas of the studies, four studies were identified to be in the area of Services, two in the area of Risk Factors, two in the Treatments and Interventions category, one in Biology, one in Diagnosis, and one study both in Biology and Treatments and Interventions categories. There were no studies investigating lifespan issues; similarly, none of the included articles reported findings in the area of infrastructure and surveillance. None of the studies reported co-authorship of scientists from various Central Asian countries.

Conclusions: The findings of our study show that the overwhelming majority of the included studies were conducted in Kazakhstan with only one study – in Uzbekistan. There were no studies from Kyrgyzstan, Tajikistan, and Turkmenistan that met the inclusion criteria for our study. The absence of studies investigating lifespan issues, infrastructure and surveillance highlights a gap in research. Scarcity of autism research in the region and lack of collaboration among Central Asian scholars is concerning. These findings can be the first step towards identifying future research areas in Central Asia to meet the needs of autistic people.

403.180 (Poster) Autism and Indigenous Peoples in Canada: A Scoping Review and Local Service Access Study
M. Ressel and G. Iarocci, (1)Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada

Background: Indigenous leaders have identified supporting the well-being of autistic individuals and their families as a growing concern in First Nations communities across British Columbia. Decades of research have demonstrated that access to timely and appropriate evidence-based diagnostic and support services are essential to autistic well-being. Yet, Black, Indigenous, and People of Colour (BIPOC) are diagnosed with autism later, report lower satisfaction and greater difficulty accessing services, and remain underrepresented in autism research compared to their white counterparts. Research on the unique experience and impact of autism in Indigenous communities is critical step towards achieving equity in autism services.

Objectives: N/A

Methods: In study 1, a scoping review of the peer-reviewed and grey literature was conducted to identify what information has been published to date on autism among Indigenous peoples in Canada. The review elucidated key gaps in current knowledge, and priorities for future research. Included publications were analyzed for the type of research, stated objectives, methodologies, and level of engagement with Indigenous communities. In study 2, descriptive analyses of data provided by British Columbia’s Ministry of Child and Family Development examined differences in proportional and timely access to autism funding programs between Indigenous and non-Indigenous children aged 0-18. Study 2 also analyzed and depicted the dispersion of registered autism service professionals (RASP) across BC in geographic relation to Indigenous
Background: Over the past two decades, there have been increasing discussions around which terms should be used to talk about autism. Whilst these discussions have largely revolved around the suitability of identity-first language (e.g., autistic person) and person-first language (e.g., person with autism), more recently this debate has broadened to encompass other autism-related terminology (e.g., “high-functioning”). To date, academic studies have not investigated the language preferences of autistic individuals outside of the UK or Australia, nor have they compared levels of endorsement across countries.

Objectives: The current study adopted a mixed-methods approach, employing both quantitative and qualitative techniques. The main objectives were to explore the linguistic preferences of English-speaking autistic adults across the globe and to qualify these with thematic analysis of detailed free-text responses.

Methods: Autistic adults (18 years or older) were recruited via an international autism research database (part of the U21 Autism Research Network collaboration), social media advertising, and through emails to autism charities and organizations across the globe. In total, 654 English-speaking autistic adults (128 self-identified) participated in this online survey from 30 different countries (M_age=31.90). They were asked to identify, by selecting from a list, which terms they endorsed being used against 6 terminology categories. These included (1) nomenclature (e.g., Autism, Autism Spectrum Disorder, Autism Spectrum Condition), (2) referring to the person (e.g., Autistic, Autistic person, Person with autism), (3) describing someone’s autistic identity (e.g., Has autism, Is autistic), (4) talking about autism more broadly (e.g., Condition, Disability, Neurological Difference), (5) talking about abilities or challenges (e.g., Deficits, Differences) and (6) talking about people without an autism diagnosis (e.g., Healthy controls, Neurotypical people, Non-autistic people). Finally, in a free-text response question, participants were asked to tell us more about their language preferences.

Results: Quantitative endorsement comparisons were made between countries where there was a minimum of 50 participants, including Australia, Canada, Ireland, New Zealand, UK and USA. Despite some variation in levels of endorsement between countries, we found that the most popular terms were similar- the terms “Autism”, “Autistic person”, “Is autistic”, “Neurological/Brain Difference”, “Differences”, “Challenges”, “Difficulties” and “Neurotypical people” were consistently favored across countries (see Figure 1). Thematic analysis of 414 free-text responses revealed the reasons underlying participants’ preferences, generating six core themes (see Figure 2); Problems of differentiation; We are different, not less; Autism is me; Claiming language and community; Be concise, be accurate, be specific; and Respect and hear our voices.

Conclusions: Despite relative consensus across countries to use identity-first, non-deficit-based language, both our quantitative and qualitative data demonstrate that there is no universally accepted way to talk about autism. These findings have significant implications for informing practice, research and language policy worldwide and our qualitative findings illuminated an important guiding principle: to respect people’s personal preferences.

403.181 (Poster) Autism-Related Language Preferences of English-Speaking Individuals across the Globe: A Mixed Methods Investigation

S. Sowden, C. T. Keating, L. J. Hickman, J. Leung, R. Monk, A. Montgomery and H. Heath; (1)University of Birmingham, Birmingham, United Kingdom, (2)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (3)University of Auckland, Auckland, New Zealand, (4)Sydney Local Health District, Camperdown, NSW, Australia

403.182 (Poster) CST: Caregiver Skills Training Mediated Intervention in Adverse Contexts.

CST is an intervention program mediated by Caregivers of children with developmental delays or disorders, including autism, developed by the WHO and Autism Speaks. The program has proven efficacy and has been found to be beneficial in underserved populations, given the difficulties in access to support, lack or modest economic resources, or due to distance. Families with children between 2-7 years of age are included, and no specific diagnosis of autism was required.

Objectives: To explore the program’s feasibility to increase communication, management of disruptive behavior, promoting autonomy, and heighten coping skills from parents. The intervention aimed at supporting parent-child interactions. It also contributed to the formation of networks and better integration of families into their communities.

Methods:

The format included 8 weekly group meetings plus 3 individual sessions in a virtual format through ECHO AUTISM PROTECTEA Model. Caregivers received booklets with the essential contents. Topics were presented and explained during training sessions. In addition, the caregivers received booklets with the essential contents covered and illustrated stories that served as an identification models. Reflective discussions were generated. Personal goal-setting were included. An assessment was carried out before and 12 weeks after completing the workshop sessions. Caregivers completed a pretest and a posttest survey regarding their feelings towards different skills taught through the course. Quantitative assessment is reported elsewhere.

Participants: 164 families of children from March 2021 to June 2022. They were derived from early childhood Daycare Centers and Primary Care Health Centers in vulnerable areas from the City of Buenos Aires, or other 5 cities (Burzaco, Tres de Febrero, Mercedes, Mar del Plata and Santa Fe, Argentina). Inclusion criteria were failure in communication and social individual areas detected by screening with the Ages and Stages Questionnaire 3rd Version (ASQ-3).

Results:

Ninety percent of families completed the intervention. All these families were currently without any treatment due to the COVID-19 pandemic. Caregivers reported improvement in their skills to engage their child to participate in a back-and-forth game from 28.5% to 59.2% after the workshop. They also could increase their abilities to create opportunities for their child to communicate from 55.9% to 75.7% when the course was completed. They also could manage challenging behaviors from 43.5% to 61.1%. Children could increase autonomy from 31.9% to 67% after completing CST Course. Families reported that training fulfilled their expectations at 87%. They observed that 9 of 10 children improved their behavior and around 90% of parents could enhance their abilities as caregivers and achieved favorable changes in their everyday life.

Conclusions: CST intervention demonstrated very positive results in overall parent self-efficacy and family functioning. Parents felt empowered and knowledgeable on how to stimulate the development of their children and reported great improvements in their child’s communication, engagement, and behavior. The virtual modality increased adherence to treatment. CST showed continued success as a tool to enhance parent skills. As a team, it was gratifying to observe families move through the process and provide tools to improve their quality of life.

403.183 (Poster) Comparison between Brazilian and British Mothers Concerning the Diagnosis and Intervention of Their Children with ASD

C. S. Paula, L. C. Silva, M. C. Teixeira, K. Woodcock and C. Mevorach, (1)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (2)Developmental Disorder Program, Mackenzie Presbiterian University, Sao Paulo, Brazil, (3)University of Birmingham, Birmingham, United Kingdom, (4)School of Psychology, University of Birmingham - Centre for Human Brain Health, Birmingham, United Kingdom

Background: The diagnosis of ASD in a child impact greatly on the whole family. Many families feel isolated and have little social support. Mothers, especially, report many symptoms of anxiety, depression, and stress. One of the main reasons for these symptoms is the long process of diagnosis and the subsequent search for treatments.

Each country has a public policy for diagnosis and treatment, and this situation, added to cultural issues, brings different ways of dealing with the situation and different perceptions.

Objectives: To compare the perception of Brazilians and British mothers about their experiences of the trajectory of searching for a diagnosis and treatment for autistic children. In addition, understanding how cultural aspects affect people's perception and behavior, in this case, mothers of children with ASD.

Methods: This is a cross-cultural qualitative study performed with a group of 10 Brazilian and 6 British mothers of children with ASD aged 6-12 years. Semi-structured interviews were conducted online and inquired about the journey of obtaining a diagnosis and treatment, and
the feelings involved in the process. Textual data analysis was performed using ALCESTE software to identify common aspects among mothers of both countries. The topics/classes were defined a posteriori.

Results: Brazilian mothers’ descriptions of their experiences were classified in three topics/classes, namely: Class 1: “Trajectory of interventions and satisfaction with the service provided” (54.10% of valid words), addressing contents indicative of the search for the best interventions for children, as well as the factors that make mothers continue or interrupt a therapy; the main keywords were person and professional. Class 2: “Challenges to recognizing the first signs of ASD” (31.45%), spoke about the mother’s difficulty in identifying the first signs of ASD before diagnosis; the main keywords were play and child. Class 3: “Trajectory to obtain the diagnosis” (14.54%), expressing the arduous search for a professional to diagnose children; The main words were pediatrician and neurologist.

The answers of British mothers were grouped a posteriori into three classes: Class 1: “Trajectory and difficulties in seeking intervention” (44.50% of valid words), which was characterized by reports about the difficulty of finding quality and reliable professionals; main keywords were a child and professional key. Class 2: “Social Skills and Functionality” (10.83%), which had as content the concern of mothers with the children’s challenges in the social and functional life of their children. The main keywords were power and part (party, parties). Class 3: “Diagnostic Challenges” (44.67%), in which the mothers talked about the difficulties of managing typical ASD behaviors and the challenges of acquiring knowledge on the subject; the main keywords knowing and diagnosis.

Conclusions: For Brazilian mothers, it was difficult to recognize the early signs of ASD and to get a diagnosis, while among British mothers, the main difficulty seemed to be acquiring knowledge after diagnosis to deal with the behavior’s problems. Also, there was a particular concern with the functional and social life of children post-diagnosis in the UK, which was not so important among Brazilian families.

403.184 (Poster) Cross-Cultural Comparison between the Experiences of Autistic Adults with Social Expectations in the UK and Spain before the Pandemic and during the First Covid-19 Lockdown in the UK

Background:

The socialising style of the autistic population informs diagnostic procedures. While Goffman theorised the social individual as a performer in front of an audience, camouflaging behaviours are known to be implemented by autistic people during social interactions to hide their own identity, comply with expectations, and also as a response to stigma. Camouflaging also impacts diagnostic processes, identity development, and may have damaging effects for the mental health associated to depression, anxiety, social isolation, or suicidal ideation.

As an emergency period was imposed in England due to the Covid-19 outbreak, the first lockdown involved lifestyle adaptations and movement restrictions. Research revealed positive experiences for the autistic population, such as flexibility of time and space, community connections and solidarity, and a reduction of the need for camouflaging. However, other research showed intense detriments related to depression, anxiety, loneliness, and uncertainty heightened by an inconsistent information surrounding the global situation.

Objectives:

This research aims at exploring the experiences of autistic adults with social expectations prior to the pandemic in the UK and Spain, comparing these to those lived during the early stages of the outbreak in the UK.

Methods:

Thirty-four photo elicitation interviews were analysed following a double-step, sequential process through first, a Reflexive Thematic Analysis and, second, the application of a phenomenological interpretation of eight fractions of the participants’ Lifeworld.

Results:

Prior to the Covid-19 pandemic, the findings from both countries indicate positive interactions between an autism diagnosis and the autistic identity. On the other hand, participants emphasised feeling in the middle of a social imbalance, being eager to socialise whilst perceiving the stigma towards autism and experiencing mental health detriments.
During the first Covid-19 lockdown in the UK, albeit reporting some pleasant experiences, a series of struggles were emphasised, such as living with uncertainty and anxiety whilst experiencing discriminating situations, altogether amplified by the ineffective reaction from the support services.

Conclusions:

Before the pandemic, the findings add information about the detrimental forces which constrain the lives of the autistic population. The participants felt overpowered by the harmful interplay of camouflaging, stigma, and mental health. A lifelong social discrepancy was found between feeling compelled to fulfill social expectations through camouflaging whilst facing the stigma towards autism, continuously living a Double Empathy Problem. These experiences generate feelings of guilt and loss of identity which enhance long-lasting mental health detriments.

During the first Covid-19 lockdown in the UK, whilst experiencing a reduction of societal expectations and the need to camouflage, the participants experienced permanent uncertainty and anxiety. Experiences of discrimination towards the autistic community revealed a structural stigma. When seeking support, a specialised, high-quality provision failed to reciprocate and meet their needs, contributing to intensify situations of vulnerability. A series of recommendations are highlighted to improve the support access and networks, whilst increasing the autistic community involvement and the available information.

403.185 (Poster) Cultural Diversity Career Advancement Program (C-CAP): Increasing Research from Low/Middle Income Countries

Background: A recent analysis identified that 95% of children with developmental disabilities under age 5 years reside in low/middle income countries (LMIC; Global Research on Developmental Disabilities Collaborators, 2018). However, strikingly little autism research is conducted in LMIC (Franz et al., 2017). LMIC are also the countries where most people, and therefore autistic people, live in the world. In the United States, a high-income country (HIC), there is a shortage of Black psychologists and underrepresented minorities in the field of ASD research. The manifestations of this absence are multifold, impacting ASD research itself, and further disenfranchising minority communities. Research is lacking in all areas, but particularly areas with direct impact on autistic individuals and their communities, such as epidemiology, intervention efficacy, health and education needs, lifespan needs, and community and cultural perspectives on autism.

Objectives: The INSAR Cultural diversity Career Advancement Program (C-CAP) was established in 2021 to provide mentorship to researchers, clinicians, and scholars from LMIC and underrepresented groups HIC, with the goal of advancing autism research. C-CAP is tracking enrollment of mentors and mentees and the outcomes and products that result from mentorship to evaluate the impact of cross-cultural mentoring on autism research.

Methods: C-CAP recruited and paired mentors and mentees who are required to meet consistently for at least a one-year period, with the goal to provide mentorship individualized to the mentee. Mentoring tools and a curriculum were developed to facilitate mentoring sessions, C-CAP also held webinars throughout the year with globally representative panels of experts to speak on topics of interest. C-CAP collected data on the number of mentor-mentee pairs, attendance at webinars, as well as webinar evaluations data. Surveys were distributed during C-CAP development and implementation to identify needed topics and curriculum materials, and evaluation surveys were collected after C-CAP webinars to assess satisfaction and utility.

Results: Twenty-eight students and early career researchers applied as mentees, and 20 ASD researchers from around the globe applied to be mentors through this initiative. Ten mentor pairs were created in year 1 of C-CAP, with each mentor peer mentoring 2-3 mentees. Webinars were completed on grant writing and manuscript preparation, attended by over 150 participants from a wide range of countries, and evaluation surveys showed high satisfaction and utility ratings. Surveys regarding mentoring progress and satisfaction with mentor-mentee pairs are underway, and descriptive results will be reported.

Conclusions: The successful implementation of C-CAP will serve to increase the number of autism and developmental disability researchers from, and in, LMIC and those from underrepresented groups in HIC, thereby helping expand the current boundaries of autism and developmental disability research and move toward a more comprehensive understanding of developmental disability and its impacts globally. Further expansion of such services, with the support of the members of INSAR, is needed to address the world-wide need for autism research.

403.186 (Poster) Culturally Responsive Support for Caregivers of Children with ASD: A Systematic Review

Objectives: The INSAR Cultural diversity Career Advancement Program (C-CAP) was established in 2021 to provide mentorship to researchers, clinicians, and scholars from LMIC and underrepresented groups HIC, with the goal of advancing autism research. C-CAP is tracking enrollment of mentors and mentees and the outcomes and products that result from mentorship to evaluate the impact of cross-cultural mentoring on autism research.

Methods: C-CAP recruited and paired mentors and mentees who are required to meet consistently for at least a one-year period, with the goal to provide mentorship individualized to the mentee. Mentoring tools and a curriculum were developed to facilitate mentoring sessions, C-CAP also held webinars throughout the year with globally representative panels of experts to speak on topics of interest. C-CAP collected data on the number of mentor-mentee pairs, attendance at webinars, as well as webinar evaluations data. Surveys were distributed during C-CAP development and implementation to identify needed topics and curriculum materials, and evaluation surveys were collected after C-CAP webinars to assess satisfaction and utility.

Results: Twenty-eight students and early career researchers applied as mentees, and 20 ASD researchers from around the globe applied to be mentors through this initiative. Ten mentor pairs were created in year 1 of C-CAP, with each mentor peer mentoring 2-3 mentees. Webinars were completed on grant writing and manuscript preparation, attended by over 150 participants from a wide range of countries, and evaluation surveys showed high satisfaction and utility ratings. Surveys regarding mentoring progress and satisfaction with mentor-mentee pairs are underway, and descriptive results will be reported.

Conclusions: The successful implementation of C-CAP will serve to increase the number of autism and developmental disability researchers from, and in, LMIC and those from underrepresented groups in HIC, thereby helping expand the current boundaries of autism and developmental disability research and move toward a more comprehensive understanding of developmental disability and its impacts globally. Further expansion of such services, with the support of the members of INSAR, is needed to address the world-wide need for autism research.
Background: Studies have shown that caregivers of children with ASD frequently experience depression and anxiety. Social supports such as psychological and emotional assistance, resources, and services appear to have positive effects on caregivers in terms of their personal well-being and child-rearing practices. However, social support programs that are effective for White, middle to upper-class, English-speaking caregivers may not have same effects on ethnically diverse or international communities.

Objectives: The present review aims to address the following questions: (a) What types of culturally responsive support programs are available for caregivers of children with ASD?, (b) What was the process to make the programs culturally appropriate?, and (c) Are culturally responsive support programs effective in improving caregiver outcomes?

Methods: Six electronic databases including American Psychological Association Psycnet, PubMed, ERIC, ProQuest Social Science Premium Collection, Academic search premier, and ProQuest Dissertations & Theses were used to search for articles that consist of a combination of following terms: (a) cultur* OR linguistic*, (b) adapt* OR appropriate OR tailor* OR sensitive OR responsive, (c) caregiver OR parent*, (d) train* OR coach* OR educat* OR support OR interven*, and (e) autism OR ASD OR autistic in their title or abstract. Eligible studies must provide information on the development/adaptation detail of a caregiver support program and/or examined effects of a culturally responsive caregiver support program. Also, the programs addressed in the studies must be for caregivers of autistic children ages birth through eight to be eligible. The following variables and outcomes were extracted to summarize the information from included articles: study design, purpose, target population, components of a support program, participants involved in the development/adaptation process and their characteristics, development/adaptation procedure, methodological rigor, as well as the implementation and outcomes.

Results: Nineteen studies met inclusion criteria and addressed fifteen different culturally responsive caregiver support programs. Findings suggested that nine of the programs were culturally adapted to meet unique needs of target populations while six were specifically developed for diverse or international communities. Eleven of the programs were for diverse caregiver communities in developed countries while four were for caregivers in low-resourced countries. Frameworks such as the Ecological Validity Model and the SHARP framework were applied in eight programs to facilitate their development or cultural adaptation. While community-based participatory research is an important approach to address disparities, six of the programs did not specify the inclusion of caregivers in their development/adaptation process. Sixteen studies reported the implementation of a support program and evaluated its effects. Twelve of the sixteen studies collected social validity data. Overall, caregivers participated in the support programs found the programs acceptable and beneficial, and they had increased confidence and frequency in implementing evidence-based intervention strategies. However, improvements in parental well-being were not consistently found across studies.

Conclusions: Future research needs to examine how effects of culturally adapted caregiver support programs are different from programs developed for target populations and how effects of culturally responsive caregiver support programs are different from those that are not tailored for target populations.

403.187  (Poster) Culture and Connection: Building Strong Home-School Partnerships with Culturally and Linguistically Diverse Families of Autistic Children

J. A. Smith1, E. Pellicano1, A. S. Rabba2, P. Datta3, E. Dresens3, G. Hall4, M. Heyworth5, W. Lawson5, R. Lilley6 and N. Syeda7, (1)Childhood Autism Phenotype Team, La Trobe University, Melbourne, VIC, Australia, (2)Macquarie School of Education, University College London, Sydney, NSW, United Kingdom, (3)La Trobe University, Melbourne, VIC, Australia, (4)Macquarie School of Education, Macquarie University, Sydney, NSW, Australia, (5)Positive Partnerships, Sydney, NSW, Australia, (6)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (7)Macquarie School of Education, Self, Macquarie University, NSW, Australia

Background:

Strong, effective partnerships between teachers and caregivers can substantially improve all children and young people’s success in and out of school, including autistic children and young people. Such partnerships may be especially important for autistic students since they can benefit from learning supports and consistent approaches across contexts. Yet, we know little about the experiences of home-school partnerships for families of autistic children from Culturally and Linguistically Diverse (CALD) backgrounds.

Objectives:

This research sought to bridge the gap in knowledge for CALD families of autistic children. Specifically, we worked with four separate community groups, namely Chinese, Vietnamese, Somali and Middle Eastern, to understand parents’ views and experiences of interacting with Australian schools for their autistic child(ren) and how culture might influence these interactions.
Methods:

We adopted a participatory approach. A team of autistic and non-autistic researchers worked together to make decisions about the overall study. Four separate advisory groups, each comprising 3-5 parents of autistic children from each community group, then collaborated with the broader team on individual projects. Semi-structured interviews were conducted with 56 parents (mostly mothers, aged 23 – 65 years) in preferred languages, including 17 Chinese parents, 15 Vietnamese parents, 15 Somali parents and 9 parents from Middle Eastern backgrounds. Parents together had 67 autistic children (aged 2 – 18 years), who attended kindergarten, primary and secondary schools across mainstream and specialist settings. Parents were asked about their and their child’s experiences of school, navigating the school system, and relationships with school staff. We followed Braun and Clarke’s method for reflexive thematic analysis to analyse the data using an inductive (bottom-up) approach to identify patterned meanings within the dataset.

Results:

Despite the differences between the four communities, parents shared a range of (mostly negative) experiences as they navigated the schooling system. Many parents were respectful and deferential towards teachers and had clear role boundaries between themselves and educators. They reported having high expectations for their children but were disappointed these were not shared by teachers. They were further frustrated by the apparently limited teacher knowledge of autism and the inadequate and inconsistent communication from schools. These issues were exacerbated by parents’ own difficulties with spoken and written English and their limited understanding of Australian education and funding systems. Parents also reported experiencing widespread stigma and misunderstanding about autism in their own communities, as well as overt discrimination, with racial profiling and prejudice reported. Despite stigma, limited resources and deference, many parents felt that they had no choice but to advocate on behalf of their children and their community.

Conclusions:

In this study, we elicited the views and experiences of parents from CALD backgrounds, who are all too often overlooked in autism research. Their testimonies reveal important ways to encourage more successful partnerships between CALD communities and kindergartens/schools, ensuring that these settings are more inclusive and culturally safe for families. Future research should examine the most effective ways that parents and schools can collaborate to help secure positive futures for autistic children with CALD backgrounds.

403.188 (Poster) Development of Spark@Grow Developmental Screening Mobile Application in Malaysia

P. Y. Wong, S. W. Wo, G. L. Tan, T. H. Toh and P. J. Woo, (1) Health Sciences Library, Sunway University, Toronto, ON, Malaysia, (2) Sunway University, Subang Jaya, Malaysia, (3) SPARK Child Development Centre, Petaling Jaya, Malaysia, (4) Clinical Research Centre & Department of Pediatrics, Sibu Hospital, Ministry of Health, Sarawak, Malaysia, (5) Sunway University, Petaling Jaya, Malaysia

Background: Importance of early screening for neurodevelopmental disorders (NDD) has increasingly been recognised. However, there are barriers to effective developmental screening in Malaysia: low awareness of NDD; low paediatrician-to-children ratio (0.08:1000); lack of culturally relevant screening tool; and COVID-19 pandemic.

Objectives: (1) To develop a mobile application for Malaysian parents to conduct developmental screening on infants and toddlers of zero to 23-month-old. (2) To examine the feasibility and user-friendliness of the mobile application.

Methods: During Stage One, a panel of four subject matter experts (SMEs) was formed. They rated developmental milestones from a few widely used developmental screening tools and developmental milestones guidelines on a five-point Likert’s scale to determine the suitable milestones to be used as NDD red flags in Malaysia. Fifty-six new items were developed for four domains: Motor Development (Gross and Fine Motor), Speech and Language Development, Social-Emotional Development, and Cognitive Development. Each item was asking for corresponding milestone were stated. Methods to assess each item were also listed out.

In Stage Two, the newly developed 56 items were then built into a mobile application (Spark@grow) by computer science personnel, containing features such as developmental screening items, pictures and video demonstrations, and brief reports. In Spark@grow, there were two types of items: parents’ proxy report items and interactive games.

Stage Three was a pilot study to examine the feasibility and user-friendliness of Spark@grow via cognitive interview and User-Experience Questionnaire. Fifty-six Malaysian parents (mean age = 21.17, SD = 1.12) with various ethnicities and income levels were recruited from Klang Valley. They conducted developmental screening on their children (age between 0 to 23 months) using Spark@grow. Then, they rated the user-friendliness of Spark@grow and the researcher conducted one-on-one cognitive interviews with them.

Results: Spark@grow was reported easy to used by the participants (e.g., Perspicuity subscale, $M = 1.70, S.D. = 0.90$). All 56 participants were able to download and use Spark@grow to complete the developmental screening independently without additional guidance on the general operation. They also had no trouble recalling their children’s attainment of milestones and providing specific examples of those
attainments. Most items were found to be easy to understand and relevant to their children’s development by the participants. The interactive games were also found to be feasible for some children. However, some items needed to be amended to improve their clarity and relevance. Alternative assessments (for interactive games) should also be provided to children who had not been exposed to smartphones before.

Conclusions: Spark@grow was both feasible and user-friendly for parents of 0- to 23-month-old children in Malaysia. It had great potential to improve the effectiveness of developmental screening in Malaysia.

**403.189 (Poster) Dutch and Romanian Teachers’ Attitudes Towards Inclusive Education Related to Self-Efficacy, Burnout, and Autism Knowledge and Stigma**

A. K. Smir, P. J. Hoekstra, A. de Bildt, and F. Kalambayi, (1) Accare UCKJP, Groningen, Netherlands, (2) Department of Child and Adolescent Psychiatry & Accare Child Study Center, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, (3) Department of Child and Adolescent Psychiatry & Accare Child Study Center, University Medical Center Groningen, Groningen, NETHERLANDS, (4) RAA, Bucharest, Romania

**Background:**

Inclusive education endorses autistic children’s rights to receive the support needed to achieve their full academic potential. It has its roots in social justice and attempts to move away from a medical classification model of care needs. Instead, it promotes inclusive societies, social participation, and the value of diversity. Knowledge and beliefs about the etiology of autism may be associated with attitudes towards inclusive education.

**Objectives:**

We aimed to examine factors that potentially impact the success of teacher training to increase autism knowledge and reduce stigma in two European countries. We focused on teachers’ attitudes concerning core perspectives, expected outcomes and classroom practices for inclusive education and self-efficacy, as these are known to be important for inclusive education. We hypothesized that less self-efficacy, less autism knowledge, more autism stigma, more student-related burnout, not knowing autistic persons outside of work, less teaching experience, no (post)master’s degree in Educational Needs, and demographics (being a teacher versus a trainee, working in special education, country, and sex) would predict teachers’ negative attitudes. Also, we hypothesized that the negative effects of no (post)master’s degree, working in special education, and more student-related burnout on teachers’ attitudes would be partially mediated by lower self-efficacy. For country and sex, we had no specific expectations for the direction of effects.

**Methods:**

Dutch and Romanian teachers and trainees \((N = 1509)\) reported their attitudes, self-efficacy, burnout symptoms, autism knowledge and stigma, teaching and training experience, and several demographic factors. Path analysis with manual backward selection indicated which teacher- and work-related factors were associated with teacher attitudes concerning core perspectives, expected outcomes and classroom practices for inclusive education.

**Results:**

Teacher’s attitudes towards classroom practices associated with inclusive education were more negative than their neutral attitudes towards core perspectives and expected outcomes. Attitudes differed depending on whether participants were Romanian or Dutch and a teacher or a trainee, mediated by self-efficacy. Most predictive for a negative attitude towards inclusive education were having low self-efficacy, autism stigma and reporting student-related burnout. Self-efficacy mediated the effect of burnout.

**Conclusions:**

We now have a better understanding of which factors are related to teachers’ attitudes towards inclusive education for autistic students in different populations. Our results confirm that teachers who perceive themselves as effective teachers are indeed those who have positive attitudes towards inclusive education. In addition, teachers who have positive attitudes are those who experience little or no student-related burnout and those who do not subscribe to stigmatizing ideas about autism. When implementing inclusive practices in primary and secondary education, policy makers and care professionals should focus on making teachers feel efficient and energized in addition to preventing or correcting misconceptions about autistic students.

**403.190 (Poster) Educational Experiences of Marginalised Children and Their Families**

P. Perepa, K. Guldberg, and S. Wallace, (1) University of Birmingham, Birmingham, UNITED KINGDOM, (2) University of Birmingham, Birmingham, United Kingdom
Background:

The autism research community is increasingly aware that certain groups are often marginalised from community settings (such as schools) because of their status in terms of ethnicity, language and socio-economic status. They are also a voice that is often absent from research studies. Education performance in the general UK school population varies depending on the ethnic background of students, the area of the country the school is located and whether parents have achieved in their own schooling (Boag-Munroe and Evangelou 2012). Moreover, given the current climate with Covid-19, children in the UK from these often-marginalised groups were identified by UNICEF (2020) as those who experienced the greatest negative impact on their education.

Objectives:

This England based study focused on children and families who are marginalised because of four reasons; (1) belonging to minority ethnic communities, (2) whose first language is not English, (3) families from poorer socio-economic backgrounds, (4) and children who are in social care. The main objective of the research was to understand the educational experiences of families belonging to these communities and to understand the experiences of educational staff in supporting these children and their families.

Methods:

Online interviews were conducted with 21 parents from various parts of England. Online questionnaires were used to collect data from 11 local educational authorities and 27 teachers with follow up interviews with 20 educational professionals.

Results:

Descriptive statistics and thematic analysis was used to analyse data produced from questionnaires and interviews. Our data shows that educational professionals feel that they face specific challenges in communicating with families from marginalised communities. They also feel that families belonging to minority ethnic communities are less accepting of their child’s autism. Lack of teachers’ knowledge about diversity and autism and limited resources have been identified as main barriers in supporting such children and their families. Most parents in this study have expressed that their families had negative experiences in the education system. This was mainly the result of limited knowledge amongst the staff and lack of inclusive practice. Families reported they felt stigmatised by teachers/schools as well as wider community. Positive experiences were often the result of finding a ‘good’ professional.

Conclusions:

The results indicate that parents from marginalised backgrounds feel discriminated at multiple levels and are often misunderstood by educational professionals. It appears that there is difference of views between both sets of participants as to where the problems lie, with educational professionals sometimes blaming families. There is a clear need for better knowledge amongst school staff about the impact of cultural, linguistic and social economic backgrounds on the experiences of children and their families. More research is required in this area to develop principles of good practice for working with marginalised families, especially in the current climate of limited economic resources.

403.191 (Poster) Eight Years on : Training Professionals in Autistic Girls and Women in Hispanic Countries
C. I. D’Agostino1,2 and L. Echenique, (1)Universidad Caecce, Universidad de Buenos Aires, Mujeres TEA, Buenos Aires, Argentina, (2)Universidad de Buenos Aires, Buenos Aires, Argentina, (3)Grupo Cidep, Mujeres TEA, Buenos Aires, Argentina

Background:

Awareness and recognition of the presentation and diagnosis in autistic girls and women (AGW) is relatively recent. Additional language barriers might present in those countries where updated research findings and training of professionals is not widespread like many Hispanic-American countries. As many experts reported, training and education of the presentation and research findings along with experience, is one of the roads for a better identification and equity in autism. We report a project of 8 years for AGW.

Objectives:

We analyzed quantitative descriptive data from for awareness, support and training for professionals in AGW, in collaboration with autistic women (AW), and mothers of autistic girls (AG) from 2014-2022. The project has three main areas, empowerment for AW, support for mothers of AG and training for professionals working with AGW.

Methods:
We conducted a year to year analysis of all the actions in each domain to assess results to have an estimate of the impact in Hispanic professionals from different countries.

Results:

4 AW Voices Symposium with 10/15 AW participating in each one. A total of 40 AW participated and collaborated in the training project, symposiums and university courses. Online support group was the first in Spanish and with over a 100 international members.

Online support mothers groups during 8 years had an average of 1100 members. In 2021-2022, 12 online meetings were set up with 300 participants from 5 countries. The group was coordinated by mothers of AG the focus for the meetings were support, caregiver care and quality of life.

Professional trainings we delivered in short courses (8hr.) with an average of 2 per year, total 16, with over a 1000 participants 2014-2022. A University Diploma (100 hr.) training in person in 2019 and online in 2022. A University Program (50 hr.) online in 2020, 2021, 2022 due to COVID. Over 170 professionals participated in the 50 hr. courses online from 11 countries, and another 97 participated in the 100 hr. course from 12 countries. Additionally, over the 2014-2022, we delivered over 30 short conferences in 8 countries with a total of 2000 participants and collaborated with more than 10 Universities, and 15 organizations. More than 30 professionals participated from Spanish speaking countries. Overall 3277 professionals participated.

In the time frame analysis, the amount of professionals interested in AGW grew exponentially, and awareness and services became more available in different Spanish speaking countries. We are still collecting ongoing data analysis to have a map, directory and distribution of professionals and services.

Conclusions:

Barriers to the access to diagnosis and support for AGW are common worldwide, but some countries might be more advanced than others in putting research intro practice. Language was a barrier for many Spanish speaking countries at the beginning of the project. After 8 years, the area of AGW with autism is installed in the scientific, academic, and advocate agenda in many Spanish speaking countries and in an ongoing process. We suggest that many mid-and low income countries with language, economic, or cultural barriers might face similar challenges.

403.192 (Poster) Ethnicity and Language Information for Autistic Patients within the Asian Diaspora Is Limited in Healthcare Records

Background: Research on autistic individuals within the Asian diaspora is very limited. In large health systems, the electronic health record (EHR) should contain the information needed to support culturally responsive care and research about patients and families’ Autism experiences across the lifespan. Unfortunately, the widely used default “Asian” demographic variable in most US social systems (including EHR) lacks the inclusion of critical information that attends to the diverse experience within the Asian diaspora (e.g., ethnicities, languages). Identifying family’s cultural identities and experience have shown invaluable in supporting culturally responsive autism care for providers (e.g., help-seeking behaviors, treatment choices). Identifying what is present and missing is a critical first step toward building a social system that is inclusive and responsive to all identities of Autistic individuals within the Asian diaspora.

Objectives: First, we set out to determine what demographic information could be found within the EHR to potentially describe the intersectional experience of the families of Autistic children from the Asian diaspora. Second, the reliability and validity of documentation related to referrals, diagnostics, and intervention were examined.

Methods: Participants came from a published toddler cohort of 25,999 children (Guthrie et al., 2019). Fifty-three children were both Autistic and identified as “Asian” in their EHR. Manual chart reviews were conducted on all 53 and identified any reference to referrals from progress notes, diagnostics, direct evaluation reports, or scanned external documents, per Wong et al.’s (2023 INSAR abstract submission) methods. If dates were not explicitly reported, they were estimated with consensus from the study team. Each chart review took at least 45 minutes. 10% of records were reviewed twice.

Results: Specific demographic information was inconsistently documented in the EHR, even if the family had immigrated relatively recently or was multilingual. We could not identify any documentation of specific ethnicity (i.e. country of origin before migrating) for 24.5% of families (Table 1). Similarly, family language information was inconsistently recorded. For example, of the 53 in the sample, 58.5% were multilingual. Of these, 13.2% routinely asked for an interpreter, 83.9% did not. While at least 10 different Asian languages were identified, many families’ specific languages were not documented. Regarding clinical care, like Wong et al., we found high rates of
reliable documentation for Autism diagnostic evaluations (inter-rater reliability on 10% of records was >90%), but not for the dates of general intervention initiation, Autism diagnostic referral or for Autism-specific interventions (inter-rater reliabilities were below 60%).

Conclusions: The Asian diaspora is often excluded in research and practice. Illuminating what’s absent is as critical as what’s available in the EHR system to improve cultural responsiveness in current healthcare practices with the diverse Asian diaspora. A sample of 53 children does not reflect the entire community. However, our preliminary results highlight that culturally responsive information was inconsistently recorded or completely missed. Next steps include (1) understanding how demographic information is collected at healthcare visits, and (2) qualitatively analyzing progress notes and other documentation to describe the families’ experience from screening to diagnosis to intervention.

403.193 (Poster) Evaluating the Caregiver Skills Training Program for Ethiopian and Eritrean Immigrant Families of Children with Autism
W. A. Zeleke1, S. Dababnah2 and P. Dixon3, (1)Counseling, Psychology and Special Education, Duquesne University, Pittsburgh, PA, (2)University of Maryland, Baltimore, Baltimore, MD, (3)Autism Speaks, Ann Arbor, MI

Background:
Compared with children of US-born parents, children with autism spectrum disorder (ASD) in immigrant families confront unique challenges in accessing healthcare services. One of the main challenges is limited access to quality parenting programs that may improve child outcomes, decrease parent stress, and increase parent efficacy. In addition to stressors commonly affecting families raising children with autism, immigrant families often experience some unique stressors, including trauma and negative cultural attitudes toward autism. Thus, family-centered, culturally responsive, trauma-informed approaches are critically needed to serve these vulnerable populations. Furthermore, among the largest and fastest-growing immigrant populations in the US are the Ethiopian and Eritrean Americans. For these immigrant families, navigating the healthcare system and accessing services for their members with ASD could be a daunting experience. The World Health Organization Caregiver Skills Training (CST) program has been implemented in the Ethiopian context (Tekola et al., 2018). Yet, no published literature has focused on Ethiopian immigrants in the US or elsewhere.

Objectives:
To explore the acceptability and feasibility of an adapted version of a 12-session manualized program among Ethiopian and Eritrean immigrant caregivers raising children with ASD (ages 2-9) in the US. This project aims to support Ethiopian and Eritrean immigrant families of children with ASD to increase their quality of life and reduce stress.

Methods:
We used mixed methods to adapt, pilot, and evaluate CST for Ethiopian and Eritrean American immigrant families. We formed an advisory board composed of Ethiopian and Eritrean parents, community leaders, providers, and other stakeholders to review the CST manual and provide recommendations for program adaptations. We also recruited four Master Trainers to pre-pilot CST and trained three facilitators for the pilot phase. The trainers delivered the program to five groups of parents (N=30). Participants completed pre-post measures on parenting stress, anxiety, depression, and coping; autism knowledge; family empowerment; child behavior and communication; and feedback forms after home visits and group sessions. The Master Trainers collected attendance data and completed feedback forms after each group session. Finally, we conducted post-program focus groups with participants, Master Trainers, and facilitators.

Results:
This study has completed data collection and is in the data analysis phase. We will present CST feasibility and acceptability results for the Ethiopian and Eritrean American communities based on integrated data from the focus groups, attendance, and post-session feedback forms. Our preliminary analyses have found overall high acceptability of program content. Suggestions for improvement included refining the Amharic translations and providing options for parent self-care.

Conclusions:
We undertook a significant stakeholder-engaged process to adapt, pilot, and evaluate an intervention aimed at Ethiopian and Eritrean immigrant families raising autistic children in the US. The results of this study can inform future efforts to deliver culturally responsive psychoeducation to diverse families raising young children with autism.

403.194 (Poster) Examining the Potential for Future Educators to Combat Autism Stigma in Their Communities through a Cross-Cultural Lens
**T. Antony**, D. Williams, G. Y. H. Lam, J. MacCormack and K. Gillespie-Lynch, (1)College of Staten Island CUNY, Staten Island, NY, (2)Department of Educational and Psychological Studies, The Chinese University of Hong Kong, Tampa, FL, Hong Kong, (3)University of Lethbridge, Lethbridge, AB, Canada, (4)Department of Psychology, CUNY Graduate Center, Staten Island, NY

Background: Family members of autistic people experience stigma, which may be heightened in some Asian cultures due to pressure to conform to social norms (Liao et al., 2019). High academic pressures may contribute to stigma towards families of autistic people in Hong Kong (HK; Mak & Kwok, 2010). Future educators may be uniquely situated to help autistic people and their families combat stigma. Experience educating autistic students can foster beliefs and practices that are vital for combating stigma (Segall, 2008).

Objectives:

1) Examine if prior experience educating autistic people influences preservice teachers’ confidence educating autistic people in HK and Canada,

2) Evaluate if prior experience and country impact beliefs about how community members treat family members of autistic people,

3) Explore beliefs about clinicians/educators’ influence on attitudes toward autistic people in their communities in HK.

Methods: Preservice teachers from HK (n=57) and Canada (n=56) answered: “How confident are you in your ability to interact with an autistic person as an educator/support staff?”, “Have you been an educator for autistic people in the past?” and: “How do people in your community/ies treat family members of autistic people?”. Participants from HK (n=35) answered, “How do clinicians and educators influence attitudes toward autism in your community/ies?”. Responses were coded after inter-rater reliability > 80% was reached for 20% of the data. Reliability wasn’t obtained for one code, excluded from analyses.

Results:

Preservice educators in HK (53%) were more likely to report experience educating autistic people (24%; p=.002) but less confidence educating autistic people (M=3.51, SD=.928) than participants in Canada (M=3.96, SD=.719 ; p<.001).

Participants in Canada were less likely to say family members of autistic people were treated with pity/sympathy (p=.008) and more likely to say they were treated indifferently (p=.007) than Hongkongers (Table 1). Participants in both countries with experience educating autistic people were more likely to state that community attitudes towards family members were negative than those without experience (ps<.05).

Most respondents thought clinicians/educators had a positive effect on community attitudes towards autism (Table 2). Although the question asked about community attitudes, many shared how their own attitudes changed through the influence of clinicians/educators or through experiences as an educator (e.g. “There are psychologists explaining autism..makes me more empathetic” or “I’ve learnt how to get along with them and have become more accepting…”).

Conclusions: Preservice teachers in HK reported less confidence educating autistic people than peers in Canada, despite more experience, suggesting limited training and/or challenging working conditions. Preservice teachers with experience educating autistic people in both Canada and HK were more aware of negative community attitudes towards family members of autistic people than those without experience. They believed that clinicians/educators have a positive effect on community attitudes. These findings suggest that educators are potential agents of change in their communities when it comes to combating stigma against autistic people and their family members, but need support.

---

**403.195 (Poster) Exploring International Differences to Sentencing Settings and Practices for Autistic Individuals: A Qualitative Comparative Study**

Background: Autism and criminal justice system intersections are garnering increasing attention, and sharing best practices and models across nations is critical for improving outcomes. Innovative policies and programs are emerging globally that are rooted in rehabilitation and offer an evidence base for adaptions within varying justice systems and nation-specific contexts. A key driver for international differences in justice systems involves how nations prioritize rehabilitation versus punishing convicted offenders. Some nations, like the
United States tend to opt for more punitive sentencing options. Scandinavian countries, however, often emphasize diversion and rehabilitation. For autistic individuals who interact with the justice system frequently, the approach each nation takes is consequential, especially as individuals become further enmeshed in the justice system. Research has demonstrated that incarcerated autistic individuals find prison experiences to be overwhelmingly and uniquely negative with frequent victimization from other inmates and high rates of self-harm.

Objectives: The objectives of this study are to examine and discern differences in sentencing settings and practices across nations to inform best practices.

Methods: Field leading experts collaborated in a qualitative comparative study to document and contrast sentencing settings and practices for autistic offenders in nations around the world. Correctional institutions from the state of Pennsylvania in the United States were included, along with institutions in various Scandinavian countries.

Results: Within Pennsylvania, where the justice system is the primary response to illegal activities, even by autistic individuals, there is significant variability between how, and if, state correctional institutions provide accommodations and support. This variability is reflective of the even more stark differences that occur in settings at the local, state, and federal levels of the United States. Although notable variations exist between Scandinavian countries, experts determined that the greatest differences were between Pennsylvania and Scandinavia overall. For instance, rehabilitation was prioritized through mandatory care practices in Norway and sentences for care in Sweden. In Norway, a national forensic unit is responsible for treatment and risk management for all persons convicted to mandatory care. After a relatively short stay in a specialized institution, autistic individuals are established in their home district in a specially adapted home under national unit supervision. In Sweden approximately 60% of all serious offenders with autism are referred to forensic psychiatric care. However, current legislation contributes to significant lengths of stay and autism awareness among staff is varying.

Conclusions: As the autistic population ages and high rates of contact with the justice system continue, varying sentences contribute to differential re-entry outcomes. Results from this study indicate that more rehabilitative practices are occurring in Scandinavian correctional institutions, compared to Pennsylvania. However, certain institutions in Pennsylvania are shifting significantly and implementing reforms to better mirror Scandinavian counterparts. These changes are rooted in rehabilitating convicted offenders to better transition back to communities post-sentencing. As Scandinavian institutions offer guidance for other nations to adopt, the reforms occurring in Pennsylvania institutions can inform needed changes to settings in the nation with the largest prison population.

403.196 (Poster) Understanding the Perspectives of Autistic Bilingual Children
R. V. Davis, R. Morris, S. Fletcher-Watson and A. Sorace, (1)Queen Margaret University, Edinburgh, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom, (3)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, UNITED KINGDOM, (4)Department of Linguistics, University of Edinburgh, Edinburgh, United Kingdom

Background:

There are unfounded concerns among parents and practitioners that bilingualism may be harmful for autistic children. As a result, many autistic children are being denied access to dual language learning. These concerns are not based on evidence, and research suggests that bilingualism could confer some advantages in cognitive and social domains and wellbeing. However, research to date is limited and disregards the child’s own lived experiences of bilingualism. Important questions remain about how autistic children view the impact of bilingualism on their cultural identity, community inclusion and quality of life.

Objectives:

The aim of this research is to understand the perspectives of autistic bilingual children with a focus on cultural and linguistic experiences. In order to do this, we co-created an autism-specific interview tool with members of the autism community, families and practitioners.

Methods:

Twelve participants (aged 8-17 years, 5 male, 7 female) were recruited. Participants were based in the UK and had received a diagnosis of autism. The interview tools were co-produced with parents, practitioners, and a Young Researcher advisory group; a group of three autistic bilingual young people, aged 19-21 years. Three iterations of the interview tool were designed to accommodate a wide range of communication and support needs, including minimally verbal young people. Participants completed one of the following: a talking interview, an activity-based interview, or a simplified activity-based interview. Areas of focus for the interview tool were:

- Exploring children’s understanding of being autistic and bilingual
- Family and sibling dynamics
- Everyday life experiences including friends and hobbies
• Situation-dependent language use and emotion-dependent language use

Results:

The interview data of nine participants with a sole diagnosis of autism were analysed using thematic analysis. Interview data of autistic participants with an intellectual disability were analysed using interpretative phenomenological analysis.

The emerging results show that bilingualism plays a key role in the identity of the participants. The interviews demonstrated the value of exposure to the family language as an additional means of self-expression for younger participants, and as a means of fostering relationships and communication with non-English-speaking relatives for older participants. Participants who were confident using their family language were able to demonstrate a deeper understanding of their culture and family. Those who were less fluent expressed a desire to improve their family language so they are better able to engage with their relatives. Participants with an intellectual disability comfortably switched between speaking English with their interviewer and family language with their parents, providing them with clarification and comfort during the interview.

Conclusions:

There is a wealth of information and insight that can be offered by autistic bilingual children regarding the value that bilingualism brings to their lives and the challenges that come with it. This is the first study to examine the experiences of autistic bilingual children outside of a school setting. The results from this study will ensure that families and practitioners consider the importance of children’s relationships with their cultural identity and the role language plays in that experience.

403.197 (Poster) Toddler Autism Symptom Inventory (TASI) in Spanish: Preliminary Results of a Validation Study

Background: Best practices for detection of autism spectrum disorder (ASD) symptoms in early childhood integrates assessment of the child’s usual behaviors through parent report with a clinician’s behavioral observation. The most commonly used diagnostic interview in research, the Autism Diagnostic Interview, Revised (ADI-R), has limited utility for very young children, and it is costly and labor intensive to learn to administer and code reliably. Further, it covers the lifespan, rather than targeting symptom expression in toddlers. The Toddler Autism Symptom Inventory (TASI) is a parent interview tool to assess autism symptoms in children ages 12 to 36 months, with good inter-rater reliability, easy to administer, and affordable. However, its use has been limited in other languages is essential to promote global equity in ASD diagnosis.

Objectives: To determine the preliminary psychometric properties of the Toddler Autism Symptom Inventory (TASI) in Spanish.

Methods: We recruited 51 toddlers (Nmale=30, Mean age=2.6 y, SD=0.72) and their parents who attended diagnostic evaluations after screening “at risk” on M-CHAT-R/F through a research study either in Monterrey, Mexico (N=38) or Texas, USA (N=13). We collected demographic information to characterize the sample. The diagnostic evaluation included a developmental assessment (Merrill-Palmer for Monterrey subsample, and Mullen Scales of Early Learning for Texas subsample), and an autism-specific assessment (Autism Diagnostic Observation Schedule, 2nd ed., ADOS-2) and the Toddler Autism Symptom Inventory (TASI) in Spanish. Experienced bilingual clinicians conducted all evaluations. A 2x2 table was generated to calculate sensitivity and specificity of the TASI.

Results: From the 51 children who were assessed, 42 were diagnosed with ASD, 5 with developmental delay, one with language delay, and 3 were typically developing. Sensitivity for the TASI in Spanish was 100% and specificity was 33.33%.

Conclusions: The TASI in Spanish was useful in collecting parent report for ASD-related symptoms, with a sensitivity of 100% in a sample of children who had screened at risk. However, specificity was unacceptably low (only 3 of 9 nonASD cases were correctly classified); differentiating ASD from other developmental delays is critical for the TASI’s utility. Future research will evaluate TASI in a larger sample of children who do not have autism, and will examine performance of specific TASI items and domains, in order to identify areas where additional cultural adaptation may be warranted.

403.198 (Poster) Impact of Autism-Related Stigma on Social Camouflaging: A Cross-Cultural Study
Background: Social camouflaging (Hull et al., 2017) is the strategy used by autistic people to hide or mask their autistic traits. Camouflaging contributes to social adaptation and leads to extreme fatigue, depression, and anxiety. Previous studies have suggested that camouflaging is a response to autism-related stigma, but there are very few quantitative studies investigating their relationships.

Objectives: This study aimed to quantitively investigate the relationships between camouflaging and autism-related stigma drawing on Social Identity Theory (Cooper et al., 2017; SIT). We established four hypotheses: 1) Perceived stigma positively predicts camouflaging, and 2) Individualistic strategy use seems to be similar to camouflaging and positively correlates with camouflaging. Conversely, collective strategy use seems to be the opposite of camouflaging; it negatively predicts camouflaging. 3) Camouflaging mediates the negative impact of stigma on the mental health of autistic people. 4) The degrees of camouflaging and perceived stigma differ by cultural, social, and ethnic background.

Methods: This study is a quasi-replication of the study conducted by Perry et al. in 2021. We studied 287 individuals diagnosed with autism spectrum disorder aged between 20 and 63. The participants completed an online survey regarding their social camouflaging, perceived stigma, strategies against stigma, depression, generalized anxiety, social anxiety, and mental well-being. Two multiple regressions were run for hypotheses one and two, investigating the effect of stigma on camouflaging and strategy use. Four mediation models were employed to test hypothesis three. For hypothesis four, we used two-sample t-tests for summary data to compare participants of our study with those of Perry et al.’s.

Results: Stigma (B=2.43, p<0.001) and individualistic strategy use (B=0.84, p<0.001) positively predicted camouflaging of autistic people. Contrary to our hypothesis, collective strategy use has also positively correlated with camouflaging (B=0.19, p=0.02). The results of mediation analyses showed that camouflage mediated relationships between stigma and depression (99% CI 0.06 to 0.08), generalized anxiety (99% CI 0.02 to 0.04), and social anxiety (99% CI 0.021 to 0.024). However, there was no significant mediation effect on the relationship between stigma and mental well-being (99% CI -0.14 to 0.09).

The results of two sample t-tests for summary data suggested that Japanese people had less perceived stigma (t=-9.21, p<0.001), less camouflaged (t=-8.00, p<0.001), had more negative well-being(t=-4.95, p<0.001). Moreover, compared to western people, the Japanese tended to use individualistic strategies against stigma(t= 5.43, p<0.001).

Conclusions: The results supported the hypothesis that camouflage response to stigma. In the framework of SIT, camouflage was considered to be very similar to the individualistic strategy. However, it might be a more multifactorial concept. The negative impacts of stigma on the mental health of autistic people were due to increased camouflage, at least in part. Compared with the results of Perry et al.’s study, the degrees of perceived stigma, camouflaging, and mental health conditions of autistic people might differ by cultural, social, and ethnic background.

403.199 (Poster) Implementation Drivers for Improved ASD Educational Service Delivery in South Africa
S. Pillay, P. J. de Vries and M. Duncan, (1)Health Sciences, Centre for Autism Research Africa (CARA), Cape Town, South Africa, (2)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Occupational Therapy, University of Cape Town, Cape Town, South Africa

Background:
Educational systems in South Africa are challenged with meeting the needs of children with autism spectrum disorder (ASD) and many children are out of school or inappropriately placed in the system. Therefore, a whole systems analysis of the ‘hardware’ and ‘software’ elements of the education system for children with ASD was performed to generate data informed recommendations for ASD educational service improvements.

Objectives:
The objectives of the study were to understand the landscape of education for children with ASD and to generate evidence-based recommendations to strengthen ASD educational service delivery.

Methods:
An exploratory mixed-methods approach was used across two phases. The first quantitative phase described the profile of children with ASD in the education system as well as those waiting for educational services. The second qualitative phase examined stakeholder perspectives of current ASD educational and other services and recommendations for service improvements.
Results:

Synthesis of findings across the study generated six key actions for service improvements that included a) designing and implementing early intervention programmes, b) developing curricular to accommodate a range of diverse learning needs, c) inclusion of children with ASD across the education system, d) creating a dedicated rural inclusive ASD plan, e) developing transectoral planning, monitoring and evaluation systems and f) developing integrated policies for ASD. Implementation drivers including competency drivers, leadership drivers and organizational drivers could potentially translate these actions into practice for improved ASD service delivery.

Conclusions:

The six actions generated in this study aligns with the Lancet Commission Report on the future of care and clinical research in autism and if implemented could go a long way in improving services for children with ASD and their families in South Africa. Findings from this study may have relevance to other low- and middle-income countries.

403.200 (Poster) Implementation of the Echo Autism Model in North Macedonia: Understanding Professional Development Needs and Barriers for Educators in the Classroom and Beyond

Background: The estimated prevalence of autism spectrum disorder (ASD) worldwide is approximately 1 in 100 children (1). In Eastern Europe, research is limited, including in North Macedonia. There is a dearth of specialists and decreased access to evidence-based practices for clinicians and educators. The Project Extension for Community Healthcare Outcomes (ECHO) framework represents an innovative solution for building capacity for best-practice in healthcare and education for autistic people. ECHO Autism leverages technology to train community-based clinicians or educators through mentoring, case-based learning, and guided practice. The ECHO Autism model is an innovative global model that adapts to local and regional norms and constructs. The model supports local professionals working with autistic people from childhood to late adulthood. In December 2021, 70 CVETOVI ECHO Autism, a hub of ECHO Autism Communities, launched a pilot project to increase access to evidence-based practices for educators in North Macedonia and Europe.

Objectives: 70 CVETOVI ECHO Autism’s objective is to increase access to evidence-based practices for educators in Europe. This pilot project aims to decrease disparities in knowledge and training of professionals in the education and medical fields and increase access to best-practice care for individuals with autism throughout the region.

Methods: 70 CVETOVI ECHO Autism’s team of specialists includes developmental-behavioral pediatrics, speech and language pathology, child psychiatry, and psychology. It meets monthly and includes a de-identified case study from one of the participating schools, followed by a discussion with the hub team and participating professionals, and an autism-focused didactic to reinforce specific knowledge. Didactics have been selected based on participant-identified need and include: the Project ECHO model; autism & co-occurring conditions; apraxia; strategies for the classroom for deaf autistic children; and management of challenging behaviors and tics in the classroom.

Results: To date, 70 CVETOVI ECHO Autism includes 7 sessions with 149 attendees from 8 different countries. Forty-two percent of participants are therapists, 27% physicians, 19% mainstream educators, 18% special educators, and 4% autism advocates. Didactics have focused on strategies to support educators in the classroom. Data collection is ongoing for qualitative feedback from participants.

Conclusions: ECHO Autism is a feasible and acceptable model to increase access to evidence-based practices with professionals in Europe. To our knowledge, 70 CVETOVI ECHO Autism is the first in Europe and is well received by educators. The ECHO Autism program in North Macedonia demonstrates the adaptability of the model to reduce disparities across cultures and professional disciplines. Future directions include adding educators to the hub team as well as improving access to screening and diagnostic protocols in the educational setting.

403.201 (Poster) Implementation of the Echo Autism Model in Poland

A. Rynkiewicz, A. Mazur, K. Plata-Nazar, I. Luckar, A. Ossolińska, A. Słopień and A. Pieniążek, (1)Department of Psychiatry, College of Medical Sciences, University of Rzeszow, Rzeszow, POLAND, (2)Center for Diagnosis, Therapy and Education SPECTRUM ASC-MED, Gdansk, Poland, (3)Department of Pediatrics, College of Medical Sciences, University of Rzeszow, Rzeszow, Poland, (4)Department of Pediatrics, Endocrinology and Diabetology, Clinical Hospital № 2, Rzeszow, Poland, (5)Department of Pediatrics, Gastroenterology, Allergology and Nutrition, Faculty of Medicine, Medical University of Gdansk, Gdansk, Poland, (6)Department of Developmental Psychiatry, Psychotic and Geriatric Disorders, Medical University of Gdansk, Gdansk, Poland, (7)Students Research Club, Department of Psychiatry, College of Medical Sciences, University of Rzeszow, Rzeszow, Poland, (8)Department of Child and Adolescent Psychiatry, Poznan University of Medical Sciences, Poznan, Poland, (9)College of Medical Sciences, University of Rzeszow, Rzeszow,
Background: The Extension for Community Health Outcomes (ECHO) Autism model is now for the first time introduced in Poland (Rynkiewicz et al. 2022; Sohl et al. 2022). ECHO Autism is disseminated globally due to its flexibility in adapting to local and regional differences in social norms and constructs. The model supports local professionals working with patients with autism spectrum disorder (ASD) from childhood to late adulthood. ASD is more common among males than females where autistic females still represent a highly underestimated and underserved group of ASD patients. Especially adult autistic women, are particularly affected by insufficient knowledge and shortage of trained specialists (Karavidas & Visser, 2022; Moseley et al. 2021). Standard curriculum in medical schools and professional development curriculum for general clinicians in Poland often lacks specificity in core elements of ASD and standardized instruments used in ASD assessment.

Objectives: The project aims to train professionals in best-practice care of ASD patients and guided practice on the comorbidities in ASD, with main focus on underserved population of autistic females. It also aims to train in the standardized assessments of ADI-R and ADOS-2, creating the meaningful collaboration between global ECHO Autism teams.

Methods: In mid-2022, ECHO Autism Poland, a hub of ECHO Autism Communities, launched a pilot project to increase access to evidence-based practices and specialized trainings in standardized instruments: ADI-R (Autism Diagnostic Interview – Revised) and ADOS-2 (Autism Diagnostic Observation Schedule, Second Edition) for clinicians in Poland. Both instruments have been available in clinical practices in Poland only in recent years: ADI-R since 2021, ADOS-2 since 2017. Subject matter experts of Polish hub include psychiatrists, pediatricians, child and adolescent psychiatrists, speech and language pathologists, educators, physical therapists, psychologists additionally to adult autistic individuals, their parents, grandparents and sibling which constitutes the fundamentals of this model.

Results: In the first 2-months circle of implementation of the project over 200 Polish professionals were trained in ADI-R and ADOS-2 by certified, internationally recognized trainers. Participants emphasized the opportunity to be able to develop strong multidisciplinary networks and collaborative partnerships across the sites.

Conclusions: For the first time, to our knowledge, the activities and results of ECHO Autism model in Poland are presented. This model has already created the network of collaboration among the local partners in Poland and global partners. ECHO Autism in Poland shows great promise to create the opportunities for meaningful collaboration between global teams and valuable cross-cultural learning.

403.202 (Poster) Improvement of Social Communication with Caregivers Skills Training Intervention in Argentinian Population - Preliminary Findings

M. B. Pertica and N. E. Granana, (1)Hospital Durand, Buenos Aires, Argentina, (2)Servicio de Neurología Infantil, Hospital Durand, CABA, Argentina

Background:

It is known that early intervention strategies may significantly improve the development of children with social communication impairments. In Argentina, such services in the public health system are scarce. In this context, parent mediated interventions could help reduce expand health services in an economically feasible way. Among such interventions, the Caregivers Skills Training (CST) is a family centered approach that focuses on training parents and caregivers in using daily living activities, routines and play activities as an opportunity for development and learning. This program comprises 3 individual home visits and 8 group sessions that address strategies to improve social communication, interaction, challenging behaviors and coping skills for caregivers.

Objectives: To assess the effectivity of CST intervention on social communication skills of children with neurodevelopmental disorders.

Methods: We report the preliminary findings of a 20 week follow up of children who received the CST intervention delivered remotely, as part of a randomized controlled trial. The sample (n=30) included minimally verbal children aged between 2-4,11 years old with social communication impairments. To assess social communication changes the Brief Observation of Social Communication Change (BOSCC) was applied at baseline (T1) and on the follow ups on weeks 12 (T2) and 20 (T3). Additionally, the Achenbach Child Behavior Checklist (CBCL) was administered on T1 and T3 to evaluate behavior.

Results: Out of the initial sample (n=30), 26 children (86%) completed the intervention and follow up assessments. Friedman test was conducted to determine whether BOSCC total score exhibited a reduction between T1, T2 and T3. The results show a significant difference χ²(2) = 15.235, p<.001; with total score means of T1 □=28,8; T2 □=24,8; and T3 □=23,26. A Wileoxon signed-rank test indicated no significant differences in CBCL measures between T1 and T3.
Conclusions: Preliminary data shows promising evidence that the CST intervention may improve social communication skills in children with neurodevelopmental disorders. The fact that most of the families included in the sample could complete the program, demonstrates the feasibility of a remote delivered parent mediated intervention that could help increase the access to early intervention.

403.203 (Poster) Title: Social Communication in Children with Chronic Malnutrition from 2 to 3 Years Old  
M. A. Vasconez Hidalgo and N. E. Granana1, (1)Asores Health Center, Ecuador Public Health Ministry, Cuenca, Ecuador, (2)Servicio de Neurologia Infantil, Hospital Durand, CABA, Argentina

Background:  
The assessment of autism spectrum disorders and social communication deficits in children from a population with chronic malnutrition is a relevant topic in the field of neuropsychology. Its detection would allow to arrive to an early diagnosis and implement interventions that help mitigate the difficulties in the development and well-being of the subjects.  

Objectives: To determine the risk of alteration in social communication and global neurodevelopment in children with chronic malnutrition.  

Methods: A sample of 94 children divided into 2 groups (47 with chronic malnutrition and 47 control group) was assessed. They were compared to a sample of 167 neurotypical children for the pilot study of the ASQ 3 validation in Ecuadorian population. The PRUNAPE, ASQ 3, ASQ SE 2, mChat and communication questionnaires plus ASQ 3 socio-individual area were used for the screening of neurodevelopment and social communication. Data analysis was made using the SSPS software.

Results:  
About 83% of the children presented risk of neurodevelopmental compromise and 25% presented a risk of global developmental delay. It was observed a greater affection in the gross motor area (51%), personal social autonomy (36%) and problem solving (28%), and to a lesser extent, in language (24%).

Conclusions: It was concluded that there was no significant association in social communication or autism in children with chronic malnutrition [χ2(1, n=47) =2.84, p=.09]. Malnourished children aged 2 to 3 years did have a higher risk of neurodevelopmental deficits compared to their neurotypical peers, in relation to their sociodemographic level [χ2(1, N=94) =40.89, p<.01].

403.204 (Poster) Lessons Learned from Adapting and Piloting the World Health Organization’s Caregiver Skills Training Program in Egypt  

Background: Despite progress to raise awareness of the global need for autism awareness and intervention, autism services continue to be inadequate in low- and middle-income countries. Studies in the Middle East and North Africa (MENA) suggest rising autism trends, yet studies in the region report specialist shortages, limited diagnostic tools in Arabic, and lack of culturally relevant interventions.

While the World Health Organization’s Caregivers Skills Training (CST) Program has been successfully adapted and evaluated in other countries with limited resources, the caregiver-mediated program has not been formally adapted and evaluated in the MENA context. A global partnership of autism intervention experts partnered with Egyptian colleagues to culturally adapt, train, and deliver CST to Egyptian caregivers of young autistic children.

Objectives: We will report on the process of adapting, training, and pre-piloting CST, a 12-session manualized intervention focused on child-directed play and engagement, home routines, social communication, positive behavior and emotion regulation, and caregiver well-being. Our presentation will focus on the first two aims of the project: 1) engage key stakeholders in the local implementation of CST; and 2) assess acceptability and feasibility of CST for Egyptian caregivers of autistic children ages 2-9.

Methods: We used mixed methods to carry out our research objectives. To accomplish Aims 1-2, we worked closely with contacts in the Egyptian Ministry of Health to identify and train “Master Trainers” to deliver CST and train and supervise non-specialist facilitators. Master Trainers were recruited if they worked within the public health system in Egypt. For Aim 2, the Master Trainers pre-piloted CST with groups of caregivers in three Egyptian cities (Alexandria, Asyut, and Cairo). Master Trainers collected attendance and demographic data. Our research team is in the process of conducting post-program interviews with groups of Master Trainers and participants.
Results: We trained 18 Egyptian providers on the CST program. Despite challenges associated with the COVID-19 pandemic, 12 Master Trainers delivered the program to five parent groups. The Alexandria, Asyut, and one of the Cairo groups were held in person. Master Trainers delivered two of the Cairo groups remotely. Fifty-two parents joined the program; however, 13 did not attend any sessions. Thus, 39 parents participated in CST across sites. Our research team regularly consulted with Egyptian stakeholders, including local researchers, service providers, and community advocates, on delivery and evaluation methods. We will discuss various challenges we encountered during the training and implementation processes, as well as the ways in which we addressed these obstacles. We will also present findings regarding Master Trainers’ and parents’ perspectives on CST’s acceptability and feasibility, based on data analyses of group interviews.

Conclusions: The “lessons learned” from developing and implementing a caregiver-mediated intervention in Egypt can be useful for informing future research in the MENA region and in other countries affected by limited resources and culturally relevant, family-centered interventions.

403.205 (Poster) Nonlinear, Multi-Element Behaviour Support for Autistic People: Conceptualisation, Assessment, and Intervention That Affirms Person-Centred and Culturally Diverse Practice in Australia

R. L. Beights and G. Potter, (1) The Centre for Positive Behaviour Support, Manly, QLD, Australia, (2) The Centre for Positive Behaviour Support (CPBS), Manly, QLD, Australia

Background: Conceptualization, assessment, and treatment of behaviors of autism spectrum disorder (ASD) span many disciplines and analytic explanations. Behavioral perspective to understand and treat ASD have largely focused on applied behaviour analysis (ABA) and a linear, operant paradigm. However, the traditional linear ABA paradigm often minimizes or ignores notable contextual variables and valuable outcomes from a person-centered, systematic framework. More importantly, a linear ABA paradigm may include aversive and restrictive practices that are damaging to the person and divisive within the larger autistic community.

Objectives: A nonlinear, multielement framework is an evidence-based ABA paradigm that champions strong clinical goals and ethical standards to improve behaviour and quality of life of autistic individuals in socially meaningful ways. Within Australia, the improvement of quality of life and reduction or elimination of restrictive practice is essential to supporting autistic people. The current presentation defines a nonlinear, multielement behaviour support (MEBS) framework for assessment and intervention for autistic participants within an Australian clinical setting.

Methods: A detailed, single-subject design analysis of assessment, intervention, and outcome was conducted for a sample of 5 representative participants from a larger lifespan sample of 30 cases. The analysis of MEBS procedures emphasized examination of independent variables of functional assessment strategies and proactive nonaversive intervention strategies. Primary dependent variables specified outcomes on episodic severity for behaviors of concern. Cultural variables are also highlighted within the MEBS assessment and intervention plans.

Results: Results support the use of a person-centered, MEBS framework to conceptualize behavioral presentations, reduce behaviors of concern, and improve quality of life.

Conclusions: Implications of these results point to recommendations for the implementation of MEBS, particularly for culturally diverse groups.

403.206 (Poster) Stakeholder Perspectives on Including Children with Autism and Developmental Disabilities in Mainstream School Settings in Ethiopia

E. Genovesi, I. Ahmed, F. Girma, M. Ayele, C. Hanlon, and R. A. Hoekstra, (1) Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (2) Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (3) School of Psychology, College of Education and Behavioral Studies, Addis Ababa University, Addis Ababa, Ethiopia, (4) Centre for Innovative Drug Development and Therapeutic Trials for Africa, and Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (5) Centre for Global Mental Health, Health Service and Population Research Department, and WHO Collaborating Centre for Mental Health Research and Training, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (6) Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, UNITED KINGDOM

Background:

Services for children with developmental disabilities (DD), including autism and intellectual disabilities, are limited in Ethiopia and a large gap in education provision has been identified (Tilahun et al., 2016), with most children with DD being out of school.

Objectives:
We aimed to explore stakeholder perspectives on ways to meet the education needs of children with DD in the Ethiopian capital city Addis Ababa and to address barriers and facilitators for including them in mainstream primary schools.

Methods:

We conducted 36 in-depth individual interviews and one interactive consultation workshop with caregivers of children with DD, primary school principals and teachers, health and education decision makers (national and local), clinicians, academics and representatives of relevant non-governmental organisations and special education centres. The topic guides focused on priorities and goals to improve education provision for children with DD and the barriers and facilitators to achieve these goals. We used thematic analysis to develop themes deductively, guided by the three dimensions of the Context and Implementation of Complex Interventions framework (Pfadenhauer et al., 2017): Context, Setting, Implementation.

Results:

All stakeholders affirmed the right to education of children with DD, although only a minority promoted inclusive education for all children with DD. Some thought that the latter was an appropriate goal for higher-resourced countries, but not Ethiopia. Many stakeholders suggested that children with mild and moderate DD should access inclusive classes, while special classes and schools are a better fit for those with severe and profound DD. Similarly, caregivers’ preference was typically for inclusive classes if their child’s disability was mild or moderate, and for special schools or units if it was severe or profound. Professional stakeholders reported that this is the model currently in use, though only accessible for a very small minority, while most children remain excluded or on school waiting lists. In the interactive workshop, stakeholders reached a consensus that the intervention goal should be to provide access to mainstream primary schools for children with DD in special units and inclusive classes, depending on individual abilities and needs. They considered it crucial that special units provided opportunities for growth across grade levels, compared to most existing special classes grouping children regardless of progression. According to indirect stakeholder reports, parents of neurotypical children and teachers often oppose the inclusion of children with disabilities in mainstream schools. Stakeholders reported that educating children with disabilities is low on the political agenda, with decision-makers prioritising the allocation of resources for schooling children without disabilities, a proportion of whom are still out of school. Consequently, stakeholders recommended activities to reduce stigma towards children with DD both within schools and in the broader community and advocacy campaigns to promote their education.

Conclusions:

Stakeholders affirmed the need to promote the education of children with DD in Addis Ababa and suggested a mixed model of inclusive and special education based on the complexity of individual needs. Stakeholder recommendations and reports of further barriers and facilitators will inform the development of an intervention for implementing such a model.

403.207  (Poster) Strategies to Support Trust Building for Increasing Diversity of Representation in Autism Research: A Rapid Review

T. Paul1, P. France2 and A. Kushki3, (1)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Autism Research Centre, Bloorview Research Institute, Bloorview Research Institute, Toronto, ON, Canada

Background: Autism research has historically excluded equity-deserving groups, especially Indigenous communities, racialized individuals, women, non-verbal communicators, and individuals with lower IQ scores, and continues to grossly lack diversity1. A barrier contributing to the underrepresentation of these groups in research is the lack of trust between many equity-deserving groups and the research community2. However, very little is known about strategies that can promote trust building in the context of research participation. To address this gap, we conducted a rapid review of the literature to characterise existing strategies for trust building with equity-deserving groups, especially focusing on racialized communities.

Objectives: To synthesize strategies that can be implemented to support trust building for increasing recruitment and retention of racially and ethnically minoritized (REM) groups in autism research in Canada and the United States?

Methods: We followed guidelines set out by Cochrane Collaboration for rapid reviews to systematically search and select publications that focus on our research question1. We included peer-reviewed English articles published in Canada and the United States. We extracted findings from eight publications. We grouped similar findings and strategies extracted from these publications to develop three categories (Fig. 1).

Results: The findings from our rapid review suggest that strategies that can support trust building with REM communities for recruitment and retention in autism research can grouped into three broad categories:

1. Partnering with community members throughout the research process (i.e., fostering an interconnected/bi-directional environment) by collaborating with community-academic partnerships, or community-based and/or advocacy organizations.
These partnerships can inform research design, design of research documents and materials (e.g., clear and easy to read consent forms with shorter sentences, bullet points, and visuals), and recruitment of local community leaders to reach REM populations.

2. Recruitment and training of trusted researchers from REM populations who share similar physical and socioeconomic characteristics and experiences.

3. Increasing trust and maintaining relationship at the researcher-participant level by collaborating with individuals’ trusted healthcare provider, sharing study findings in lay terms, ensuring contact from the research team is constructive and friendly, and maintaining a long-term relationship with the community organizations study participants belong to.

**Conclusions:** Our rapid review synthesizes the current knowledge on strategies that can increase trust building with racially and ethnically minoritized groups. Ensuring that research studies are designed to include individuals they claim to support, will result in research findings and services that are relevant to and impactful for a more diverse range of families.

### 403.208 (Poster) Teachers’ Beliefs about Autism Spectrum Disorder in Yemen

**S. Pu, S. M. M. Taresh, L. Morett, and N. A. Ahmad**

(1)Qiannan Preschool Education College for Nationalities, Qiannan, China,

(2)Universiti Putra Malaysia, Taiz, Yemen,

(3)University of Alabama, Tuscaloosa, AL,

(4)Psychology of education, upm, Malaysia, Malaysia

**Background:**

At a time when the world is moving towards integrating autistic youth towards adapting to working life, building a family, and participating in the labor market. Yemen is still facing the problem of accepting autistic children it is a particular need, not a demonic touch. Yemen is considered one of the low-income countries that suffer from poverty, ignorance, and the continuation of the war since 2015. These country conditions generally reflect on the public in Yemen, especially children with disability and special needs.

**Objectives:**

This study has attempted to look beneath the surface of the Yemeni beliefs regarding autistic children. Based on the data collected from 32 teachers (20–30/31–40/≥40 age) in the Taiz district,

**Methods:**

To achieve the aims of this study, The qualitative interview was carried out among 32 teachers recruited and interviewed in two sessions in their schools. A mixed method approach was used to understand Yemeni teachers’ reactions to receiving beliefs towards ASD. The interview time was around 30 to 60 min. A mixed-method system was considered for this study. A semi-structured interview schedule was prepared for the qualitative part, and teachers’ questionnaires were developed for the quantitative part. A thematic analysis approach was adopted, and the interviews were transcribed verbatim and were categorized according to their thematic contents. An Independent rater re-categorized the teachers’ responses, and 95% of consensus between the two independents was reported. Counting and using percentages and frequencies was considered integral to the analysis process in qualitative studies, and numbers were used to establish the significance of findings even with the qualitative method of analysis.

**Results:**

This study found that misconceptions about autistic children were strongly evidenced among teachers who are considered the most educated level in society. Based on the findings, it is argued that since Yemeni teachers had different explanations regarding their beliefs toward ASD, awareness campaigns must be conducted within a cultural context. To increase understanding of parents’ concerns and their need for educational and psychological services in cultures wherever autism is less well-known, undiagnosed, misdiagnosed, or even stigmatized, Studying how ASD is seen differently in different cultural contexts encourages stakeholders like service providers and politicians, to understand and value cultural and personal diversity in the twenty-first century.

**Conclusions:**

Due to personal ignorance and growing superstitions, these teachers tend to believe society’s perceptions of those children, thus resulting in the ignorance of scientific views. However, the mass media can increase this group’s awareness of autistic children by continually assessing the inaccurate statements of those children and correcting them. And by influencing the teachers to take a more conceptual scientific approach in serving their special needs students, informing teachers of children’s rights in everyday life in the future by providing children with an optimal chance of development through early intervention.

### 403.209 (Poster) The Caregiver Skills Training (CST) Program: A Feasibility Randomized Controlled Trial in Canada
Background: The World Health Organization Caregiver Skills Training (CST) Program is a recently developed caregiver mediated intervention that is currently being implemented and evaluated in over 30 countries. CST is a component of the WHO Mental Health Gap Action Program (mHGap), focused on development, implementation, and evaluation of an integrated package of key evidence-based interventions within a collaborating network of community-based services. CST provides evidence-based skills training to caregivers of young children with autism and related neurodevelopmental conditions. In addition to being brief and requiring less specialist time than most evidence informed interventions for autism, CST is also more easily scalable because it uses a cascade training model.

Objectives: We report on preliminary data from an ongoing multisite feasibility randomized controlled trial (RCT) in Canada (Registration ID: ISRCTN58638141). The CST initiative is focused on expanding access to intervention through partnership with five partner sites, who are community-based service providers with established reach for underserved communities.

Methods: We are currently enrolling children suspected or diagnosed with autism aged 2-7 years old and their caregivers in the feasibility RCT. The CST intervention is delivered by Master Trainers who are professionals from partner sites across Canada, trained to deliver CST in a previous phase of the study. The intervention is composed of nine group sessions and three individual “home visits”, all delivered virtually. Because the CST intervention involves group sessions (with 10 caregivers per group), 20 caregiver-child dyads are enrolled per intervention block. Once this recruitment target is reached for each block, the dyad is randomly allocated to either CST or a waitlist control group with a 1:1 ratio, stratified by preferred language (French or English). Primary outcomes are dyadic outcomes related to caregiver-child interactions. Implementation outcomes are assessed as a measure of feasibility (e.g., recruitment, representativeness, adoption and sustainability of the model in the partner sites).

Results: To date, 40 children were enrolled and randomized (71% male; M=5.1 years old; SD=1.5 years old). Recruitment data showed representative distributions across key demographic variables including ethnicity (73% self-reported ethnicity other than White/Caucasian), caregiver education (57% completed Bachelor’s or higher) and household income (65% reported less than $80K CAD annually). Retention rates have been high with 80% of enrolled participants completing post-intervention assessments. Scores on baseline measures were as follows: Social Communication Questionnaire (M=19.1, SD=6.4), Distress Thermometer (M=5.8, SD=2.1), Family Empowerment Scale (total M=10.0, SD=1.8), Strengths & Difficulties Questionnaire (M=17.7, SD=4.9). Qualitative measures with enrolled families indicate acceptability and perceived value of the model.

Conclusions: Although CST has been widely implemented around the world, the model has not yet been tested in rigorous trials. Preliminary analysis suggests that a nationwide trial in Canada is feasible in reaching under-served families, showing promise for its scalability and sustainability as a community-based program. Further analysis will establish the impact of CST on caregiver and child outcomes.

403.210 (Poster) The Influence of Homeland Culture on First-Generation Immigrant Parents Caring for Children with Autism
P. F. Duggins. Department of Education, Lesley University, Cambridge, MA; Advocacy, Federation for Children with Special Needs, Boston, MA

Background: The increase in the prevalence of autism to 1 in 44 children born in the U.S. (Maenner et al., 2021) coupled with the nation’s growing immigrant population led to this study’s investigation of the influence of homeland culture on lived experiences of five first-generation immigrant parents caring for children with autism.

Objectives: To investigate the influence of homeland culture on lived experiences of five first-generation immigrant parents caring for children with autism.

Methods: This empirical phenomenological study explored parental decision-making, family roles and responsibilities, and outcome expectations for their children with autism through semi-structured interviews, evidence garnered from participants’ photographs and artifacts, and researcher observations of parents’ interactions with educational and related professional service personnel.

Results: The study’s six findings support and extend academic literature related to the importance of emotional and functional support from homeland associations and intergenerational familial relationships, the repercussions stemming from a lack of homeland experience with disability and autism, and the challenges that participants faced when navigating unfamiliar U.S. systems.

Conclusions: The fact that all five participants from different global regions shared similar perceptions and experienced common challenges in navigating and securing services in different schools for their children with autism highlights the need for attention to the
Background: Autistic people are at high risk of experiencing suicidality. Population-wide studies show that autistic people are up to seven times more likely to die by suicide and six times more likely to attempt suicide than the general population. Autistic women are 13 times more likely than non-autistic women to die by suicide. Numerous barriers prevent autistic people at risk for suicide from getting the support they need, including lack of evidence-based assessment tools.

The Suicide Behaviours Questionnaire – Autism Spectrum Conditions (SBQ-ASC) is a brief self-report suicidality assessment tool in English to identify suicidal thoughts and behaviors in autistic individuals. The SBQ-ASC was developed and validated with and for autistic adults, without co-occurring intellectual disability. Considering the importance of this issue, REAL (Latin American Autism Spectrum Network) undertook the translation and adaptation of the SBQ-ASC into Spanish and Portuguese, as a first step towards having a validated tool to identify suicidality in autistic people in Spanish and Portuguese speaking LAMI countries.

Objectives: To translate and adapt the SBQ-ASC into Spanish and Portuguese following International test commission guidelines for test adaptation, such as:

- Pre-Condition Guidelines: 1. Obtain the necessary permission from the holder of the intellectual property rights relating to the test before carrying out any adaptation. Evaluate that the amount of overlap in the definition and content of the construct measured by the test and the item content in the populations of interest is sufficient for the intended use of the scores. 3. Minimize the influence of any cultural and linguistic differences that are irrelevant to the intended uses of the test in the populations of interest.
- Test Development Guidelines: 1. Ensure that the translation and adaptation processes consider linguistic, psychological, and cultural differences in the intended populations through the choice of experts with relevant expertise. 2. Use appropriate translation designs and procedures to maximize the suitability of the test adaptation in the intended populations. 3. Provide evidence that the test instructions and item content have similar meaning for all intended populations. 4. Provide evidence that the item formats, rating scales, scoring categories, test conventions, modes of administration, and other procedures are suitable for all intended populations.

Methods: 10 mental health professionals and autism researchers plus 14 autistic individuals in different countries such as Argentina, Brazil, Chile, Dominican Republic, Mexico, Spain and Uruguay worked on the translation and adaptation of the SBQ-ASC into Spanish and Portuguese speaking LAMI countries, following International test commission guidelines for test adaptation.

Results: SBQ-ASC was translated into a Portuguese version for Brazil and Spanish versions for Argentina, Chile, Dominican Republic, Mexico, Spain and Uruguay. All versions were culturally adapted.

Conclusions: Suicide in autism is a hidden crisis. It is essential to address and remove barriers to effectively identify autistic people at risk for suicide. Having translated and adapted assessment tools in Spanish and Portuguese speaking LAMI countries is a first step towards the pursuit of future validity studies of evidence-based tools such as the SBQ-ASC, which may allow early identification of suicidal thoughts in autistic people.
Autism knowledge and attitudes have been investigated in predominantly Western countries, while how cultural factors impact understanding of autism in non-Western nations is underexplored. Prior research suggests that autism stigma is higher in non-Western countries and among people with heightened acceptance of inequality and adherence to social norms. Hong Kong has a unique mix of traditional Chinese traditions and influences of Western values. Relative to America, Hong Kong is characterized by a culture where social harmony and hierarchy are more valued, which may suggest heightened negative attitudes towards autistic people. Understanding educators’ knowledge and attitudes towards autism cross-culturally can inform training needs and approaches that work for specific cultures.

Objectives:

(1) Compare knowledge and attitudes towards autism among preservice teachers in Hong Kong and Canada

(2) Evaluate the effect of an online training on autism knowledge and attitudes

Methods:

57 and 55 preservice teachers from Hong Kong and Canada respectively completed a brief, self-paced online training that included research-based information about autism across the lifespan. Pre- and post-training, participants answered questions assessing their knowledge, stigma, and inclusive attitudes towards autistic students (all αs > .75). Post-training, participants completed social dominance orientation (SDO) and social desirability questionnaires. Participants answered open-ended questions, including: “What is autism?” and “How do people in your community/ies treat autistic people?”

Results:

Baseline correlations revealed that autism stigma was negatively associated with knowledge and inclusive attitudes and negatively associated with SDO in both countries (ps < .008). Regressions predicting stigma from knowledge, inclusive attitudes, SDO and social desirability revealed that knowledge was the only predictor of stigma in each country after accounting for other variables (ps < .003).

Although Hongkongers (53%) were more likely to report prior experience educating autistic people than their peers in (Canada 24%; p = .002), they demonstrated lower knowledge and reported higher stigma than Canadian participants (ps < .001), at both pre- and post-test. Despite reduced overall knowledge, Hongkongers were more likely to indicate that autism is caused by new mutations, inherited genetic differences, and environmental factors than Canadians (ps < .05).

Participants in both countries commonly described difficulties in social interaction/communication in their open-ended descriptions of autism (Table 1). Compared to Canadians, Hongkongers were more likely to include misconceptions about autism (e.g. autistic people are antisocial) and less likely to describe autism as a “spectrum.” Hongkongers were also more likely to say community members lack respect for and treat autistic people as “weird” than Canadians (Table 2).

Knowledge, stigma, and attitudes toward inclusion improved with training in both countries (ps <=.001). No interactions between country and training-related changes were observed.

Conclusions:

Participation in a brief online training was associated with reduced stigma and improved knowledge and inclusive attitudes in preservice teachers in Hong Kong and Canada. Autism knowledge emerged as the strongest predictor of stigma across countries. Culturally-specific perspectives on autism may impact how people in particular communities view and treat autistic people. Training should be culturally-adapted to address knowledge domains that are particularly limited in specific cultures.

403.213 (Poster) How Does the Neurodiversity Movement Play out in Non-Western Context? a Critical Review of Hong Kong Autism Research Literature

G. Y. H. Lam¹, Y. Cheng², W. Chan¹ and M. Zhang¹, (1)Department of Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)The University of Hong Kong, Hong Kong, Hong Kong

Background:

The neurodiversity movement and critical autism studies have challenged dominant assumptions about autism, prompting a re-evaluation of how autism is traditionally studied and understood. However, these movements have grown in the context of Western social development, leaving a gap unaddressed as to whether these paradigms are compatible with non-Western cultures. Hong Kong is unique in...
its rich traditional Chinese culture and influences of Western values. Hong Kong has a relatively vibrant research scene, but it is not known how much the local autism research aligns with the neurodiversity framework.

Objectives:

We conduct a critical narrative review of autism research in Hong Kong and synthesize its state of knowledge. We critically examine the extent to which Hong Kong autism research has been conducted in line with neurodiversity tenets, specifically focusing on (1) how autism is conceptualized, (2) the degree to which autism community participates and contributes to research processes, and (3) how the local community needs are being addressed in research.

Methods:

A search of seven databases for autism-focus empirical research conducted in Hong Kong between 2010 and 2021 yielded 182 English-language peer-reviewed articles. We read the full text and used a pro-forma to extract textual information relevant to the research objectives. We categorized the articles according to the 2018 Interagency Autism Coordinating Committee Strategic Plan and summarized research findings in each category. We used thematic analysis and critical discourse analysis techniques to synthesize themes that describe research practices and procedures that align with neurodiversity or lack thereof.

Results:

The top three autism research areas in Hong Kong were treatments and interventions (N = 53; 29%), biological and cognitive processes (N = 51; 28%), and services and supports (N = 46; 25%). Research topics were generally similar to Western research with some culturally-specific elements (e.g., Chinese language processing, acupuncture, martial arts therapy). Research population was mostly children and adolescents, with only 4% of articles investigating adult issues.

Most articles portrayed autism as a disorder characterized by symptoms described in the diagnostic criteria, while only few studies challenged this deficit-oriented framework. The local autism community’s involvement in the research process was primarily restricted to participating in data collection and intervention procedures, while only occasional feedback was collected from stakeholders to inform research designs. Research approaches adapted for the needs and wants of autistic individuals were limited, while autistic input into research was absent. The most common cultural adaptations involved translation of research materials into Chinese, while only few described specific strategies to make their research more relevant and accessible to the local community.

Conclusions:

The autism research landscape in Hong Kong is dominated by deficit-oriented biomedical and intervention research and lacks diverse autistic representations and community participatory input, a pattern reminiscent of the West in the past. No signs of growth in research advancing the contemporary neurodiversity agendas are observed. Potential barriers of applying the neurodiversity paradigm in Hong Kong may be attributed to the city’s culture of low acceptance of diversity and the broader socio-political pressure on democratic movements.

403.214 (Poster) Toilet Training Autistic Children in Malaysia and Morocco, a Qualitative Study.

C. Y. M. Chang, M. de Vries, N. Peters-Scheffer, N. A. Binti Zulfaker, N. Chekkouh and M. V. de Jonge, (1) School of Psychology, University of Nottingham Malaysia, Semenyih, Malaysia, (2) University of Nottingham Malaysia Campus, Semenyih, Malaysia, (3) Pedagogische Wetenschappen & Behavioural Science Institute, Radboud Universiteit, Nijmegen, Netherlands, (4) Psychologie, Sciences humaines et sociales, Université Ibn Tofail, Kenitra, Morocco, (5) Faculty of Social Science, Education and Child Studies, Clinical neuroscience and developmental disorders, Leiden University, Leiden, Netherlands

Background:

Toilet training is often challenging for autistic children. Independent toileting is an essential daily living skill and increases autonomy, which is of utmost importance for autistic children. A toilet training protocol developed in the United States (Azrin & Foxx, 1971) has been adapted and studied extensively. However, it has been minimally studied in low-resource areas, minority groups, or other cultures. A recent review (in prep) showed that, despite several adaptations, no specific cultural adaptations have been studied and described thus far.

Objectives:

The current project aimed to study which challenges parents encounter when toilet training their autistic children in two developing countries, Morocco, and Malaysia.

Methods:
Seven focus groups (two in Morocco and five in Malaysia) were organized to gain qualitative insight into barriers and opportunities when toilet training autistic children. Each focus group included 4-9 parents of children with autism (or related conditions), in the age range of 2-9 years.

Results:

Themes that emerged were (1) Toilet training methods, including toilet visits, modelling, reinforcement, and punishment; (2) Challenges, including communication, working parents, generalization to outside the home, and defecation; (3) Goals and aims, including diapers, independence, and school; (4) Need for resources, including lack of Malaysian specific information, the need of support (groups), and need of affordable resources (e.g., video).

Conclusions:

There were specific debatable topics, such as using punishment, the need for verbal communication, when to start, and how to continue toilet training (after relapse). Most parents agreed on the necessity of toilet training, amongst other reasons, for school. Parents in the focus groups showed to be inventive and creative in toilet training their children. However, they did report struggling and experiencing a lack of understanding in their environment. Although they took full responsibility, many parents indicated that they wished to have more support, either professional or from peers. Moreover, they missed culture-specific information, provided in local languages.

403.215 (Poster) The Relationship between Mindreading and Autism Traits: A Comparison between Malaysia and the UK

S. Abu Bakar, E. Sheppard and M. de Vries. (1)Department of Psychology, Monash University Malaysia, Subang Jaya, Malaysia, (2)University of Nottingham, Nottingham, UNITED KINGDOM, (3)University of Nottingham Malaysia Campus, Semenyih, Malaysia

Background:

Autism is characterised by persistent and pervasive difficulties in social communication and interaction. However, what is considered appropriate social behaviour varies between different cultures; e.g., eye contact during conversation is considered inappropriate in Asia whereas eye contact indicates attentiveness during conversation in Western countries.

Social difficulties in autism are suggested to result partly from a divergence in the development of Theory of Mind (ToM). Divergent ToM in autistic individuals seems to be universal, it is yet unclear whether there are pre-existing cultural differences in baseline ToM in the general population. Members of the Malaysian general population score higher on the Autism Spectrum Quotient (AQ), including on the social skills and communication subscales, compared to the UK. Whilst these findings could reflect cultural biases in the questionnaire, it could also indicate cultural differences in ToM. This contrasts with previous research suggesting collectivistic countries, such as Malaysia, could potentially have better ToM than individualistic countries.

Objectives:

We investigated potential differences in ToM between Malaysians and British general population samples, and whether these influenced differences on the AQ. Given the contradiction in previous literature, two opposing hypotheses were proposed. If differences on the AQ reflect underlying differences in ToM, Malaysians were expected to score higher on the AQ and perform worse on the ToM tasks compared to British participants (hypothesis A). However, if Malaysians were more collectivistic, and collectivism leads to greater ToM abilities, Malaysians would perform better than British participants on ToM tasks (hypothesis B).

Methods:

120 Malaysian (99 females and 21 males, aged 18-29) and 121 British (88 females and 33 males, aged 18-70) participants completed two classic measures of ToM; the Reading the Mind in the Eyes Task (RMET) and the Strange Stories Task (SST). We administered the AQ, and two measures of cultural orientation; the Cultural Orientation Scale (COS) and the Adherence to Asian Values Scale (AVS). To supplement our cross-cultural comparisons, mediation analyses were performed to study the interrelation between these measures.

Results:

Direct country comparisons showed that Malaysians scored higher than British participants on the AQ, individualism and the AVS, but there were no differences in collectivism or ToM tasks. Correlational analyses showed that the RMET was significantly negatively correlated with the AQ and the AVS. The SST was significantly negatively correlated with the AVS. Three mediation analysis were done to test the influence of collectivism, individualism and AVS on the AQ, mediated by ToM tasks. Although the effect of individualism and collectivism on the AQ was not mediated by ToM tasks, the relationship between the AVS and the AQ was partially mediated by the RMET. Both collectivism and the AVS predicted AQ scores.
Conclusions:

We found cross-cultural differences on the AQ which were partly explained by cultural values. The findings for ToM were more nuanced; adherence to specific Asian values, rather than a traditional cultural orientation paradigm, may better capture cultural differences between the two countries, and might influence ToM and in turn might explain differences in AQ scores between the UK and Malaysia.

403.216 (Poster) Assessing Empathy in Adults: A Malay Language Validation of the Empathy Quotient (EQ)
S. W. Wo and M. H. Yong; (1)Sunway University, Subang Jaya, Malaysia, (2)Bradfold University, Bradfold, United Kingdom

Background: Empathy is defined as an intricate set of cognitive and affective processes that generates individuals’ capability to understand and respond to other people’s mental states. One of the main characteristics of autism is impairment in social functioning and communication and therefore autistic individual often have difficulty in reading social cues. However, this does not necessarily means that they are lack of empathy. The Empathy Quotient is a 40-items questionnaire developed by Baron-Cohen and Wheelwright (2004) which is able to identify sex and group differences in both general population and in clinical groups such as Autism Spectrum Disorders (ASD).

Objectives: To translate and validate the Malay version of the EQ-40 among Malaysian adults.

Methods: An expert panel of two psychologists, an applied behavioural analysis therapist and two parents of adult with ASD to assess the face validity of M-EQ. All five found that all 40 items were direct, specific and easy to understand, except for item 32. The item was then revised. Then, we recruited 354 participants aged between 18 to 53 years (Mage = 26.3, SD = 6.7) to complete the M-EQ and brief Interpersonal Reactivity Index (IRI) in Malay to assess convergent validity.

Results: Our exploratory factor analysis results showed that the M-EQ had three factors: cognitive empathy, emotional empathy, and social skills, which was aligned with the original EQ. In addition, results showed good convergent validity with M-B-IRI. The M-EQ also showed good internal consistency (Cronbach’s α value=0.864) and test-retest reliability. Our findings also showed that females scored higher on M-EQ, similar to past studies.

Conclusions: This shows that the M-EQ is valid and reliable for the present Malaysian sample. Further study should assess the confirmatory factor analysis and compare EQ-40 with adults with ASD.

S. W. Wo and E. Yong; (1)Sunway University, Subang Jaya, Malaysia, (2)Sunway University, Petaling Jaya, Malaysia

Background: The Malaysian Ministry of Education aspires to have 75% of participants of children with special needs education (SEN) in mainstream classroom in 2025. To create an inclusive and learning-friendly environment, “Zero Reject Policy” was implemented in January 2019. However, when movement of control (MCO) was implemented to combat covid-19 pandemic back in March 2020, schools were shut down multiple times. As a result, there were significant challenges to SEN children in particularly autistic children when routines and learning activities were disruptive and children has to learn from online platform. While the educators are making a significant effort to develop effective online learning approaches for special needs children, the engagement of these children and pursue inclusion are unknown.

Objectives: To explore the experience of schooling during Covid-19 pandemic among autistic children and the impact of inclusion in Malaysia.

Methods: In-depth interviews were conducted with 16 families of children with Autism Spectrum Disorder via Zoom. The children aged from 6-18 years old who have attended school at least 6 months before MCO. Data were transcribed verbatim and thematically analyzed using the descriptive phenomenology approach.

Results: The experience of schooling can be divided into two timeframes: “the beginning of MCO” and “after MCO was lifted and future plan”. Most parents reported that younger autistic children experienced meltdown due to the sudden changed of routine. The younger autistic children were unable to learn effectively in online class and parents struggled to guide their children to complete homework assigned by teachers via online platform (eg. Google drive) or communication tools (eg. Whatsapp). Most parents also reported that they are worry on their children’s physical and mental health due to the drastic increased use of electronic gadget (eg. iPad). Some parents also stopped schooling due to the fear of infectious covid-19 virus. On the other hand, most parents reported that their older autistic children were benefited from online learning. Autistic adolescents who have higher self-awareness on their physical appearance and academic performance were more comfortable communicate with their peers virtually and to learn at their own pace. Due to the disruption on school/ academic progress, the parents are uncertain on their children education plans. The parents also unaware about zero reject policy or unsure how this policy would benefit their autistic children.
Conclusions: The study provides an insight into the perceptions of parents supporting an autistic child through a unique time for schooling in Malaysia. While younger autistic children struggle to learn at home with untrained parents and limited resources at home during the pandemic, online learning created a unique and improved approaches for autism teenagers. The parents' heterogeneity view emphasizes the importance of engaging with the autism community to inform policy and practice, particularly in inclusive education that aligned with Malaysia Education Blueprint 2013-2025.

Panels Discussion — INTERVENTIONS - NON-PHARMACOLOGIC - PRESCHOOL & INFANT

217 - Current Directions and Diverse Perspectives on Pre-Diagnostic Supports, Begun Very Early in Life, for Infants More Likely to be Autistic

Panel Chair: Kristelle Hudry, La Trobe University, Melbourne, VIC, AUSTRALIA

Discussant: Kristelle Hudry, La Trobe University, Melbourne, VIC, AUSTRALIA

Early intervention seeks to minimise disability potentially associated with autism. Most early supports are targeted post diagnosis. However, supports offered very early in life—sometimes called pre-emptive or prodromal interventions—may be begun well before diagnosis, when autism likelihood is first recognised; when infants have a known family history of autism/related conditions, or when signs of possible autism are identified. This is a highly topical and potentially divisive topic, and our panel brings together groups working independently and collaboratively across multiple countries/regions, drawing on different disciplinary backgrounds/methodologies, and at different stages in the evaluation cycle. Our objective is to showcase a range of contemporary projects, consider diverse perspectives, and stimulate productive respectful discussion. Individual presentations will consider: 1) proof-of-concept evidence for a new 8-session program occurring between ages 10- and 12-months; 2) health-economic analysis of an established 10-session program recently trialled with community-ascertained infants showing early signs of autism around age 12-months and followed up to 3-years; 3) thematic analysis of experiences shared by Brazilian Portuguese-speaking caregivers on this same established program translated for novel case-series evaluation in a culturally/linguistically diverse context; and 4) mixed-methods research seeking autistic- and autism-community views on the acceptability of very early life autism supports.

217.001 (Panel Discussion) Pilot Randomized Controlled Trial of an Embodied Infant Intervention Approach (Infant Achievements) Shows Promise of Efficacy for Social Communication Outcomes

R. Landa1, C. Hess1, R. Reetzke2 and E. Holliday3, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Center for Autism and Related Disorders, Center for Autism and Related Disorders, Kennedy Krieger Institute, Johns Hopkins School of Medicine, Baltimore, MD, (4)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD

Background: Social communication delays are early indicators of autism. High quality early interventions, prior to age 3, can improve developmental trajectories for children with early social communication delays. Infancy, a formative period of neurodevelopment, may be a period of particular malleability to tailored supports. Yet much remains to be learned about potent ingredients of infant interventions, accelerators of caregiver fidelity attainment, and malleability of critical aspects of infant social communication in infants with such delays. We conducted a proof-of-concept study to preliminarily examine efficacy of an infant intervention (Infant Achievements [IA]) that paired two hypothesized active ingredients: selected naturalistic developmental behavioral intervention strategies and multi-affordance objects to elicit caregivers' and infants' joint engagement and facilitate caregivers' developmentally-appropriate communication behavior.

Objectives: Determine whether: (1) caregivers randomized to receive coaching in implementation of IA demonstrate superior fidelity of IA implementation outcomes compared to caregivers receiving unrelated caregiver education (CE) without coaching; and (2) infants with social communication delays in the IA group demonstrate superior social-communication outcomes compared to those in the CE group.

Methods: Caregivers and their infant with social communication delay were assigned to the IA (n=17; MAge=10.8, SDAge=2.2) or CE (n=16; MAge=9.3, SDAge=1.2) group. IA caregivers received eight weeks (16 sessions) of home-based in-person coaching in Naturalistic Developmental Behavioral Intervention (NDBI) strategies to target infant social communication development. The collaborative, evidence-based, Practice-Based Coaching (Snyder et al., 2022) approach was used, encouraging caregiver reflection and supporting video review of caregiver implementation and child behavior each session with the coach. The CE group received weekly interactive education about child development in-person along with weekly phone check-ins for 8 weeks. Caregiver fidelity, infant duration of joint engagement (adapted for infants from Adamson et al., 2020), and child frequency of initiation of joint attention bids were coded at pre- and post-intervention, and at follow-up (8 weeks post-intervention) from 7-minute video-recorded samples of caregiver-infant play. Caregiver fidelity was also assessed bi-weekly. Coding was done by staff blinded to group and time of assessment. See Table 1 for data at each datapoint.
Results: Gains in the IA caregivers’ fidelity of implementation was superior to that of CE caregivers at all datapoints (all $p$s < 0.03, all $g$s > 0.40), except at follow-up ($\beta=5.4$, $p=0.15$). IA infants’ gains in duration of coordinated joint engagement with caregivers ($\beta=36.8$, $p=0.046$) and initiation of joint attention (IJA) bids via triadic gaze shifts ($\beta=5.7$, $p=0.01$) were superior to the CE infants’ from pre- to post-intervention. IA treatment effects on infant outcomes at follow-up were attenuated.

Conclusions: Results supported our hypothesis that this innovative pairing of potent NDBI strategies and objects with development- and engagement-facilitating affordances would kickstart caregiver fidelity of implementation and infant social communication gains. In a post-intervention focus group, IA caregivers reported that IA inspired their self-efficacy regarding caring for their infant with social communication delays; they attributed their infants’ positive outcomes to their use of the IA strategies and strategically selected objects. Results also highlight the need for ongoing caregiver coaching as infants’ social and communication development advances.

217.002 (Panel Discussion) Economic Evaluation of Ibasis-Vipp Vs. Services As Usual in Australia, for Infants Showing Early Signs of Autism

L. Segal, J. Green, A. Twizeyemariya, K. Hudry, A. J. Whitehouse and T. AICES Team, (1)University of South Australia, Adelaide, SA, Australia, (2)University of Manchester, Manchester, United Kingdom, (3)La Trobe University, Melbourne, VIC, AUSTRALIA, (4)Telethon Kids Institute, Perth, Western Australia, AUSTRALIA, (5)AICES Team, Perth/Melbourne, Western Australia, Australia

Background: Markedly increased rates of autism diagnosis place current global prevalence estimates between 1.2-2% (Chiarotti & Venerosi, 2020) and in Australia, over half of all child-aged participants accessing disability-related supports through the National Disability Insurance Scheme (NDIS) have a primary registered diagnosis of autism. The nature and cost of disability-related supports for autism varies by age and disability level, with childhood supports largely related to fostering early skill acquisition and minimising environmental barriers, while later-life supports aim toward independent living (Lavelle et al., 2014). Knapp et al. (2009) have estimated lifetime autism support costs around US$1.4 million in the US and £0.8 million (~US$1 million) in the UK, increasing to US$2.4 million and £1.2 million (~US$1.5 million) respectively, with co-occurring intellectual disability. A challenge for healthcare policy is how best to apportion finite funds to support those with disability and their families.

Objectives: This research extends a decade-long research program begun in the UK (Green et al., 2015; 2017) and recently expanded in Australia (Whitehouse et al. 2019; 2021) showing the efficacy of iBASIS-VIPP to support the development of infants with possible emerging autism. Among 103 infants with early signs of autism around the first birthday (range 9-14 months)—half of whom received 10 iBASIS-VIPP parent-mediated intervention sessions over 5-months—followed up to age 3-years, Whitehouse et al. (2021) reported reduction in the rate of children meeting ASD criteria in the iBASIS-VIPP (6.7%) vs. services as usual (SAU) group (20.5%; OR=0.18 [95%CI 0.0-0.68] $p=.02$; number needed to treat=7.2). Here, we asked whether iBASS-VIPP represents good value societal investment, taking a 3rd party payer perspective to model the net cost impact for government.

Methods: Drawing on data for the 89 infants retained to 3-year follow-up by Whitehouse et al. (2021), we appraised the economic performance of iBASIS-VIPP vs. SAU using cost-minimisation and cost-effectiveness approaches, and modelling outcomes observed at age 3 years and projected downstream costs to age 13. Diagnostic outcome decisions of ASD and Developmental Delay determined at 3 years were used to project diagnostic trajectory and associated disability support costs.

Results: Per child, the estimated mean differential support cost (iBASIS-VIPP - SAU) was AU$5,131, downstream cost saving was AU$13,655, and NPV cost saving was AU$7,335 (discounted 3%pa). Each dollar invested in iBASIS-VIPP yielded an estimated AU$2.66 saving, with ‘break-even’ cost achieved at age 8 years. Modelled to age 13, there was an 85% chance that iBASIS-VIPP would be cost saving.

Conclusions: Modelling outcomes to age 13 with a conservative approach to estimated cost savings (i.e., covering 3rd party-payer costs only), iBASIS-VIPP likely represents good-value societal investment. As a key driver of disability-related support costs sought by families for children in Australia, there is clear policy relevance of offering effective support for infants showing signs of possible emerging autism very early in life, well before diagnosis is confirmed. That this, the benefits for child developmental outcomes achieved through iBASIS-VIPP (Whitehouse et al., 2021) were at an expected net cost saving to government.

217.003 (Panel Discussion) A Qualitative Exploration of Parental Experiences of Receiving a Translated, Western, Evidence-Based Therapy for Infants with Elevated Likelihood for Autism and ADHD in a Non-English-Speaking, Low/Middle-Income Country

E. Shephard, J. Prieto Bruckner, P. Godoy, L. Coraça Figueiredo, G. Ubeid, L. Otoch, K. Leadbitter and J. Green, (1)University of São Paulo, São Paulo, Brazil, (2)University of Manchester, Manchester, United Kingdom

Background: Infants with a first-degree family member with a diagnosis of autism or attention-deficit/hyperactivity disorder (ADHD) are more likely to meet diagnostic criteria for the same condition later in childhood. Prospective longitudinal studies of these infants indicate that differences in social-communication can be seen from as early as the first year of life. Differences in dyadic social-communication during day-to-day interactions between these infants and their parents have also been found. The parent-mediated iBASIS-VIPP therapy (e.g., Green et al., 2015) was developed based on these findings; targeting parental behaviour to enrich the early socio-communicative
environment of the infant and support any early-appearing differences in infant development and parent-infant interaction. iBASIS-VIPP has shown efficacy in improving early social-communication abilities and parent-infant interaction in infants with family history of autism (Green et al., 2015), but has not yet been evaluated for infants with family history of ADHD, nor in non-English-speaking lower resource contexts.

Objectives: To explore experiences of receiving the iBASIS-VIPP therapy amongst mothers of infants with and without family history of autism and ADHD in Brazil.

Methods: This qualitative study involved delivery of iBASIS-VIPP to a case-series of 8 mother-infant dyads resident in Brazil, by four trained therapists. Therapy was delivered in Brazilian Portuguese in online format during March-July 2022. Infants were aged 6-13 months at the beginning of the therapy. Two of the infants had an autistic older sibling, two had an older sibling with ADHD, three had neurotypical older siblings, and one had no older siblings but showed delays in communication development. At the end of therapy, all mothers completed a structured interview in which the therapist asked about their perceptions and experiences of receiving iBASIS-VIPP. Interviews were transcribed verbatim and analysed thematically by one researcher fluent in Brazilian Portuguese.

Results: All mothers reported positive feelings about taking part in the therapy, stating that it was a novel experience during which they felt welcomed, cared for and supported in reflecting on their baby’s development and their interactions and relationship with the baby (Theme 1). Mothers also noted positive changes in themselves and their babies which they attributed to the iBASIS-VIPP therapy (Theme 2). Perceived changes in the mothers included deeper understanding of their baby’s needs, emotions and interests, and improved ability to understand and respond sensitively to their infant’s communication signals. Perceived changes in the infants included improved communication development, increased happiness and security and lower frustration. All mothers also reported that their connection with their baby strengthened and that their day-to-day interactions became more synchronous, empathic and respectful. Finally, the mothers noted that the practical aspects of the therapy were feasible (Theme 3), particularly the fortnightly session frequency, online delivery, and daily home practice.

Conclusions: The Brazilian mothers in this study reported positive experiences of the iBASIS-VIPP therapy and improvements consistent with the therapy targets. While further work is needed with a larger and more diverse sample, the current findings suggest iBASIS-VIPP is appropriate and feasible for implementation in Brazil.

217.004 (Panel Discussion) Autistic and Autism Communities’ Perspectives on Providing Supports to Infants and Their Families Very Early in Life
C. A. Bent, A. Aulich, E. Fidock, C. Constantine, A. Gurba, P. Dwyer, L. Harrington, J. A. Smith, K. E. Gore, A. S. Rabba, C. C. Green, and K. Hudry, (1)La Trobe University, Melbourne, VIC, AUSTRALIA, (2)La Trobe University, Melbourne, VIC, Australia, (3)The Social Competence and Treatment Lab at Stony Brook University, Stony Brook, NY, (4)Department of Psychology, Center for Mind and Brain, UC-Davis, Davis, CA, (5)University of Washington, Seattle, WA, (6)Childhood Autism Phenotype Team, La Trobe University, Melbourne, VIC, Australia

Background: Parenting supports provided early in life are intended to support all children to lead happy, healthy lives. Research examining the efficacy of supports provided to parents of infants more likely to be autistic (i.e., because they have an autistic or neurodivergent family member or show early signs of neurodivergence) provides emerging evidence of benefit for parents and infants. While well-founded in developmental science, ‘pre-emptive’ approaches to autism intervention are topical and potentially highly polarising with critical questions regarding the perceived appropriateness of these supports yet to be examined.

Objectives: Within the context of a larger study which sought to understand autistic and autism communities’ views on providing supports to families very early in life - this presentation will examine similarities and differences in perspectives reported by autistic and non-autistic members of the autism community.

Methods: We utilised a mixed-methods, participatory research design, including an online survey and in-depth individual interviews. Autistic adults and parents were actively engaged in the research process and provided equal input into the design and conduct of the project, including the development of survey/interview questions, conducting interviews, and interpreting data. To date, 187 participants have completed (and 78 partially completed) the online survey, including 153 autistic and 112 non-autistic adults representing parents, researchers, and health/education professionals (see Table 1). Twenty-eight in-depth individual interviews have been conducted with thematic analysis to be presented alongside survey findings.

Results: The responses most frequently endorsed by autistic and non-autistic participants are presented in Table 2. Findings indicate broad similarities, with both autistic and non-autistic adults agreeing that the aim of supports for infants more likely to be autistic should be to help parents understand and respond to infants’ feelings, needs and behaviours, and to improve infant quality of life. Autistic and non-autistic adults also agreed that the delivery of supports be adapted for infant and family needs, involve parents supporting infants, include educating parents about autism, and creating opportunities for infants to have choice and control.
Autistic adults were more likely to indicate that supports involve autistic adults working with parents, changing the environment to meet an infant’s needs, and activities that an infant is interested in (whether or not these are usual for neurotypical infants). Non-autistic adults were more likely to report that professionals should work directly with parents, promote positive interactions between parents and infants, and create natural teaching opportunities within daily routine and interactions.

Both autistic and non-autistic adults indicated that the terms ‘support’ and ‘early in life’ were preferable over terminology including ‘at-risk’, ‘pre-emptive’, ‘preventatively’ and ‘prodromally’.

Conclusions: Broad similarities were evident in the perspectives of autistic and non-autistic members of the autism community, particularly regarding the aims and delivery of early supports, with more differences in the specific techniques and approaches thought to be appropriate. Engaging with stakeholders as equal partners is essential to ensure that supports developed are consistent with the needs of the community, and able to reach those they intend to benefit.

**Background:**

Early intervention is thought to be key to facilitating more positive later-life outcomes for autistic children. Among early interventions, different evidence-based approaches have combined the principles of behavioral analysis and developmental science within a naturalistic and interactive frame and grouped under the umbrella of Naturalistic Developmental Behavioral Interventions (NDBI). In the context of NDBIs, the Early Start Denver Model (ESDM) is a manualized intervention that reported repeated evidence of efficacy for therapist-, group- and caregiver-implemented interventions, in multiple research and community based settings. Understanding the effects of intervention characteristics and intensity on individual outcomes has a major impact on the delivery systems organization and policies, sustainability in low resources communities and to provide the necessary support to the family. However, a direct comparison among different types and intensity of early interventions in community setting and relatively low access to standardized and intensive programs, have not been adequately explored.

**Objectives:**

We aimed to investigate, in a community setting in the Italian context, the impact of two different treatment types and treatment intensity on individual developmental trajectories.

**Methods:**

A total sample of n=105 young children with autism, aged between 17 and 42 months, both males and females (19% females) were evaluated longitudinally throughout the course of high or low intensity ESDM (ESDM-higher, n=29; ESDM-lower, n=18) or an as usual treatment (TAU, n=58) program, implemented in the context of the autism territory service of Catania.

The ESDM was delivered at two different low intensities such as 3- versus 6 hours a week (ESDM-higher and ESDM-lower, respectively), while TAU treatment was implemented at 6 hours a week. Children were assessed at treatment start and after 6 months of intervention using the Griffiths Mental Developmental Scale (GMDS) to have a measure of individual trajectories in the different developmental domains.
A linear mixed-effect model (lme4 library in R) was applied and individual developmental gains were estimated by the subject-specific slope obtained from the lmer for modeling on the longitudinal GMDS scores. We operationalized developmental gains in terms of treatment response as the rate of change over time and will refer to this concept from here on as ‘treatment slopes’.

**Results:**

The ESDM-higher group displayed steeper treatment slopes compared to TAU on all the developmental domains (language, personal-social, performance, locomotor and hand-eye coordination; p<.029, .014, .017, .000, .001, respectively). The ESDM-lower group showed treatment slopes comparable to the ESDM-higher group for the language, performance, locomotor and hand-eye coordination domains (p>.05), and significantly higher treatment slopes than the TAU group for language and personal-social developmental domains (p<.005, .002, respectively).

**Conclusions:**

We found that higher intensity of treatment and treatment type (e.g., ESDM) matter for improving developmental outcomes. Interestingly, the ESDM intervention delivered at half of the intensity is associated with significantly better treatment slopes, compared to TAU delivered at a double of intensity in all the developmental domains. These findings have an impact for their clinical translation into low resources settings and countries worldwide, where treatment intensity and standardization of procedures is unfortunately not feasible nor sustainable.

**316.002 (Oral) Modifiable Characteristics That Predict Outcomes in a Community-Based Intervention for Preschoolers with ASD**

**M. Raja**, M. Ferland, H. E. Flanagan, D. J. Chitty, N. Garon and I. M. Smith, (1)Psychology and Neuroscience, Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (2)York University, Toronto, ON, CANADA, (3)IWK Health Centre, Halifax, NS, Canada, (4)IWK Health Centre, Halifax, NS, CANADA, (5)Mount Allison University, Sackville, NB, Canada, (6)Dalhousie University / IWK Health Centre, Halifax, Canada

**Background:** Pivotal Response Treatment (PRT) is an evidence-based intervention that targets key aspects of development such as functional communication and social engagement. Early interventions (EIs) for children with ASD such as PRT can ameliorate developmental trajectories and life outcomes of these children. Understanding factors that enhance response to PRT can inform the development of more targeted approaches by identifying behavioural characteristics that are directly modifiable. Research indicates that characteristics such as imitation, appropriate object/toy play, and positive affect can influence outcomes after behavioural EIs. A study using a retrospective design found that appropriate toy play, higher levels of positive affect, and less social avoidance at the start of the intervention predicted expressive language (EL) gains in a PRT-based program for preschoolers with ASD.

**Objectives:** To replicate and extend earlier findings by determining whether prospectively derived PRT responder profiles can be identified based on levels of imitation, appropriate toy play, and positive affect at the start of a PRT-based intervention for preschoolers with ASD.

**Methods:** Data were collected from 108 preschoolers with ASD (75% boys; mean age = 57.6 months, SD = 2.2) participating in a study evaluating a province-wide PRT-based EI program. EL was assessed at pre- and post-intervention using the Vineland-II EL subdomain age-equivalent score. Each participant took part in a video-recorded 10-minute pre-intervention standardized play interaction with a clinician trained in the protocol. Videos were coded by trained coders with good inter-rater reliability (mean kappa = 0.79; ICC= 0.813). Proportions of time that children engaged in imitation, appropriate toy play, and positive affect were coded. A latent profile analysis was used to determine whether these predictors together formed distinct profiles that could predict post-intervention EL gains. Nonverbal cognitive ability was measured using the Cognitive index of the Merrill-Palmer-Revised Scales of Development (n = 71).

**Results:** Examination of fit indices showed that a two-profile model was optimal. One-way ANOVAs indicated that the two profiles significantly differed based on levels of imitation (F(1,106) = 243.4, p<.0001, n² = 0.70), toy play (F(1,106) = 180.3, p<.0001, n² = 0.63) and positive affect (F(1,106) = 47.7, p<.05, n² = 0.04). Profile 1 represented a smaller subgroup of children (38%) who at the start of the intervention presented with lower levels of appropriate play, positive affect, and imitation skills, compared to children in Profile 2. A multilevel modeling analysis indicated that profiles predicted gains in EL following the intervention (β = -0.44, (51) =-2.07, p<0.05), with children in Profile 1 showing lower gains. This effect was no longer significant when nonverbal cognitive ability was added to the model.

**Conclusions:** Pre-intervention levels of children’s positive affect, toy play, and imitation skills influence gains made during PRT-based EI. This is moderated by children’s baseline cognitive abilities, which is not surprising as early cognitive scores are associated with modifiable variables that include imitation and play level. These profiles provide important information regarding who is most likely to benefit most from PRT-based EI. It also identifies key modifiable targets that may “prime” children’s responsiveness to treatment.

**316.003 (Oral) Predictors of Developmental and Adaptive Behavior Outcomes in Response to Two Models of Early Intervention: The Early Start Denver Model and Early Intensive Behavioral Intervention**
C. Dissanayake, C. A. Bent, S. Glencross, K. McKinney, K. Hudry and G. Vivanti, (1)Olga Tennison Autism Research Centre, Olga Tennison Autism Research Centre, Melbourne, VIC, Australia, (2)Psychology & Counselling, La Trobe University, Bundoora, VIC, Australia, (3)27-31 Munster Terrace, Autism Partnership, North Melbourne, VIC, Australia, (4)Autism Partnership, Melbourne, VIC, Australia, (5)La Trobe University, Melbourne, VIC, AUSTRALIA, (6)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

Background: Many young autistic children require support to meet their learning needs. However, the wide heterogeneity within the autism spectrum means that different types of early intervention (EI) may be better suited to different children. Two relatively common EI approaches are the Early Start Denver Model (ESDM), a Naturalistic Developmental Behavioral Intervention, and Early Intensive Behavioral Intervention (EIBI), with outcome studies suggesting each are efficacious in improving children’s cognition and adaptive behavior. However, research on which intervention works best for which children remains limited with little knowledge available to help families and service providers know what type of support may work best for individual children.

Objectives: While we anticipated similar and significant developmental gains following receipt of each type of EI program, our main objective was to understand which baseline child characteristics might be associated with the degree of individual response to intervention—whether prognostically (i.e., irrespective of intervention received) or predictively (i.e., specifically in the context of one or other EI approach).

Methods: Participants comprised two matched groups of preschool-aged autistic children receiving one of two community-based EI approaches - Group-based ESDM (n = 42) delivered in a 1:3-4 staff:child ratio, and an Early Intensive Behavioral Intervention (EIBI) delivered in combination of 1:1 and 1:2 staff:child ratio. Children were administered the Mullen Scales of Early Learning (MSEL) at intake and follow-up one year later, and parents completed the Vinland Adaptive Behavior Scales (VABS) at both times. A battery of eye-tracking tasks was administered at intake to measure sustained attention, preferential social attention, response to joint attention and attention to a playful adult.

Results: Children in both groups made significant and equivalent gains on Developmental Quotient (DQ) scores derived from the MSEL and on the VABS. Regression analyses indicated that attention to a playful adult was predictive of both verbal DQ and adaptive behavior for the cohort overall.Moderation analyses indicated that children with poorer sustained attention receiving the G-ESDM made fewer non-verbal gains, while attention span did not predict outcomes for children receiving EIBI.

Conclusions: Children benefited from both ESDM and EIBI with no clear evidence of superiority for developmental outcomes of one program over another, as delivered in community-based settings. Moreover, children who started either program with more social interest (in a playful adult) made more gains in verbal abilities and functional skills. However, sustained attention only impacted gains on non-verbal abilities at outcome for those receiving the G-ESDM. Our findings suggest that fine-grained measures of learning skills offer promise towards the selection and tailoring of intervention approaches to meet individual children’s learning needs.

316.004 (Oral) Towards Personalization: Identifying Differential Response to Intervention Approaches in Profiles of Minimally Verbal Children with Autism

Background:

Comparing intervention approaches across the spectrum has found few differences (e.g. Rogers, et al., 2021), so moving beyond a one-size-fits-all model is necessary. Characterizations of heterogeneity, a noted barrier to intervention evaluation (e.g. French & Kennedy, 2018), generally group minimally verbal children together (e.g. Tager-Flusberg & Joseph, 2003). Optimizing intervention efficacy requires matching approach with a child’s unique needs.

Objectives:

To examine the differential response of minimally verbal subgroups to intervention approaches.

Methods:

Entry and exit data from two multisite RCTs (n=352) with minimally verbal children age 3-8 and a confirmed autism diagnosis were used. “Minimally verbal” was defined as 30 spontaneous words maximum spoken during a taped play activity. Participants were randomly assigned to DTT or JASPER, delivered regularly over 4-6 months. DTT is a structured, adult-directed approach (Lovaas, 1987). JASPER
(Kasari, et al., 2010; Kasari, et al., 2008) is a Naturalistic Developmental Behavioral Intervention (NDBI, Schreibman, et. al., 2015), that combines behavioral and developmental strategies.

Subgroups

Profiles, previously identified via latent profile analysis with baseline characteristics, are described elsewhere (Pizzano, et al., in preparation; Pizzano & Kasari, INSAR 2021), and in Table 1.

Outcome Variables

Coders blind to timepoint and treatment assignment, at >80% reliability, coded data. Expressive language age equivalent (ELAE) (Mullen Scales of Early Learning (MSEL, Mullen, 1995) & Preschool Language Scales (PLS, Zimmerman, et al., 2011)), was scored from standardized evaluations of receptive and spoken communication. Spontaneous communicative utterances (SCU) were transcribed, coded, and summed from a Language Sample (LS) or parent-child interaction (CCX, Kasari, et al., 2014). Language to share was coded from the Early Social Communication Scales (ESCS; Mundy, et al., 2003), a videotaped assessment.

Analysis

Three-way interactions between profile, timepoint, and treatment group assignment were modeled in R (R Core Team, 2020). Control terms for child chronological age, study site, and study were included in all models.

Results:

Participants

Characteristics are detailed in Table 1, and treatment effect sizes are detailed in Figure 1.

Influence of profile on expressive language improvements in response to treatment

Profile moderated the effect of treatment on ELAE from entry to exit ($\chi^2 = 12.97(2), p=0.002$). Profile 1 significantly improved with DTT, but not JASPER. Profile 2 improved equally with DTT and JASPER. Profile 3 significantly improved with both approaches, but gains with JASPER were significantly greater than with DTT.

The three-way interaction was significant ($\chi^2 = 5.97(2), p=0.050$) in the count model for language to share. Profile 1 significantly improved with DTT but not JASPER. Profile 2 made significant improvements with both DTT and JASPER. Profile 3 significantly improved with JASPER but not with DTT.

The three-way interaction ($\chi^2 = 7.80(2), p=0.020$) was significant for SCU. Profile 1 significantly improved with DTT but not JASPER. Profile 2 significantly improved with JASPER but not DTT, and Profile 3 did not significantly improve with either approach.

Conclusions:

Intervention effects differed by profile and treatment group. DTT consistently improved the expressive language of Profile 1 over JASPER, but JASPER was most beneficial for increasing verbal expression of Profiles 2 and 3.

POSTER SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - PRESCHOOL & INFANT

404 - Interventions - Non-pharmacologic - Preschool & Infant I

404.220 (Poster) A Culturally Adapted Telehealth Intervention for Parents of Autistic Children in China

L. Qu, C. Colombi, W. Chen, A. Miller, H. L. Miller and D. A. Ulrich; (1)Institute of AI for Education, East China Normal University, Shanghai, MI, China, (2)Costanza Colombi, Pisa, MI, Italy, (3)School of Kinesiology, University of Michigan, Ann Arbor, MI, (4)School of Public Health, University of Michigan, Ann Arbor, MI, (5)School of Kinesiology, University of Michigan, Ann Arbor, Ann Arbor, MI

Background:
Autism affects at least 4.57 million children worldwide, and 95% of these children lived in low-and-middle-income countries where the access to healthcare and education services are limited. In China, there was and still is a scarcity of professionals who can provide evidence-based treatments. Families of autistic children often experience delays in diagnosis and treatment, and this waiting period could be used for initial parent education and training.

Objectives:

This study focused on translating Parent-mediated Early Start Denver Model into a group-based parent coaching intervention via telehealth. We developed a culturally appropriate telehealth intervention to facilitate families with a newly diagnosed child in mainland China. The study aimed to: (1) culturally adapt P-ESDM using the Ecological Validity Model (EVM) and family-centered capacity-building approach, (2) determine the feasibility of conducting a randomized controlled trial of this telehealth intervention in the Chinese context, (3) explore the effectiveness of this telehealth intervention on both children’s and parents’ outcomes.

Methods:

A randomized controlled trial was conducted with two telehealth conditions: self-directed and web + group therapy. 18 parents in the self-directed group received intervention individually through the online learning platform. 19 parents in the web + group therapy condition navigated the same program with a weekly 1.5-hour group coaching therapy via videoconferencing. Linear Mixed Models were conducted to estimate treatment effects across time and model the longitudinal trajectories of outcomes in both children and parents.

Results:

Five dimensions in the EVM were modified: language, person, content, methods, and context. We developed a 12-week telehealth intervention with sixty-three lectures, seventy-five demonstrations, fifty-three commentary videos, eleven practice manuals, and eleven group agendas. The study presented promising results in recruitment capability, retention, parental adherence and participation. High attendance (92%), high completion (90%), and low drop-out rate (10.5%) were observed in the web + group therapy condition. The results indicate this culturally adapted telehealth intervention effectively improved children’s communication skills and social engagement and alleviated the parenting stress. Specifically, group-based parent coaching via videoconferencing showed greater improvement in children’s quality of life and parents’ anxiety outcome.

Conclusions:

This study highlights the cultural adaptation and intervention implementation, and it may serve as a reference for clinicians to develop culturally appropriate interventions. The preliminary findings in feasibility, implementation, and effectiveness indicate the potential of using videoconferencing to deliver group-based parent coaching across borders.
different words (NDW) used during sessions was the primary child outcome assessed. Reliability of measures and training fidelity were calculated for 33% of sessions and exceeded acceptable standards.

**Results:** Results indicate that caregivers can be taught to deliver EMT with high levels of fidelity and acceptable dosage to their children via telehealth. Functional relations between systematic training and caregiver use of each strategy was demonstrated in all nine dyads. The effects of caregiver's use of EMT on child outcomes varied, with half of the children demonstrating statistically significant increases in NDW when caregivers delivered EMT at-fidelity. Caregivers rated the intervention as highly acceptable and helpful. During interviews, caregivers indicated that the just-in-time model prepared their families for participation in subsequent intensive intervention.

**Conclusions:** A just-in-time telehealth service delivery model is a tenable method for teaching caregivers of children with ASD to implement evidence-based language intervention with their children between diagnosis and later services. There is mixed evidence regarding children’s response to treatment that should be studied. Finally, social validity data indicate that this model is acceptable and may be a valuable resource to families in the gap between diagnosis and enrollment in more intensive services.

404.222 (Poster) Results from Toddler Pre-Emptive Intervention on Reduction of Early Problem Behavior and Increased Communication L. Neely, A. Carnett, K. Cantrell, S. Stegemann and M. Svoboda, (1)Educational Psychology, The University of Texas at San Antonio, San Antonio, TX, (2)Victoria University at Wellington, Wellington, New Zealand, (3)Educational Psychology, University of Texas at San Antonio, San Antonio, TX, (4)Autism Treatment Center, San Antonio, TX, (5)Baylor College of Medicine, San Antonio, TX

**Background:**

Social-communication delays are a core characteristic of autism spectrum disorder. For toddlers at-risk for autism, a delayed communicative repertoire might result in the children utilizing dangerous behavior (e.g., head banging) to communicate needs/emotions. For up to 30% of the population, speech as a communication modality never develops. Pre-emptive interventions during the critical developmental phase where speech should develop (9 mos to 3 yrs) may mitigate development of dangerous behavior and promote-social communication. Researchers have validated teaching of functional communication (FCT) in older populations as an effective intervention to teach communication that is safe and generalizable. FCT might be particularly effective as a pre-emptive intervention during the formidable developmental period of 9-mos to 3-yrs-old. However, to date, there is little research evaluating this technique as a pre-emptive intervention.

**Objectives:**

The researchers conducted the current project within the scope of a larger project investigating pre-emptive interventions at-risk toddlers. The presented project aimed to teach communication to toddlers who were engaging in early dangerous behavior (e.g., head banging).

**Methods:**

A total of 23 at-risk toddlers (aged 12-36 months) have participated in the project to date. Researchers conducted single-case experiments for eight of the participants to evaluate the effects of the intervention on the participants’ communication and early dangerous behavior. For the children who engaged in early dangerous behavior, researchers conducted a functional analysis to identify the communicative function of the behavior. Researchers also conducted communication modality assessments for all participants presenting with severe speech delays. Following identification of the function of the early dangerous behavior and preferred method of communication, researchers implemented FCT with the participant and their caregiver.

**Results:**

Researchers evaluated the results using visual and statistical analysis. Visual analysis of graphical displays is the gold-standard technique using in single-case evaluations. The researchers complimented their visual analysis of the graphical displays with effect size analysis using the Tau-U effect size. Visual analysis of the intervention results indicated immediate and large improvements from baseline to intervention phase for functional communication. The graphs also indicated a large and immediate decrease in dangerous behaviors. Resulting Tau-U effect sizes ranged from 0.85 to 1.0 suggesting large effects across all dependent variables.

**Conclusions:**

Preliminary results support the use of the FCT intervention to treat the early dangerous behavior and teach functional communication. While the researchers did not directly target happiness, the researchers did note increases in indices of happiness correlating with intervention, suggesting the participants enjoyed the intervention.
**404.223 (Poster)** A Social-Competence Group Intervention (SCGI) with a Combination of Didactic Teaching and Practice in Play Contexts for Preschool Children with Autism Spectrum Disorders

Y. T. Yu, F. M. Chiang, M. H. Liu, C. C. Kuo, Y. L. Chen and K. L. Chen, (1) School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (2) Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan, (3) Department of Physical Medicine and Rehabilitation, National Taiwan University Hospital, Taipei, Taiwan, (4) Department of Rehabilitation, Ton-Yen General Hospital, Hsinchu, Taiwan, (5) Department of Physical Medicine and Rehabilitation, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, (6) Institute of Allied Health Sciences, National Cheng Kung University, Tainan, Taiwan

Background:

Children with autistic spectrum disorder (ASD) exhibit deficits in social competence. To date, few intervention programs specifically targeting social competence have been designed for children with ASD under the age of 6 years. Didactic teaching may be an effective approach to improve the social competence of these children. Practice in play contexts can improve preschool children’s motivation and learning and also their ability to generalize such practice to real life. Therefore, we designed a social-competence group intervention (SCGI) with a combination of didactic teaching and practice in play contexts for children with ASD under the age of 6 years.

Objectives:

This study investigated the effectiveness of the SCGI, which included didactic teaching and practice in play contexts, on social competence with a randomized controlled trial design.

Methods:

Children were recruited if they were under 6 years of age and had a diagnosis of ASD without apparent verbal comprehension impairments. Recruited children were randomly assigned into the SCGI and control groups. Children in the SCGI group received 16 group-based sessions. Each session met for 50 minutes once per week and targeted specific social topics (i.e., greeting and encouraging others). Didactic teaching was applied in each session to describe the targeted social behavior, provide meaningful rationales, and analyze small steps in the target behavior. Play activities were designed to rehearse and reinforce the targeted social behaviors in a naturalistic play context. Children in the control group participated in their regular occupational therapy, which did not focus on social competence, during the study period. Two evaluations were scheduled before and after the intervention for the baseline and outcome data collection. In these two evaluations, children’s social competence and adaptive behaviors were assessed with the Observational Social Competence Assessment (OSCA), Social Responsiveness Scale, Second Edition (SRS-2), and Vineland Adaptive Behavior Scales, Third Edition, Chinese version (VABS3-C). Caregivers were asked to fill out the Parenting Stress Index Short Form-Chinese version (PSI/SF-C) to measure their parental stress. Repeated measures analysis of variance (rmANOVA) was applied to analyze the intervention effectiveness.

Results:

A total of 25 children (12 in the SCGI and 13 in the control groups) completed their interventions and assessments. The results of the rmANOVA showed that the SCGI showed significant effects on the social adjustment subdomain of the OSCA, the social cognition, social communication, and total scores of the SRS-2, and the parent–child dysfunctional interaction score of the PSI/SF-C ($\eta^2 = 0.17–0.41$, all $p < 0.05$). However, the intervention effects of the SCGI were not significant on any of the 5 subscale scores of the VABS3-C ($p = 0.06–0.94$).

Conclusions:

This study indicates that the SCGI, with the combination of didactic teaching and practice in play contexts, was effective in improving children’s social competence and reducing caregivers’ parenting stress in children with ASD aged under 6 years. The study results provide evidence of the effectiveness of the SCGI and guidance for clinicians to improve the social competence of preschool children with ASD.

**404.224 (Poster)** Parent-Strategies Among Latino Parents of Children with Down Syndrome Following a Parent-Mediated Social Communication Intervention

M. A. Tafolla, W. I. Shih and C. Kasari, (1) UCLA, Los Angeles, CA, (2) University of California - Los Angeles, Los Angeles, CA, (3) University of California Los Angeles, Los Angeles, CA

Background: JASPER is a parent-mediated social communication intervention effective in improving social communication outcomes for autistic children (Kasari et al., 2021) but has not been tested in children with other neurodevelopmental disorders like Down syndrome (DS). Additionally, few early intervention studies have focused on recruiting Latinx families despite the important role culture plays in parent-child interactions (Hoff et al., 2019).
Objectives: To explore whether parent level of education and primary language spoken at home are associated with JASPER fidelity before and after treatment among Latinx parents of children with DS. To assess whether parent JASPER fidelity at exit is concurrently associated with child language outcomes and moderated by treatment.

Methods: This was a secondary data analysis of 34 Latinx parent-child dyads randomized into the JASPER-EMT intervention (a blended early intervention designed to support language development) or waitlist control arm. Children’s average chronological age was 41.65 months (SD_{age}=7.40; 44% female). The mean visual receptive age equivalent score was 23.58 months (SD=5.07 months). Most caregivers (88%) were mothers (M_{age} = 39.58 years, SD_{age}= 6.37 years). Forty-one percent of families spoke primarily Spanish at home. Number of different word roots (NDWR), coded from a natural language sample, were used to assess language outcomes (Tager-Flusberg et al., 2009). Two sample t-test were used to compare (1) JASPER fidelity scores at entry between mothers with lower education levels (attended some high school or below) and higher education levels (completed high school or above) and (2) JASPER fidelity scores between mothers who used Spanish vs. English as their primary language at home. ANCOVAs were then used to assess whether (1) treatment predicted exit JASPER fidelity scores, controlling for baseline JASPER fidelity, (2) mother’s level of education predicted JASPER fidelity at exit, controlling for baseline JASPER fidelity and (3) primary language at home predicted JASPER fidelity at exit, controlling for baseline JASPER fidelity. Lastly, negative binomial regressions were used to assess whether (1) JASPER fidelity at exit was associated with NDWR at exit, controlling for entry NDWR and (2) whether the relationship was moderated by treatment.

Results: Mothers with higher education had JASPER fidelity ratings that were, on average, 10% higher at entry compared to parents with less education (35.9% vs. 25.9%, p=.018). Primary language spoken at home was not associated with JASPER fidelity at entry (30% vs. 32.8%, p=.532). There was a significant treatment effect on JASPER fidelity at exit (p<.001) but no significant associations between JASPER fidelity at exit and level of education (p=.122) or primary language spoken at home (p=.992). JASPER fidelity at exit was associated with NDWR at exit, controlling for entry NDWR (p=.03). The relationship between JASPER fidelity at exit and NDWR at exit was moderated by treatment (p=.04). Higher JASPER fidelity was associated with higher NDWR for those in the intervention group.

Conclusions: Regardless of level of education and primary language spoken, parents were able to make notable gains and uptake JASPER strategies. Additionally, this study establishes preliminary evidence that the parent-mediated JASPER intervention is efficacious for Latinx children with DS.

404.225 (Poster) AI-Based Non-Invasive Analysis of Child-Therapist Acoustic Interaction Features in Autism Treatment with Preschool Children in Unconstrained Clinical Contexts: A Feasibility Study

G. Bertamini, C. Furlanello, S. Perzollì, A. Bentenuto, E. Paolizi, M. Chetouani, D. Cohen, and P. Venuti
(1)Department of Psychology and Cognitive Science, Laboratory of Observation, Diagnosis, and Education (ODFLab) - University of Trento, Rovereto (TN), Italy, (2)Department of Child and Adolescent Psychiatry, Hôpital Universitaire Pitié-Salpêtrière, Sorbonne University, Paris, France, (3)Data Science for Health (DSH), Bruno Kessler Foundation (FBK), Trento, Italy, (4)Institut des Systèmes Intelligents et de Robotiques, CNRS UMR 7222, Sorbonne University, Paris, France, (5)HK3 Lab, Rovereto, Italy, (6)Oroboris Life Science, Bergamo, Italy, (7)Department of Psychology and Cognitive Science, Laboratory of Observation, Diagnosis, and Education (ODFLab) - University of Trento, Rovereto (TN), Italy, (8)Laboratory of Observation, Diagnosis, and Education (ODFLab), University of Trento, Rovereto, Italy

Background:

Unconstrained clinical contexts challenge the automation and the objective quantification of behavior and interaction pattern analysis to bridge research and clinical practice in Autism Spectrum Conditions (ASC), especially during treatment (MoFitt et al., 2022). Non-invasive systems leveraging Artificial Intelligence (AI) may significantly improve the study of treatment response trajectories and enable Precision Psychology approaches in ASC.

Objectives:

To validate a Deep Learning (DL) system for automatically classifying audio signals from video-recorded sessions of Autism Naturalistic Developmental Behavioral Intervention (NDBI) with preschool children.

We aimed at: (1) identifying the presence of human voice; (2) performing child-therapist diarization, for the analysis of the child-therapist interaction dynamics in unconstrained, noisy clinical contexts, non-invasively and in presence of data scarcity and imbalance.

Methods:

For audio analysis, we trained 2D Convolutional Siamese Neural Network (SNN) with self-attention and dilated convolutions, over a set of Mel-Frequency Cepstral Coefficients (MFCCs) extracted from 1-sec audio segments recorded during Autism NDB Intervention and clinical assessments with preschool children. Feature augmentation and online triplet mining strategies were employed and data were projected to a 128-dimensional embedding space to perform similarity-based classification through Euclidean distance.
The train set comprised N=10249 segments (Nu=2402 unvoiced; Nc=3781 child’s vocalizations; Nt=3149 therapist’s vocalizations;Nm=917 mixed). Classification was evaluated through accuracy, F1-score, sensitivity, specificity, Positive Predictive Value (PPV), and Matthews Correlation Coefficient (MCC), robust to data imbalance.

The model was evaluated on: (1) a test set of N=762 (Nu=172; Nc=392; Nt=149; Nm=49) segments not in the train set sessions; (2) an external robust test set of N=430 (Nu=88; Nc=104; Nt=194; Nm=44) segments involving previously unseen children, therapists, recorded elsewhere by different devices, to evaluate generalization.

We compared our architecture with other Machine Learning (ML) and state-of-the-art DL models, i.e., EfficientNetV7 with transfer learning and fine tuning and a Transformer architecture (Vaswani et al., 2017), by means of Area Under the Curve (AUC) and DeLong test.

Results:

For human voice recognition, the Siamese net model achieved high performance on both the test (AUC=0.963; accuracy=0.890; F1=0.925; sens=0.881; spec=0.919; PPV=0.974; MCC=0.730) and the robust test (AUC=0.974; accuracy=0.944; F1=0.965; sens=0.971; spec=0.841; PPV=0.951; MCC=0.826) sets, with higher specificity and PPV than the state-of-the-art DL methods.

The Siamese net model was also accurate in the child-therapist diarization task, on both the test (AUC=0.950; accuracy=0.869; F1=0.905; sens=0.860; spec=0.893; PPV=0.955; MCC=0.706) and the robust test (AUC=0.911; accuracy=0.829; F1=0.783; sens=0.885; spec=0.799; PPV=0.702; MCC=0.656) sets, significantly outperforming the other methods (p<0.001).

Conclusions:

The feasibility of an accurate audio analysis based on AI in real-world settings is relevant for a translation for clinical intervention in Autism, possibly enabling AI-assisted Precision Psychology.

Current research aims at applying the Deep Learning model on longitudinal clinical data and videos in order to integrate audio features with dyadic interaction features in the predictive analysis of treatment outcome.

AI may represent a valuable resource to provide clinicians precious information for treatment monitoring and optimization in naturalistic clinical contexts.

Adapting and Piloting a Teacher Coaching Model Based on the Who Caregiver Skills Training in Public Preschool Settings in Italy

C. Ferrante1, A. Salandin1, S. Rizzo1, S. Ghersi1, L. Pacione1, C. Servili1 and E. Salomone2,3, (1)Department of Psychology, University of Milan-Bicocca, Milan, Italy, (2)Fondazione Paideia, Turin, Italy, (3)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland

Background: In the public preschool education system in Italy, children with ASD are enrolled in regular classes led by a classroom teacher, supported by a special education teacher for part of the time. While this model has the potential to promote inclusion and reduce stigma, little or no access to hands-on teacher training in strategies to promote engagement, communication, cognitive and daily living skills has negative consequences on child learning as well as teacher confidence.

Objectives: To adapt and pre-test a teacher-coaching model based on the Caregiver Skills Training (CST), a naturalistic developmental behavioural open access caregiver-mediated intervention developed by WHO (2022)

Methods: The study consisted of an adaptation phase and pre-pilot implementation phase. In the adaptation phase, clinical psychologists with experience of CST implementation and a WHO CST Team member adapted WHO CST materials to develop an individual coaching model for preschool teachers. All core psychoeducational contents and intervention strategies of CST were included, with the exception of adult self-care and problem-solving skills. The adapted intervention consisted of 4 individual virtual sessions with a standard schedule (Figure 1 and Table 1). Participants of the pilot implementation were 23 preschool teachers of the public education system in a city in Northern Italy (M age 43.35 years, SD = 11.68). 11 were classroom teachers and 12 special education teachers; 60% had attended lecture-style seminars on autism. At treatment endpoint, teachers completed an acceptability and feasibility questionnaire adapted from the WHO CST Monitoring & Evaluation Framework. Teacher competence (knowledge and skills) and self-efficacy were assessed at baseline and endpoint with an adaptation of the WHO Caregiver Knowledge and Skills Test. Endpoint interviews were conducted to explore perceived benefits, barriers and challenges of the coaching model.

Results: 22 (96%) teachers attended at least 3 coaching sessions; all submitted at least 2 practice videos. Acceptability ratings were in the ‘good’ range (≥ 4) across relevance, usefulness, value of the sessions and representativeness of teacher behavior; child behavior was
considered insufficiently representative by 4 (29%) teachers. Feasibility ratings for the coaching sessions were ‘satisfactory’ (> 3) across the following dimensions: prevalence of IT difficulties, low audio-visual quality, distractions and interruptions. 5 (36%) of teachers reported that the child was distracted by the camera, and 2 (14%) reported difficulties sharing the video in between sessions. Paired samples t-tests showed a significant improvement on both competence [pretest, M=48.95, SD=6.50), posttest: M=53.70, SD=5.92; \( t(19) = -3.67 \) (16), \( p=.001 \), and self-efficacy [pretest, M=99.30, SD=6.48), posttest: M=103.94, SD=8.44; \( t(19) = -3.17 \) (16), \( p=.003 \). Thematic analysis of 14 interviews identified several benefits (flexibility of remote sessions; self-reflection facilitated by videofeedback) as well as challenges (child being distracted by camera; lack of observation of peer relationships).

Conclusions: The adapted CST teacher-coaching model was found to be acceptable and feasible in public preschool settings in Italy. The remote coaching sessions were highly acceptable, relevant and perceived as beneficial; however, challenges to implementation were identified. Future studies with a randomized design should address barriers to participation and provide evidence of effectiveness on child and teacher outcomes.

**404.227 (Poster) Age Is Related to Better Outcomes in Young Autistic Children Attending Special Education Preschool: A Follow-up Study**

**Background:**

The impact of age on intervention outcomes among autistic toddlers has been previously examined in different contexts. However, the effect of age on outcomes in various developmental domains among young children receiving special education instruction has not yet been examined.

**Objectives:**

To examine the impact of age on outcomes in autism severity, language, and adaptive skills among autistic children following one year of intensive intervention at special education classes for autistic children.

**Methods:**

Seventy-three autistic children (12 girls) aged 2:10-7:6 years (\( M = 4:10, \ SD = 1:0 \)) were divided according to the cohort’s median age into a younger group (n=35, \( M_{age}=3:11, \ SD=0:7 \)) and an older group (n=38, \( M_{age}=5:7 \ SD=0:7 \)). The groups did not differ in baseline cognition, autism severity, or adaptive skills scores. Participants underwent evaluation at the beginning (T1) and end (T2) of one academic year, including measures of autism severity using the Social Responsiveness Scale (SRS-2), adaptive behavior using the Vineland Adaptive Behavior Scales (VABS), and language assessment using the Goralnik Screening Test for Hebrew. All participants were attending special education classes for autism that were operational 50 hours a week over 6 days. The curriculum included group and individual activities provided by educational and para-medical interdisciplinary professionals, and each child’s intervention program had been customized.

**Results:**

To assess autism severity, a 2x2 (2Age groups x 2Times) MANOVA with repeated measures for Time was conducted for the SRS subdomains, yielding a significant Time x Group interaction [F(4,65)=4.87, \( p=.002, \eta^2=.23 \)]. Specifically, significant interactions were observed for awareness, communication, and motivation subdomain scores, but only the younger group, not the older group, showed decreased SRS subdomain scores over time (Table 1). For outcomes in language abilities, a 2x2 MANOVA with repeated measures for Time was conducted for the Goralnik language subdomains (naming, articulation, comprehension, imitation, expression, and storytelling) scores, revealing a significant Time effect [F(4,42)=23.08, \( p<.001, \eta^2=.69 \)] and a significant Time x Group interaction [F(4,42)=4.33, \( p=.005, \eta^2=.29 \)]. For all language subdomains a significant increase was found from T1 to T2. However, the younger group had a more robust increase in vocabulary and expressive language subdomain scores than the older group. For adaptive skills, a significant Time effect [F(4,64)=9.47, \( p<.001, \eta^2=.38 \)] and a significant Time x Group interaction [F(4,64)=4.48, \( p=.003, \eta^2=.23 \)] were found (2x2 MANOVA). For the VABS communication, DLS, and socialization subdomain scores, only the Time effect was significant, as both groups showed a similar increase from T1 to T2. For the VABS motor subdomain, a significant Time x Group interaction was noted as only the younger group showed an increase from T1 to T2.

**Conclusions:**
Autistic children attending special education classes and receiving intensive intervention showed increased language abilities and adaptive skills among both age ranges. However, only the younger children showed decreased autism severity and a more robust increase in verbal abilities. These findings emphasize the importance of starting intensive intervention as early as possible as a younger age is associated with better outcomes.

### 404.228 (Poster) Blended E-Health for Children at Early Risk (BEAR): Development of the Intervention and Pilot Results.

M. Snijder, C. Dietz, M. van Andel, E. Ruiters, J. K. Buitelaar and I. J. Servatius-Oosterling, (1)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (2)Karakter, Child and Adolescent Psychiatry University Centre Nijmegen, Nijmegen, Netherlands, (3)KOOS, Utrecht, Netherlands, (4)GGD Gelderland-Zuid, Nijmegen, Netherlands, (5)Department of Cognitive Neuroscience, Radboud University, Nijmegen, NETHERLANDS, (6)Karakter Child and Adolescent Psychiatry University Center, Nijmegen, Netherlands

Background: The importance of early detection and intervention of autism spectrum disorder (ASD) is widely recognized. Difficulties in early identification and access to early interventions are multifaceted, with barriers related to child, parent, professional and organizational levels. As part of a wider strategy to overcome these barriers, the BEAR (Blended E-health for children at eArly Risk) intervention was developed. This is a relatively short and acceptable home-based early intervention offered to parents with symptomatic high risk infants and toddlers. There might be ASD related concerns regarding the child’s development, but not necessarily a confirmed ASD diagnosis.

Objectives: The aims are to present (1) the BEAR intervention protocol, and (2) results of pilot testing the protocol in a small sample (N=6).

Methods: BEAR is a parent adopted, blended e-health intervention. The global focus is supporting parents to understand their child’s behavior, promoting sensitivity in parents to their child’s needs and to motivate the child to socially engage (e.g. improving joint engagement). During pilot testing, six children completed the intervention. The primary outcome measure is joint engagement measured by the Joint Engagement Rating Inventory (JERI) during videotaped parent-child interaction. Secondary outcome measures include severity of ASD symptoms (BOSCC), parental well-being (PSQ, WEMWBS), parental skills (JERI) and satisfaction with healthcare.

Results: Most children (n=4) improved on total time spent in joint engagement. One child seemed to decrease and another child stayed the same. Looking at severity of ASD symptoms, three children decreased in severity. Two children neither increased nor decreased and one child showed slightly more severe ASD symptoms. Looking at parental skills, most parents improved on following in and symbol highlighting skills. There was hardly any improvement measured on scaffolding. All parents reported improved mental well-being after completing the intervention. As for parental stress (N=4), results varied; two parents experienced reduced parental stress, one did not experience any change and one parent seemed to experience more parental stress. After completing the intervention, parents and the interventionist indicated how satisfied they were with the BEAR intervention. All parents reported satisfaction and improvement on multiple areas (child behaviour, raising their child, understanding child’s behaviour) and would recommend the BEAR intervention to others. Interventionists were more critical on the effect of the training that they provided, but were overall satisfied with the effect on family functioning, child upbringing and parental insight in the behaviour of the child.

Conclusions: Preliminary results are promising, with most parents and children seem to improve after BEAR on multiple levels (joint engagement, parental skills and parental well-being), although some other parents and children seem to decrease. BEAR is a helpful first step in parent's supporting their child’s needs with being actively involved during the whole process. For some children, this intervention will be the influx to follow-up healthcare, whereas for other children BEAR can function as a preventive intervention. Naturally, robust replication and analyses on larger scale is needed. Our next step is testing short-term and six month effects in a cluster-randomized controlled trial (N=88).

### 404.229 (Poster) Brief Virtual Consultation Model of Behavioral Sleep Treatment for Parents with Autistic Preschool Children

N. C. Russell and A. S. Levine, Child Development Center, Nationwide Children’s Hospital, Columbus, OH

Background: Poor sleep quality and duration have been suggested to affect more than half of autistic preschoolers and have been associated with a greater prevalence of daytime behavioral challenges and increased difficulty with functional skills and communication. It also impacts the sleep quality and duration of parents and families, as well as reducing the time available for other activities, due the time often required to help initiate sleep, manage nighttime awakenings, or being with early-rising children. Parents often engage in activities which unintentionally positively reinforce child behaviors that interfere with sleep schedules (e.g., providing food or drink during the night). Increasing parents’ understanding of positive sleep principles and implementing interventions has the potential to help both the child and their family.

Objectives: This pilot study examined the clinical impact of a pilot brief virtual consultation model to provide behavioral sleep education and intervention to parents of autistic preschoolers. Sleep onset latency (SOL), wake after sleep onset (WASO), and total sleep time (TST) were the main clinical parameters examined.
Methods: Parents of autistic preschool children (n = 26; mean age = 37.3 months) were seen via telehealth for between one and three 60-minute sessions focusing on behavioral sleep education and intervention. Families were referred by psychologists and medical providers, either at their autism evaluation or a medical follow-up appointment. Data regarding sleep schedule were collected at each session and recorded in sleep diaries.

Results: The SOL decreased between session one (mean SOL₁ = 72 minutes) and session two (mean SOL₂ = 32 minutes). For those with nighttime awakenings, WASO decreased between session one (mean WASO₁ = 48 minutes) and session two (mean WASO₂ = 19 minutes). The TST increased from session one (mean TST₁ = 9 hours 56 minutes) to session two (mean TST₂ = 10 hours 26 minutes). In addition, at the first session, 84.6% of parents stayed with their child until they fell asleep and 42.3% of parents put their child to bed in the parent’s room or bed. While the most frequent interventions included improving bedtime routines, fading parental presence, time-based visiting, and putting the child to bed later/when tired, interventions typically had to be tailored to the individual family situation – whether due to particular challenges facing their child or the family’s individual capacity for change – and parents were able to choose which interventions were most appropriate for their family, becoming an active part of the treatment team.

Conclusions: Implementing a brief behavioral sleep intervention, administered via telehealth and including psychoeducation to support future skills and parental choice regarding interventions, appears to be able to reduce the time it takes preschool age autistic children to get to sleep, increase how long they sleep for, and reduce the length of time they are awake for during the night. Further research should explore the impact of this intervention model on the daytime behaviors of autistic preschool-age children and their family’s functioning, as well as the merits of utilizing standardized measurement to identify potential referrals and to gauge improvement.

Results: (1) Child Outcomes after Therapist-Delivered Interventions: Overall, MSEL DQ and VABS ABC were significantly higher (i.e., higher level of skills) at T3 compared to T1. There were no effects for group (i.e., ESDM, G-ESDM, Community Services). All other findings were non-significant. (2) Child Outcomes after Parent Coaching: MSEL DQ was significantly higher at T3 vs T1 and at T2 vs T2 for the No Coaching group. VABS ABC was higher at T3 vs T2 and at T2 vs T1; there was no main effect of group nor interaction of group*time. (3) Parent Outcomes after Parent Coaching: Parents reported significantly higher Clarke-QRS scores (i.e., more parenting stress) at T3 vs T2 and at T3 vs T1; there was no main effect of group nor interaction of group*time. There was a significant time*group interaction, but not main effects, for PSOC, driven by a trend ($p = 0.051$) for the No Coaching group to have lower PSOC scores (i.e., lower parenting sense of competence) at T3 vs. T1. To determine if participation in P-ESDM mediated the association between parenting sense of competence at T1 and T3, a follow-up mediation analysis was performed. The results indicated that the total effect between PSOC scores at T1 and T3 was significant ($B = 0.628$, $p < 0.01$), however the indirect mediating effect was non-significant ($B = -0.024$, $p = 0.582$).

Conclusions: Our findings suggest beneficial effects of early intervention for autistic children and, to a lesser extent, parents.
Background: Autism-specific, parent-mediated intervention for children under age 3 leads to developmental gains. Transferring evidence-based, parent-mediated treatment approaches from research settings to the community has proven challenging. A recent US implementation study using key components for community delivery of the Early Start Denver Model (C-ESDM), including online video lessons and parent coaching, showed promising results in improving parent fidelity to ESDM strategies compared to usual care.

Objectives: To translate and adapt the C-ESDM model, including the Help is in Your Hands (HIIYH) video modules for Spanish-speaking communities and pilot test satisfaction and effectiveness in a group telehealth format.

Methods: During the first year of the COVID-19 pandemic, Spanish-speaking ESDM-trained providers used the HIIYH (www.helpisinyourhands.org) online program with four families whose young children had autism. Parents attended weekly 90-min group online sessions for 16 weeks. Providers shared HIIYH video modules using simultaneous English-to-Spanish translation and adjusted for specific Spanish terminologies and cultural adaptations. This field test informed the language translation and caregivers’ acceptability in a telehealth group-based delivery. A formal English-to-Spanish professional translation of the HIIYH English scripts was conducted with eight new caregivers (four per group). Families’ feedback was used to further adapt the Spanish script. Finally, a consensus technical review was conducted between two ESDM-certified autism specialists. Adaptations will be described. Caregivers’ satisfaction (hospital patient experience Ad-hoc online questionnaire), knowledge acquisition (Ad-hoc online questionnaire of the core knowledge for each HIIYH lesson), child’s autism characteristics (ADOS-2), and developmental level (BSID-III, P-ESDM Curriculum-Checklist) were examined before and after the program through descriptive statistics and paired T-tests. Participants currently include eight caregivers (87.5% mothers) between 30-37 years old (75%). Many had a university degree (50%) and were employed (75%) in a skilled occupation (37.5%). Participating children included eight toddlers with autism (ADOS; $M = 19.13, SD = 3.56$), all male with a mean age of 27 months ($SD = 2.59$). BSID-III scores showed mean cognitive scores in the borderline range ($M = 76.88, SD = 15.34$), and significant language delay ($M = 53.00, SD = 5.55$), at the study entry. The sample will at least double by the time of the INSAR meeting.

Results: Caregivers rated the C-ESDM program using the HIIYH modules as “positive” (33%) to “very-positive” (66%). HIIYH video examples were especially well received as they directly supported caregiver strategy use during daily activities. Participants appreciated the group component and shared experiences. Therapist support during the telehealth session was rated as “very positive.” Caregivers’ knowledge showed a significant improvement ($M_{pre} = 16.63, M_{post} = 18.5, SD = 1.59, t = -2.707, p = 0.03$). Significant child differences involved the BSID-III -language scales ($M_{pre} = 53, M_{post} = 60.5; t = -2.758; p = 0.028$) and on the P-ESDM Curriculum-Checklist ($M_{pre} = 46.75, M_{post} = 68; t = -6.211; p = 0.01$).

Conclusions: The C-ESDM program, including the supported use of HIIYH online modules, shows promising pilot responses for community implementation of group telehealth parent training. The C-ESDM group model could be an important resource for Spanish-speaking community service delivery.

Objectives: This study’s main objective was to evaluate whether a PCIT adaptation for children with ASD and severe language and cognitive delays improves child behavioral and social functioning and reduces parenting stress.

Background: Children with autism spectrum disorder (ASD) frequently present with co-occurring problem behaviors (e.g., noncompliance, aggression, tantrums). Parent-Child Interaction Therapy (PCIT) is an effective caregiver-mediated behavioral intervention for children with ASD, resulting in improvements in child externalizing behavior, parenting skills, parenting stress and core symptoms of ASD (e.g., Parlade et al., 2019). There is limited research regarding the application of PCIT among children with ASD and severe developmental delays. An adapted version of PCIT has been introduced in a handful of case studies (e.g., Lesack et al., 2014). In this adaptation of PCIT, the Child Directed Interaction (CDI) phase is largely consistent with traditional PCIT, as it coaches caregivers to use positive parenting skills to strengthen the caregiver-child relationship by promoting social communication and play skills. Additional considerations for children with ASD (e.g., visual supports) are included. The Parent Directed Interaction (PDI) phase teaches caregivers to use effective commands to address noncompliance. In the modified version of PDI, caregivers deliver “compliance training” in which they are taught to use a three-step sequence based on a least-to-most prompting model (i.e., verbal/gestural, model, physical). The present study expands on previous work by examining the efficacy of this PCIT adaptation in a small sample of children with ASD and significant delays.

Objective: To translate and adapt the C-ESDM model, including the Help is in Your Hands (HIIYH) video modules for Spanish-speaking communities and pilot test satisfaction and effectiveness in a group telehealth format.
Regarding peer review latencies, multiple studies in our sample have been flagged for unexpectedly short latencies. At present, none of the currently coded articles have reported COIs. We included 290 reports identified in the updated Project AIM search. Full texts were searched for terms related to adverse event monitoring and reporting, including “adverse”, “harm”, “side effect”, and “complication”. Acknowledgement and disclosure texts were searched for COI statements, and these were categorized by type (e.g., author developed the intervention, author is affiliated with/employed by a clinical provider). To code latency of peer review, publicly available submission and acceptance dates were extracted for all studies published in journals that publicize such information. Efforts to collect these dates for remaining studies via email to journal editors is ongoing. Once this information is collected, reports will be plotted by latency to identify a cut-off point that characterizes potentially inadequate peer review (e.g., less than 1 week). We will then apply robust variance estimation to examine whether effects from reports with potentially inadequate peer review are significantly larger than effects from reports with longer peer review latencies.

Conclusions: Changes from pre- to post-treatment demonstrate improvements in child disruptive behavior and compliance, and decreases in parenting stress, while changes in core symptoms of ASD were not detected. These findings support the use of a compliance training PCIT adaptation in improving the caregiver-child relationship for more impacted children with ASD and severe developmental delays. Suggestions for when this adaptation may be appropriate will be discussed.

**404.233 (Poster) Conflicts of Interest, Adverse Events, and Inadequate Peer Review: Frequently Ignored Aspects of Study Quality**

*S. LaPoint*, K. Bottema-Beutel, Y. C. Syu and M. Sandbank; (1)University of North Carolina-Chapel Hill, TEACCH Autism Program, Carrboro, NC, (2)Lynch School of Education and Human Development, Boston College, Chestnut Hill, MA, (3)University of North Carolina - Chapel Hill, Chapel Hill, NC, (4)The University of Texas at Austin, Austin, TX

**Methods:**

We included 290 reports identified in the updated Project AIM search. Full texts were searched for terms related to adverse event monitoring and reporting, including “adverse”, “harm”, “side effect”, and “complication”. Acknowledgement and disclosure texts were searched for COI statements, and these were categorized by type (e.g., author developed the intervention, author is affiliated with/employed by a clinical provider). To code latency of peer review, publicly available submission and acceptance dates were extracted for all studies published in journals that publicize such information. Efforts to collect these dates for remaining studies via email to journal editors is ongoing. Once this information is collected, reports will be plotted by latency to identify a cut-off point that characterizes potentially inadequate peer review (e.g., less than 1 week). We will then apply robust variance estimation to examine whether effects from reports with potentially inadequate peer review are significantly larger than effects from reports with longer peer review latencies.

Results:

We have coded approximately 25% of articles published between 2017 and 2022 for adverse event reporting, and have found that 15% mentioned adverse events and 10% reported monitoring procedures. At present, none of the currently coded articles have reported COIs. Regarding peer review latencies, multiple studies in our sample have been flagged for unexpectedly short latencies.
Conclusions:

Despite some positive movement in adverse event monitoring and reporting and conflict of interest disclosure, these ethical aspects of conducting and reporting intervention research findings still appear to be an issue in autism research. In addition, peer review practices in this body of literature suggest additional unethical practices that have yet to be substantively addressed by autism researchers.

404.234 (Poster) Counterfactual Conditions in Studies of Early Childhood Interventions for Autistic Children

S. Albarran and M. Sandbank, The University of Texas at Austin, Austin, TX

Background:

Systematic reviews and meta-analyses of early childhood interventions for autistic children rarely describe or consider the counterfactual conditions provided to comparison groups in included studies. As such, little is known about the types of counterfactual conditions typically employed in such studies, the frequency with which certain categories of counterfactual conditions are employed, and whether this varies by intervention type (where studies of one category of intervention are more likely to feature an active control than studies of another category of intervention). This matters because estimates of intervention effectiveness are derived from the comparison between the intervention and control groups, and active controls may reduce the potential inflationary effects of performance bias. Thus, choice of counterfactual comparison has the potential to substantially influence estimates of intervention effectiveness in a comprehensive meta-analysis and corresponding clinical recommendations.

Objectives:

1. Describe the categories of counterfactual conditions employed in studies of early childhood interventions for autistic children, the frequency with which they are employed, and whether this varies by intervention type.
2. Determine whether intervention effects systematically vary by counterfactual condition.

Methods:

All comparisons in 290 reports included in the updated Project AIM data set (where some reports featured more than one comparison group) were coded for counterfactual condition. Counterfactual conditions were independently double coded as either business as usual (BAU), alternate intervention (AI), modified intervention (MI), or a sham condition. Interrater agreement was high (Kappa = 0.82). Descriptive statistics were calculated to characterize the frequency of counterfactual categories across the full set of studies and by intervention type. Counterfactual condition coding is currently being integrated into outcome level data sets in preparation for moderator analyses. We will then apply robust variance estimation, specifically using a subgroup correlated effects model, to determine whether effects significantly vary by counterfactual condition category.

Results:

Across 290 reports, there were a total of 317 counterfactual conditions. Of these, 241 (76%) were BAU, 43 (14%) were MI, 19 (6%) were AI, and 14(4%) were sham conditions. Developmental Interventions were exclusively compared to BAU counterfactuals. AI and MI counterfactual conditions were more frequently represented in studies of Behavioral interventions and NDBIs than in studies of other intervention types. Sensory-based interventions and technology-based interventions were the only intervention type that were compared to sham counterfactual conditions. We plan to indicate during the panel presentation whether effect sizes significantly vary by counterfactual condition category.

Conclusions:

The vast majority of counterfactual conditions in early childhood autism intervention literature are BAU. However, more established intervention types, such as behavioral interventions and NDBI, have been more frequently tested against modified or alternative intervention counterfactuals. It is likely that the characteristics of certain types of interventions, including technology-based interventions and sensory-based interventions, permit comparison to a sham counterfactual.
Background:

In the last decade, parent-mediated intervention programs have been increasingly adopted in the autism spectrum disorder (ASD) clinical field. The Cooperative Parent-Mediated Therapy (CPMT) is an individual parent coaching program based on Naturalistic Developmental Behavioral strategies aimed at promoting and leveraging positive parental interactional skills in interactions with their ASD-diagnosed children. The CPMT targets the following selected parental skills: Socio-emotional engagement, Emotional Regulation, Imitation, Ostensive Communication, Communication, Joint Attention, Play and Cognitive Flexibility, and Cooperative Interaction.

Objectives:

The present study evaluated the effect of the CPMT on a sample of 10 dyads including Italian preschool children “at risk” for autism (7 males and 3 females, age from 10 to 36 months) and their parents (either father or mother). Participating children were recruited through and assessed by trained clinicians at the Bambino Gesù Pediatric Hospital in Rome in a pre-therapy diagnostic session with ADOS (Autism Diagnostic Observation Schedule) and ADI-R (Autism Diagnostic Interview-Revised).

Methods:

To compare pre and post intervention interactions of participating dyads, video recordings at two different time points were selected and analysed: before the CPMT intervention (T0) and at 6 months follow ups after the intervention (T1). In both T0 and T1 sessions, parents were asked to play with their children as they usually do at home, using props and objects provided during the therapy, e.g. books and toys for pretend play. A combination of qualitative and quantitative measures was adopted on the video data. First, parent’s behaviors in interaction were coded by using PICCOLO (Checklist Observations Linked to Outcomes, Roggman et al. 2013), a rating scale including four behavioral domains considered as good predictors of positive developmental outcomes for children: Affection, Responsiveness, Encouragement, and Teaching.

Results:

Results from pre and post assessment with PICCOLO were analyzed by using a repeated measures ANOVA comparing data collected before and after the therapy, for each parent-child dyad. Analyses revealed significant improvements in each domain from T0 to T1, with the responsiveness domain having the most significant effect (Affection \( t = -3.881, p_{\text{Tukey}} = 0.047 \); Responsiveness \( t = -6.692, p_{\text{Tukey}} = 0.001 \); Encouragement \( t = -5.250, p_{\text{Tukey}} = 0.008 \); Teaching \( t = -5.014, p_{\text{Tukey}} = 0.010 \)). Then, based on statistical evidence from PICCOLO, focused in depth microanalyses were carried out on RESPONSIVENESS to investigate changes in this domain as a result of the CMPT.

Qualitative analyses were conducted with ELAN (Brugman et al., 2004) on the most significant video-recorded observations, and included vocalization, audio pitch and intensity, action and gaze of caregiver and child. Results showed that responsiveness improved after therapy, especially at the beginning of the interactive episodes. Qualitative, in depth observation of a sub-set of parent child interactions confirmed the increased ability of the parent to follow the child's activities with flexibility after therapy.

Conclusions:

To conclude, this study presents preliminary but sound evidence of the benefits of using CMPT as an early intervention aimed at improving interactional dynamics in families with ASD children, supporting scientific understanding of how these improvements are mutually achieved by parents and children.

404.236 (Poster) Developing a Comprehensive Theory of Change of a Naturalistic Developmental Behavioral Intervention Using an Exploratory Sequential Mixed Methods Design

K. M. Frost\(^ 1\) and B. R. Ingersoll\(^ 1\), (1)Psychology, Michigan State University, East Lansing, MI, (2)University of Colorado School of Medicine, Aurora, CO

Background: Mounting evidence suggests that naturalistic developmental behavioral interventions (NDBIs) support social communication development in young autistic children. NDBIs are increasingly being researched and deployed in community settings. Yet, there is relatively little empirical evidence pertaining to the active ingredients, mechanisms of change, and long-term outcomes of these complex interventions.

Objectives: This study engaged a variety of intervention shareholders, including treatment experts, community providers, and caregivers, to develop a comprehensive theory of change of Project ImPACT, a parent-mediated NDBI.

Methods: We used an exploratory sequential (qual -> quan) mixed methods design. First, shareholders (10 expert trainers, 21 certified providers, and 12 caregivers) completed semi-structured interviews about their experiences with Project ImPACT, in which they described mechanisms of change associated with various components of the intervention as well as short- and long-term outcomes for children and
Developmental Delays in Children with Autism Spectrum Disorder Enrolled in Early Intervention Programs

Background: The presence of developmental delays is considered to be a critical factor affecting outcomes in individuals with Autism Spectrum Disorder (ASD). However, estimates of the co-occurrence of developmental delays in ASD vary greatly, ranging from 10-70% across studies and age-groups (Zeidan et al., 2022). This variability across studies and populations is problematic because it provides limited information on services and supports for different age-groups and populations on the autism spectrum, including young children who enroll in early intervention (EI) programs.

Objectives: The current study examines the presence of developmental delays in a large and well-characterized sample of autistic children enrolled in EI programs.

Methods: Our research question was addressed using baseline data from an aggregate dataset collected for a broader study that includes child-level data for 913 children with ASD (male 82%; aged 13-75 mos., mean = 38; SD = 13) who enrolled in EIs as part of their participation across 15 EI trials. As children from different trials were administered different developmental assessments (including Mullen Scale of Early Learning, Leiter International Performance Scale-3rd edition, Merrill Palmer-Revised Scales of Development, and the Bayley Scales of Infant Development) a common metric was obtain by generating developmental quotient (DQ) scores, calculated through the ratio of developmental and chronological age. Following Manner et al., 2020, we used DQ ≤70 as a proxy for the presence of developmental delays, while children with DQ of 71-85 were classified as being in the borderline range.

Results: Overall 73% of participants had a DQ ≤70, i.e., consistent with the presence of developmental delays at enrollment, with significant variations related to age of intervention enrollment. As illustrated in Figure 1, 57% of children initiating EI at <24 months had a DQ ≤70, whereas that was the case for 68% of those who initiated EI between 24-35 months, 81% of those who were 36-47 months, and 83% of those who were ≥48 months old at intervention start (X²(6) = 44.53, p < .001). There were no statistically significant differences associated with race (X²(4) = 2.14, p = .71).

Conclusion: Our mixed methods approach emphasized practice-based knowledge from community clinicians as well as caregiver perspectives, allowing us to identify change processes which seem important or meaningful to end-users of the intervention and to consider potential change processes which have been overlooked in research to date. Our research pointed to a variety of downstream effects pertaining to quality of life; in many cases, the caregiver-child dyad’s ability to have fun, mutually engaging interactions was the most meaningful intervention outcome reported by caregivers. Consistent with calls from neurodiversity advocates to focus more on outcomes relating to quality of life, social support, and wellbeing, we believe this is an important area for increased study. This study presents with some limitations. Although our sample for qualitative analysis was relatively large, the respondents were not necessarily representative of all consumers of Project ImPACT. In addition, because we used archival data in the quantitative phase of this study, we did not have access to measures that could assess each hypothesized mediator and outcome in an ideal sequence or at the appropriate times for an ideal longitudinal mediation analysis.
Conclusions: Although a diagnosis of intellectual disability requires additional information and might not be established until later in life, and sampling biases might have affected our results, our data suggest that developmental delays are common in children entering early intervention studies. The proportion of children with DQ scores consistent with developmental delays appeared to increase with age at intervention start, pointing to the importance of closely monitoring developmental progression in the population of children accessing EI, and implementing comprehensive supports accordingly.

404.238 (Poster) Do Child Characteristics at Intervention Start Correlate with Positive Reinforcement Situations at Different Times in an Individualized NDBI Approach?

S. K. Kleber, S. C. Mueller1, J. Kitzerow-Cleven1, L. Polzer2, N. Raji1, C. Lemler1, K. Teufel1, Z. Kim1, N. Bast3 and C. M. Freitag4, (1)Autism Research and Intervention Center of Excellence Frankfurt, Dept. Child and Adolescent Psychiatry, Psychosomatics & Psychotherapy, Goethe-University Frankfurt, Frankfurt, Germany, (2)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany, (3)Autism Research and Intervention Center of Excellence Frankfurt, Goethe University Frankfurt / Department of Child and Adolescent Psychiatry, Frankfurt, Germany, (4)Autism Research and Intervention Center of Excellence Frankfurt, Goethe Universitat Frankfurt am Main, Frankfurt, GERMANY

Background:

Naturalistic developmental behavioural interventions (NDBI), such as the Frankfurt Early Intervention Program A-FFIP, are the treatment method of choice when aiming at improving core ASD symptoms in preschoolers with ASD. It has been discussed that the individual child's characteristics may influence individual applicability of intervention methods. In NDBIs, natural positive reinforcement (PR) are implemented in different ways, such as with non-social, social and combined types of PR (TPRs). To study the individual course of intervention, the amount of change of TPRs and its relation to the child's characteristics at study entry are interesting targets, to exemplify the influence of child's characteristics on the applicability of intervention methods.

Objectives: We explore [1] whether the frequency of different TPRs differs between the first A-FFIP session (T1) and a session approx. six months later (T2). Further, [2] we investigate correlations between the child's characteristics prior to intervention and different TPRs at T1 and T2 and [3] explore if the child's characteristics prior to intervention are correlated with change in TPRs between T1 and T2.

Methods: Data were obtained within the multi-centre, randomised-controlled phase-II trial on the A-FFIP intervention (Kitzerow et al., 2020). Data of N=19 children with ASD, aged M=49 months (SD=11.42) at study entry are presented. For each child, different aspects of PR-situations of T1 and T2 were coded from video (i.e. frequency of PR-situations, TPR [percentage of social, non-social, paired in relation to all PR]). The codings were done by two raters using the OPRIS coding system (inter-rater agreement on the single item level ≥.95). Child characteristics prior to intervention: chronological age (CA), cognitive developmental age (DA; Bayley-III/WPPSI-III), restrictive-repetitive and stereotypic behavior (RBS-R), initiating (IJA) and response to joint attention (RJA; ESCS).

Results:

[1] On the group level, the overall frequency of PR-situations at T1 (M=27, SD=11.9) and T2 (M=31, SD=15.8) did not differ (t(18)=-1.00, p=.33), and no differences were found between TPRs (social: Z=1.15, p=.26; non-social: Z=0.26, p=.80; paired: Z=-1.19, p=.24).

However, on the individual level, change in frequency as well as TPRs was observed (see figure). [2] Small to medium correlations were found between the child’s characteristics prior to intervention and frequency of PR-situations and TPRs in T1 and T2 (see table). [3] Change in frequency of PR-situations and TPR were correlated with CA at study entry (frequency: r=-.48, 95% CI [-.77, -.03]; non-social TPR: r=.30, 95% CI [.18, .66]), DA (social TPR: r=-.33, 95% CI [-.68, -.14]), and IJA (frequency: r=-.44, 95% CI [-.76, -.05]; non-social TPR: r=-.41, 95% CI [-.74, .09], social TPR: r=.34, 95% CI [-.17, .70]).

Conclusions: The results indicate that child characteristics have an impact on the applicability of intervention methods, namely frequency of PR-situations and TPR over the course of the A-FFIP intervention. On an individual level, change in frequency and types of PR were found, which correlated with child characteristics at start of intervention. Planned mediation analyses with a larger sample will provide more insight into the development and possible influences in the future.

404.240 (Poster) EEG Cap Tolerance Training for Parents of Children with Autism: Preliminary Feasibility Study

Background:

Hypersensitivity is common in Autism Spectrum Disorder (ASD), and may interfere with electroencephalogram (EEG) wearable neuroimaging data collection. Differential negative reinforcement of other behavior (DNRO), in which the learner accesses a break from the device, may be an optimal intervention as noncompliance with medical devices may be maintained by access to escape.

Objectives:

The study evaluates preliminary feasibility of DNRO procedures when teaching children to tolerate an EEG head cap.

Methods:

Caregivers of children (2-4 years) enrolled in a study exploring emotion expression were trained to teach their own child to tolerate wearing an EEG cap for 1.5 hours. A fabric cap covering head from inion to nasion on the sagittal axis, and preauricular points on the coronal axis, simulating a full-head EEG cap, was mailed to participant’s homes to practice wearing, prior to clinic appointment. One-hour Behavior Skills Training (BST) training was delivered via Zoom: providing written instructions, modeling, roleplay, feedback on roleplay, and repetition of roleplay until the parent meets mastery criterion. During BST, modeling and roleplay used a doll or stuffed animal. Following completion of BST, the parent practiced DNRO procedures with their own child over Zoom while the instructor observed and provided feedback. Parents were instructed that if the child kept the cap on for a predetermined interval of time (based upon baseline performance), the child could access a 30 second break from the cap and a preferred activity. The instructor recorded the duration of compliance (i.e., seconds or minutes) wearing the cap without attempts to remove or disruptive behavior (e.g., aggression, self-injurious behavior). Generalization data in the clinic setting were collected during the study appointment.

Results:

Of the 20 children who participated in the larger study, 8 completed the BST cap training protocol, and 2 reviewed the mailed materials and received supplemental instruction via phone call (see Figure 1). These 10 participants (50% of larger sample, 100% male, 80% autistic) completed cap training an average of 9 days before the in-person session. Excluded participants (85% typically developing) declined the training as there was no concern of the child not tolerating the EEG cap. Baseline cap tolerance at the training differed among participants (5 children ranged 0 seconds – 6 minutes; 3 children reached >15 minutes). Of those who received training or materials, 70% (n = 7) tolerated the EEG cap for the 1.5-hour session. Three participants were unable to tolerate the EEG cap and did not contribute EEG data. Further, 57% of participants who were trained by their parents to tolerate the cap at home and had a baseline tolerance less than 15 minutes, demonstrated improvements in EEG cap wearing tolerance from baseline to study appointment.

Conclusions:

Preliminary data provide initial evidence that remote BST is successful in teaching parents to implement DNRO procedures with their children. Findings suggest that BST paired with DNRO procedures may facilitate increasing representativeness of study participants by scaffolding tolerance that serves as a requisite for participation. Limitations, variations to implementation, and considerations for future adaptation will be discussed.

404.241 (Poster) Effect of Group Consultation Training Activities on Clinician Adherence to the Project Impact Manual and Parent Coaching Competency

D. Straiton1, J. Greatorex2, M. Moeyaert3 and B. R. Ingersoll1, (1)Psychology, Michigan State University, East Lansing, MI, (2)Michigan State University Psychology Department, East Lansing, MI, (3)Educational and Counseling Psychology, University at Albany, State University of New York, Albany, NY

Background: Clinicians working in lower-resourced settings like the Medicaid system infrequently utilize evidence-based parent coaching interventions and report numerous barriers (e.g., limited training; Straiton et al., 2021). Little is known about the effectiveness of implementation strategies like group consultation at improving clinician fidelity to parent coaching interventions.

Objectives: Identify the “active ingredients” of consultation by examining which training activities (i.e., feedback on taped sessions, role play, case support discussions) are most effective at improving: a) adherence to the Project ImPACT manual, and b) competency in parent coaching.

Methods: Coders analyzed 174 taped Project ImPACT telehealth sessions from 16 ABA clinicians working in five agencies with Medicaid-enrolled autistic youth. Clinicians were provided the manual and completed a 6-hour online tutorial on Project ImPACT prior to meeting with families. During the baseline period (length was randomized by agency from 3 to 9 weeks), clinicians followed the Project ImPACT manual without additional support. During the 12-week consultation period, clinicians met with colleagues and a Project
Background: Caregiver use of "Toy Talk" strategies (e.g., talking about toys and giving objects names) has been shown to increase sentence diversity (Hadley et al., 2017a) and the productivity of tense and agreement morphemes (Hadley et al., 2017b) in typically developing toddlers. In a recent study of toddlers with ASD who were receiving naturalistic developmental behavioral interventions (NDBIs), naturally occurring caregiver Toy Talk was associated with improvement in child lexical diversity beyond the child's initial cognitive and symptom levels (Clark-Whitney et al., 2022). Additionally, the effect of caregiver baseline Toy Talk on children's sentence diversity change was stronger when caregiver NDBI strategy use improved over time. However, the past study was based on data from studies that did not directly target Toy Talk in caregivers. Thus, we combined NDBI and Toy Talk strategies (Hadley & Rispoli, 2015) sequentially in a pilot telehealth intervention incorporating caregiver education and in vivo coaching.

Objectives: (1) Examine whether there are significant changes in child outcomes, defined as child scores on the Brief Observation of Social Communication Change [BOSCC], mean length of utterance (MLU), and the number of unique subject-verb combinations; (2) examine caregiver behaviors, defined as caregiver scores on the Measure of NDBI Strategy Implementation [MONSI] and use of Toy Talk; (3) explore the relation between caregiver behaviors and child outcomes.

Methods: Using a nonconcurrent multiple baseline design, 14 children with ASD between the ages of 2 and 4 years who had at least 50 single words at baseline (3 females; \( M_{age} = 36.9 \) months; \( SD = 8.4 \) months) and their caregivers participated in the study. Language transcripts of caregiver and child utterances were obtained using 12-minute recordings of the BOSCC and analyzed using Systematic Analysis of Language Transcripts (SALT) software. Visual inspection of session data was used to examine changes in child outcomes (i.e., BOSCC scores; MLU; unique subject-verb combinations) as well as caregiver behaviors (i.e., MONSI-CC scores; use of Toy Talk) from baseline to end of treatment and at follow-up. Generalized Linear Mixed Models (GLMM) were performed examining the effect of time on the aforementioned variables while controlling for baseline age, nonverbal IQ, and gender. Finally, correlation analyses were conducted to examine the relation between caregiver behaviors and child outcomes.

Results: Visual inspection of session data indicated variability across individual children and caregivers (Figure 1), although there was a significant effect of time for some outcome variables. Specifically, GLMM revealed significant improvements in child MLU and unique subject-verb combinations as well as caregiver use of Toy Talk and MONSI-CC scores over time. In contrast, time did not have a significant effect on the child's BOSCC scores. Finally, caregiver use of Toy Talk was significantly negatively correlated with child total BOSCC scores \( (r = -.45, p < .001) \), and significantly positively correlated with the number of unique subject-verb combinations children used \( (r = 0.44, p < .001) \).
Conclusions: The pilot telehealth-based NDBI+Toy Talk intervention appears to be a promising approach to increase caregiver use of NDBI strategies and to booster child language development; however, replication in a larger sample is needed.

404.243 (Poster) Effect of a Focused Social and Communication Intervention (SCI) on Preterm Children at Risk for ASD: A Follow-up Study
Á. Bejarano, M. Magan Maganto, R. Canal-Bedia, A. Hernández Fabián, A. Calvarro-Castañeda, S. Manso de Dios, P. Malmierca, E. Diez Villoria, C. Jenaro and M. Posada, (1)UNIVERSITY OF SALAMANCA, Salamanca, Spain, (2)UNIVERSITY OF SALAMANCA, Salamanca, SPAIN, (3)Instituto Universitario de Integración a la Comunidad INICO-InfAutismo., Universidad de Salamanca, Salamanca, Spain, (4)University Clinic Hospital of Salamanca, Salamanca, Spain, (5)University of Salamanca, Salamanca, Spain, (6)Institute of Rare Diseases Research, Instituto de Salud Carlos III, Madrid, Spain

Background: Globally, 15 million babies are born prematurely (<37 weeks' gestation) each year. Advances in intensive neonatal care have greatly improved the survival rate of preterm infants. However, the incidence of neurodevelopmental disorders in this group, such as autism, is one of these behavioral conditions observed. There is scarce evidence of programs that monitor the development of this group when the first developmental concerns appear until the diagnosis is finally confirmed and not many studies report follow-up results.

Objectives: To this end, we conducted a pilot focused social-communication intervention aimed to investigate results in broader gains in social, cognitive, language and adaptive functioning in young preterm children with a higher probability to have autism (measured withADOS and M-CHAT-R/F) 6 months after finishing intervention. Moreover, this is the first study to use individual change indices in a pre-post-follow-up design with preterm infants with ASD, a comparison group, and a control group.

Methods: Eighteen children between the ages of 18 and 20 months participated in the study. Children were recruited from a developmental disorder diagnostic and rehabilitation centre and from the Salamanca Clinical Hospital, and allocated to the three groups in accordance with the respective inclusion criteria: (1) preterm children at risk for autism who received intervention (experimental), (2) full-term children at risk for autism who received intervention (comparison), and (3) preterm children (control). In the intervention, children participated in fifteen weekly individualized 2-h session with a researcher that emphasized embedding strategies targeting imitation, joint attention and play into everyday routines and play activities. Children were evaluated 6 months after the end of the intervention.

Results: Findings indicate that children in the intervention groups maintained the improvements showed post-intervention. There were significant differences in imitation skills (.045), joint attention (.031), and play (.025) in the follow-up results compared to post-intervention. There were no significant differences between preterm and term children with autism in any area. Individual analyses showed similar results, except for ADOS-T module results and cognitive functioning, in which the mean of preterm children with autism showed reliable changes maintained 6 months after finishing intervention.

Conclusions: These results shows that change can be made and maintained in core developmental areas for preterm children with a higher probability to develop autism, when applying a low-intensity intervention targeting social and communication skills. Even though such core areas of impairment are not easy to change, the intervention had an appreciable effect. Most of the participants improved significantly in socio-communicative skills, cognitive development, language, and adaptive behavior, and ASD signs were reduced. Thus, this study emphasized the need for further research and implementation of early interventions in young preterm children with autism when targeting social-communication skills as a main objective for intervention.

404.244 (Poster) Effectiveness of Compression Garments and Related Therapies for Children with Sensory Processing Differences: A Rapid Assessment of a Decade of Evidence
L. Chetcuti, P. Scaife and A. E. Lane, (1)La Trobe University, Melbourne, VIC, Australia, (2)JettProof, Newcastle, NSW, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia

Background: Therapies involving use of compression, touch and weight have become a popular and accessible means to support sensory processing needs in children. However, the mechanism by which these approaches may benefit children with sensory processing differences is yet to be explicated. Further, evidence for the effectiveness of these therapies has yet to be reviewed exclusively in populations of children with sensory differences, and independently of other sensory-based approaches.

Objectives: To synthesize recent research on the effectiveness of compression and related therapies for supporting health and wellbeing among children with sensory processing differences.

Methods: A rapid evidence review was conducted (Grant et al. 2009). CINAHL,ERIC, PsycInfo databases were searched on 02/02/2022 for articles published over the last 10-years, using these search terms: weighted OR pressure OR compressi* OR sensory OR massag* OR Qigong OR therapressure OR Wilbarger OR brush OR sensory diet AND therapy OR intervention OR support OR strategy OR protocol.
Articles were included if the sample population had known sensory processing differences and were aged 4-to-12 years. Unpublished/grey- and non-English-language articles were excluded, as were qualitative analyses.

Results: 5,414 articles were retrieved and 20 articles met inclusion/exclusion criteria. Children on the autism spectrum were the predominant study participants (n=14), followed by attention-deficit/hyperactivity disorder (n=3) and other sensory processing needs (n=3). Studies included participants in pre-school (3-to-5 years; n=8) and primary-school (6-to-9 years; n=12) age ranges. Research designs were a mixture of case studies (n=11), non-randomized- (n=3) and randomized controlled trials (n=6). 17 studies provided evaluation of a single therapy modality: weighted items/garments (n=8), compression garments (n=2), brushing (n=3), massage (n=3), and therapeutic body wraps (n=1). Two evaluated the effects of weighted versus compression garments, and one study evaluated an individualized therapy curriculum that incorporated use of weight and/or compression and/or brushing. Dosage and duration of therapy varied across studies and ranged from 28 minutes spread across four weeks to 3,600 minutes spread across 12 weeks. Multiple outcomes of interest were reported, within and across studies, and these were broadly classified as: sensory reactivity (n=10), diagnostic symptoms (n=10), sleep (n=7), cognition/attention/learning (n=6), general behaviour/global functioning (n=6), behaviour that challenges (n=3), occupational performance (n=3), acceptability/tolerability (n=3), activity/movement (n=1), sensory perception (n=1), health-related quality of life (n=1), salivary oxytocin (n=1), and caregiver stress (n=1). Overall effects were mixed; 13 studies reported positive or mixed results and 8 studies reported no therapeutic benefit. A fine-grained analysis of therapeutic effects differentiated by type of therapy and outcome domain is underway.

Conclusions: Current evidence provides mixed support for use of compression, touch and weight to support health and wellbeing among children with sensory processing differences. However, there was wide variability across studies in therapeutic approach (including dosage and duration) and outcomes of interest, making it difficult to compare effects across studies. Furthermore, the internal validity of most studies was questionable due to small sample size and a lack of blinding and random allocation. Further investigations in large and phenotypically diverse samples is warranted to determine “for what” and “whom” there is therapeutic benefit.

404.245 (Poster) Effects of Ayres Sensory Integration Therapy on Daily Life Activities and Participation of Children with Autism Spectrum Disorder
A. Pereira, A. A. Cardoso Rodrigues, I. Lambertucci Cardoso, A. B. S. Dutra and C. T. Araújo, (1)Federal University of Minas Gerais, Belo Horizonte, Brazil, (2)Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, (3)UFMG Federal University of Minas Gerais, Belo Horizonte, Brazil

Background:

It is known that more than 90% of people with autism spectrum disorder (ASD) have some sensory integration dysfunction (DIS). DIS can lead to difficulties in participating in activities of daily living (ADL), motor performance and learning, as well as emotional and behavioral problems. As a result, Ayres Sensory Integration Therapy (ISA) came to be considered an evidence-based practice for the treatment of autism, with the aim of reducing challenges related to sensory processing, increasing participation and improving occupational performance.

Objectives:

To verify the effects of ISA Therapy on ADL and the participation of Brazilian preschool-age children diagnosed with ASD, based on the analysis of the results of the Pediatric Evaluation of Disability Inventory PEDI.

Methods:

This study is a part of a large study of quasi-experimental methodology, with 9 children with ASD, aged 3 to 6 years, who have sensory integration dysfunction. Recruitment was by convenience sample, according to the waiting list of the Sensory Integration Laboratory (LAIS) at UFMG. Participants underwent an individualized intervention, performed by an occupational therapist certified in sensory integration, twice a week, lasting 50 minutes per session, for 4 months (30 sessions). Participation was voluntary, upon signature of the Free Clarified Term. For the analysis of the outcome measure, PEDI was performed, pre and post-intervention. The PEDI is a standardized instrument that assesses the functional profile and participation of children aged 6 months to 7 and a half years, in relation to functional skills of self-care, mobility and social function; environmental changes and caregiver assistance. Data analysis was performed using a simple average of the results of the PEDI continuous score, in relation to the functional skills of self-care and mobility and assistance of the caregiver.

Results:

For functional skills, the initial PEDI indicated a mean of 47.04 points for self-care and 60.42 points for mobility. In the reassessment, the mean for self-care increased to 62.01 points and mobility to 64.92. Regarding caregiver assistance, initially, a mean of 48.56 points was obtained for self-care and 78.12 for mobility. Post-intervention, the means were 62.85 for self-care and 85.77 for mobility.
Conclusions:

An improvement in the level of functionality was observed in the functional skills of self-care and mobility and a decrease in the level of assistance from caregivers, indicated by the increase in the average. In this way, the present study points out that ISA Therapy can have positive effects for the improvement in occupational performance and participation of children with ASD in their activities of daily living.

404.246 (Poster) Effects of Procedural Integrity in Error Correction Compared to Programmed Commission and Omission Errors on Tact Acquisition during a Discrete Trial Instruction Format.

K. Strauss and L. Fava, (1)Umbrella Autism, Rome, ITALY, (2)Association for Treatment and Research in Autism Spectrum Disorders “UmbrellaAutism”, Rome, Italy

Conclusions: Thus, awareness is facilitated that common procedural integrity errors affect teaching efficiency. In conclusion, the current study supports previous research demonstrating that high level of treatment integrity yield more efficient skill acquisition rates, whereas low integrity produced adverse effects on teaching outcome, requiring more teaching trials. Given the tremendous deficits that are seen for individuals with ASD and thus a need for well-spent time in treatment sessions, it is important for clinicians and researchers to differentiate the most efficient procedures.

404.247 (Poster) Emotion Regulation Parent Coaching for ASD

M. Jimenez Munoz, T. W. Vernon and A. Tae, (1)University of California, Santa Barbara, Santa Barbara, CA, (2)University of California Santa Barbara, Santa Barbara, CA, (3)University of California, Santa Barbara, Goleta, CA

Background: The prevalence of challenging behavior is especially pronounced in children with autism (Maskey et al., 2013). Therefore, families with children on the autism spectrum are in desperate need of accessible, high-quality evidence-based treatments that target disruptive behavior. Parent Child Interaction Therapy (PCIT), one of the most supported evidence-based interventions for defiance and non-compliance (Greco, Sorrel, & McNeil, 2001), has shown promising results for families of autistic children (Parlade et al., 2020). However, there is still debate about the use of time out procedures with this population. This study aims to gain a better understanding of parent and child progress during their enrollment in telehealth-delivered PCIT and a modified emotion-focused version of the intensive PCIT curriculum for young children with ASD.

Objectives: To examine differences in parent perceived and observed efficacy, as well as parent-reported disruptive behaviors over time and across treatment groups.

Methods: The current study is a randomized control trial with 24 families randomized into one of two treatment conditions (CDI followed by PDI or CDI followed by Emotion Based Module (EB)). All families receive a daily, time-limited, telehealth-delivered version of PCIT. Child ages range from 4 to 7. The selection criteria included (a) a child chronological age of 2 -7, (b) participating caregiver being the primary caregiver and/or legal guardian of the child, (c) a formal diagnosis of autism (d) parent’s report of emotion dysregulation or disruptive behavior as their main concern. Participating caregivers completed a series of online assessment batteries, which included parent-reported measures of child disruptive behaviors (ECBI) and parental self-efficacy. These batteries were completed at four different time points: intake, mid-treatment, post treatment and 1-month follow-up. All participants were coded for their use of PRIDE skills and “don’t behaviors” at the same time points.
Results: Preliminary results from 18 participants show that parent’s perceived self-efficacy scores increased from intake (M = 83.77; SD = 9.1) to post treatment (M = 87.06; SD = 12.24) across conditions. Use of PCIT skills remained relatively low during baseline sessions for all 18 participants, with a mean of 5.41 (SD = 4.7) observed PRIDE skills. Positive parenting behavior increased over time and across conditions. At post-treatment, a mean of 26.05 (SD = 5.65) PRIDE skills were observed (Cohen’s d effect size = 3.94, indicative of a large treatment effect). ECBI intensity scores fell from baseline (M = 124.11; SD = 37.01) to post-treatment (M = 112; SD = 39.62, Cohen’s d = 0.30).

Conclusions: Preliminary results from this study suggest that telehealth-delivered PCIT leads to significant improvements in parent’s use of positive parenting skills across EB and PDI conditions, and modest improvements in parent’s perceived self-efficacy and reported disruptive behaviors. The study highlights two different intervention approaches that could maximize treatment acceptability while effectively promoting positive parenting skills.

404.248 (Poster) Evaluating Feasibility and Acceptability of the Incredible Years® Autism Spectrum and Language Delays Program for Parents Delivered Via Telehealth (IY-ASLD-T)

Background: Webster-Stratton’s (2021) The Incredible Years® Autism Spectrum and Language Delays (IY-ASLD) Program for Parents offers a low-cost, empirically-based intervention for children’s behavioral and psychosocial challenges. Recent studies have assessed the feasibility and acceptability of IY-ASLD in community-based settings (Dababnah & Parish, 2016; Dababnah et al., 2019; Williams et al., 2020; Hutchings et al., 2016) with promising results. However, no prior studies have investigated telehealth delivery of the IY-ASLD intervention. Parents of preschool children with autism spectrum disorder and language delays have unique treatment barriers and a study of IY-ASLD revealed that 60% of eligible parents who did not participate in the study indicated scheduling or work conflicts and 16% reported distance of the program as the reason (Dababnah & Parish, 2016).

Objectives: This pilot study examines the feasibility and acceptability of IY-ASLD-T (IY-ASLD delivered via telehealth) using measures of study retention, participant satisfaction, and uptake of intervention strategies. Additionally, the study examines demographic and child-level factors (i.e., verbal behavior level at baseline) related to feasibility and acceptability of IY-ASLD-T.

Methods: Participants included N=17 mothers whose children (ages 2-5 years) attended a preschool primarily serving children with ASD. All mothers were fluent in English and all but two children had a diagnosis of ASD. Intervention included 14 weekly telehealth sessions lasting 90 minutes. Each group was composed of 4-5 mothers and a trained group leader. Measures of parents’ and children’s verbal behaviors and psychosocial well being were taken at baseline and post-intervention. Feasibility was assessed by study retention. Acceptability was assessed by program and telehealth satisfaction measures at post-intervention. Demographic data was collected on socioeconomic status, education level and employment at baseline. Child verbal level was assessed at baseline by the Vineland Adaptive Behavior Scales (Developmentally Delayed/Not Developmentally Delayed).

Results: Preliminary results from 18 participants show that parent’s perceived self-efficacy scores increased from intake (M = 83.77; SD = 9.1) to post treatment (M = 87.06; SD = 12.24) across conditions. Use of PCIT skills remained relatively low during baseline sessions for all 18 participants, with a mean of 5.41 (SD = 4.7) observed PRIDE skills. Positive parenting behavior increased over time and across conditions. At post-treatment, a mean of 26.05 (SD = 5.65) PRIDE skills were observed (Cohen’s d effect size = 3.94, indicative of a large treatment effect). ECBI intensity scores fell from baseline (M = 124.11; SD = 37.01) to post-treatment (M = 112; SD = 39.62, Cohen’s d = 0.30).

Conclusions: Preliminary results from this study suggest that telehealth-delivered PCIT leads to significant improvements in parent’s use of positive parenting skills across EB and PDI conditions, and modest improvements in parent’s perceived self-efficacy and reported disruptive behaviors. The study highlights two different intervention approaches that could maximize treatment acceptability while effectively promoting positive parenting skills.

404.249 (Poster) Examining How Training in a Caregiver Coaching Program Affects Early Intervention Provider Practices over Time

S. F. Fernandes, E. M. Harrington, A. Wainer, A. S. Carter, W. L. Stone and B. R. Ingersoll, (1)Psychology, Michigan State University, Department of Psychology, East Lansing, MI, (2)Psychology, Michigan State University Psychology Department, East Lansing, MI, (3)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (4)Department of Psychology, University of Massachusetts Boston, Boston, MA, (5)Psychology, University of Washington, Seattle, WA, (6)Psychology, Michigan State University, East Lansing, MI

Background:
Caregiver coaching is a recommended best practice for family-centered care in Early Intervention (EI). However, there have been persistent difficulties with implementing caregiver coaching due to a scarcity of studies focused on training EI providers to use these strategies and a lack of EI providers participating in research (Romano & Schnurr, 2022). A previous study examined effects of caregiver-implemented Reciprocal Imitation Teaching (CI-RIT) training in EI settings but did not report changes in providers’ practices beyond RIT adoption post-training (Ibañez et al., 2020). The present study aims to bridge the research-to-practice gap by investigating how training EI providers in CI-RIT changes their caregiver coaching practices over time.

Objectives:

This study examines how EI providers’ caregiver coaching practices change over time after being trained in a caregiver-implemented coaching program for young children with social communication delays.

Methods:

The data for this study was collected as part of a larger randomized controlled trial investigating the effectiveness of training EI providers to deliver caregiver-implemented Reciprocal Imitation Teaching (CI-RIT) within the Part C Early Intervention System. Thirty-eight EI providers were randomly assigned to an immediate training group (RIT Now) or waitlist control group (RIT Later). Providers reported how frequently they engaged in 10 common coaching practices during typical sessions with children with social communication delays on a 5-point Likert scale at two timepoints - before randomization (Time 1) and 6 months later (Time 2). A principal components analysis (PCA) with direct oblimin rotation was used to identify three sets of coaching practices for the Time 1 data. Items from each subscale were averaged for both time points. A repeated measures ANOVA was used to compare EI providers’ use of the three sets of coaching practices at Time 1, and mixed model repeated measures ANOVAs were used to examine the effect of training on EI providers use of coaching practices over time.

Results:

The PCA suggested a 3-factor structure of coaching practices: 1) Live Coaching, 2) Instruction, and 3) Curriculum Use (See Table 1). At Time 1 there was a significant difference in strategy use, F(2,36)=122.15, p<.001. Providers used both Live Coaching (M=4.05, SD=.67) and Instruction (M=4.24, SD=.48) at a higher rate than Curriculum Use (M=2.33, SD=.74). Mixed model ANOVAs indicated no main effect of time or group, and no group X time interaction for Live Coaching (η²=.03). or Instruction (η²=.00). However, there was a significant group X time interaction for Curriculum Use, F(1,36)=7.02, p=.012, with a large effect: η²=.16. Follow-up t-tests with Bonferroni corrections indicated that EI providers in the RIT Now group made significant gains in Curriculum Use over time, while the RIT Later group did not.

Conclusions:

This study found that providers who received training had a significant increase in reported Curriculum Use post-training in comparison to providers who did not receive training. Further investigation of how trainings impact the use of various caregiver coaching components can highlight current gaps in coaching practices and inform how to shape trainings to increase those practices.

404.250 (Poster) Examining Mechanisms of Caregiver-Mediated Intervention with Toddlers on the Autism Spectrum

S. F. Vejnoska, S. J. Rogers, S. Dufek, A. M. Estes and A. C. Stahmer, (1)UC Davis MIND Institute, UC Davis MIND Institute, Sacramento, CA, (2)Department of Psychiatry and Behavioral Sciences, University of California Davis, MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (4)Speech and Hearing Sciences, University of Washington, Seattle, WA, (5)UC Davis MIND Institute, University of California, Davis, Sacramento, CA

Background:

Caregiver participation in early intervention is a leading evidence-based practice in autism, but the specific strategies caregivers learn vary by intervention (Ingersoll, 2010; Oono et al., 2013). Both structured behavioral interventions and naturalistic developmental behavioral interventions (NDBIs) rely on adapting adult-child interactions to increase access to learning opportunities for children. Lack of consistent methodology for measuring caregiver behavior across interventions stymies efforts to understand the effects of changes in caregiver behavior on child behavior (Rojas-Torres et al., 2020).

Sensitivity/responsivity and learning opportunities can be compared across interventions to understand commonalities and differences amongst approaches and identify potential mechanisms of action. To our knowledge, no studies have compared caregiver behavior after learning structured behavioral and NDBIs.

Objectives:
These data describe how caregiver sensitivity/responsivity and the quality and quantity of learning opportunities provided affect child engagement in caregiver-child interactions.

Methods:

This study examines caregiver-child interactions for 80 caregiver-autistic child dyads. Caregivers received coaching in a structured behavioral intervention, Early Intensive Behavioral Intervention (EIBI), or an NDBI, the Early Start Denver Model (ESDM), as part of a larger study in which children also received therapist-implemented in-home treatment (Rogers et al., 2021). Video recordings were collected monthly for 12 months of a caregiver/child toy play activity. Naïve raters coded 287 videos from months 1, 4, 8, and 12 for: (1) caregiver sensitivity/responsivity using the Parenting Interactions with Children: Checklist of Observations Linked to Outcomes (Roggman et al., 2009); (2) the variety, frequency, and quality of learning opportunities provided, and the use of motivational strategies (i.e., environmental arrangement and incorporation of motivating materials) adapted from Davlantis and colleagues’ (2019) Learning Opportunities coding; and (3) the child’s dyadic engagement using the Joint Engagement Rating Inventory (Adamson et al., 2016).

Results:

Caregiver sensitivity/responsivity started high and did not improve significantly over time ($\beta = 1.22, SE = 0.89, p=0.17$). For caregivers who did increase their scores, change was associated with higher child engagement ($\beta = 0.07, SE = 0.02, p < 0.0001$). Caregivers in both conditions improved similarly in their delivery of Learning Opportunities, with caregiver use of motivational strategies most strongly predicting child engagement, even when controlling for sensitivity/responsivity ($\beta = 0.41, SE = 0.08, p < 0.0001$).

Conclusions:

This is the first study to look at a proximal measure of child outcome to examine the effects of caregiver coaching across autism-specific interventions. These findings suggest that caregiver sensitivity/responsivity is an important component of child dyadic engagement to consider. However, focusing solely on caregiver sensitivity/responsivity as a primary mechanism for child engagement may not be sufficient. Caregiver teaching strategies inside learning opportunities, especially child motivation-related strategies, had a positive impact on child dyadic engagement. Measuring active ingredients that occur in various approaches rather than fidelity to a particular intervention may lead to a greater understanding of general mechanisms by which caregiver-mediated interventions operate to support child learning.

404.251 (Poster) Examining Potential Predictors of Response to Early Start Denver Model in Preschoolers with Autism Spectrum Disorder

M. Schaer, M. Godel, F. Robain and N. Kojovic, (1)Psychiatry Department, University of Geneva, Geneva, Switzerland, (2)Department of Psychiatry, University of Geneva School of Medicine, Geneva, Switzerland, Geneva, Switzerland, (3)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland

Background: It is now well established that naturalistic developmental behavioral intervention (NDBI) started in the 3 first years of life can dramatically decrease the social deficits and learning difficulties associated with ASD. These interventions typically entail a massive commitment from families and professionals. Despite the highly significant gains associated with early intervention at the group level, response at the individual level is highly variable: some children exhibit a spectacular response, while a sizeable minority show only marginal improvement. It is therefore of critical importance to better understand “what works for whom”, in order to foster personalized therapeutic decision making.

Objectives: Exploit data from a longitudinal cohort of 84 preschoolers with ASD who have received 20h/week of early intervention following the Early Start Denver Model (ESDM) for a duration of 2 years, to examine potential predictors of response to intervention.

Methods: Following our previously published data in a smaller cohort of 55 children (Godel et al., 2022), we used a cluster analysis to determine different subgroups with different response to intervention. We then compared the obtained subgroups on various measures of functioning at baseline (cognitive & adaptive), as well as on the level of social orientation using eye-tracking (Latrèche et al., 2021).

Results: Replicating our previous result in a smaller cohort, we showed 3 distinct subgroups of response to intervention. The first subgroup showed a mild cognitive delay at intake and nearly no cognitive delay by the end of intervention. The children in the two other groups all presented with severe cognitive delay at baseline. However, they had two very different patterns of response to intervention. The majority significantly improved developmental scores over the course of intervention (in average, 34 points gained in Developmental Quotient), whereas a minority of children showed little to no improvement (in average, 9 points lost in Developmental Quotient). Further analyses showed that children who ended up having an optimal two-year intervention outcome showed rapid developmental improvement, already measurable after 6 months of intervention. There was however no difference in sex, or cognitive measures that could distinguish between children who showed the most improvement and children with minimal improvement. The only clinical measure that distinguished them at baseline was a slightly better adaptive functioning as measured with the Vineland. However, we observed a significantly higher level of...
social orienting as measured with eye-tracking in the children who showed the best response to ESDM. We further observed that parents reported increased quality of life in all subgroups, even when their child showed only moderate cognitive gain.

Conclusions: Identifying specific subgroups associated with different prognosis, sensitivity to treatment, or neurobiological mechanisms, represents a critical step toward the development of precision medicine in autism. Our results show that predicting response to ESDM intervention was better predicted using eye-tracking measures of social orienting, rather than using classically used clinical measures.

404.252 (Poster) Examining Relationships between Provider Fidelity, Caregiver Satisfaction, Therapeutic Alliance, and Child Skill Gain within a Parent-Mediated Intervention Delivered in an Early Intervention System

M. Yohannes, K. Pickard and N. M. Hendrix, (1)Marcus Autism Center, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA, (2)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA

Background: Research has shown parent-mediated interventions (PMIs) to be an effective approach to early intervention (EI) for autistic children (Nevill et al., 2018; Oono et al., 2013). Given their evidence base, emerging research has attempted to increase access to PMIs by training community providers to deliver them within diverse community settings, including Part C EI systems (Stahmer et al., 2020; Rogers et al., 2022). Although this research has shown that community providers can learn to deliver PMIs, it has focused less on caregivers’ experience receiving PMIs. This important gap limits our understanding of whether PMIs are aligned with the needs of all families, particularly those who are underrepresented in research (Pickard et al., 2016).

Objectives: To 1) examine caregiver satisfaction receiving one of two PMIs, Project ImPACT or the Autism Navigator, within Georgia’s EI system; 2) determine whether intervention fidelity is associated with therapeutic alliance or caregiver satisfaction; 3) assess the association between intervention fidelity and child skill gain.

Methods: Participants included 42 caregivers of children (12-30 months) receiving services within Georgia’s EI system. Children included those with an autism diagnosis or an increased likelihood of having autism. Caregivers completed surveys prior to (N=42) and following (N=14) receiving Project ImPACT or the Autism Navigator from their EI provider. Specific surveys included sociodemographic information; the Measure of Processes of Care (MPOC; King et al., 2004); and parent-reported intervention satisfaction. Caregivers rated their child’s skills using the Social Communication Checklist (Wainer et al., 2017) before and after receiving intervention as an indicator of child skill gain. All caregiver data was linked to their providers’ intervention fidelity, which was scored alongside their training in Project ImPACT or the Autism Navigator. Correlation analyses were used to assess the relationship between provider fidelity and therapeutic alliance, caregiver satisfaction, and child skill gain.

Results: Data collection is ongoing with anticipated data from an additional 20 caregivers by May 2023. In preliminary analyses, caregiver satisfaction and therapeutic alliance were rated highly, with mean scores of 4.70/5 (SD=0.33) and 4.60/5 (SD=0.43), respectively. Provider fidelity to either Project ImPACT or the Autism Navigator averaged 73.40%, with scores ranging from 58%-100%. Correlation analyses between intervention fidelity, parent satisfaction (r=0.001; p=.997), therapeutic alliance (r=-0.204; p=0.484), as well as child skill gain in communication (r=0.108; p=0.725) and social engagement (r=0.132; p=0.663) did not yield significance.

Conclusions: Although data collection is ongoing and the sample size is not powered to detect significant relationships, preliminary analyses suggest that caregivers are highly satisfied with their providers’ delivery of EI services and perceive having good rapport with their provider. Interestingly, provider fidelity to Project ImPACT or the Autism Navigator is not associated with caregiver satisfaction, perceptions of therapeutic alliance, and child skill gain. Next steps are to examine these relationships in a larger sample. These findings are important to understand what factors drive both caregiver and child outcomes in regards to the implementation of PMIs within public EI systems.

404.253 (Poster) Examining the Characteristics of Clinicians in an Echo (Extension for Community Health Outcomes) Autism Program

J. Scorah, M. L. Beauchamp, K. Amorim, M. Habra, A. Yusuf and M. Elsabbagh, (1)Montreal Neurological Institute-Hospital, Montreal, QC, Canada, (2)McGill University, Montreal, QC, Canada, (3)RI-MUHC, Montreal, QC, Canada, (4)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada

Background: Individuals with Autism Spectrum Disorder (ASD) have many unmet health needs and there is a shortage of service providers with the training to diagnose and manage these patients. The ECHO (Extension for Community Health Outcomes) Autism project addresses the need for training in best practice care in ASD. ECHO is an evidence-based, tele-mentoring program for clinicians that employs a combination of didactic lectures and case-based learning delivered by a panel of content experts. We are currently offering an ECHO-Autism program in the Canadian context.

Objectives: The goal of the study is to evaluate an ongoing ECHO Autism program in Canada focusing on autism and co-occurring conditions. Here, we examined the link between clinician’s knowledge of ASD and their perceived self-efficacy in diagnosing and managing the needs of individuals with ASD. We also examined whether indicators of experience in ASD were related to clinician’s knowledge of ASD and self-efficacy.
Methods: The current ECHO-Autism program included seven bi-weekly 90-minute sessions spanning a 3-month period. The program is offered at no fee and was offered to clinicians of any profession working in the field of neurodevelopmental disorders. Didactic lecture topics covered genetic assessment, language disorder, ADHD, epilepsy, sleep disorders, and parent perspectives on comorbid complexity.

Twenty-two clinicians who registered for the current ECHO-Autism series were recruited to participate in this study. Participants completed a demographic survey that collected information about years of practice, the proportion of caseload comprised of patients with ASD, and practice setting. Participants also completed an ASD Knowledge Survey to measure knowledge of the topics to be covered during the current ECHO-Autism program at the time of enrolment. Participants also completed the Self-Efficacy Survey to measure how effective they felt at entry into the program in working with individuals with ASD.

Results: As table 1 shows, psychologists were the most represented clinical profession (45.5%) and as a group, clinicians had a mean of 7.16 years of practice (Range 0.5-22). The clinician’s mean score on the ASD Knowledge Survey was 12.73 (range 9-17; maximum score=20) and their mean rating of their self-efficacy was 88.41 (range 40-135; minimum possible score=27, maximum possible score=162). Additionally, we found a correlation between autism knowledge and self-efficacy ($r_1 = .317; p = 0.049$). Interestingly, there was no significant correlation between indicators of prior experience in ASD (years of practice, proportion of patients with ASD, prior attendance in an ECHO-Autism program) and clinician’s performance on the knowledge survey or their self-efficacy ratings.

Conclusions: The ECHO-Autism model seeks to improve clinical practice by modifying clinicians’ knowledge and perceived self-efficacy. Although clinician’s knowledge and self-efficacy were correlated, neither were predicted by their years of experience or the amount of their clinical caseload with ASD. Our findings highlight the need for ECHO programs to carefully assess characteristics of enrolled clinicians.

Background: There are many advantages to multi-site research, notably increased sample size and participant diversity, and the ability to divide responsibilities across sites. There are also challenges to conducting multi-site studies, including cross-site communication, cross-site staff training, standardization of procedures, staff travel distance and time, and participant recruitment and retention (Forjuah et al., 2015). The Reciprocal Imitation and Social Engagement (RISE) study is a multi-institutional, multi-site, type 1 hybrid effectiveness-implementation trial of a caregiver-implemented NDBI for young children with social communication delays (reciprocal imitation teaching; RIT). This trial is being conducted within the Part C Early Intervention (EI) System in 4 states (Illinois, Michigan, Massachusetts, & Washington). Due to the COVID-19 pandemic, all study activities are being implemented virtually, including research staff and EI provider training, caregiver/child assessment, and data management, supported by virtual, cross-institution research teams.

Objectives: To describe the model of our virtual, multi-site intervention-effectiveness trial. To examine the feasibility and affordances of using virtual research teams, virtual EI provider training, and virtual caregiver/child assessment protocols, as well as identify facilitators and barriers to this unique design.

Methods: Research administration data from REDCap were examined to identify participant enrollment, attrition, and demographics, the number of EI provider training and caregiver/child assessments activities completed, and research staff involved (within and cross-site). Provider training and caregiver/child assessment activities were coded as cross-site if any research staff involved were employed by a different institution than institution that enrolled the participant. Descriptive statistics were used to examine variations in participant demographics by site. Survey data of the research team after 18 months of active data collection will be examined to identify perceived benefits and challenges to this approach.

Results: Multiple virtual teams were created with research staff (PIs, post-docs, research staff, and graduate students). See Figure 1. In the first 16 months of data collection, the Liaison/Study Coordinator team has enrolled 86 EI providers and 91 families (primary caregiver and child), with an attrition rate of 15% for both groups. The Provider Training Team has conducted 5 virtual workshops, 62 virtual consultation sessions, and 47 virtual case support meetings with the 32 EI providers assigned to the intervention condition. Of these providers, 29 have been trained to certification in RIT. Depending on the provider training activity, 47-100% of EI providers were trained cross-site. The Caregiver Assessment Team has completed at least one virtual assessment with 75 families for a total of 150 assessments. Of these assessments, 53.2% were administered cross-site. Demographic characteristics of the family participants varied significantly by site, in terms of child sex (15.0-40.0% female), child minority status (28.6-80.0%), household income (6.7%-58.4% with combined income ≥ $125,000), and parent education (20.0-75.0% college degree or higher). See Table 1.
Conclusions: Our data illustrate the feasibility of using virtual teams, training, and data collection in a multi-site autism intervention trial in the Part C system. Our research staff survey data will provide additional information on facilitators and barriers to this approach.

404.255 (Poster) Examining the Infrastructure for the Adoption of Autism Evidence-Based Practices within an Early Intervention System

K. Pickard, N. M. Hendrix, and E. Greenfield, (1)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA, (3)Emory University, Santa Barbara, CA

Background: Naturalistic developmental behavioral interventions (NDBIs) are considered an evidence-based approach to autism early intervention (Schreibman et al., 2015). Public Early Intervention (EI) systems are frequently called upon to deliver NDBIs given that they serve a large number of young autistic children and those who have an increased likelihood of being autistic (Eisenhower et al., 2020). Although EI systems may facilitate early access to evidence-based care for autistic children, research also suggests that EI systems are complex, with both provider- and system-level factors impacting the uptake and use of EBPs (Aranbarri et al., 2021; Pickard et al., 2020). However, limited research has systematically examined how EI system infrastructure impacts the adoption and implementation of EBPs.

Objectives: 1) Examine the infrastructure for the adoption and implementation of EBPs within a public EI system, and 2) Identify how multilevel factors influence one another to impact service access and quality.

Methods: Participants were 100 providers and 9 leaders within Georgia’s Early Intervention system. Participants were 97% Female and 83% identified as contracting independently with the state. All providers completed a survey that included the following measures: 1) demographic information including age, disciplinary background, and years of experience working within EI systems and with autistic children; 2) attitudes towards adopting EBPs; 3) amount of support to attend ongoing training and consultation; and 4) amount and types of training and supervision received. A subset of 36 providers and 9 leaders also completed a semi-structured interview or focus group about factors impacting their participation in EBPs training and use of EBPs. Qualitative analysis included a combination of grounded theory and causative coding. Analyses were refined by input from providers, administrators, and other key stakeholders through round tables and presentations at the state’s interagency coordinating council.

Results: Both survey and qualitative results indicated that EI providers had generally positive attitudes towards novel EBPs and that these attitudes correlated with provider reported use of NDBIs (e.g., r = .29, p = .01). Yet a number of factors impacted the extent to which providers could adopt and implement these practices. Primary infrastructure-related themes centered on: 1) the costs associated with independent contracting structures; 2) operational demands placed on EI providers and leader; 3) workforce instability; 4) communication consistency around EBP priorities and training; and 5) leadership support for EBP training participation and implementation. Causative coding helped to demonstrate the relationships between these factors and underscored the important role of implementation leadership, including incentivization, championing, and communication in supporting EI providers’ adoption and use of EBPs.

Conclusions: Public EI systems serve as a service entry point for many families, including those with young autistic children. The current study extends previous research by demonstrating how several system-level factors play a critical role in the adoption and implementation of EBPs by EI providers, and particularly those that identify as independent contractors. These findings underscore the need for implementation strategies that target factors, such as implementation leadership, that help to increase independently contracted providers’ adoption of autism EBPs within EI systems.

404.256 (Poster) Exploring How Executive Functioning and Demographic Factors Impact Intervention Use for Young Children on the Autism Spectrum

M. Tsou, G. Schnur and S. Faja, (1)Boston Children's Hospital, Boston, MA, (2)Laboratories of Cognitive Neuroscience, Boston Children's Hospital, Brookline, MA, (3)Boston Children's Hospital, Boston, MA

Background: Interventions and services for autism spectrum disorder (ASD) strive to provide children on the spectrum and their families with educational strategies, behavioral support, and tools to improve overall quality of life. Although differences in executive function (EF) are a common characteristic of ASD, little research has been conducted to identify correlates of EF and intervention use and how it may be confounded by demographic factors. Evidence suggests that access to services differs by community, notably for those of marginalized and oppressed people (Nguyen et al., 2016; Smith et al., 2020). This study will examine how EF and demographic factors impact intervention use and satisfaction.

Objectives: Our study aims to explore how lab-based measures of EF and demographic factors are associated with intervention use to better understand gaps in access and use of services in various backgrounds.

Methods: Data were collected as a part of a larger observational study examining children’s EF over time (n=54). Caregivers of children with a diagnosis of ASD completed a demographics survey, intervention history interview and children completed behavioral measures of EF.
Results: On average, children (mean age=46.8 months, SD =16.45; 83% male) participated in 4.69 types of interventions (SD=2.568) and attended 99.445 hours (SD=79.902) over the six month period. A simple linear regression was run to explore the relationship between the hours of services a child attended and household income. The regression was statistically significant (R²=.115, F(1,37)=4.03) and moderately correlated (β=.339, p=.053). Household income was also found to be significantly and positively correlated with inhibition skills (r=.486, p=.008). Another linear regression examined caregiver education and the number of interventions types a child attended. Findings were statistically significant (R² =.133, F(1,37)=5.677) with moderate positive correlations (β=.365, p=.022). EF composite scores were calculated for set shifting, delay, working memory, and inhibition using behavioral tasks and observations. No significant correlations were found for EF composites and intervention use or satisfaction.

Conclusions: Our results show significant moderate associations between family income and hours per week of intervention. These results are consistent with previous literature documenting that families from lower SES experience greater structural barriers to accessing services, such as work schedule and transportation complications (Pickard et al., 2015). Additionally, the lack of correlation between EF composites and intervention use suggests that intervention use is more greatly impacted by family income and caregiver education than EF skills. Investigating these associations with a greater sample size may increase the demographic and EF heterogeneity of the sample to better understand disparities in access to services. The longitudinal design of this ongoing study will allow for a more robust analysis in the future aimed towards assessing potential impacts of intervention on EF as well as demographic factors on characteristics such as caregiver involvement and perceived progress.

404.257 (Poster) Exploring Predictors of Response to a Peer-Mediated Communication Intervention for Autistic Preschoolers with Limited or No Spoken Language

K. Bourque and K. K. Fleming, (1)University of Kansas, Kansas City, KS, (2)Life Span Institute, University of Kansas, Lawrence, KS

Background: Studies on treatment response to early interventions for autistic children report contradictory findings, possibly due to a lack of analysis of behavioral predictors at the individual level (Vivanti et al., 2014). Peer-mediated interventions (PMIs) are an evidence-based approach to improve social communication of autistic children (Watkins et al., 2015). Thiemann-Bourque et al. (2018) documented positive benefits of incorporating an iPad as a speech-generating device into PMIs for autistic children with limited or no spoken communication. Results showed clear treatment gains, yet considerable variability in peer-directed communication over time. Identifying proximal child variables that predict response to treatment has important clinical implications for tailoring PMIs for autistic preschoolers with complex communication needs.

Objectives: Determine (1) if peer-directed child communication and reciprocal exchanges change in response to intervention across inclusive settings, and (2) if change in each outcome is related to baseline levels of child predictors.

Methods: N=9 children with autism and limited spoken communication (i.e., less than 20 words) between 4-5 years participated. We have 9 children enrolled in Year 2; thus, data for n=18 will be summarized for INSAR. Pre-treatment assessments included the Preschool Language Scale-5 (Zimmerman et al., 2011) and the Mullen Scales of Early Learning (Mullen, 1995). Each autistic child was paired with 1-2 peers without disabilities (n=17; 4-5 years). Baseline rates of child-peer communication were collected in dyadic play at a table (30 min), snack (10 min), and free play (10 min). The peers were taught to Stay-Play-Talk with iPad (60 min). The peers then took turns engaging with the autistic child in dyadic play for 16 30-min treatment sessions over 8 to 12 weeks. Post-treatment observations were collected in all three social contexts.

Results: From baseline to post-treatment, rates of peer-directed communication increased significantly within the three social contexts: dyadic play (t(8)=-4.84, p<.001, d=1.61), snack (t(8)=2.55, p=.017, d=1.59), and free play (t(8)=2.17, p=.031, d=.72). Reciprocal exchanges increased significantly in dyadic play (t(8)=4.59, p<.001, d=1.53) and snack (t(8)=2.52, p=.018, d=.84). There were strong correlations between pre-treatment receptive language scores on the Mullen and change in rate of peer-directed communication during dyadic play (r =.78, p=.014), and between auditory comprehension scores on the PLS-5 and change in peer-directed communication during dyadic play (r=.64, p=.064). In addition, change in the rate of peer-directed communication in free play was strongly related to pre-treatment receptive and expressive language scores (PLS_AC r=.78, p=.014; Mullen Expressive r=.75, p=.020; and Mullen Receptive r=.63, p=.068) while change in this behavior in snack was not related to pretreatment scores (PLS_AC r=-.10, p=.081; Mullen Exp r=.27, p=.49; and Mullen Rec r=.01, p=.98).

Conclusions: Results demonstrated that Stay-Play-Talk with iPad effectively improved spontaneous peer-directed communication and reciprocity in multiple preschool settings. Preliminary outcomes show that children with higher receptive language at baseline demonstrate greater gains in communication, and the measurement context may impact outcomes. Measuring proximal child behaviors using multiple methods may allow for identifying individual differences that are relevant for tailoring PMIs to be most effective.

404.258 (Poster) Exploring the Measurement of Parent and Child Factors As Moderators of Outcome in Parent-Mediated-Intervention (PMI) for Preschool Autistic Children and Children Awaiting Diagnostic Assessments: A Feasibility Study

S. Fincham-Majumdar, T. Loucas and E. Pagamenta, (1)The University of Reading, Reading, United Kingdom, (2)University of Reading, Reading, United Kingdom, (3)School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom

INSAR 2023 ANNUAL MEETING ABSTRACTS
**Background:** Every parent/carer of a preschool autistic child, seeking support, has a right to know whether intervention will benefit their child, to maximise early intervention potential. Parent-mediated-intervention (PMI) is an approach advocated by UK National Institute for Health and Care Excellence (NICE, 2013).

PMI for young autistic children leads to changes in parent-child interaction and improved receptive language skills (Oono et al., 2013). Intervention appears to work by increasing parental responsiveness: specific mediators include parental synchrony (Pickles et al., 2015) and mirrored pacing (Gulsrud et al., 2015). Less is known about moderators of outcome (Vivanti et al., 2014); individual responses to PMI highlight variability. Parent and child factors influencing success of intervention (Trembath et al., 2019, Shalev et al., 2020, Roberts et al., 2022) are infrequently cited in the literature and theoretical motivation is rarely provided (Vivanti et al., 2014).

Often, protected characteristics are missing in autism research (Wong et al., 2015). This study responds to calls to explore for whom intervention works (Lord et al., 2022). Detailing family and child characteristics could lead to personalised support and efficacious outcomes.

**Objectives:** To evaluate the feasibility of measuring parent and child characteristics, in a clinical setting offering PMI for preschool autistic children and children awaiting assessment. Aspects of feasibility include accessibility of measures for children, acceptability of measures to parents, practicality of administration of measures and utility of data.

**Methods:** Eight parents/carers participated, their children were aged 2;9-4;11 (mean 3;5), 7 male/ 1 female. Three children were raised in bilingual environments. Two children were diagnosed with Autism Spectrum Disorder; the remainder were awaiting assessment. Three children had co-occurring conditions (e.g., Avoidant/Restrictive Food Intake Disorder/ Global Developmental Delay).

Dyads received an eleven-week PMI programme focused on parental synchrony, mirrored pacing, and environmental arrangement. Indirect and direct measures of parent and child characteristics were taken at baseline/outcome (table 1).

Five parent/carers consented to semi-structured interviews about their experience of assessment measures with interviewers not involved in intervention. Braun and Clarke’s thematic analysis guidelines were followed on anonymised transcripts using NVivo software.

**Results:** Eight children completed intervention, baseline/outcome assessment. Parent and child report measures, direct assessments considering autism symptomology and sensory reactivity were administrable, completed by all, yielding usable data.

Language, cognition and socio-cognitive assessments were completed by 100%, 62.5% and 25% respectively. Task demands meant some stimuli were inaccessible; missing results were due to children indicating their wish to stop, difficulty accessing the requirements and duration/number of assessments.

Thematic analysis of interviews revealed overall acceptability of measures to parents, learning about child’s profile of strengths and needs were perceived benefits, though burden of assessment and emotive responses to the assessment process were highlighted as needing consideration.

**Conclusions:** Measuring parent and child characteristics is feasible using direct and indirect measures, though assessments were not equally accessible. Despite assessment burden, measures were acceptable to parents, though due diligence is required to support parents when answering emotive questions about their family. Further study could determine if characteristics moderate outcomes; thus, informing decision-making, maximising early intervention potential.

---

**404.259 (Poster) Eye-C: A Deep Learning System for Fine-Grained Eye Contact Analysis to Support ASD Intervention in Real-World Clinical Scenarios**

**G. Alvari**1, C. Furlanello2, L. Coviello5,6 and P. Venuti2,3, (1)Department of Psychology and Cognitive Science, ODFLab - Università di Trento - Italy - Department of Psychology and Cognitive Science, Rovereto, Italy, (2)Laboratory of Observation, Diagnosis, and Education (ODFLab), University of Trento, Rovereto, Italy, (3)HK3 Lab, Rovereto, Italy, (4)Orobix Life Science, Bergamo, Italy, (5)University of Trento, Trento, Italy, (6)Enogis, Trento, Italy, (7)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy

**Background:** Predicting intervention outcomes and identifying better-tailored treatments for children with ASD are major challenges (Dawson & Sapiro, 2019). Computational phenotyping may assist therapists in monitoring child behavior by providing quantitative and fine-grained measures more sensitive to behavioral variations (Jaliaawala et al., 2020). Still, real-world behavioral analysis is an ongoing challenge and literature is lacking concrete solutions.

**Objectives:** In this study, we present a novel validation of EYE-C, a system based on Deep Learning (DL) and Behavior Imaging for the analysis of eye contact in unconstrained therapist-child interactions via a single video camera (Alvari et al., 2021). The EYE-C measures are integrated with clinical features to test their potential as predictors of outcome of intensive early intervention.
Methods: EYE-C is a 3-module Deep Learning system capable of robustly deriving 2D head coordinates (Cao et al., 2019), 3D gaze vectors (Kellnhofer et al., 2019), and a frame-by-frame prediction of eye contact episodes between individuals in videos (Alvari et al., 2021). To implement a translational and robust system under real-world conditions, we defined 3 thresholds related to the 2D headboxes position, the 3D gaze orientation, and the episode duration as model hyper-parameters for optimization. Validation was applied to manually coded segments of 5 videos of ADOS sessions involving a therapist and a preschool child with ASD dyads. The videos had different resolutions and room settings. We extracted a continuous interactive dyadic 10-minute sequence from each video (over 70,000 total frames). The hyper-parameter selection was based on Leave-One-Out Cross-Validation (LOOCV) over videos by testing all parameters combinations (900 combinations). The Matthews Correlation Coefficient (MCC) was used to measure eye-contact classification performance. To test the predictive value of the eye-contact features, we collected a sample of 25 preschool children with ASD (2-6 years) undergoing an early intensive intervention. We considered re-evaluation data of the subjects after 12 months of therapy (T1). First, we employed Random Forest (RF) regressors with LOOCV to predict ADOS score and General Quotient (GQ) at T1 by using only variables from the pre-intervention clinical evaluation (T0) as predictors. Next, we combined the eye contact features with the clinical features at T0.

Results: An average MCC=0.66 (SD=.13) was obtained on the test data, confirming good overall consistency with the manual coding, even when considering low-resolution video or larger environments. In the intervention outcome prediction task, integrating the eye-contact features with the clinical predictors at T0 baseline significantly improved performance in predicting both ADOS (from MSE=22.4 to MSE=16.2, in testing) and GQ (from MSE=229.2 to MSE=127.9, in testing) after the intervention (T1).

Conclusions: Findings from this study show the feasibility of DL-based measures within real-world scenarios. The EYE-C has the potential to help clinicians monitor behaviors; further investigation will focus on the AI/ML integration for therapy outcome prediction as a tool for personalized intervention. Prospective approaches need to close the gap between research and healthcare frameworks in order to offer effective real-world solutions to support therapists and families.

404.260 (Poster) Fathers’ Involvement: How Dyadic Affective Profile Evolve during Intervention with Preschoolers

S. Perzoli, A. Bentenuto, A. Peripoli and P. Venuti, (1)Department of Psychology and Cognitive Science, Laboratory of Observation, Diagnosis, and Education (ODFLab) - University of Trento, Rovereto (TN), Italy, (2)Department of Psychology, University of Trento, Rovereto, Italy, (3)Laboratory of Observation, Diagnosis, and Education (ODFLab), University of Trento, Rovereto, Italy

Background: Despite robust evidence of fathers’ impact on children and mothers’ well-being, engaging with fathers is one of the least well-explored and articulated aspects of parenting interventions (Fox, Nordquist, Billen & Savoca, 2015). The literature highlighted the lack of empirical evidence considering fathers in the context of intervention, and most studies were conducted on mothers (Braunstein et al., 2013; Rankin et al., 2019). Previous studies focused on the evolution of specific intervention strategies delivered by fathers with less attention to emotional and affective changes in interaction with their children.

Objectives: We first aimed to investigate changes in father-child Emotional Availability (EAS, Biringen et al., 2008) during intervention with paternal involvement. Second, we analyzed paternal features influencing the child’s variables.

Methods: Participants were 20 fathers (M age = 38.80; SD age = 3.79) and their children with ASD (M chronological age = 38.25 months; SD = 11.84; M mental age = 29.74 months; SD = 13.03). Emotional Availability Scales were applied to ten minutes of video-recorded interactions before and after one year of an Intersubjectivity Parental-Based Intervention (I-PBI). Child characteristics are assessed at T0 and T1 with the GMDS-ER (Luiz et al., 2006) for cognitive functioning and with the ADOS-2 (Lord et al., 2012) for symptom severity.

Results: We found a significant difference in the total amount of the Sensitivity domain of fathers (t(19)=−4.09; p=0.001). A significant difference also emerged in the Structuring scale (t(19)=−6.25;p<0.001) and in the Non-Intrusiveness scale (t(19)=−5.45;P<0.001). However, Non-hostility scale showed no significant differences (t(19)=−1.00;p=0.33). See table 1 for Descriptive and Inferential Statistics of Fathers’ EA at T1 and T2. Concerning the child’s domains we found significant increases in the main scale of Responsiveness (t(19)=−5.10;p<0.001) and Involvement (t(19)=−4.77;p<0.001). See table 2 for Descriptive and Inferential Statistics of Child’s EA at T1 and T2. Concerning the second aim, we implemented linear regression models with the child’s cognitive functioning set as dependent variables and paternal affective behaviors of sensitivity, structuring, non-intrusiveness, and non-hostility as predictors. We found a significant model (F(4,31)=3.18; p=0.027) suggesting that non-intrusiveness (beta=0.76; p=0.28) was associated with the child’s general cognitive functioning.

Conclusions: These first results shed new light on the evolution of affective dyadic aspects of the father-child relationship, which was scarcely investigated in previous literature. Despite the difficulties in dealing with children with ASD due to the alterations in early interactions (Adamson et al., 2010; Wong & Kasari, 2012), fathers seem to benefit from a developmental intervention focused on restoring dysfunctional interactive circuits in line with previous findings (Sandbank et al., 2020). These preliminary results highlight the importance of considering not only the child’s characteristics but also paternal and dyadic features to optimize treatment outcomes.
404.261 (Poster) Feasibility and Preliminary Boscc Outcome of Brief Facial Interaction-Focused Parent Guidance for Toddlers with Prodromal ASD

E. Lehtonen1, T. M. Helminen1, J. Lauttia1, E. Jones1, P. Warreyn1, T. Charman1, Á. Bejarano1 and A. Kylliainen1, (1)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland, (2)Faculty of Social Sciences/Psychology, Tampere University, Tampere, FINLAND, (3)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (4)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, BELGIUM, (5)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, UNITED KINGDOM, (6)UNIVERSITY OF SALAMANCA, Salamanca, Spain

Background: Parents of autistic children typically have developmental concerns about their child long before the formal diagnosis. Toddler’s use of eye gaze is one of the most common early concerns. These parents might lack professional support for their worries and knowledge of how to facilitate interaction with their child in a child-friendly way.

Objectives: The present study aimed to evaluate the feasibility and preliminary efficacy of brief parent guidance to support facial interaction with toddlers having prodromal ASD.

Methods: Participants were recruited from welfare clinics of Tampere city, or the Department of Paediatric Neurology at Tampere University Hospital based on parent-reported positive screening (M-CHAT-R/F) or reports of autistic symptoms. Eleven children (aged 15 to 29 months) with prodromal ASD (ADOS-2 ≥ 13 and/or high parent concern and/or family risk) participated in the brief parent guidance. The guidance consists of five sessions (three in clinic and two with telehealth) over three months (M = 11, range 6–18 weeks). Guidance principles were based on techniques of Naturalistic Developmental Behavioral Interventions having an emphasis on supporting facial interaction and motivating the use of eye gaze in a child-friendly way.

Measures included feasibility outcome measures i.e., parent satisfaction questionnaire (14 questions, coded with a 5-point scale) and interventionist fidelity checklist, and the primary outcome measure Brief Observation of Social Communication Change (BOSCC). The BOSCC was observed before and after the program in a 12-minute parent-child play session, and measures two core domains: social communication (SC) and restricted repetitive behaviours (RRB). The differences between baseline and post measures in BOSCC were calculated with Wilcoxon signed rank test in within sample design. If the difference was statistically significant, reliable change index (RCI) was calculated to assess at an individual level whether the change was clinically meaningful (±1.96). To calculate the RCI, test-retest reliability estimates were applied for BOSCC core total, SC, and RRB (0.90, 0.89, and 0.79).

Results: Results indicated that brief parent guidance was acceptable and feasible. Parents reported being very satisfied to the guidance (M = 4.29, range 2–5, response rate 73%). The fidelity of interventionist was acceptable (> 0.80).

The Wilcoxon signed rank test revealed a statistically significant difference between baseline and post measures in BOSCC core total (z = -2.14, p = .033, r = .46). Differences were not statistically significant separately for SC (z = -1.69, p = .090, r = .36) or RRB (z = -1.52, p = .130, r = .32), although the effect sizes were medium. The RCI values based on the BOSCC core total indicated that after parent guidance seven children (64 %) showed clinically meaningful improvement, one child (9 %) clinically meaningful deterioration, and for three children (27 %) changes were not clinically meaningful.

Conclusions: The feasibility findings of the brief parental guidance were promising and support the further efficacy study with a larger sample size. According to a participatory view, it seems highly essential to support parents also before the formal diagnosis when their concern of their child’s development is high.

404.262 (Poster) Feasibility of an Integrated Cognitive-Behavioral Treatment for Anxiety in Young Autistic Children

A. Keefer1, V. Singh2, J. Perrin3, C. B. Holingue4, S. Winchell and R. A. Vasa5, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Department of Psychiatry and Behavioral Sciences, Johns Hopkins School of Medicine, Baltimore, MD, (3)Kennedy Krieger Institute, Baltimore, MD, (4)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background:

In autistic children, anxiety often begins in early childhood, i.e., 6 years and under, and causes lifelong impairment. Yet, few studies have examined anxiety treatments for this group. Additionally, no studies have examined if targeting mechanistic factors that maintain anxiety, such as intolerance of uncertainty (IU; negative response to uncertainty) and parental accommodation (PA; helping child avoid anxiety), in the context of anxiety treatment enhances treatment response. More work is urgently needed to trial new interventions targeting anxiety, IU, and PA in young autistic children.

Objectives:

This Phase I clinical trial investigates the feasibility of a novel anxiety intervention, DINO Strategies for Anxiety and Intolerance of Uncertainty Reduction (DINOSAUR), in 4-6 year-old autistic children with anxiety.
Methods:

Fourteen young autistic children (4-6 years) and their parents participated in DINOSAUR, a manualized 14-week group telehealth intervention that utilizes cognitive-behavioral strategies to target IU and anxiety. Feasibility was assessed using descriptive statistics of participant retention, group attendance, and weekly parental satisfaction ratings. Qualitative data regarding parental satisfaction obtained through two focus groups (n=7) was also examined using thematic analysis. An inductive, or “bottom-up” approach to coding was used, which prioritized participants’ experiences. Preliminary efficacy was also explored using descriptive data from the 1) Anxiety Disorder Interview Schedule-Autism Spectrum Addendum primary anxiety disorder clinician severity rating (CSR) which ranges from 0 to 8 (≥ 4 = clinically significant) and 2) Clinical Global Impressions Scale (CGIS) which ranges from 1 “very much improved” to 7 “very much worse.” Both measures were completed at pre- and post-treatment by a trained tester who did not deliver the intervention.

Results:

Descriptive data indicate low attrition (16%), high attendance rates (96% of sessions), and high parent satisfaction ratings (1-5 Likert scale; M=4.3, SD=.86). Qualitative parental data indicate that the intervention was helpful and decreased child anxiety levels. While many parents were familiar with the topic of anxiety, the concepts of IU and PA and their impact on child anxiety were novel. Furthermore, differentiating anxiety and autism traits, cueing relaxation strategies when children were behaviorally escalated, and weaknesses in child emotional awareness remained difficult for many parents following the intervention, though these skills did improve. (“I still don't think he understands even the definition of anxiety or that he's getting there when he's feeling those feelings, but for the first time he made the connection that he can kind of control his breathing, control his heart rate, things like that.”) Descriptive outcome data also supported the potential of treatment efficacy. Nine out of 11 participants demonstrated a reduction in ADIS/ASA primary anxiety disorder CSR (Figure 1), and 55% of participants were rated “much improved” to “very much improved” on the CGIS.

Conclusions:

An integrated treatment targeting anxiety, IU, and PA is feasible for young autistic children. Data support a large-scale, randomized-controlled, Phase II trial examining preliminary efficacy.

404.263 (Poster) Feasibility, Acceptability and Effectiveness of a Model of Online Parent-Mediated Intervention for Children with Autism Spectrum Disorder in Vietnam

H. Hoang¹, H. S. Vu², C. Q. Tran¹, T. Ho¹ and T. Quach¹, (¹)Center for Creative Initiatives in Health and Population, Hanoi, Viet Nam, (²)Center for Creative Initiatives in Health and Population, hanoi, Viet Nam

Background:

Early intervention is crucial to maximise the developmental outcomes for children with autism spectrum disorder (ASD). However, the majority of children with ASD who live in low and middle-income countries (LMICs) do not receive treatment due to a lack of feasible and effective intervention services and a chronic shortage of therapists. Parent-mediated interventions (PMI) shows promising potential to improve parents’ knowledge and skills to deliver intervention for their children and address core deficits of children with ASD. At the same time, interventions delivered via internet was shown to be feasible to bridge geographic and resource gaps and increase the accessibility to services, especially during Covid-19 pandemic.

Objectives:

Assessing the feasibility, acceptability, and effectiveness of a PMI e-training program which was designed based on Applied Behaviors Analysis theory and naturalistic developmental approaches to support parents to learn skills to conduct intervention for their children. This online PMI program has three components: recorded e-lectures, group e-meeting sessions and e-coaching. The recorded e-lectures has three modules comprising 21 e-lectures, each lasting 20 minutes. Parents are also invited to attend 9 one-hour group discussion each week and receive individual 9-week coaching through weekly video feedback and 03 individual sessions (one hour each) for each family.

Methods:

This study used a mixed method. Structured interview was conducted using “Caregiver Knowledge and Skills Test” self-administered questionnaire designed by CST training program of WHO and in-depth interviews and group discussions. Data on parents’ attendance and usage of course materials are also analyzed to assess feasibility and acceptability. The study was conducted from February to May 2020 (baseline assessment) and from June to August 2020 (intervention) in two provinces of Vietnam. 30 caregiver-child pairs in intervention group and 25 caregiver-child pairs in control group participated in the study.

Results:
Background: Parent-child interaction (PCI) is the proximal target of pre-emptive interventions focused on optimising the infant’s social environment, and has been shown to be affected in infants at elevated likelihood of autism (EL-ASD) (Wan et al., 2019), predictive of ASD in EL-ASD infants (Wan et al., 2013), and enhanced with pre-emptive intervention (Green et al., 2015). The latter is the iBASIS trial (Intervention within the British Autism Study of Infant Siblings), which involved video-feedback to sensitize parents to relational and communicative qualities of their PCI (iBASIS-VIPP), and which reported significant PCI effects but which attenuated at long-term follow-up (Green et al., 2017). Further analysis of PCI videos can enrich our understanding of this key mechanism of interest in infancy interventions.

Objectives: (1) **Trial Follow-up study:** Were research lab PCI improvements (in parent nondirectiveness and child attentiveness to parent) from iBASIS sustained at 36 months when the MACI was used? (2) **Subsample Home PCI study:** Were baseline ‘low parent-sensitivity’ dyads more (or less) amenable to PCI change through the course of the home therapy? (3) **Predictors study:** Which parent-infant dyads are most amenable to PCI change in the trial?

Methods: The MACI (Manchester Assessment of Caregiver-Infant Interaction) was utilised, a validated global measure of PCI (Wan et al., 2018). Videotaped PCIs from the iBASIS trial were blind-coded: (1) at post-intervention follow-up (24m, 36m), enabling longitudinal analyses across 4 time points (follow-up and predictors studies); (2) from home therapy sessions (sessions 0, 2, 4, 6 and end point) in a subsample of 13 dyads, randomly selected from high and low baseline parent PCI ratings, totalling 61 PCI samples coded in random order (home PCI study).

Results: (1) The parent nondirectiveness/synchrony effect which attenuated at follow-up, as previously reported using DCMA (Dyadic Communication Measure for Autism; Green et al. 2017), was confirmed using MACI nondirectiveness only. By contrast, the effect on child attentiveness/initiation, also reported previously using a MACI/DCMA combination, was not found using MACI child attentiveness alone. (2) Quite high stability was found between subsample baseline home and lab PCIs (e.g. infant attentiveness to parent; \( r = .65 \)). The ‘low parent sensitivity’ dyads at baseline in both parent and infant behaviours, based on home and lab PCIs, showed high amenability to change, with interactions improving mostly between therapy session 4 to endpoint. (3) Baseline predictors (parental education, infant non-verbal IQ, infant verbal communication, autism symptomatology) of PCI trajectories will be reported.

Conclusions: Overall, the MACI (infant and toddler versions) successfully captured continuities and change across multiple time points, charting therapy progression (home visits) and research evaluation visits from 10-36m (in the lab). Adding to previous iBASIS trial findings, child attentiveness to parent/communication initiation diverged between the two measures as the child moved beyond two years. Reasons for this divergence are discussed. The sub-sample findings on 7 EL families who began with low parent PCI ratings showed both parent and infant interactional changes as therapy progressed.

404.265 **(Poster)** Identifying Predictors of Parent Motivation to Participate in Caregiver-Mediated Early Intervention Programs for Autism

H. Tokish1, A. Pomales-Ramos1, W. L. Stone1, A. S. Carter1, A. Wainer2 and B. R. Ingersoll1. (1)Psychology, Michigan State University, East Lansing, MI, (2)Psychology, University of Washington, Seattle, WA. (3)Department of Psychology, University of Massachusetts Boston, Boston, MA, (4)Department of Psychiatry, Rush University Medical Center, Chicago, IL
Background:

Parent motivation early in treatment has been associated with increased parent participation in caregiver-mediated interventions and improved outcomes for children with behavioral challenges (Haine-Schlagel & Walsh, 2015). However, the extent to which this is true for caregiver-mediated interventions for autism remains unclear. There is also evidence that community providers’ perceptions of parent motivation influence their likelihood of recommending caregiver-mediated interventions for autism, and that these perceptions may be related to family sociodemographic characteristics (Tomczuk et al., 2022). Thus, it is vital to understand the parent, child, and demographic factors that influence parent motivation in caregiver-mediated interventions for autism to address participation barriers.

Objectives:

This study examines 1) whether parent motivation is associated with parent participation in caregiver-mediated Naturalistic Developmental Behavioral Interventions (NDBIs) and 2) whether parent, child, and demographic characteristics predict parent-reported motivation to participate in caregiver-mediated NDBIs.

Methods:

Parents of young children with autism or social-communication delays from two studies of caregiver-mediated NDBIs participated. Parents in Sample 1 (n=46; M<sub>age(years)</sub>=35.54, SD=6.08) participated in a study of a telehealth-delivered caregiver-mediated NDBI (Project ImPACT Online). Parents in Sample 2 (n=65; M<sub>age(years)</sub>=34.59, SD=5.99) participated in a study of a caregiver-mediated NDBI (Reciprocal Imitation Training; RIT) in the Part C Early Intervention System. At intake, parents completed questionnaires including the Parent Motivation Inventory (PMI) “Readiness to Change” subscale, Parenting Stress Index (PSI), and demographic surveys. To measure parental self-efficacy, Sample 1 completed the Parenting Sense of Competence Scale (PSOC) while Sample 2 filled out the Parenting Efficacy Scale (PES). Sample 2 additionally completed the Brief Infant-Toddler Social and Emotional Assessment (BITSEA). For Sample 1, parent participation in the online tutorial of Project ImPACT Online (percentage of learning activities accessed) and program completion were available.

Results:

In Sample 1, a hierarchical linear regression controlling for correlated sociodemographic variables (parent age) in the first step found that parent PMI Readiness significantly predicted program participation (β=.32, t=2.26, p=.03). Pearson correlations revealed that the PSI Total Score, BITSEA Total Problem Score (Sample 2 only), and demographic factors (caregiver sex, minoritized status, college education, age, marital status, and household income) were not significantly correlated with PMI Readiness in either sample. While parental self-efficacy measured by the PSOC was significantly correlated with PMI Readiness in Sample 1 (r(38)=.31, p=.048), self-efficacy measured by the PES was not significantly correlated with PMI Readiness in Sample 2 (r(63)=.04, p=.77).

Conclusions:

Preliminary results suggest that higher parent-reported motivation on the PMI predicted increased participation in a telehealth-based caregiver-mediated NDBI for autism. Surprisingly, few child, family, and demographic characteristics were related to parent motivation across samples. While the PMI has been well-established as a predictor of treatment adherence in the literature and in our study, more knowledge is needed about factors associated with parent motivation. Parental self-efficacy may be correlated with motivation and further analyses will examine how distinct measures differentially predict motivation. Future research will also investigate how family sociodemographic factors may predict in-session parent engagement with the provider and intervention strategies using an observational coding scheme rather than parent report.

404.266 (Poster) Implementing a Sustainable Parent-Mediated Intervention for Toddlers with Autism Spectrum Disorder in Goa, India: Partnership, Training, and Locally Sustainable Growth

K. Bernardi, E. M. Dowds, A. Velho, M. Kantawalla, N. de Souza and J. A. Brian, (1)Holland Bloorview Kids Rehab Hospital - ARC, Toronto, ON, Canada, (2)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital-Autism Research Centre, Burlington, ON, Canada, (3)Autism Services, Sethu Child Development and Family Guidance Centre, North Goa, India, (4)Child Development Clinic, Sethu Child Development and Family Guidance Centre, North Goa, India, (5)Autism Research Centre, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

Background: Social ABCs is a low-cost, parent-mediated NDBI developed in Canada to meet the need for evidence-based, cost-effective intervention for toddlers with suspected or confirmed Autism Spectrum Disorder. With strong evidence of community translation established across Canada, this pilot project evaluates the feasibility of remotely training staff in India to become certified as coaches and community trainers. This training model offers lower resourced countries such as India the ability to access high-quality training, and the future opportunity for trainers in India to train teams across India at substantially lower cost.
Objectives: To determine feasibility and acceptability of remotely training staff at a non-profit child development centre in Goa, India to effectively implement and attain community-trainer certification in the evidence-based Social ABCs parent-mediated early intervention program using the established Canadian training model and materials.

Methods: Two staff from Sethu Centre for Child Development were identified by the Canadian Social ABCs team through the Indo-Canadian Autism Network. Eligibility included English-fluency and a background child development. The team met virtually over six months, working with local families. Trainees’ implementation, parent-coaching skills, and didactic content delivery were evaluated using Canadian fidelity measures via video coding. Parent fidelity and child responsiveness were measured to ensure efficacy. Once certified as coaches, trainees were supported by the Canadian team to train and evaluate two of their internal staff. Indian site trainers are now poised to train an external clinical site. No adaptations were made to the training model, program materials, or delivered service. Costs of receiving training from the Canadian team versus receiving locally from the Indian team were compared.

Results: Completing the 6-month training, the two trainees achieved >85% in both implementation and coaching fidelity with 3 three parent-child dyads and were certified as Social ABCs parent coaches. To complete site-trainer status, they have trained one internal staff, who also achieved >85% fidelity in both implementation and coaching fidelity, and are actively training an additional staff (to be signed off early 2023) for a local team of 4. The community trainer phase is underway, with a contract to train two external staff at a centre in northern India. To date, 10 rounds of the Social ABCs program have been completed with 55 families in India, achieving implementation fidelity and child responsiveness rates comparable to Canadian families (reported in a linked submission; Kantawalla, et al). There is a 47% cost savings ($30,000 versus $16,000 CAD) having local trainers in India deliver training with Canadian supervision. Once independent, the cost is reduced further, to approx. $11,000 CAD, representing a reduction by almost two-thirds.

Conclusions: Remote training is a cost-efficient method of training staff to achieve parent-coaching certification in the Social ABCs, transcending geographical and cultural barriers. The Canadian team successfully trained two staff from different disciplines to achieve both Parent Coach and Site Trainer certification, on-track to achieve Community Trainer status in 2023, whereby they can train external teams. This sustainable training model increases equity and accessibility of high-quality intervention across lower resourced countries such as India.

404.267 (Poster) A Qualitative Inquiry into Autistic Adults’ Views on Intervention Goals for Young Autistic Children

R. K. Schuck, H. Croussore, A. Genge, F. Lin, P. Dwyer, K. M. Baiden, Z. J. Williams and M. Wang, (1)Gevirtz Graduate School of Education, University of California, Santa Barbara, Santa Barbara, CA, (2)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (3)Department of Psychology, Center for Mind and Brain, UC-Davis, Davis, CA, (4)Gevirtz Graduate School of Education, UCSB Koegel Autism Center, Santa Barbara, CA, (5)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN

Background: Behavioral intervention programs and Individualized Education Programs for autistic children are structured around goals targeting skills based on assessments of children’s strengths and challenges. Skill domains commonly include social interaction, communication, daily living, academics, and behavior. While advocates have argued that some goals are discriminatory toward disabled individuals and may contribute to masking of autistic traits, little empirical research has explored autistic individuals’ perspectives toward such intervention goals.

Objectives: This study aimed to elicit feedback from autistic adults regarding their perspectives on common intervention goals for young autistic children. The following more specific research questions were investigated: 1) Why do participants view some intervention goals more positively or negatively than others? 2) What suggestions do participants make for improving intervention goals in the future?

Methods: 235 autistic adults took an online survey and were presented with 19 statements about intervention goals (e.g., “Improving Interpersonal Skills is a good intervention goal”). Participants rated their agreement with the statement (presented elsewhere) and were then provided with a textbox and asked, “Is there anything you’d like to add regarding your feelings toward this statement?” The number of responses to each question ranged from 120 to 189. Responses were analyzed using reflexive thematic analysis. The research team includes both autistic and non-autistic researchers.

Results: Preliminary analysis generated three themes: 1) Goals Should Lead to Autistic Wellbeing; 2) Tension between Intervention Goals & Methods; and 3) Remedies to the Double Empathy Problem.

Many responses categorized into the first theme (Goals Should Lead to Autistic Wellbeing) touched upon the idea that goals for autistic children need to be defined from an autistic—not neurotypical—perspective. For example, when trying to improve an autistic individual’s quality of life, who defines what a high quality of life looks like? Participants also raised issues surrounding the difference between independence and autonomy/interdependence and the importance of considering intersectionality.

With regards to Tension Between Intervention Goals & Methods, participants pointed out that some goals (e.g. reducing self-injurious behavior) were highly acceptable, but just reducing behavior was not enough: interventionists need to dig deeper into the root causes of such behavior. Participants also noted that goals can be acceptable but the methods used to teach skills might not be.
The final theme (Remedies to the Double Empathy Problem) related to how interventionists and society as a whole could shift away from placing the burden of successful interactions entirely on autistic individuals. Many participants suggested that neurotypical individuals need education about how to interact with neurodivergent people. Some felt it would be helpful to teach autistic children about neurotypical norms without enforcing compliance with them.

Conclusions: This analysis provides insight into how autistic adults view intervention goals for young autistic children. The themes generated could be useful for interventionists and educators as they attempt to select goals aligned with the autistic community’s needs. Notably, nuanced approaches seem necessary and simply adopting a “good” goal without considering contextual factors, definitions, and intervention procedures is unlikely to be seen as acceptable.

404.268 (Poster) A Systematic Review of Social Validity Assessment in Pivotal Response Treatment Research

R. K. Schuck and A. Young, Gevirtz Graduate School of Education, University of California, Santa Barbara, Santa Barbara, CA

Background: Social validity refers to the extent to which stakeholders find an intervention acceptable and consists of three features: significance of goals, appropriateness of procedures, and importance of outcomes. Social validity is recognized as a crucial part of any intervention and is listed as a criterion for establishing evidence-based practices. Despite its importance, recent reviews have found that social validity is not frequently assessed in behavioral intervention studies. When it is assessed, parents or providers are often asked for their perspectives, while the disabled participants themselves are rarely consulted (though few reviews actually report on this). Some interventions, however, such as Naturalistic Developmental Behavioral Interventions (NDBIs), are specifically designed to center autistic children’s needs, strengths, and preferences. While this framework suggests such interventions are socially valid, the extent to which social validity is actually assessed in NDBI research is unknown.

Objectives: This study aimed to systematically review literature to determine how social validity is assessed in research on Pivotal Response Treatment (PRT), a prominent NDBI. More specifically, research questions focused on 1) frequency of social validity assessment; 2) assessment methods; and 3) who was asked to make the assessments.

Methods: This analysis is part of a larger systematic review on social validity assessment in all NDBI research. Studies were eligible to be included in the review if they were 1) focused on one of the six NDBIs listed in Bruinsma et al. (2020); 2) reported on an intervention with at least one autistic individual; and 3) were written in English. 747 abstracts (excluding duplicates) were retrieved from ProQuest, EBSCOhost, and Web of Science. 153 eligible reports focused on PRT; 150 full texts have been analyzed (3 full texts have not yet been located). The authors coded each article for relevant study details and information pertaining to social validity (e.g. intention to assess “social validity”/“satisfaction”/“acceptability”, who was involved in the assessment, etc.). Analysis is ongoing.

Results: Studies were published between 1991-2022. Most included infant, preschool, and/or elementary school children, though some included middle schoolers (n=15) and high schoolers (n=2). Interventionists in these studies included research staff (n=63), parents (n=62), community practitioners (n=36), and peers (n=14). Of the 150 articles reviewed, 48 intentionally sought to assess social validity. Studies often assessed social validity by consulting parents (n=28), teachers/clinicians (n=17), or others (e.g., blind raters, peers; n=13). Only four studies sought out the autistic intervention recipient’s perspective, all of which were published within the past five years. These studies used interviews and/or questionnaires to elicit feedback from the autistic participant.

Conclusions: The majority of PRT research reports do not assess social validity, and very few report eliciting feedback from the autistic intervention recipients. Future PRT studies must assess social validity more frequently and include the perspective of autistic participants. Increased social validity assessment represents one step toward ensuring interventions are acceptable to autistic individuals and do not cause them harm.

434 - Interventions - Non-pharmacologic - Preschool & Infant II

434.184 (Poster) Improvement in Autism-Related Challenges for Autistic Youth Receiving Project Impact in the Medicaid System

J. Greatesne; D. Stratton; M. Moeyenart and B. R. Ingersoll; (1)Michigan State University Psychology Department, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI, (3)Educational and Counseling Psychology, University at Albany, State University of New York, Albany, NY

Background: Project ImPACT is a manualized parent-mediated intervention that targets social communication skills in young autistic children. Though it is effective when delivered in lower-resourced early intervention systems (Stuhmer et al., 2014), no studies have taken place in the Medicaid system.

Objectives: Examine changes in autism-related challenges in Medicaid-enrolled autistic children receiving Project ImPACT.
Methods: The sample included 19 families of Medicaid-enrolled autistic youth aged 6 and under who received Project ImPACT. Caregivers completed the Autism Impact Measure at 5 time points. It includes five subscales: Communication, Social Reciprocity, Peer Interaction, Repetitive Behavior, and Atypical Behavior. We ran a series of two-level hierarchical linear models to estimate the linear time trend on each subscale and determining whether the time trend interacted with child demographics (age and racial/ethnic minority status).

Results: See Table 1 for results. Racial/ethnic minority status was not associated with outcomes, though the interaction of age X time was marginally significant for some subscales (see below).

Controlling for demographic variables, there was a marginally significant linear decrease in amount of autism-related challenges, such that with every additional week, total autism-related challenges decreased by 1.83 points (t(38.90) = -1.71, p = .10).

Controlling for demographic variables, there was a marginally significant effect of the interaction of age X time on atypical behavior, t(11.52) = -1.92, p = .08. A simple slopes analysis demonstrated that atypical behavior in younger children did not change over time. There was a marginally significant linear increase in atypical behavior for older children (1 SD above mean), such that, with every additional week, older children were rated as becoming more atypical, with ratings increasing by 1.73 points each week (t(13.54) = -1.96, p = .07).

Controlling for demographic variables, there was a marginally significant effect of the interaction of age X time on repetitive behavior, (t(41.49) = -1.80, p = .08. A simple slopes analysis demonstrated that there was a significant linear decrease in repetitive behavior for younger children (1 SD below mean), such that, with each additional week, ratings of repetitive behavior decreased by 2.14 points (t(42.57) = -2.08, p = .04). Repetitive behavior in older children (1 SD above mean age) did not change significantly over time. See Figure A.

Controlling for demographic variables, there was a marginally significant linear decrease in peer interaction challenges, such that, with each additional week, ratings of peer interaction challenges decreased by 0.29 points (t(30.13) = -2.01, p = .05).

For communication and social reciprocity, there were no significant linear time trends when controlling for demographics.

Conclusions: Overall autism symptomology and challenges with peer interaction improved. There were marginal effects of the interaction of age X time for repetitive behavior and atypical behavior, such that younger children improved in repetitive behavior, and older children had more atypical behavior over time. Contrary to hypotheses, children did not significantly improve in communication or social reciprocity. Clinician fidelity was low, likely affecting child outcomes. Future studies should examine outcomes in a larger sample that may be more powered to detect changes.

Background: Behavioral contingency, or ensuring that a child’s actions predictably lead to desirable items and activities, is a critical component of early autism intervention efforts (McDaniel et al., 2020). This if-then relationship is a powerful teaching tool that can propel children’s first word development, increasingly complex language use, and the use of appropriate behavior to access favorite activities and objects. Therefore, behavioral contingency is a particularly important skill to equip parents with for use in their home environment. Caregivers who struggle to stay contingent and give in to undesirable behavior and/or offer their child desired items non-contingently can lead to a de-incentivization of their child’s use of language. Self-directed parent training efforts may be effective in teaching early autism intervention strategies, including the use of behavioral contingency (de Korte et al., 2022; White et al., 2021). The current study examines improvements in parent contingency after completion of the PRT app-based training program.

Objectives: The aim of this study is to examine improvements in parent use of behavioral contingency in the context of 5-minute parent-child intervention probes, submitted during participation in an app-based parent training program.

Methods: Participants include 48 parent-child dyads across the U.S., analyzed as a single cohort to allow researchers to remain blind to group assignment during this phase of the project. 24 dyads were randomized to a video self-scoring PRT app version and 24 to a standard PRT app without self-scoring functionality. All child participants are between 1 and 4.5 years of age and have an existing diagnosis of ASD in addition to parent concerns of language development. Parents complete intake and follow-up assessments, eight PRT lessons, and record and review parent-child videos in-app after each lesson, which are then reviewed by the research team for analysis. Research assistants were blinded to study condition and coded each parent-child video submission for the presence of intervention components and child behaviors. Parent contingency was defined as parents successfully creating a three-step ABC learning opportunity and successfully reinforcing a child’s language attempt or withholding the reinforcer if the child did not respond.
Results: A paired-samples T-test was performed, analysis revealed that the entire project cohort of parents significantly improved their use of behavioral contingency (p = .011, Cohen’s d = 1.03). Specifically, participant parents improved their use of behavioral contingency from baseline (M= 29.3%, SD = 25.9) to program completion (M= 57.7%, SD = 26.6).

Conclusions: Technology-assisted self-directed training efforts show promise for teaching parents core intervention skills. This continued use of behavioral contingency is likely to contribute to desirable child language and broader developmental outcomes.

434.186 (Poster) Improvements to Parent Intervention Fidelity and Dosage after Participation in a Pivotal Response Treatment App-Based Training Program

(1)UCSB Koegel Autism Center, Santa Barbara, CA, (2)University of California, Santa Barbara, Santa Barbara, CA, (3)UC Santa Barbara, Santa Barbara, CA, (4)University of California Santa Barbara, Santa Barbara, CA

Background: In order for parent-mediated intervention efforts to be optimally impactful, caregivers must deliver interventions with both (a) treatment fidelity, or close adherence to the intervention protocol, and (b) sufficient dosage during parent-child interactions to be therapeutically beneficial (Trembath et al. 2019). These training outcomes are particularly important to examine in the context of self-directed and telehealth training experiences, as parents are often the sole deliverer of the intervention. Given the lack of clinical support from trained professionals in self-directed training models, the need for effective parent mastery and regular use of skills and concepts should be prioritized and carefully monitored. In the current study, we examined changes in parent treatment fidelity and therapeutic dosage after completion of a self-directed app-based training program, Pivotal, which provided training in the Pivotal Response Treatment (PRT) early autism intervention model. PRT is a parent-friendly naturalistic developmental behavioral intervention (NDBI, Schreibman et al., 2015) that combines motivational and behavioral principles to target social communication skills in naturalistic settings.

Objectives: To examine the increase in the dosage of successful parent-initiated PRT sequences and overall mastery of PRT components following the completion of the Pivotal App.

Methods: Participants include 48 parent-child dyads across the U.S. (24 randomized to a video self-scoring PRT app version and 24 to a standard PRT app without self-scoring functionality). Child participants (1 - 4.5 years) have an existing diagnosis of ASD and parent concerns of language development. Parents complete intake and follow-up assessments, eight PRT lessons, and record and review parent-child videos in-app after each lesson, which are then reviewed by the research team for analysis. Researchers, blinded to the treatment conditions, score all videos for a stringent measure of PRT fidelity of implementation (requiring the presence of all components to be considered a “passing trial”), along with dosage during a 5-minute parent-child intervention probe, with dosage defined as one successful PRT sequence containing all PRT Fidelity components outlined in Table 1.

Results: Preliminary analysis of baseline (Module 0) and end of study (Module 8) intervention videos from participating families indicate an increase in the number of successful parent-initiated PRT trials. Overall, the number of parent-initiated PRT trials increased from a mean of 2.25 (SD = 2.55) at Module 0 to 6.12 (SD = 5.59) at Module 8 during each 5-minute parent-child intervention video. Additionally, the percentage of PRT components achieved by caregivers increased significantly from a mean of 25% (SD = .2) at Module 0 to 57% (SD = .25) at Module 8, p<.05.

Conclusions: The Pivotal app demonstrates promising improvements in parent implementation of PRT strategies. Specifically, analysis of parent-uploaded videos were indicative of an increase in the total number of successfully delivered PRT trials and fidelity of PRT components used. These data provide promising evidence that parents are effectively learning PRT skills through the Pivotal app and providing increased language opportunities for their child.

434.187 (Poster) Increases in Child Language Attempts Following Parent Training in Pivotal Response Treatment

T. W. Vernon, S. Licona, E. F. Ferguson, M. Jimenez Munoz, A. Arias and K. M. Russell;

(1)University of California Santa Barbara, Santa Barbara, CA, (2)University of California, Santa Barbara, Santa Barbara, CA, (3)UC Santa Barbara, Santa Barbara, CA

Background: Delays in social communication is a hallmark characteristic of autism and key target for early intervention efforts (Lane, Liberman-Betz, & Gast, 2015). As such, natural language samples of child word use and word attempts can provide important insights into linguistic improvements associated with early intervention efforts (Barokova & Tager-Flusberg, 2020). Specifically, examining videos of parent-child interactions can yield important data regarding the frequency of a child’s verbal requests, responses to prompts, and social uses of language. These data provide evidence of improvement accompanied by a high degree of ecological validity, as they capture interactions within the natural home environment with a natural social partner (the child’s caregiver). The current investigations examined parent-child videos collected before and after a parent-training clinical trial.

Objectives: To examine improvements in total child verbal utterances, responses to prompts, initiated requests, and social uses of language in the context of a parent-training clinical trial.
Methods: This investigation used a randomized clinical trial design to compare two versions of an app-based parent training model in Pivotal Response Treatment. Participants were 48 parent/child dyads who completed the 8-lesson program over the course of 4-12 weeks. Parents submitted 5-minute parent-child interaction videos at intake and after every two lessons were complete. For the current investigation, all participants were analyzed in a single cohort and pre- and post-project videos were coded by research assistants masked to study condition and timepoint. Coded measures were as follows: Total Child Vocalizations were defined as all directed child word or word attempts. Child Spontaneous Verbal Requests were defined as an unprompted child word or word attempt intended to obtain a desired item or activity. Child Responses to Prompts were defined as responses to a caregiver’s verbal model or question that was intended to elicit a response. Finally, Child Social Language was defined as words or word attempts intended to attract or direct social attention.

Results: A series of repeated measures T-tests were conducted to compare pre-post means. Significant differences were found for Total Child Vocalizations (p = .006; Cohen’s d = 1.18), Responses to Prompts (p = .028; Cohen’s d = .81), and Social Language (p = .007; Cohen’s d = 1.16), but not for Child Spontaneous Verbal Requests (p = .170; Cohen’s d = .36). Total Child Vocalizations improved from a mean of 18.6 vocalizations/words (SD = 13.4) at intake to a mean of 32.9 vocalizations/words (SD = 19.0) at post-intervention. Responses to Prompts improved from a mean of 8.5 vocalizations/words (SD = 5.2) to a mean of 13.6 vocalizations/words (SD = 8.7). Social Language improved from a mean of 8 vocalizations/words (SD = 10.7) to a mean of 15.1 vocalizations/words (SD = 13.0).

Conclusions: The results of this relatively brief app-based parent-training program yielded exciting improvements in child verbal communication skills. These data support of promise of technology-assisted methods to empower parents to target core social-communication vulnerabilities in young children with autism.

Background: Lack of child responsiveness to social communication bids is a recognized core vulnerability of autism that has downstream implications for social engagement, social relationships, and social learning (Watkins et al., 2015). Because human learning is inextricably tied to noticing and responding to the social bids of others, this is arguably a critical target during early intervention efforts. Motivation-based intervention models such as Pivotal Response Treatment use child selected and preferred activities as a means to increase attention to an adult social partner and increase the likelihood that a child will respond to their presented learning opportunities (Gengoux et al., 2019; Lei & Ventola, 2017). The current study targeted parent intervention skills in the context of a self-directed app-based training program called Pivotal.

Objectives: To analyze increases in child responsiveness during parent-child intervention sessions between pre- and post-program 5-minute intervention probes.

Methods: Participants included 48 parent-child dyads recruited nationwide and randomized to two versions of the Pivotal app. For this study, they were analyzed as a single cohort, as the research team remains masked to group assignment at this phase in the project. Child participants (12 to 56 months) have an existing diagnosis of ASD and a language delay. Parents completed intake and follow-up assessments, eight weekly PRT lessons, and recorded and reviewed parent-child videos in-app after every two lessons, which were then reviewed by the research team for analysis. Research assistants, masked to study condition, coded each parent-child video submission (5-minute videos) for the presence of intervention components and child behaviors. In the context of this investigation, child responsiveness was defined as a percent of parent-initiated PRT antecedent bids that were immediately followed by an appropriate child verbal response.

Results: Using a paired-samples T-test, the entire project cohort of children with autism significantly improved their responsiveness to parent social communication bids (p = .005, Cohen’s d = 1.26). Specifically, children improved their responsiveness from a mean of 27.9% (SD = 20.9) of the time at intake to a mean of 58.2% (SD = 15.2) after program completion. This improvement was not simply due to an increase in the number of parent-initiated social communication bids, which did not significantly differ between intake and program completion (p = .152). This suggests that the quality (rather than quantity) of parent bids drove increases in child responsiveness as parents mastered the PRT intervention strategies.

Conclusions: Parents who participated in this app-based clinical trial appear to have learned effective strategies for engaging their child in intervention efforts. Motivation-based early intervention efforts that increase child responsiveness may have a significant impact on downstream child developmental outcomes.

434.188 (Poster) Increasing Child Responsiveness to Social Communication Bids: Results from the Pivotal App Clinical Trial
A. R. Bordofsky, S. Licona, E. F. Ferguson, M. Jimenez Munoz, A. Arias, K. M. Russell, and T. W. Vernon, (1)University of California, Santa Barbara, Santa Barbara, CA, (2)UC Santa Barbara, Santa Barbara, CA, (3)University of California Santa Barbara, Santa Barbara, CA

434.189 (Poster) Incredible Years-Asld® Delivered Via Telehealth: Examining Pre-Post Changes in Verbal Behavior during Dyadic Play
Background:

The Incredible Years-Basic Parenting Program® (IY; Webster-Stratton, 2001), is a well-established, evidence-based group parenting intervention with over 50 randomized control trials (RCTs) demonstrating its efficacy with a wide range of families in reducing disruptive child behavior and parental stress, as well as enhancing positive parenting practices (see Menting, et al., 2013 for a meta-analysis). Recently, the Incredible Years has modified its preschool program to meet the unique needs of families with young children with autism spectrum disorder and language delays (IY-ASLD; Webster-Stratton, 2018). During the pandemic, we worked with program developer, Carolyn Webster-Stratton, to adapt IY-ASLD to a telehealth format. We piloted IY-ASLD-T in small-scale quasi-experimental study before beginning an RCT now in progress. This paper reports on findings from the pilot with 17 mothers with young children (ages 2-5) classified as a preschooler with a disability attending an all-day Applied Behavior Analysis preschool. This presentation reports on observed changes in maternal language targeted by the IY-ASLD curriculum during parent-child interactions assessed over Zoom at baseline and post-treatment.

Objectives:

In the IY-ASLD program, parents are introduced to strategies to increase responsiveness, reduce directiveness, and allow play to become more child-led, with the goal of making social interactions and interpersonal play more rewarding for children. Parent verbal behaviors during a free-play activity were examined, including the frequency of directive and disapproving antecedents (questions, commands, corrections, disapproving statement) and of responsive and rewarding antecedents (descriptive statements, narration, approvals, praise). Two Factors possibly contributing to changes in parenting verbal behaviors are considered: attendance in group sessions and child level of adaptive behavior as rated by the child’s teacher.

Methods:

Twenty mothers were recruited. Seventeen began and completed a 12-week IY-ASLD-T intervention delivered over HIPPA protected Zoom. Mothers were diverse ethnically, well-educated (94% college graduate), and affluent (65% reported income over $150,000 USD). All children receiving mandated speech therapy and 15 children met criteria for ASD using the Child Autism Rating Scale-2nd edition Short Form.

The present study explores pre-post changes in vocal verbal operants (VVOs) during free play sessions recorded in the home over Zoom before and after treatment. To measure the parent’s directiveness or responsiveness, each vocal emission was coded using definitions from verbal behavior theory (e.g., mands, tacts, intraverbals, approvals, disapprovals, see Table 2).

Results:

Mothers in the IY-ASLD-T program significantly decreased their frequency of directive VVOs and increased the frequency of responsive VVOs. The overall ratio of VVOs emitted by parents shifted from more directive pre-intervention to more responsive post-intervention indicating that participants developed responsive skills and reduced the number of demands placed on their child during free play. Parents of children with more severe deficits in socialization and communication on the Vineland Adaptive Behavior Scales-3 Teacher Version were more directive and less responsive overall, across both time points measured, when compared to parents of children with lesser deficits.

Conclusions:

Parent-child play interactions play a role in the development of social and communication skills. Interventions, such as IY-ASLD help parents facilitate more rewarding play interactions with their children.

Background:

Currently, we have limited ability to predict responsiveness of an individual child or family to early intervention programs (Vivanti et al., 2014); therefore, families often face an inefficient process as they begin to seek services, and may fail to find an intervention program meeting their needs. Researchers have recently increased their examination of predictors of treatment response, with the aim of better matching early interventions to key entry characteristics of children with or at elevated likelihood for autism (ELA), or their families, that account for some variability in treatment response (Fossum et al., 2018; Grzadzinski et al., 2022; Panganiban & Kasari, 2022). Sensory
hypo-reactivity and seeking have been implicated as potential moderators of communication outcomes for ELA infants (Jatkar et al., 2022) and autistic children (Williams et al., 2018).

Objectives:

To determine whether infant hypo-reactivity and seeking moderate communication outcomes in a new parent coaching intervention for families of ELA infants. Child intentional communication (IC) is a key predictor of language growth in preverbal autistic preschoolers (Yoder et al., 2015); therefore, we targeted IC as an arguably important outcome during for ELA infants.

Methods:

In the Parents and Infants Engaged (PIE) intervention, parents are coached in responding to two types of infant cues (prelinguistic communication; sensory reactivity) to facilitate dyadic engagement. Theoretically, as dyadic engagement is optimized, children can take better advantage of opportunities to learn communication skills. Families of ELA infants (11-16 months) were identified using the First Years Inventory (FYI-Lite, v3.1b; Baranek et al., 2014; 2022). Those with scores <1 SD below the mean on the Mullen Scales of Early Learning (Mullen, 1995) Expressive or Receptive Language and with elevated levels of hyper- or hypo-reactivity on the Sensory Processing Assessment (SPA; Baranek, 1995) were invited to enroll in the 12-week intervention; 36 families enrolled (n=34 had complete pretest and posttest data). IC rates were coded from 15-minute parent-child interactions by blinded coders. We ran a random intercepts mixed model predicting IC growth after 12 weeks of PIE intervention. The model included entry hypo-reactivity and seeking as predictors of IC, and interactions between time and hypo-reactivity as well as time and seeking. Sex and age at baseline were included as covariates.

Results:

IC rates increased significantly over time, $F(30) = 22.32, p < .0001$. IC was significantly associated with entry levels of hypo-reactivity, $F(30), p < .01$, but not with entry seeking, $F(30) = 2.21, p = 0.15$. Higher hypo-reactivity predicted lower levels of IC. Neither entry hypo-reactivity $F(1,28) = 1.31, p = 0.28$, nor seeking, $F(1,28) = 1.91, p = 0.18$, moderated change in IC from entry to posttest.

Conclusions:

Given the improvements in IC over the course of the intervention, coaching parents to respond to hypo-reactivity cues of ELA infants may help improve their communication outcomes. Because initial levels of hypo-reactivity and seeking in these infants did not predict IC changes during the PIE intervention, examining other potential moderators of infant communication outcomes may provide insights into which infants will benefit most from PIE.

Objectives: The current study aims to examine the effect of P-CDI on treatment gains among P4P participants, on both social skills and difficult behaviors. We hypothesized that children with greater P-CDI at baseline would exhibit less improvements than those with less P-CDI pre-treatment.

Methods: Participants included 61 preschoolers (77% male; $M_{age} = 4.7; SD = .8$) with historical autism diagnoses and SRS-2 total scores $\geq$ 60 who completed the P4P program. Each participant had a P-CDI score determined by baseline parent-reports on the Parental Stress Index – Fourth Edition Short Form (PSI-4-SF; Abidin, 2012). Higher scores indicated more dysfunctional interactions. Treatment gains were assessed using change scores between pre- and post-intervention on the Social Skills (SSiS-SS) and Problem Behavior (SSiS-PB) domains.
of the Social Skills Improvement System (SSIS; Gresham & Elliot, 2008). Pearson correlations examined the relationship between baseline P-CDI scores and treatment gains.

Results: Paired sample t-tests showed that participants significantly improved with respect to social skills, t(39)=−3.14, p=.003, and problem behaviors, t(35)=−2.70, p=.011, post-P4P. There were significant correlations between P-CDI and baseline child social functioning as measured by the SSIS-SS, r =−.31, p =.016, and SSIS-PB domains, r =.34, p =.01, such that greater P-CDI corresponded with greater baseline behavioral challenges. No significant correlation emerged between baseline P-CDI scores and treatment gains based on SSIS-SS (r =.257, p >.124) or SSIS-PB (r =.033, p =.855) change scores, suggesting that parent-child dysfunctional interactions did not predict treatment outcome.

Conclusions: These findings suggest parent-child dysfunctional interactions do not predict treatment gains in PEERS® for Preschoolers, demonstrating similar benefits following P4P irrespective of parent-child conflict. However, there does appear to be a relationship between parent-child dysfunctional interactions and child baseline social skills and problem behavior. Future work might further examine the relationship between parent and child, especially in the context of social skills groups for this young age range. Adding observational measures of parent-child interactions in addition to parent reports might add another layer for future analysis.

434.192 (Poster) Mediation of 6 Year Mid-Childhood Follow-up Outcomes after Pre-School Social Communication Therapy for Autistic Children (PACT): Randomised Controlled Trial

J. Green, T. Charman, A. Pickles, H. McConachie, A. LeCouteur, V. Slonims, P. Howlin, E. Salomone, C. Aldred, J. R. Parr, K. Leadbetter, I. Gammer, J. Maxwell, and H. Tobin, (1)University of Manchester, Manchester, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, UNITED KINGDOM, (3)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom, (4)Newcastle University, Newcastle, United Kingdom, (5)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (6)Guy’s & St Thomas’ NHS Foundation Trust (Evelina Children’s Hospital), London, United Kingdom, (7)King's College London, London, United Kingdom, (8)Department of Psychiatry, University of Milan-Bicocca, Milan, Italy, (9)University of Manchester, Manchester, United Kingdom, (10)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (11)Newcastle University, Newcastle upon Tyne, United Kingdom

Background: There are very few mechanistic studies of the long-term impact of psychosocial interventions in childhood, including autistic interventions. Such mechanistic studies are of great importance; not only to identify the ‘active processes’ by which interventions achieve their effects, but also for the insights such trial results can give into causal processes in development. A randomised controlled trial (RCT) of the parent-mediated Paediatric Autism Communication Therapy (PACT), delivered pre-school, demonstrated significant endpoint effects to reduce symptom severity on ADOS Calibrated Severity Score (CSS) and ADOS-2 total algorithm score (Pickles et al 2016; Carruthers et al. 2021). These endpoint symptom effects were strongly mediated by a midpoint-treatment effect to increase child dyadic communication initiations with the parent (Pickles et al 2014). At follow-up, 6 years after endpoint, treatment effects on child symptom and adaptive outcomes and child initiations with parent were significantly sustained (Pickles et al 2016).

Objectives: To investigate the mechanism by which the sustained effect of PACT intervention on symptom outcomes was achieved.

Methods: Of 152 children randomised to receive PACT or treatment as usual between 2-5 years of age, 121 (79.6%) were followed 5-6 years after endpoint at a mean age of 10.5 years. Assessors, blind to intervention group, measured Autism Diagnostic Observation Scale Combined Severity Score (ADOS CSS) for child symptoms and Teacher Vineland (TVABS) for adaptive behaviour in school. Hypothesised mediator was child dyadic communication initiations with caregiver in a standard play observation (Dyadic Communication Measure for Autism, DCMA). Hypothesised moderators of mediation were baseline child non-verbal developmental quotient (DQ), communication and symbolic development (CSBS) and ‘insistence on sameness’ (IS). Structural equation modelling was used in a repeated measures mediation design.

Results: Good model fits were obtained. The treatment effect on child dyadic initiation with caregiver was sustained through the follow-up period. Increased child initiation at treatment midpoint mediated the majority (73%) of the treatment effect on follow-up ADOS CSS. A combination of midpoint child initiations and direct effect of treatment also mediated the near-significant effect on follow-up TVABS. No moderation of this mediation was found for DQ, CSBS or IS.

Conclusions: Early increase in an autistic child’s communication initiation with their caregiver is largely responsible for the long-term effects from PACT therapy on symptom and adaptive behaviour outcomes. This is the first time to our knowledge that such a mediation has been shown. The finding supports the theoretical logic model of PACT therapy but also illuminates fundamental causal processes of social and adaptive development in autism over time. Early social engagement in autism can be improved with treatment. In turn such early improvement in social engagement initiated long-term generalised outcome effects on the autistic child's phenotype and adaptation.

434.193 (Poster) Modeling Heterogeneity Amongst Caregivers in Response to Caregivers Mediated Interventions
Background: Caregiver mediated interventions have grown in popularity for caregivers of young autistic children. Teaching caregivers specific strategies to help them teach their young children who are at risk or diagnosed with autism has the potential to offset some of the worry caregivers have about their children’s development as well as providing a higher dose of intervention than current practices can accommodate with community therapists. While multiple intervention models are available, only a few have demonstrated change in caregiver’s behavior and child outcomes due to the intervention. The current study is a secondary data analysis from a two-armed randomized control trial where children were randomized to one of two treatment conditions, caregiver-mediated JASPER, or psychoeducation intervention (PEI).

Objectives: To understand the fit between caregiver style of interaction and intervention approach on child outcomes. We evaluate 1) treatment and maintenance effects of caregiver strategies, 2) whether caregivers with higher strategies at baseline have better maintenance of strategies at exit to follow-up compared with caregivers’ with lower strategies, and 3) whether baseline strategies moderate the treatment effect on child joint attention.

Methods: 86 autistic participants (average age 31.5 months) and their primary caregivers enrolled in the study. On average, these children were primarily male (81%), Caucasian (63%), and recruited from the same early intervention program consisting of 30 hours per week of a combination of behavioral, speech and occupational therapies. All children were administered the ADOS to confirm autism. Caregiver JASPER strategy use was rated across the 10-min parent-child interaction. Five composite codes (%) were included in the analyses: environmental arrangement, imitation, prompting, communication and overall strategies. The Early Social-Communication Scales were administered to assess children's type and frequency of spontaneous initiations of joint attention skills (IJA) including point, give, and show. Generalized linear mixed models (GLMM) were used to model the longitudinal trajectories of the strategies and IJA, employing an identity link for continuous outcome variables and a log link function for count outcomes.

Results: Caregivers in the JASPER intervention made more gains in overall JASPER strategies (F(1,151), p<0.001) and the 4 domain strategies (environment, prompt, communication, imitation) compared to the caregivers in PEI group (F(1,151)=35.94, p<0.001; F(1,151)=56.37, p<0.001; F(1,151)=18.69, p=0.001; F(1,151)=15.47, p=0.001) respectively from baseline to exit. While caregivers in both groups regressed in overall and subdomain strategies at follow-up, caregivers in the JASPER intervention maintained more overall, communication, and imitation strategies compared to PEI group (F(1,151)=2.83, p=0.005; F(1,151)=4.32, p=0.0394; F(1,151)=6.97, p=0.009) respectively. Further, baseline caregiver strategies moderated the treatment effect of overall strategies (F(1,68)=4.70, p=0.0336, see Figure 1a) and imitation from exit to follow-up (F(1,68)=7.75, p=0.002, see Figure 1b). Lastly, caregiver’s baseline strategies moderated the effect of treatment on child’s IJA from exit to follow-up (F(1,67)=11.02, p=0.002) where JASPER children with high baseline caregiver strategies continued to improve in JA skills post exit whereas all other children did not.

Conclusions: In summary, understanding the fit between caregiver style of interaction and the intervention is important in improving intervention strategies uptake and improving child outcomes.

434.194 (Poster) Multi-Domain Assessment of Esdm Efficacy over Time: Is One Year Enough?

Background:
Early Start Denver Model (ESDM) is nowadays recognized as one of the most recommended early intervention models for young children with ASD. Intended for preschool age children (2-4 years), it is a global and intensive -15 to 20 hours per week-, developmental and behavioral program. Several studies have shown a positive impact of ESDM on developmental level, adaptive skills and language. However, response to treatment varies significantly from child to child, and the factors that determine the efficacy are still not well understood. Specially, the optimal intensity and duration of the therapy are not well described yet.

Objectives:
The objective is to characterize the longitudinal progression and performance of ASD children on several domains over the two years of ESDM intervention.

Methods:
We assessed 30 children diagnosed with ASD at three different time points during the ESDM program: at their entry (T0), after one year (T1) and at the end of the treatment two years after T0 (T2). Our ESDM program consisted of 15 hours/week of intervention. We evaluated
children’s autism core symptomatology, as well as global cognition and neuromotor skills, and performed local polynomial regression modelling to evaluate the efficacy of ESDM intervention over time on these domains.

Results:

After 12 months of ESDM intervention, children exhibited a significant improvement in social communication and interaction, whereas no change over time was observed on the level of repetitive and restrictive behaviors (RBB). On average, these children also showed a significant gain of 19 points of IQ during the same time period. This gain was similar in both verbal and nonverbal quotients. Interestingly, all these effects persisted but remained unchanged during the second year of ESDM therapy. We also found differential progression of fine and gross motricity: fine motor skills slightly improved over time, whereas gross motor skills did not change.

Conclusions:

Our findings demonstrate a strong effectiveness of ESDM to boost cognitive and social communication competences over the first 12 months of therapy. These gains are maintained during the second year. We believe that these results hint at different underlying processes taking place during the first and the second year of ESDM intervention. If confirmed, these results could be helpful for clinicians to optimize early intervention programs and adapt the treatment over time relying on progress and child’s needs.

434.195 (Poster) Naturalistic Developmental Behavioral Interventions and Augmentative and Alternative Communication for Children on the Autism Spectrum with Minimal Speech
L. Pope, J. Light and E. Laubscher, (1)Penn State University, University Park, PA, (2)Regis College, Weston, MA

Background: Many children on the autism spectrum struggle to meet even basic communication needs via spoken language (Tager-Flusberg et al., 2005). Naturalistic developmental behavioral interventions (NDBIs) offer one promising avenue for supporting the language development of young children with ASD (e.g., Sandbank et al., 2020). However, children with ASD and minimal speech are less likely to benefit from NDBIs in their traditional format (Kasari et al., 2014). Without speech, these children have limited means to engage in the rich language learning environment. Augmentative and alternative communication (AAC) offers potential tools to support the early language development of young children with ASD and minimal speech (Ganz et al., 2012), and has been shown to be easily and effectively integrated into NDBI procedures (Kasari et al., 2014). However, most manualized NDBIs target spoken language almost exclusively.

Objectives: The goals of this study were twofold: (1) to bridge the NDBI and AAC intervention literature by systematically reviewing and comparing the relative impact of speech-only NDBIs and naturalistic AAC interventions that qualify as NDBIs on language growth for children with ASD and (2) to pilot test intervention procedures incorporating developmentally appropriate AAC technology within an NDBI framework for six children ages 2-5 with ASD and minimal speech.

Methods: Relevant studies for the systematic review were located through systematic database searching. The pilot testing procedures consist of an experimental single-case multiple probe across participants design (Kratochwill et al., 2010). The independent variable is the introduction of a visual scene display (VSD) AAC app during interactions with participants. The main dependent variable is the total number of unique vocabulary concepts expressed spontaneously by participants during 20-minute storybook reading sessions. Baseline sessions include NDBI procedures only, and intervention sessions add AAC.

Results: A total of 22 studies met inclusion criteria for the systematic review. The cumulative effect of interventions on language were aggregated across intervention type (i.e., NDBI-only or NDBI+AAC). These average effect sizes were used to compare the effectiveness of NDBI studies that did and did not incorporate AAC. Aggregate effect sizes for all study types were medium to very large, indicating that NDBIs with and without AAC as a component had a significant positive impact on language development. However, the cumulative effect size for NDBI studies including AAC was very large (Tau U = 0.84), while only in the large range (Tau U = 0.73) for those studies that did not include AAC as a component. As the pilot study is currently underway, definitive results are not yet available.

Conclusions: These results suggest that NDBIs that include AAC may be more effective in supporting language development for children with ASD than those that do not. Importantly, study characteristics were similar across those studies that included AAC and those that did not, suggesting that AAC may be incorporated into preexisting NDBI protocols with minimal alterations. The forthcoming results of the pilot study will provide additional evidence regarding the relative efficacy of NDBI procedures alone in contrast to when NDBI strategies include developmentally appropriate AAC systems.

434.196 (Poster) No Evidence for Sex Specific Characteristics in Autistic Children Enrolled in Autism Early Intervention Trials
A. C. Austin¹, A. Zitter¹, B. A. Boyd¹, C. Dissanayake¹, S. Dufek¹, H. E. Flanagan¹, S. Iadarola¹, A. P. Kaiser¹, S. H. Kim¹, L. Levato¹, J. B. Plavnick¹, D. L. Robins¹, L. F. Robinson¹, S. J. Rogers¹, I. M. Smith¹, A. C. Stahmer¹, L. R. Watson¹ and G. Vivanti¹, (1)Drexel University, Philadelphia, PA, (2)Center for Autism Research, Drexel University, Philadelphia, PA, (3)School of Education, University of
Background:

Given that Autism Spectrum Disorder (ASD) is more prevalent in males than females and females are under-represented in research, current early interventions for ASD have been developed based on the male phenotype (Benevides et al., 2020). This may be problematic, as research has pointed to potential differences in the presentations of males and females on the autism spectrum (Duvall et al., 2019; Ros-Demarize et al., 2018; Tsirgiotis et al., 2022). However, research is limited on sex-specific presentations of autism in children who enroll in early intervention programs. It is critical to examine whether females enrolled in early intervention programs present differently than males as an initial step toward determining whether current approaches to early intervention are a good fit for them.

Objectives:

We aimed to examine sex differences in a large and well-characterized sample of autistic children enrolled in early intervention trials.

Methods:

Our research question was addressed using an aggregate dataset collected for a broader study that includes child-level data for children who enrolled in evidence-based early interventions as part of their participation in early intervention trials. For the purpose of this study we analyzed baseline data for 751 males and 167 females aged 13 months to 75 months (M = 37.13, SD = 12.93) enrolled in early intervention trials across measures of a) developmental quotient (DQ) which was operationalized as the ratio between developmental age and chronological age using the Mullen Scale of Early Learning, Leiter International Performance Scale-3rd edition, Merrill Palmer-Revised Scales of Development, and Bayley Scales of Infant Development), b) adaptive functioning using the Vineland Adaptive Behavior Scales (VABS; Sparrow, Balla & Cicchetti, 2005), and c) symptom severity using the Autism Diagnostic Observation Schedule 2 (ADOS 2; Lord et al., 2012).

Results:

Since age at enrollment did not differ between males and females (p = .754, d = .14), we performed unadjusted t-tests to compare males and females across measures of verbal and nonverbal DQ, adaptive behavior, and symptom severity without adjusting for age. As reported in Table 1, no differences were found between males and females across our variables of interest (see also Figure 1).

Conclusions:

To our knowledge this is the first study to examine sex differences in a large aggregate dataset of well-characterized autistic children enrolled in early intervention trials. No sex differences were found in our sample across verbal and nonverbal DQ, adaptive behavior, or symptom severity. Although the literature informing current interventions is predominantly based on the male phenotype, the lack of differences between the male and female autistic children participating in these early interventions mitigates concerns about the appropriateness of current intervention practices for females on the autism spectrum. However, further research is needed to investigate male and female phenotypes for young children enrolled in autism early interventions across other factors not addressed in the current study (e.g., anxiety, emotion regulation).
Objectives: Online Parent Mediated Intervention for Children with ASD Program (OYNA) is a parent-mediated, online, and video-aided intervention designed to improve social communication competencies in preschool children with ASD. Families attend weekly 3-hour group sessions for 8 weeks followed by bimonthly booster sessions for 4 months (total 10 sessions). Each group consists of 10 parents (mothers and fathers). Every session follows the same procedure; in the beginning one clinician presents the strategies of the week that will be practiced at home (e.g., balanced turns, imitation) and sample videos are shown to illustrate the strategies. Between sessions, families are asked to totally do 60 minutes of daily practice. The families practice the strategies by interacting with their child throughout the week and record one sample video clip to be presented in the group session. Clinicians provide feedback for whether the parent accurately implemented the targeted intervention strategies. The aim of this study was to investigate the effect of the “OYNA” Program on ASD symptoms and on mental health of parents.

Methods: Families of a child with ASD between the ages of 18 and 60 months participated to the study. All parents (both mother and father) were asked to fill out the Social Communication Checklist (SCC), Depression Anxiety Stress Scale (DASS) and the Broad Autism Phenotype Questionnaire (BAP) both before and after the program.

Results: Parents of 75 children participated in the study. The mean age of the children was 38.2 (± 14.5) months and 68% were male. SCC total score and subscale scores (social interaction, expressive language, receptive language, imitation, and play) increased and DASS scores decreased significantly after the OYNA Program. However, BAP scores did not change after the intervention.

Conclusions: Our results are in parallel with previous studies which demonstrated improvements in children's social communicative skills, language use, and play skills and parental anxiety and stress levels.

434.198 (Poster) Parent Characteristics As Predictors of Treatment Outcome for Autistic Preschoolers Following the UCLA PEERS for Preschoolers Intervention

S. S. Gonzalez, C. T. Moody, R. S. Factor, K. L. Fisher and E. A. Laugeson, (1)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, University of California Los Angeles, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience and Human Behavior, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (4)UCLA Semel Institute for Neuroscience and Human Behavior, UCLA PEERS Clinic, Los Angeles, CA, (5)UCLA Semel Institute for Neuroscience and Human Behavior, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA

Background: Research has shown that social communication differences in autistic children are apparent in early development (Paul, 2003) and can result in long term negative sequelae (Simonoff et al., 2008). Parent involvement is widely incorporated into interventions for young autistic children (Rojas-Torres et al., 2020); however, research into how parent factors impact treatment outcomes is currently limited (Shalev et al., 2019). The PEERS® for Preschoolers (P4P) program is an evidence-based social skills intervention designed for preschool-aged autistic children with concurrent parent-training in social coaching strategies to amplify and generalize child treatment gains (Park et al., 2022). Given parents’ active roles in P4P, it is essential to understand whether parent characteristics influence outcomes in the program to inform treatment planning and program implementation.

Objectives: This study aimed to examine the influence of parent characteristics in relation to treatment gains in autistic preschoolers following P4P.

Methods: Participants included 46 autistic children (Mage=4.5, SD=0.7; 78% male) and their parents who participated in the 16-week P4P intervention. Four parental characteristics were categorized into binary variables for analysis: relationship to child of participating parent (i.e., mother, father), ethnic/racial identity (i.e., White, BIPOC), parental education (i.e., graduate degree, bachelor’s or less), and marital status (i.e., married, non-married). Treatment response was assessed via parent-report, using change scores from pre- to post-intervention on the Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2012), Social Skills Improvement System Social Skills domain and Problem Behaviors domain (SSIS-SS and SSIS-PB; Gresham & Elliott, 2008), Quality of Play Questionnaire (QPQ; Frankel and Mintz, 2008) and Parenting Stress Index, Fourth Edition, Short-Form (PSI-4-SF: Abidin, 2012).

Results: Overall, parents reported significant improvements after P4P on all outcomes, including social responsiveness (SRS-2), social skills (SSIS-SS), social engagement (QPQ), problem behaviors (SSIS-PB), and parenting stress (PSI-4-SF), ps<.05. There were no significant differences in treatment response by marital status or parental education (ps>.05). With respect to parent ethnic/racial identity, treatment response was similar for children of White and BIPOC parents on all measures except the SSIS Social Skills domain, t(37)=2.65, p=.012, on which White parents reported significant improvements on the SSIS-SS (Mchange=12.1, SD=13.4, p=.003), while BIPOC parents did not (Mchange=2.2, SD=9.7, p=.258). Finally, although both mothers and fathers reported increased playdates after P4P on the QPQ (ps<.05), fathers showed significantly greater gains in this area than mothers, t(39)=2.02, p=.05. No other differences between mothers and fathers emerged.

Conclusions: Overall, results indicate that families benefit from the P4P intervention and for a majority of outcomes, parent characteristics did not differentiate treatment response. These encouraging findings suggest diverse families largely benefit similarly from P4P. Fathers may have especially benefited from instruction in identifying playgroups and facilitating playdates given greater gains than mothers in their child’s social engagement. Discrepancy improvements in child overall social skills by parent ethnic/racial identity warrant further research.
with larger sample sizes to compare across BIPOC populations to confirm and specify differences. Additionally, investigation of BIPOC parent experiences in P4P and adaptations to enhance cultural sensitivity of P4P outcome measurement and treatment would be beneficial.

**434.199 (Poster) Parent Empowerment and Coaching in Early Intervention: Implementation Strategies to Support Caregiver Coaching in Community Settings**

**M. Pellecchia**, D. S. Mandell, R. S. Beidas, L. Tomczuk, G. Lawson, and A. C. Stahmer. (1)University of Pennsylvania, Philadelphia, PA, (2)Penn Center for Mental Health, University of Pennsylvania School of Medicine, Philadelphia, PA, (3)Northwestern University Feinberg School of Medicine, Chicago, IL, (4)Children’s Hospital of Philadelphia, Philadelphia, PA, (5)UC Davis MIND Institute, University of California, Davis, Sacramento, CA

**Background:** High-quality, caregiver-mediated early intervention (EI) improves long-term outcomes for autistic children. In contrast to university-based studies of caregiver-mediated interventions, community-based EI outcomes tend to be poor, especially in low-income communities (Nahmias et al., 2019). Attenuated outcomes may be due in part to a lack of effective caregiver coaching. Community-based EI providers, particularly those working with families from marginalized backgrounds, spend most of their time working directly with the child instead of coaching caregivers in the use of intervention strategies (Pellecchia, 2022). Improving the implementation of caregiver coaching for families of young autistic children is critical to improving equitable outcomes in EI.

**Objectives:** Develop and test a toolkit of implementation strategies to improve the use of caregiver coaching for families receiving community-based EI.

**Methods:** We used community-partnered research practices with frequent input from a diverse community advisory board to iteratively develop a toolkit of implementation strategies designed to improve caregiver coaching in community-based EI. The Parent Empowerment and Coaching in Early Intervention (PEACE) toolkit is a modular toolkit of implementation strategies with three main parts: 1) an online resource library of self-paced modules, tip sheets, and infographics designed to target implementation barriers; 2) an online chat space to foster a shared learning community; and 3) twelve weekly group facilitation meetings focused on auditing of providers’ performance, feedback, and collaborative problem solving around barriers to caregiver coaching. We evaluated the toolkit’s effectiveness using a non-concurrent multiple baseline design across three groups of community-based providers and caregiver-child dyads, randomized to baseline length. We conducted direct observations of providers’ caregiver coaching fidelity weekly for twelve weeks for each dyad. We calculated effect sizes for change in caregiver coaching fidelity using the percentage of non-overlapping data (PND). We assessed changes in caregivers’ use of responsive intervention techniques using the Parenting Interactions with Children Checklist of Observations Linked to Outcomes (PICCOLO) at baseline and after twelve weeks. We evaluated providers’ perceptions of the acceptability, appropriateness, and feasibility of the toolkit using standardized measures.

**Results:** Results of the multiple baseline design indicated that EI providers’ caregiver coaching fidelity improved following introduction of the toolkit. PND for Group 1 was 100%, indicating that the PEACE toolkit improved Group 1 providers’ overall caregiver coaching fidelity (Highly Effective). PND was 73% for Group 2 (Effective) and 64% for Group 3 (Questionable). Among those providers who did not meet fidelity benchmarks, low scores were driven by variability in fidelity to specific coaching components. Caregivers demonstrated moderate growth in their use of supportive parenting techniques from the first to second observation. All providers rated the PEACE toolkit as highly acceptable, appropriate, and feasible to use, with a mean rating of 5 out of 5 for all three measures.

**Conclusions:** Our findings suggest that a toolkit of implementation strategies developed in partnership with community stakeholders and tailored to support the unique needs of community-based providers was acceptable, feasible, led to improvements in caregiver coaching, and shows promise for improving caregivers’ use of supportive parenting techniques in community-based EI.

**434.200 (Poster) Parent-Based Stress Reduction Interventions and Their Impact on Sleep Problems in Young Children with ASD**

**C. R. Callad**, T. R. Van Dyk, A. Nair, R. M. Fenning, and C. L. Neece. (1)Psychology, Loma Linda University, Loma Linda, CA, (2)Psychological Science, Claremont McKenna College, Claremont, CA

**Background:** The challenging behaviors common in children with autism spectrum disorder (ASD) have been associated with elevated distress among caregivers (Hayes & Watson, 2013). This includes child sleep problems, which predict elevated parenting stress even after accounting for core symptoms of ASD and demographics (Hoffman et al., 2008). This relationship is likely bidirectional as increased parenting stress is associated with worse child behavior, in general (Rodriguez et al., 2019). Stress-reduction interventions for caregivers of youth with ASD may reduce parental distress (Neece, 2014) and have a collateral benefit of improving child sleep.

**Objectives:** The aim was to longitudinally assess the impact of two parent stress-reduction interventions on sleep problems among young children with ASD, and evaluate how changes in parental stress predict changes in sleep problems over time.

**Methods:** The study utilized data from the larger Stress-reduction Techniques for Enhancing Parenting Skills (STEPS) Project, an NIH-funded randomized control trial. Subsample participants included 51 parents ($M_{age}=34.76, SD=8.18, 80.39\%$ racial/ethnic minority) of children diagnosed with ASD aged 3-5 years. Parents were randomly assigned to either an 8-week Mindfulness-Based Stress Reduction
(MBSR) intervention or Psychoeducation and Support (PE) active control intervention, and both were delivered. Assessments were conducted at baseline, immediately post-intervention, and 6- and 12-months post-intervention. Parenting stress was measured using the PSI-4 Short Form Parental Distress subscale (Abidin, 1995).

Results: At baseline, there were no significant differences in demographic variables or all sleep outcomes between groups. Two-level linear growth curve models were used to test whether there were significant changes in each of the CSHQ subscales over time, whether intervention group predicted changes in sleep problems over time, and whether changes in parenting stress predicted changes in sleep problems over time. Social Responsiveness Scale (SRS-2; Constantino, 2012) total t-scores were included as a covariate to control for ASD symptom severity. Total sleep problems ($\gamma_{10}= -.91, p < .05$), bedtime resistance ($\gamma_{10}= -.39, p < .05$), and sleep duration concerns on the CSHQ significantly improved over time ($\gamma_{10}= -.37, p < .01$). Intervention group did not predict changes over time. When the PSI parental distress subscale was entered as a time-varying covariate, total sleep problems, bedtime resistance, and sleep duration concerns on the CSHQ no longer significantly changed over time, suggesting that changes in parenting stress accounted for the observed changes in parent-reported sleep problems over the course of the interventions.

Conclusions: In both treatment groups, child parent-reported sleep improved across time, even without sleep-specific intervention. These improvements were explained by the significant reductions in parenting stress. It is possible that when parent functioning improves, there are positive downstream consequences for child functioning, although future research should better account for the passage of time and/or placebo effects. Clinicians should consider the benefits of addressing parenting stress in the context of behavioral sleep interventions for youth with ASD.

434.201 (Poster) Parent-Mediated Augmentative and Alternative Communication Interventions in Early Childhood: A Scoping Review

L. Fischbacher and R. L. Dodds, (1)University of California Los Angeles, Los Angeles, CA, (2)Special Education & Counseling, California State University Los Angeles, Los Angeles, CA

Background: Parents are widely considered children’s first language teachers; however, parents of children with developmental disabilities that affect speech are less likely to spend time with their child in parent-child interaction, are less responsive to their child’s communication, are more direct when communicating, and use fewer language learning support strategies. To address these concerns, parents and caregivers of children with developmental disabilities and complex communication needs (CCN) can learn the skills and strategies to communicate with their children early using Alternative and Augmentative Communication (AAC).

Objectives: The purpose of this scoping literature review is to better understand how researchers have approached the provision of parent-mediated AAC interventions for young children, including: the characteristics of the children and caregivers included, the descriptions of the interventions utilized, the outcomes of interest, and how AAC is incorporated in the study.

Methods: A scoping review of the literature was performed. ERIC, PsycINFO, Communication & Mass Media Complete and, MEDLINE databases were searched in EBSCO and limited to peer reviewed articles, and yielded 23 results. Six manuscripts were included based on the following a priori criteria: (a) children participants were eight years of age or younger (b) parent training and/or parent implementation was present in the intervention description (c) aided AAC or SGD was utilized (d) the publication date was 2005 or later. From these articles, two ancestral articles were identified and included in the analysis.

Results: The eight articles that met inclusion criteria were read and summarized in a table utilizing the following coding categories: (a) study design; (b) type of AAC or SGD utilized (c) child participants (number, age, gender, disability; (d) caregiver description; (e) description of independent variable; (f) dependent variable; (g) if telehealth or online training was implemented and (h) What Works Clearinghouse quality rating. The articles were also coded for the level of parent involvement in the study and social validity. It was noted if the themes parent responsiveness, telehealth or online training, and naturalistic setting or elements were present in the description of the study intervention. This review found that there are very few studies reporting on parent-mediated early interventions using AAC (n = 8). The included studies found improvements in parent responsiveness and children’s improvement in communicative and social domains. Although all of the studies had elements of high-quality studies, only half of the included studies met the WWC standards without reservation (n=4). Naturalistic elements were found in five of the studies. Parent responsiveness was present in five studies as well. Telehealth was not present in any, however, an online training module was present in one.

Conclusions: There are many barriers to accessing intervention and training in AAC for families that telehealth can address. Therefore, there is a need for more research in the area of parent-mediated AAC interventions delivered by telehealth to improve accessibility and feasibility for parents of young children with CCN.

434.202 (Poster) Parent-Mediated Intervention for Children with ASD Waiting to be Enrolled in the Italian Health Services

N. Chericoni, A. Contaldo, C. Bartolini, G. Guainai, C. Pierotti, G. Santolini, R. Storino, S. Bargagna and C. Colombi, (1)IRCCS Fondazione Stella Maris, Calambrone (Pisa), Italy, (2)IRCCS Stella Maris Foundation, Calambrone (Pisa), Italy, (3)IRCCS Stella Maris, Calambrone Pisa, Italy, (4)Stella Maris Institute, Pisa, Italy, (5)IRCCS Stella Maris, Pisa, Italy, (6)Costanza Colombi, Pisa, MI, Italy
Background: In most areas of Italy, children with ASD receive low intensity non-specialized treatment. Despite the fact that intensive interventions are recommended, they are not usually available through State Programs. Moreover, due to the continuous increase in the number of diagnoses as well as the scarcity of specialized providers, it is very difficult for families of newly diagnosed children with ASD to access appropriate services. One way to address these issues is to teach evidence-based strategies to parents. However such an approach is rarely available in Italian health services. This is unfortunate, because teaching parents to embed learning opportunities into daily routines provides them with immediate access to effective intervention.

Objectives: This exploratory study addresses a critical public health issue in Italy as it aims to facilitate very early access to ASD evidence based intervention. A low intensity parent coaching model derived from the ESDM (P-ESDM) is introduced in a community-based early intervention program. The objective of this study is two-fold. First, it aims to teach parents strategies for helping their children develop new skills and to reduce their stress thereby enhancing family resilience. Second, it aims to improve child outcomes by delivering a model of treatment that can be initiated immediately following diagnosis, eliminating the gap in treatment that young children with ASD typically experience.

Methods: Twenty children aged 12-48 months at risk for ASD or with a diagnosis of ASD who were on a waiting list for community services were recruited for this study. The P-ESDM was delivered 2hrs per week, for 6 months. At the beginning (T0) and end of treatment (T1) a comprehensive assessment was performed using measures of parent stress level (PSI-4), measures of parent-child interaction (BOSCC, MONSI-CC), as well as developmental tests, parent interviews and questionnaires (Griffiths-III, MB-CDI, ADOS-2, VABS-II, RBS-R, SCQ).

Results: The analysis of the differences pre-post intervention was performed using paired samples t-tests. The PSI-4 showed a reduction in parents’ sense of incompetence and guilt (t=3.89; p<0.01), while the MONSI-CC showed an increase in parents’ capacity to provide opportunities of engagement for the child (t=2.38; p=0.05). Overall improvement in child social communication and developmental level was found both on the ESDM Curriculum Checklist (t=6.42; p<0.001), the BOSCC (t=2.16; p =0.05) and the Griffiths-III Age Equivalents (t=3.30; p =0.02).

Conclusions: Our findings support evidence from previous research on the efficacy and feasibility of a low intensity intervention with caregiver involvement. A controlled trial is an important next step to determine the efficacy and long-term effect of the P-ESDM in Italy. Indeed, this model has the potential of becoming a new clinical service in the Italian health system for young children with ASD.

434.203 (Poster) Parent-Mediated Interventions for Infants and Young Children with Autism Spectrum Disorder and Other Developmental Disorders: What Recent Reviews Tell Us.
S. M. Trigonakis and D. Pesco, (1)Education, Concordia University, Montreal, QC, (2)Concordia University, Montreal, QC, Canada

Background: Early interventions for children with Autism Spectrum Disorder (ASD) and other Developmental Disorders (DD) have been shown to be effective in improving child outcomes (Rogers et al., 2014), but many factors impede parents’ timely access to services (Helkkula et al., 2020). Moreover, the evaluation process for ASD is long to complete. The consequences of delays in intervention can be great for the child, their family and society (Horlin, 2014). As parent-mediated interventions (PMIs) can reduce these costs, they have attracted the attention of researchers, with a number offering systematic reviews of the literature and meta-analyses of PMIs and their effects on children and/or their parents.

Objectives: The current scoping review aimed to map the burgeoning literature on PMIs for infants and preschoolers with ASD and other DDs and/or their parents. Specifically, we aimed to describe characteristics of PMIs examined and the evidence of their effectiveness for children (e.g., ASD symptoms and skills). A separate investigation of the effects of PMIs on parents (e.g., parental stress and coping skills) is underway.

Methods: We conducted a search for reviews via Academic Search Complete, Education Source, ERIC, PsycNET and Medline databases. To be included, articles had to be meta-analyses, systematic or scoping reviews, published in peer-reviewed journals during the last 20 years. Additionally, the reviews had to be focused on PMIs for children (a) up to 6-years old and with (b) suspected or confirmed ASD or other DDs. The initial search yielded 90 reviews; their abstracts and methods sections (when necessary) were screened to determine eligibility. Nine reviews met all the inclusion criteria and were contained in the final analysis.

Results: Of the nine reviews, five addressed PMIs intended to affect multiple developmental domains, and four focused on a single domain (i.e., language). Several (n = 7) reviews concluded that PMIs resulted in improved child outcomes. For example, PMIs were found to reduce ASD symptoms and improve skills including language, communication, imitation, and social engagement, and some effects were substantial. In terms of intervention approaches, Pivotal Response Treatment (PRT), Functional Behavior Assessment (FBA), and Discrete Trial Training (DTT) were among those shown to be effective for targeted skills. The effects of PMIs on parental skills gained (e.g., synchrony) will also be presented. However, reviews unanimously reported great variability in the type and dosage of the interventions which limited across-study comparisons. Furthermore, many studies had methodological weaknesses, such as failing to blind participants to treatment conditions or to control for potentially confounding variables (e.g., demographic factors).
Conclusions: While many interventions have not been tested under quality experimental conditions, indicating a need for improved study designs, our review revealed some evidence of positive effects of PMIs for both child and parent outcomes. Moreover, we unearthed important recommendations for reporting on intervention characteristics, including standard reporting of frequency and length of interventions as well as child, parent and interventionist demographics. These recommendations, if followed, would allow for better comparisons of PMIs and stronger conclusions regarding their efficacy.

434.204 (Poster) Perceived Attachment in Danish Children with Autism Spectrum Disorder Associated with Parents’ Quality of Life and Use of Naturalistic Developmental Behavioral Intervention Strategies before a Parent-Mediated Autism Intervention

S. M. Ziegler, J. Christiansen, C. E. Conrad, P. Jeppesen, M. Goetzsche and N. Bilenberg, (1)Child and Adolescent Psychiatry, Psykiatrien i Syddanmark, Odense, GA, (2)Center for Autisme, Herlev, Denmark, (3)Research Unit for Child and Adolescent Psychiatry, Research Unit of Child and Adolescent Psychiatry, Aalborg, Denmark, (4)Department of Child and Adolescent Psychiatric, Region Zealand, Slagelse, Denmark, (5)University of Southern Denmark, Odense C, Denmark

Background: Having a child with autism spectrum disorder (ASD) can affect parents’ quality of life (QoL). Research indicates that securely attached autistic children can display more social competence, language skills, joint attention, and less disruptive behavior than insecurely attached peers. Some parent-mediated interventions have shown improvements in autistic children’s attachment security and studies suggest that parent-mediated naturalistic developmental behavioral interventions (NDBI) can affect positive and significant improvements in language, play, cognition, symptomatology, and social communication. However, knowledge is lacking on how perceived attachment in children with ASD, their parents’ QoL, and spontaneous use of NDBI strategies before commencing a NDBI are related. Such baseline findings are important in the future analysis of possible treatment effect moderators in a NDBI.

Objectives: I) To characterize a sample of Danish parents with a preschool-aged autistic child before their participation in a parent-mediated NDBI within a small pilot study, highlighting both their experiences with their child and NDBI strategies they may use spontaneously to support their child’s development. II) To investigate possible relationships between these characteristics.

Methods: This cross-sectional investigation assessed QoL, perception of child attachment, and NDBI strategy use in 18 Danish parents (7 fathers, 11 mothers) of 2.7-6.4 year old (Mage=4.4) children with ASD according to ICD-10 Pervasive Developmental Disorder criteria, before their participation in a parent-mediated NDBI. QoL was measured with the World Health Organization QoL Assessment-BREF (WHOQOL-BREF) using a transformed 100-point scale, attachment with the Maternal Perception of Child Attachment (MPCA) comprised of 23 questions on a 5-point Likert scale, and NDBI strategy use with the Measure of Naturalistic Developmental Behavioral Intervention Strategy Implementation-Caregiver Change (MONSI-CC), rating 20 strategies on a five-point scale. The MONSI-CC was applied to the first 10 minutes of a 12-minute video-recorded child/parent free-play interaction using a standardized toy set, in which the parent was instructed to play with their child as they “normally would”. Higher numbers indicate better scores on all three scales.

Results: Parents reported varying QoL in physical, psychological, environmental, and social relationship domains (M=74.83, SD=11.64; M=69.28, SD=17.28; M=68.50, SD=13.54; M=61.11, SD=21.39), respectively. Their mean total perception of child attachment was 76.10, SD=16.39 (range 23-115). Mean total NDBI strategy use was 15.76, SD=1.36; M=9.83, SD = 2.11 in environmental arrangement (three strategies); M=22.13, SD=1.76 in child-guided interactions (five strategies); M=26.50, SD=1.65 in active teaching and learning (seven strategies); M=5.83, SD=1.34 in opportunities for engagement (two strategies); and M=13.50, SD=0.87 in naturally reinforcing and scaffolding (three strategies). Two-tailed Pearson correlation coefficients showed significant positive relationships between MPCA Total Scores and social relationships QoL (r(17)=.73, p<.001), psychological QoL (r(17)=.54, p=.001), environmental QoL (r(17)=.73, p=.02), and MONSI-CC Active Teaching and Learning Scores (r(17)=.49, p=.04). Limitations in sample size and possible same informant bias are discussed.

Conclusions: Danish parent’s perception of their young autistic child’s attachment are associated with their QoL and implementation of active teaching strategies that support their child’s learning. These findings may predict future parent and child outcomes after participation in a parent-mediated NDBI.

434.205 (Poster) Perspectives on Behavioral Intervention Goals: Seeking Input from Autistic Adults and Adolescents

K. M. Baiden, Z. J. Williams, R. K. Schuck, P. Dwyer and M. Wang, (1)Gevirtz Graduate School of Education, UCSB Koegel Autism Center, Santa Barbara, CA, (2)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (3)Gevirtz Graduate School of Education, University of California, Santa Barbara, Santa Barbara, CA, (4)Department of Psychology, Center for Mind and Brain, UC-Davis, Davis, CA

Background: Behavioral intervention is a common intervention for autistic children. These interventions focus on teaching new skills and decreasing ‘challenging’ behaviors. Despite their popularity and extensive empirical evidence, they have received pushback from autistic advocates that these therapies cause harm due to their emphasis on normalization and compliance. However, limited empirical research exists regarding the social validity of specific intervention goals from the perspective of autistic people.
Objectives: This study aims to elicit perspectives on common intervention goals from the perspective of autistic adults and adolescents. The following research questions have guided this inquiry: 1) Which common behavioral intervention goals are seen as acceptable by autistic adults? 2) Which common behavioral intervention goals are seen as acceptable by autistic adolescents? 3) Are there differences in perspectives between autistic adults and autistic adolescents?

Methods: 235 (120F, 43M, 51 nonbinary/genderqueer, 21 other/unknown; Mage=34.36 [SD=11.13]) autistic adults took a survey evaluating 19 behavioral intervention goals. Participants rated the degree to which they agreed each goal was a good intervention goal using a 6-point Likert scale (1=strongly disagree; 6=strongly agree). The percentage of participants who endorsed the item and the mean rating were calculated for each goal statement. An exploratory graph analysis (EGA) was used to examine the structure of intervention goals and cluster them into smaller dimensions for further analysis. Hierarchical Bayesian logistic regression models were used to predict goal endorsement based on demographic variables.

The survey was adapted for the adolescent (age 13-17) group, but includes the same 19 intervention goal items. The updated survey has been evaluated by young adults (autistic and non-autistic) for face validity. The adolescent group will likely include a higher percentage of participants who have had or are currently receiving behavioral intervention, eliciting a crucial perspective. Data collection for this adolescent population is ongoing and will be analyzed in the same way as the adult population.
