MT reports having receiving speaker honoraria from Eli Lilly and NovoNordisk. MT has served on an advisory board of Abbott. DJD has served as an independent consultant for Dexcom and Insulet. DL has received honoraria for participation on advisory boards for Abbott, Novo Nordisk, Sanofi, Eli Lilly, and LifeScan and as a speaker for Abbott, LifeScan, Medtronic, Novo Nordisk, Sanofi, and Roche. All other authors have no relevant COI to report.
Summary of what is new or different

Since the 2018 guidelines, the area of glucose monitoring has evolved, especially as regards continuous glucose monitoring (CGM) systems. CGM is more widely available in many parts of the world, latest generation devices are factory-calibrated with higher accuracy and without the need for a confirmatory fingerstick test. More studies regarding the efficacy of CGM systems irrespective of the type of insulin delivery are available including long-term observational studies. With better availability and wider use, practical considerations related to daily CGM use (e.g. skin issues, physical activity) as well as educational and psychosocial aspects come to the fore, which are also addressed in this chapter.

Executive summary and recommendations

- Regular self-monitoring of glucose (using accurate fingerstick blood glucose [BG] measurements, real-time continuous glucose monitoring [rtCGM] or intermittently scanned CGM [isCGM]), are essential for diabetes management for all children and adolescents with diabetes (A).
  - Each child should have access to technology and materials for self-monitoring of glucose measurements and sufficient supplies to optimize diabetes care (B).
  - When fingerstick BGs are used, testing may need to be performed 6 to 10 times per day to optimize intensive control (B). Frequency of BG testing correlates with improved HBA1c levels and reduced acute complications (B).
  - Regular review of glucose values should be performed with adjustments to medication/nutritional therapies to optimize control (B).
  - Diabetes center personnel should advocate to nations, states, and health care funders to ensure that children and adolescents with diabetes have adequate glucose monitoring supplies (E).
- Providers should be aware of the differences in accuracy among BG meters— only meters that achieve international accuracy standards (ISO 15197:2013 or FDA-approved) should be used (E).
- Use of CGM is strongly recommended in all children, adolescents, and young adults with type 1 diabetes (A).
- Where available, CGM should be initiated in all children, adolescents and young adults with type 1 diabetes as soon as possible after diagnosis (B).
- Intermittently scanned/viewed CGM (isCGM), also known as flash glucose monitoring, in the pediatric population is safe, may improve time in range and Hba1c levels, decreases time in hypoglycemia and lowers glycemic variability (B).
- For isCGM, higher scanning frequency (11-13 scans/per day) is associated with favorable glycemic markers (HbA1c and TIR) (B).
• Real-time continuous glucose monitors (rtCGM) can be used effectively for lowering HbA1c, reaching target HbA1c, reducing glucose variability (both for insulin pumps/closed-loop systems and multiple daily injections (MDI)), increasing Time in Range (TIR), reducing mild to moderate hypoglycemia and shortening the time spent in hypoglycemia in the pediatric population with T1D (A).

• Real-time CGM data can particularly benefit children who cannot articulate symptoms of hypoglycemia or hyperglycemia and those with hypoglycemic unawareness (A).

• The effectiveness of rtCGM in children and adolescents with T1D is related to the amount of sensor use (A).

• Initiation of CGM use close to the time of diagnosis may benefit children's HbA1c through the first year (B).

• Prior to CGM start, portray the use of diabetes devices and technologies as an option that can be a good fit for many youth and families; provide education and encourage youth and families to review vetted websites and device informational materials (E).

• Structured initial and ongoing education and training in the use of CGM (including data review) is paramount to successful adoption and continued use of this technology (E).

• Setting realistic expectations for the integration of diabetes technologies is paramount to the success of persons and caregivers adopting new technologies (B).

• Identification and counseling of potential barriers to adoption of new technologies or continued use of devices is critical and can be completed using validated person-reported outcome measures (B).
1. Introduction

Home self-monitoring of glucose has a pivotal role in the management of insulin-treated children and adolescents with diabetes. It tracks immediate and daily levels of glucose control including hypo- and hyperglycemic periods, it helps guide insulin dose adjustments, it facilitates evaluation of therapy responses and achievement of glycemic targets in a safe and effective manner.

Along with major trials demonstrating the superiority of intensive insulin therapy in persons with type 1 diabetes in the early 1990’s, self-monitoring of capillary blood glucose (SMBG) using hand-held portable meters in combination with glucose test strips and a lancet became the most widely used method of glucose monitoring replacing previously predominantly used urinary glucose testing.

In recent years, systems for continuous glucose monitoring (CGM) in interstitial fluid based on subcutaneously placed glucose sensors have emerged and have become standard of care in type 1 diabetes in many countries, particularly for children, adolescents, and young adults, and have been successfully employed for insulin-treated type 2 diabetes.

Since the 2018 ISPAD guidelines, numerous advances have been made in the field of glucose monitoring. The purpose of this chapter is to review and updated the evidence on glucose monitoring devices (i.e. SMBG and CGM) in children, adolescents, and young adults and to provide practical advice and approaches on their use.

2. Self-Monitoring of capillary blood glucose

Early SMBG measurement methods relied upon reflectance assays coupled with oxidation of glucose allowing for a colorimetric readout. Currently available glucose monitors use an electrochemical method with an enzyme electrode containing either glucose oxidase or glucose dehydrogenase.

Meter standards and accuracy

There is considerable variation in the accuracy of widely-used BG monitors. Most reliable data are provided by meters meeting current international accuracy standards. The two most used standards are those of the International Organization for Standardization (ISO) (ISO 15197:2013) and the (US Food and Drug Administration (FDA) (Table 1). ISPAD recommends exclusive use of glucose meters that achieve this standard. Health care professionals should choose and advise on types that are robust, precise, accurate, and familiar to them as well as affordable to the person with diabetes.

* The range of blood glucose values for which the meter has been proven accurate and will provide readings (other than low, high, or error).

** Values outside of the “clinically acceptable” A and B regions are considered “outlier” readings and may be dangerous to use for therapeutic decisions \textsuperscript{8}

Of note, the specified accuracy standard as achieved during controlled conditions might vary significantly from actual SMBG meter performance in real world settings.\textsuperscript{4} Detailed information on the actual performance of SMBG devices is provided by The Diabetes Technology Society Blood Glucose Monitoring System Surveillance Program (www.diabetestechnology.org/surveillance/).

SMBG accuracy is dependent on proper hand washing with complete drying\textsuperscript{9} and requires proper blood application and use of adequately stored, unexpired test strips which are not counterfeit nor preowned/second hand.\textsuperscript{10} Providers and people with diabetes need to be aware of additional factors that can impair meter accuracy: Due to the enzymatic electrochemical reaction, monitors are sensitive to temperature and have a defined operating temperature range.\textsuperscript{10} Typically, an error message is displayed if the temperature is out of range. Unlike glucose dehydrogenase-based monitors, glucose oxidase monitors are sensitive to the ambient oxygen and should only be used with capillary blood of people with normal oxygen saturation. Low oxygen tensions (i.e. high altitude, hypoxia, venous blood readings) may result in false high glucose readings, higher oxygen tensions (i.e. arterial blood) may lead to false low readings.\textsuperscript{10} There are also a few substances that may interfere with glucose readings (Table 2).\textsuperscript{10}

Expert meters

Expert BG meters have integrated bolus advisors to calculate insulin dosages. Randomized controlled trials (RCTs) have shown a bolus calculator use significantly increases in the number of people achieving HbA1c targets and reduces hypoglycemia.¹¹⁻¹³

Frequency and timing of SMBG testing

SMBG frequency correlates with improved HbA1c levels and reduced acute complications.¹⁴⁻¹⁶ Generally, SMBG should be applied at a frequency to optimize each child’s diabetes control. For persons using intensive insulin regimens (multiple daily injections or insulin pump therapy), SMBG testing should be performed:

- during the day, prior to meals and snacks,
- at other times (eg, 2-3 hours after food intake) to determine appropriate meal insulin doses at bedtime and show levels of BG in response to the action profiles of insulin (at anticipated peaks and troughs of insulin action)
- to confirm hypoglycemia and after treating low BG to monitor recovery
- at bedtime, as needed overnight and on awakening to detect and prevent nocturnal hypoglycemia and hyperglycemia
- prior to and while performing critical tasks (e.g. driving)
- In association with vigorous exercise (before, during, and several hours after physical activity)
- during intercurrent illness to prevent hyperglycemic crisis.

Successful intensive insulin management requires at least six to ten checks per day, appropriate response to the observed values, and regular, frequent review of the results to identify patterns requiring adjustment to the diabetes treatment plan.¹⁵ This includes review by the person with diabetes and their caregivers/family in addition to consultation with the diabetes care team.
However, the actual number and regularity of fingerstick BG measurements should be individualized depending on:

- type of insulin regimen
- ability of the child to identify hypoglycemia
- availability of equipment

In resource limited settings, availability and affordability of glucose meters and test strips are not guaranteed. Even though many children are on multiple daily injections, only few can afford frequent BG testing needed to optimize diabetes control. Very often testing is performed 3 – 4 times a day (i.e., pre-breakfast, pre-lunch, pre-dinner and at bedtime), and many persons with diabetes must resort to 2 times daily, i.e., before breakfast and before dinner. If there are no BG monitoring capabilities, then urine testing is performed. For a comprehensive discussion on aspects of diabetes management in resource limited settings including glucose monitoring, please refer to the ISPAD 2022 Consensus guidelines Chapter 25 on ‘Management of Diabetes in Children and Adolescents in Limited Resource Settings.’

3. Continuous glucose monitoring

Rapid, capillary assessments of BG have been instrumental in permitting achievement of recommended targets over the past 30 years. However, SMBG only provides single snapshots of glucose concentrations. Consequently, episodes of hyper- and hypoglycemia, in particular nocturnal and asymptomatic episodes, as well as considerable fluctuations in BG concentrations may be missed and therefore not factored into treatment decisions.

The emergence of continuous glucose monitoring (CGM) in the late 1990’s represented a milestone in the field of glucose monitoring. Instead of single point measurements in capillary blood, CGM devices measure interstitial glucose concentrations subcutaneously at 1-15 minute intervals using enzyme-tipped electrodes or fluorescence technology. Significant improvements in device technology over the past decade (including improved accuracy, approval for non-adjunctive use, and reduced need for calibration), availability, smaller size, remote monitoring capability, and overall personal acceptance of CGM systems have contributed to the widespread adoption of this technology in clinical practice.

CGM use and uptake

In many countries CGM use has now become the standard of care for people with type 1 diabetes. According to data from German and Austrian DPV and U.S. T1D Exchange registries, CGM use increased exponentially from 2011 to 2017 in all pediatric age-groups (DPV: 4% in 2015 to 44% in 2017; T1DX: 4% in 2013 to 14% in 2015 and to 31% in 2017), with highest use among preschool-aged and early school-
aged children. From 2017 to 2020, further increase of CGM use among individuals with diabetes aged <25 years was seen in both registries each year for all age ranges (DPV: 40% in 2017 to 76% in 2020; T1DX: 25% in 2017 to 49% in 2020). In Australia and New Zealand, recent data from the Australasian Diabetes Database Network (ADDN) registry and the Australian National Diabetes Service Scheme (NDSS) indicate that 79% of people with type 1 diabetes aged <21 years are using CGM.

Barriers to technology adoption and continued use can be present at structural, person, and provider levels. Structural barriers include costs associated with the use of the technology, insurance coverage, and local clinical guidelines for CGM use. Person-level barriers include hassle of wearing diabetes devices, dislike of device, frequency of alarms, perceiving the device to be inaccurate, believing that the CGM takes too much time and effort to use, finding the device painful to wear, and adverse skin reactions to sensors. In turn, healthcare professionals may not have enough time or specific expertise to educate persons, train and promote technology.

DPV and T1D Exchange registry data indicate significant disparities in CGM use by socioeconomic status (SES). Of note, in the T1D Exchange registry, the gap of device use between highest and lowest SES quintile (52.3% vs 15.0%) was more pronounced than in the DPV population (57.1% vs 48.5%). Adequate clinic-specific resources and interventions with identification of barriers to CGM uptake are necessary to promote CGM adoption and continued use. In a multi-clinic quality improvement initiative of the T1D Exchange Quality Improvement Collaborative, center-specific interventions consisting of active person support and education, training and education of the clinical team, as well as interaction with insurance companies and vendors resulted in an increase in CGM use from 34 to 55% in adolescents and young adults over 19–22 months.

Categories of sensors

CGM systems roughly fall into one of the following categories:

1. Blinded CGM or professional CGM;
2. Real-time CGM;
3. Intermittently scanned CGM (isCGM) or Flash CGM;

Blinded/retrospective/professional CGM

Blinded or professional CGMs were the first widely used CGM devices, e.g. the MiniMed CGMS Gold system (Medtronic MiniMed, Northridge, CA, USA) released by Medtronic in 1999. Professional CGM systems obtain glucose data over a short period of time providing health care professionals to look at the data obtained glucose excursions and patterns in a masked fashion. They can provide sufficient
information to aid with diagnosis, facilitate changes in therapy, and may be utilized as an educational tool to improve glycemia. In addition to clinical practice, professional CGM systems are sometimes employed in research settings to obtain retrospective glucose data and to reduce potential bias (e.g. in certain settings people may deviate from their usual behavior when seeing their CGM readings in realtime).

Real-time CGM

Real-time CGM (rtCGM) systems automatically display glucose readings at regular intervals and can utilize programmable alarms when sensor glucose levels reach predefined hypo- or hyperglycaemia thresholds, as well as rate-of-change alarms for rapid glycemic excursions. Many commercially available rtCGM systems transmit glucose data directly to smartphones. These data can then be stored and retrieved on a web server (‘cloud’) and used for remote monitoring purposes by caregivers and healthcare professionals.

In addition to traditional, self-inserted transdermal sensors with a lifetime from 6 to 14 days, a long-term implantable sensor for up to 6-month use is available (Eversense, Senseonics, Inc., Germantown, MD, USA) that received regulatory approval in the European Union (Conformité Européenne (CE) Mark) in 2016 and subsequently in other countries outside of EU. Of note, the Eversense CGM is currently approved only for use in the adult population over 18 years of age. The sensor is implanted just beneath the skin of the upper arm. Glucose data are sent to the user’s smartphone via a wearable transmitter placed on the skin surface directly above the sensor. Calibrations are still required. The Eversense sensor is currently approved for 90 days in the United States or 180 days in Europe, and its implantation and removal require a minor in-clinic procedure performed by a trained physician or a nurse practitioner during an office visit. Unlike traditional CGM sensors, where glucose is measured using the enzyme-based electrochemical method, the Eversense implantable sensor uses non-enzymatic optical fluorescence. The next generation Eversense CGM has 180-day long-term wear time with daily calibration.

Intermittently scanned CGM

In 2014, the FreeStyle Libre Flash Glucose Monitoring System (FSL) (Abbott Diabetes Care, Alameda, California, USA) was introduced representing a different CGM category: intermittently scanned CGM (isCGM). IsCGM devices do not automatically display glucose readings at regular intervals, but report glucose levels only when the user scans the sensor by holding a reader, or a near field communication protocol (NFC)-enabled smartphone, close to the sensor. Current interstitial glucose levels and glucose trend arrows as well as a graph of current and stored glucose readings are provided on demand. As
with rtCGM, glucose data from isCGM can be transferred from a smartphone to a webserver for remote glucose monitoring purposes by caregivers or health care professionals. The sensor can provide glucose values up to 14 days with a 1-hour sensor warm-up period.

The second generation of FreeStyle Libre (FSL2) was approved in Europe (2018) and in the USA (2020). FSL2 sensors have higher accuracy (mean absolute relative difference (MARD) 9.2% and 9.7% for adults and children, respectively) and, in addition to the general FSL capabilities, have optional alarms to alert persons in case of glucose level is out of the target range. To see the actual level, the user must scan the sensor. The third generation, the FSL3, is actually a rtCGM providing real-time alarms and real-time readings without the need to scan. It has received CE marking in 2020, and is being rolled out across Europe.

**Accuracy of CGM devices**

The accuracy and precision of first generation CGM systems were notably inferior to those of capillary BG monitors. Over the past 10 years, however, there has been continuing improvement in the accuracy of CGM sensors. Discrepancies between actual BG and CGM levels occur when measuring in the hypoglycemic range and when glucose levels are changing rapidly. To a great extent this is due to the physiological delay of about 5-10 minutes between the flow of glucose from intravascular to interstitial compartments. Accuracy is also influenced by the time it takes for the sensor to react to glucose and the use of digital filters for smoothening of the sensor signal during conversion of the measured sensor signal into glucose data. Sensor performance also may be affected by biomechanical factors such as motion and pressure (typically micro-motion and micro-pressure). Methods used to assess the accuracy of CGM systems include the mean absolute relative difference (MARD) between sensor readings and reference BG values (absolute difference divided by the reference value, expressed as percentage) and error grid analysis. MARD is currently the most common metric used to assess the performance of CGM systems. The lower the MARD metric, the closer CGM readings are to the reference glucose value. Error Grid analysis allows one to assess clinically significance of the discrepancy between the sensor and the reference glucose measurement, with better accuracy corresponding to a higher percentage of results in zone A and B.

Accuracy continues to improve with each new generation of CGM sensors and systems. For most commercially available CGM systems, the accuracy in clinical trials reaches 8-10% MARD with about 99% of glucose readings within the clinically acceptable error zones A and B. It should be noted that in the home-use setting CGM system may produce higher average MARDs than during in-clinic studies.

Unlike BG meters (see Table 1), for CGM, the minimum accuracy requirements have not been determined until recently. But recently, the FDA has outlined a new 510K (premarket approval) route for...
for some CGM systems, designated as “integrated CGM” (iCGM) with additional special controls governing accuracy ability of this device to work with different types of compatible diabetes management devices, including automatic insulin dosing systems, insulin pumps and BG meters.

Sensor interference

Certain exogenous and endogenous interstitial fluid substances, including some commonly-used medications, may interfere with CGM system accuracy. This can result in a falsely high or low report of glucose values.

In particular, therapeutic doses of hydroxyurea can markedly elevate of sensor glucose readings compared with glucometer values, the same applies to acetaminophen which at a dose of 1000 mg can falsely elevates sensor glucose values in certain CGM systems. Salicylic acid at doses ≥650 mg may mildly reduce glucose readings, and ascorbic acid (vitamin C) at doses ≥500 mg may cause falsely higher readings. CGM readings may also be affected by ingestion of lisinopril, albuterol, atenolol, and red wine. The effect of different substances on the glucose reading depends on sensor technology. Specifically, CGM systems that use enzymatic electrochemical sensors to measure glucose concentrations seem to be more susceptible to influence than systems using abiotic (non-enzyme based), fluorescent glucose-indicating polymer to measure glucose. In particular, for the long-term implantable fluorescence-based sensor only tetracycline and mannitol produced significant sensor bias when tested in vitro within therapeutic concentration ranges.

Medications such as salicylic acid, paracetamol and vitamin C commonly available over the counter for self-administration and may be present in combination products or supplement formulations leading to persons with diabetes not knowing that they are taking specific substances. Sensor bias produced from various substances can be most significant for persons using CGM data without confirmatory measurements of capillary BG or for those using CGM data to inform insulin delivery in closed-loop systems. Therefore CGM users should be aware of how certain systems may be impaired by common medications and always test with a conventional glucose meter whenever symptoms do not match a CGM reading.

Calibrations/factory calibrated systems

Sensor calibration (entering BG readings from BG meter into the CGM system) is intended for mathematical conversion of sensor signals directly into glucose values. The latest generations of rtCGM systems (i.e. Dexcom G6, Dexcom G7, Guardian 4) and all available isCGM (FSL1, FSL2) are factory-calibrated, meaning that user calibrations using fingerprick measurements are generally not needed.
This eliminates pain and inconvenience and takes away a significant source of error from sensor calibration. Factory calibration is performed under laboratory conditions during the sensor manufacturing process. To be able to implement factory calibration a set of requirements related to sensor stability and reproducibility have to be met and maintained over the product life: consistent sensor manufacturing, shelf life and wear stability. For rtCGM manual calibration is still possible, e.g. if CGM readings and results from capillary BG readings do not line up well over a prolonged period of time.

For older generation CGM sensors still depending on manual calibrations, the required calibration frequency varies by device. Typically, the first calibration is performed 1–2 hours after insertion of the sensor and then a minimum of one calibration is required every 12 hours. For these systems, regular calibrations are essential to maintain the accuracy and optimum sensor performance. Apart from discomfort due to finger punctures, user calibrations have certain limitations and disadvantages, including additional cost, and technical errors under data entry (delayed BG entry, transcription error).

The effect of the current glucose level (hypo-/eu- or hyperglycemic range) and the moment of glucose measurement (pre- or postprandial). The optimum times to calibrate are when the interstitial fluid glucose concentration is in equilibrium with the capillary blood, i.e. when glucose levels are least likely to be changing rapidly: before meals, before bedtime, before insulin, when there are no trend arrows on the CGM/pump screen. Moreover, user calibration can lead to wrong sensor reading if at the time of calibration the sensor signal has a temporarily falsely reduced or elevated value, for example, caused by interfering substances or body compression (‘compression lows’). Additionally, bias in BG meter readings can translate to bias in CGM data, hence accuracy of the SMBG directly determines the accuracy of the CGM system.

**Non-adjuvant use**

RtCGM systems were originally approved for adjunctive use, meaning the sensor glucose results needed to be verified by capillary SMBG before taking action (e.g. insulin dosing). Along with significant improvements in accuracy, more and more sensors have received approval for non-adjuvant use, i.e. diabetes-related decisions and insulin dosing are made on CGM values alone.

Studies utilizing computer modeling have shown that the threshold MARD level of ≤10% is safe for non-adjuvant use of CGM and most currently-available commercial CGM systems meet this condition. Furthermore, the T1D Exchange REPLACE BG study provided evidence of the safety and effectiveness of non-adjuvant sensor use.

Dexcom sensors (G5 and G6 Mobile CGM, Dexcom, San Diego, California, USA) have received FDA and CE approval for non-adjuvant use in persons aged 2 years and older. The Abbot Libre Flash Glucose
Monitors (Abbott Diabetes Care, Alameda, California, USA) have received FDA and CE approval for treatment decisions in persons aged 4 and older. The Medtronic Guardian 4 sensor are CE marked for nonadjunctive use from the age of 7 years. Fingerprick testing may still be recommended under certain circumstances: hypoglycemia, if glucose is changing rapidly, and especially if symptoms are not concordant with the system readings.

**Efficacy of CGM**

*Real-time CGM systems*

Early-generation rtCGM systems use for children with T1D was associated with only modest benefits in glycemia when compared with SMBG.\(^4^4\)-\(^4^6\) The JDRF landmark randomized clinical trial (RCT),\(^4^7\) in 2008, showed no overall glycemia benefit with CGM use in the younger age groups (8-14 years and 14-25 years), likely related to <50% wear adherence in these groups. A secondary analysis demonstrated benefits across all age groups when the sensor was used ≥6 days/week.\(^4^8\) RCTs and meta-analyses conducted since 2010 utilizing newer generation rtCGM systems, more consistently show that use of rtCGM is able to improve glycemia in both children and adults with T1D, and depending on population studied, benefits are seen in terms of lower HbA1c concentrations, increased time in range (TIR), reduced hypoglycemia (including severe hypoglycemia), and reduced glucose variability.\(^3\),\(^4^4\),\(^4^9\)-\(^5^3\) There is now emerging evidence that improvement in glycemia is equivalent in users of insulin pump therapy and MDI therapy.\(^5^1\),\(^5^4\)-\(^5^8\)

Contemporary large registry-based studies have shown that rtCGM use is clearly associated to lower HbA1c, higher achievement of ISPAD HbA1c targets, and fewer episodes of DKA in children and adolescents in respect to SMBG.\(^2\),\(^1^7\),\(^5^9\)-\(^6^4\) This positive effect on HbA1c has also been seen in a Swedish registry-based study that described a progressive decrease of HbA1c in very young children during the 2008-2018 period, in parallel with the increasing use of pumps and CGM.\(^6^5\) Data from national population-based registries following rtCGM/isCGM reimbursement programs report improvement of T1D glycemic outcomes at the population level in children, adolescents and adults.\(^6^6\)-\(^6^8\)

In contrast, registry-based studies have not consistently shown a lower number of severe hypoglycemic events in people using rtCGM.\(^2\),\(^6^1\)-\(^6^3\) Tauschmann et al. used real world data from people with type 1 diabetes aged < 18 from Germany, Austria and Luxemburg in the DPV Registry and described a reduction in severe hypoglycemic events during the first year of CGM use.\(^6^0\) Interestingly, data from observational studies in children and adolescents, suggest that, irrespective of insulin delivery system, early initiation of CGM within 1 year from T1D diagnosis is associated with fewer severe hypoglycemic events and more favorable glucose outcomes.\(^6^9\),\(^7^0\)
RCTs using the latest-generation non-adjunctive rtCGM systems have shown positive effects on both HbA1c and TIR\textsuperscript{71,72} in adolescents and young adults. The MILLENIAL Study that assessed the use of a factory-calibrated rtCGM showed that TIR increased when compared with SMBG.\textsuperscript{72} Supporting this finding, data from single-center observational studies with selected population aged <20 years describe a decrease of HbA1c after initiation with uninterrupted use of rtCGM.\textsuperscript{69,73}

Data from RCTs in small children have replicated the results of studies from adolescents and young adults. Though data from small observational studies suggest that CGM can be used successfully in children <8 years,\textsuperscript{74-76} a more recent trial of non-adjunctive rtCGM in 143 very young children (mean age 5.7 years) did not show a statistically significant improvement in TIR. However there was a substantial reduction in the rate of hypoglycemia seen with rtCGM vs traditional capillary measures over 6 months.\textsuperscript{77}

Notwithstanding, based on data from the Slovenian National Registry, Dovc et al demonstrated that the use of CGM system was well tolerated by pre-school children and that a positive effect was observed in glucose variability.\textsuperscript{76}

\textit{isCGM systems}

Unlike rtCGM devices, intermittently scanned CGM (isCGM) systems display readings on demand only when the sensor is scanned with a reading device. To date very few RCTs have been conducted using isCGM,\textsuperscript{56,78} only one in adolescents and young adults.\textsuperscript{78} The IMPACT multicenter isCGM RCT focused on ameliorating hypoglycemia and involved adults with HbA1c <7.5% at study entry. It demonstrated that isCGM use reduced time spent in hypoglycemia, reduced glucose variability, and improved TIR (3.9 to 10.0 mmol/l, 70 to 180 mg/dl) when compared to SMBG.\textsuperscript{56} Similar results including significantly reduced time in hypoglycemia without deterioration of HbA1c were observed in a subgroup analysis of the IMPACT RCT in adults with T1D managed with MDI therapy.\textsuperscript{79} However, applying this technology in those with suboptimal glycaemia remains less certain. In a 6-month RCT in youth aged 13 to 20 years with elevated HbA1c (HbA1c ≥ 9%), Boucher et al did not demonstrate differences in HbA1c levels when using isCGM compared to SMBG.\textsuperscript{78} Nevertheless, this unique youth population increased testing frequency 2.5 fold and reported a higher satisfaction with its treatment.\textsuperscript{80}

Data from observational clinical studies in children aged 4-18 years at isCGM initiation have shown greater TIR\textsuperscript{81} and lower HbA1c\textsuperscript{81,82} compared to SMBG use prior to isCGM start,\textsuperscript{81,82} similarly to what is described in adults.\textsuperscript{83-85} Interestingly, when comparing isCGM users across different age groups,\textsuperscript{86,87} benefits were more pronounced in children under 12 years\textsuperscript{86} and preschool children\textsuperscript{87} compared to adolescents\textsuperscript{86,87} and adults.\textsuperscript{86} Scanning frequency (11-13 scans/per day) is clearly associated with favorable glycemic markers (HbA1c and TIR) though not with reduction of time in hypoglycemia.\textsuperscript{81,82,86,88,89} These studies all were performed using first-generation systems without alarms.
for impending hypo- and hyperglycemia. Studies using newer systems with optional real time alarms and improved accuracy are needed.

In addition, anonymized real-world data studies have also shown increased scanning frequency benefits time in hypoglycemia. One observational study in children and adults using data from 12,256 individuals in the Scotland national diabetes registry found that isCGM initiation was associated with significant reductions in HbA1c with the greatest reductions in those with highest starting HbA1c values and children aged below 13 years; DKA episodes were also decreased except in adolescents; among those at higher risk for severe hypoglycemia requiring hospitalization (SHH), a marked reduction in SHH event rates was also observe. A prospective real-world cohort study including individuals after 1 year of nationwide reimbursement of isCGM in Belgium reported a lower number of severe hypoglycemia and DKA events with the use of the isCGM.

Rt CGM vs isCGM

In recent years, studies directly comparing rtCGM and isCGM systems have been published, including observational studies in children and adolescents and adults with type 1 diabetes, and one RCT in adults only. All of these studies show superiority of rtCGM over isCGM in terms of improved time in range and reduced percentage of time in hypoglycemia. However, the number of studies and the number of trial participants were limited, particularly in children and adolescents. Additionally, mainly older generation devices were used.

Retrospective CGM

Though intermittent application of retrospective or rtCGM may be of use in children and adolescents with T1D to diagnose postprandial hyperglycemia, the dawn phenomenon, asymptotic and nocturnal hypoglycemia, and in evaluating the effect of major changes in treatment regimens, there are no data to support long-lasting clinical benefits of intermittent short-term use of retrospective CGM (3-day applications every three to eight weeks for up to 6 months).

CGM use from diabetes onset

Tight glycemia from diabetes onset has been shown to benefit long-term glycemic trajectories in individuals with T1D. Early introduction of CGM among children with new onset diabetes was associated with a 0.66% lower HbA1c at 12 months of diagnosis compared to those who did not start CGM. Long-term improvement in HbA1c over a 7-year follow up period was seen when CGM was initiated in the first year of type 1 diabetes diagnosis compared to no CGM use or when CGM was initiated after the first year.
Residual beta-cell preservation, often assessed by residual c-peptide secretion, has long been a goal of interventions for persons with new onset type 1 diabetes to decrease risk of long-term diabetes related complications.\textsuperscript{102-104} There are several ongoing new onset studies investigating the benefit of more modern factory-calibrated CGM and hybrid closed loop systems in preserving beta-cell function in the new onset period. As the role of CGM and CGM-derived metrics in clinical trials as outcome parameters is being established,\textsuperscript{105} CGM will be used to monitor glycemic trajectories in pharmaceutical intervention studies on diabetes onset or prevention.

**Practical considerations**

**Education**

Initial and ongoing education and training in CGM use remains a keystone to optimizing CGM uptake and long-term use, as glycemic benefits are only observed if the device is worn consistently.\textsuperscript{106} While many aspects of CGM use remain largely intuitive,\textsuperscript{107} structured training of youth and parents/caregivers about CGM device components, insertion, skin care and data interpretation is critical to assure a safe and effective use of this technology.\textsuperscript{106,108} Further, ongoing education and support are recognized as essential to overcome barriers to consistent CGM use and as technologies are continuously updated.\textsuperscript{106,109} Follow-up training is recommended also for the glucose data use and retrospective analysis.\textsuperscript{110,111} In addition, psycho-educational support is of help to set realistic device expectations and to address individual’s education and training needs.\textsuperscript{106}

Structured educational material and written healthcare plans to support CGM use should also be provided to caregivers of children with diabetes, including daycare providers, school nurses, teachers, babysitters, after-school program supervisors.\textsuperscript{106,112,113} Table 3 provides an overview of the structured education aspects to consider at CGM initiation.
Table 3 - Basic guidelines for starting CGM use

### Before initiation
- Review device components and features
- Advocate for insurance coverage/reimbursement
- Support for consistent options for CGM supply provision
- Provide access to customer service contact for technological support
- Ensure/arrange access to CGM data platforms

### Device insertion and adherence
- Review sensor site selection, site rotation, signs and symptoms of cutaneous/subcutaneous issues
- Review insertion techniques
- Offer supplementary adhesive products. These include:
  - Wipes: skin tac IV prep, skin prep
  - Dressings and barriers: tegaderm, IV-3000, hypafix
  - External Wraps: Coban, Pre-Wrap
- Offer adjunctive adhesive removers, such as unisolve or detachol, or products one may have at home, like baby oil
- Review signs/symptoms of skin irritation/contact dermatitis

### Calibration
- For sensors requiring calibrations, discuss frequency of calibrations and ideal times to calibrate
  - Consider pre-emptive calibration schedule. If calibrations are required every 12 hours, encourage persons to calibrate three times a day (for example, prior to breakfast, dinner and bedtime)
  - Discuss calibrating when glucose is relatively stable (no arrows present, no rapid change on sensor glucose graph)

### Alerts and alarms
- Consider leaving alerts off initially to help prevent alarm fatigue.
- When incorporating alerts, personalize them and use wide thresholds at first (i.e. 70-250mg/dL (3.9-13.9mmol/L)). These can be adjusted over time.
  - For those with recurrent hypoglycaemia, set low alert first.
  - For those with sub-optimal control, consider setting high alert first.
- In the beginning, do not employ rate of change or predictive alerts. Consider how these additional alerts may be actionable moments prior to incorporating them. This will help prevent alarm fatigue.
- Rate of change alerts or predictive alerts might be turned on in situations where rapid changes in glucose levels are more likely than under normal everyday conditions (e.g. more physical activity, eating different types of foods).

### Retrospective Review
- Encourage downloading, if this is required to review data
- Encourage retrospective review of data to help inform insulin dose titrations

### Real-time data
- As appropriate discuss non-adjunctive use of sensor data
- Review sensor lag significance
- Review trend arrow significance
- Consider recommendations on adjustments of insulin doses based on sensor glucose values and trend arrows\textsuperscript{114,115}
Exercise

CGMs can be helpful in reducing glycemic excursions associated with exercise, which represent a challenge for youth and their parents/caregivers.\textsuperscript{116} RtCGM has proven to be effective in both the prevention and early detection of exercise induced hypoglycemia.\textsuperscript{117}

Limited data exist on the efficacy of isCGM in maintaining optimal glycemia during exercise when compared to rtCGM. In a RCT in adults with T1D, the use of rtCGM was superior to isCGM in reducing hypoglycemia and improving time in range during exercise.\textsuperscript{95}

The use of predictive hypoglycemia thresholds and rate-of-change-in-glucose alerts within rtCGM devices, allow a prompt action to avoid glycemic fluctuations during and after exercise.\textsuperscript{95,118,119} Also, the use of thresholds for lower glucose values allows the user to consider carbohydrate consumption with respect to the rate of change in glucose and the trend arrows.\textsuperscript{118-121}

A recent position statement recommends different glycemic ranges before, during and after exercise according to the age group, the type of exercise, the risk for hypoglycemia and in accordance with the trend arrows.\textsuperscript{120} However, these recommendations represent a general approach that need to be personalized in accordance with the child and parents/caregivers.

CGM remote monitoring tools also offer the possibility for parents/caregivers to facilitate supportive action in case of glycemic excursions associated with exercise\textsuperscript{121} or to avoid post-exercise nocturnal hypoglycemia in children.\textsuperscript{122}

For more information on exercise in children and adolescents with diabetes, please refer to the ISPAD 2022 Consensus Guidelines Chapter 14 on Exercise in children and adolescents with diabetes.

CGM and skin issues

Inflammatory skin reactions elicited by unspecific skin irritation or delayed-type allergy to adhesive or device materials remain a barrier to consistent long-term CGM use, especially in young children.\textsuperscript{123} Rate of cutaneous complications of CGM use in clinical trials were comparably low with one event per eight weeks of sensor wear-time.\textsuperscript{124} However, there appear to be discrepancies between trial reporting and observational data.\textsuperscript{124} Reports on skin issues related with CGM use are becoming more frequent with the longtime use of sensors and the availability of devices with longer wear time.\textsuperscript{125,126} CGM-associated skin conditions include localized eczematous reactions under the device or the fixation plasters, post-inflammatory hyperpigmentation at CGM sensor insertion sites, device-associated pruritus at the
Increasing evidence identifies sensitizing components of sensors and adhesives as factors possibly responsible for skin reactions, including allergic contact dermatitis. The exact adhesive composition is rarely made available by manufacturers, but most devices contain acrylate which is known to cause contact dermatitis. Recently, initiatives for full and accurate labelling of the chemical composition of devices were presented. Strategies to preserve skin integrity include correct device placement, prophylactic skincare, accurate removal techniques and promoting skin healing. In addition, barrier agents to minimize the risk of hypersensitivity reactions may reduce the risk of skin irritation due to frequent sensor use.

For more information on skin related issues, please refer to the ISPAD 2022 Consensus Guidelines Chapter 14 on Other complications and associated conditions in children and adolescents with type 1 diabetes.

Remote monitoring

Mobile phone-based CGM systems have the ability to transmit glucose data to the ‘cloud’, and allow for digital remote monitoring, through which parents/caregivers are able to view a person’s CGM tracing and receive alerts on their own devices, such as smartphones, tablets, and smart watches. Remote monitoring of CGM has been reported to improve several psychosocial outcomes in parents of children with diabetes including quality of life, reduced family stress, and improved parental sleep.

Parents may have increased comfort in leaving their children with other caregivers (e.g., daycare, school, sitters, etc.), given their awareness of the child’s glucose levels and well-being from afar with remote monitoring of CGM data. Remote monitoring of CGM data in the school setting may enable a collaborative approach to diabetes management between the student with diabetes, parents, and school personnel.

Parental fear of hypoglycemia has been associated with suboptimal glycemia in children with diabetes, especially hypoglycemia during the night-time. The ability to remotely monitor CGM data has been shown to prevent prolonged nocturnal hypoglycemia in youth with diabetes. The peace of mind afforded by the ability to remotely monitor CGM data and receive real-time alerts for glucose excursions enables better parental sleep, and possibly comfort with in-range glucose values to enable improved glycemia.

However, conflicts can also arise because of remote monitoring of CGM data. For example, youth with diabetes may have the feeling of being “policed” by their loved one, resulting in feelings of frustration. On the other hand, remote caregivers might experience unnecessary panic in certain situations such as falsely low alerts due to compression. This highlights the need for constructive communication around diabetes management with clear expectations regarding when and how
caregivers should intervene based on remote monitoring of glucose data and alerts received. This is particularly important in adolescents who may desire increasing autonomy in diabetes management but can still benefit from the support of their parents and other caregivers.

**Telemedicine**

CGM can be a helpful tool for facilitating real-time data sharing via web-based software solutions in the context of telemedicine visits so that healthcare professionals have retrospective glucose data for review. This allows healthcare professionals to easily review and interpret glucose data to make recommendations on therapy adjustments during telemedicine consultations. To that end, CGM use has become fundamental to delivery of effective remote diabetes care, as cloud-based data acquisition can support meaningful interactions between families and the diabetes team. The COVID-19 pandemic in early 2020 accelerated the widespread adoption of telemedicine and remote person engagement.136 Pediatric diabetes centers were among those who rapidly expanded telemedicine services to facilitate person care.137,138

Many observational studies regarding the utility of CGM were conducted during the Covid-19 pandemic.139 However, solid evidence demonstrating the benefit of utilizing CGM data via telemedicine in improving clinical outcomes in youth with diabetes are lacking, but it will likely remain an important tool well beyond the COVID-19 pandemic. To achieve the greatest benefit from CGM, persons with T1D and caregivers may need more frequent touchpoints via telemedicine with the diabetes care team to learn how to leverage its full potential.

Despite the widespread adoption of telemedicine for people with diabetes and one of its key elements, i.e. remote availability of glucose data for simultaneous review by people with diabetes and their healthcare professionals, socio-economic factors, including poverty and limited access to diabetes technology pose major obstacles to realizing its successful application. ISPAD advocates for more availability and equal access to diabetes technology for all people with diabetes.

4. **Quality of Life and Person with Diabetes Perspectives on use of CGM**

Uptake and continuous use of diabetes devices and technologies are associated with psychosocial and family factors. Psychosocial factors are broadly defined as behavioral, emotional, and social variables that characterize an individual across both dimensions of promoting health (e.g., resilience) and having negative effects on health (e.g., depression). The focus on psychosocial factors in relation to diabetes device and technology use has grown out of the broader interest in understanding how these factors impact diabetes management and health outcomes. For example, it is well established that
personal strength and resilience factors, along with positive family communication, are associated with optimal management and outcomes.\textsuperscript{140-142} Likewise, psychosocial factors such as diabetes distress, depression and family conflict are common in youth with diabetes and often lead to suboptimal management and outcomes.\textsuperscript{143-146} Herein, the current understanding of the association between psychosocial factors and CGM use will be highlighted.

ISPAD guidelines on the psychosocial care of youth and the American Diabetes Association guidelines for the psychosocial care of people with diabetes\textsuperscript{147,148} highlight that attending to the psychosocial needs of all youth and their families is critical. Please refer to ISPAD 2022 Consensus Guidelines Chapter 15 on Psychological care of children and adolescents with type 1 diabetes.

Similarly, when considering whether diabetes devices and technologies should be recommended or encouraged, understanding the psychosocial aspects of the user and family will help optimize a good fit for the device. The most evidence is available for insulin pumps and CGM. CGM is linked to optimal glycemic outcomes and many users report greater treatment satisfaction.\textsuperscript{149,150} There are also recent reports of significant alleviation of diabetes distress, worries about hypoglycemia, and general well-being.\textsuperscript{151,152} Further, there are benefits of using CGM early in the course of type of diabetes\textsuperscript{153} and during the global pandemic.\textsuperscript{154} Person-reported outcomes have become integral and accepted parts of randomized trials on CGM, and offer a broader view of the lived experience of using devices in type 1 diabetes management.\textsuperscript{71} While there are significant benefits of CGM use, there are reports of heightened worries\textsuperscript{155,156} among adolescents and young adults and many discontinue CGM for a variety of reasons including cost, too many alarms, issues with accuracy, and discomfort wearing a device on one’s body.\textsuperscript{23} Thus, setting realistic expectations for potential users and their families and providing referrals for any psychosocial need that may serve as a barrier to optimal use, are indicated. In addition, the following recommendations are made when considering CGM use (and more broadly device and technology use) in diabetes care practices:

- Portray the use of diabetes devices and technologies as an option that can be a good fit for many youth and families; provide education and encourage youth and families to review vetted websites and device informational materials.
- Encourage uptake and refrain from having youth and families “earn” the right to use devices (i.e., achieve a certain hemoglobin HbA1c before considering starting a device). If payers/insurance companies require logging or other documentation prior to device approval, convey that directly instead of a requirement of the diabetes care practice.
- Conduct a brief assessment of expectations and barriers to uptake and use. Common barriers are cost (often noted by parents of youth, and the youth themselves,\textsuperscript{157} wearing multiple devices,
sensation of wearing a device on changing and growing body, frequent alarms and maintenance of device.

- Problem solve with the youth and their family on ways to break down barriers. This may require referral to a psychological care provider to teach problem solving skills.
- If psychosocial needs are reported or identified, refer to psychological care provider.
- Support youth and families in initiating CGM use, interpreting and using the CGM data to optimize diabetes management and reduce diabetes burden.

Beyond CGM, other device and technology use offer additional advice for prescribers and supporters of diabetes devices. For example, In a report of 284 potential users of closed loop in the US and UK, three themes were identified as critical for uptake: developing trust in the system and degree of control of it; features of the closed loop systems; and concerns about the everyday barriers to adoption. Of note, children and adolescents differed from parents in that youth primarily identified needs specific to their immediate contexts (e.g. school and peers). Parents were most concerned about the accuracy and ensuring that systems stabilize glucose levels and reduce risk for long-term complications. Other reports emphasize these same ideas of setting realistic expectations and potential benefits on quality of life and well-being are already being realized with closed loop systems. In the US, the FDA recognized the first Medical Device Development Tool (MDDT) as the INSPIRE scales, a person reported outcome survey evaluating expectations and well-being related to device use. This can be considered when formally evaluating programs for initiating and sustaining device use.

In sum, the current evidence base points to psychosocial and quality of life benefits from using CGM and other devices such as closed loop. Interventions to reduce barriers to technology use are actively being investigated. However, more clinically-translatable research, specifically conducted in the pediatric population is needed on the best ways to break down barriers to device and technology use and prevent discontinuation. This likely rests in setting realistic expectations, teaching effective problem-solving skills (general and technology specific), and viewing digital health applications as a scaffolding for youth to internalize the salience and routine of specific health behaviors.

5. Conclusions:
Over the past 30 years, glucose monitoring has evolved from urinary glucose testing and capillary BG measurements to continuous glucose monitoring systems using factory-calibrated interstitial sensor technology. Along with significant improvements in CGM technology (including accuracy, device size, prolonged sensor lifetime and user-friendliness), more wide availability of CGM systems due to better coverage by national and private insurance in more parts of the world and demonstrated benefits of
their application compared to SMBG in type 1 diabetes, CGM has become standard of care for people with type 1 diabetes in many countries.

Today, CGM technology is at the heart of diabetes management. CGM specific metrics, in particular “time in range” (defined as percentage of time with sensor readings between 70 to 180mg/dL (3.9 to 10mmol/L) have been adopted as useful clinical markers$^{164}$ and outcome measurements$^{105}$ that supersede or complement HbA1C for a wide range of people with diabetes (see Chapter Glycemic Target chapter). Manual or automated upload of CGM data to cloud-based platforms enables sharing and remote reviewing of the data. This has been and will continue to be instrumental in providing teledmedical care during the Sars-Cov2-pandemic and beyond. Particularly noteworthy, significant progress has been made in CGM-enabled algorithm-driven automated insulin delivery (AID) delivery in the form of a hybrid artificial pancreas (see Chapter on Insulin delivery).

With the advent of factory-calibrated CGM sensors licensed for non-adjuvant use, it seems as if SMBG has started to take a back seat in glucose monitoring. However, it still has an important role. Even users of AID systems with calibration-free non-adjuvant CGM will still have to take capillary measurements in certain situation, i.e. if sensor readings and personal perception do not match, to confirm hypoglycemia, to do manual calibrations if sensor readings are not accurate, and when no CGM data are available.

Of course, people who do not have access to CGM will still rely on SMBG devices. CGM devices and sensors are expensive and may not be available in many countries. Insurance coverage may also be limited. Over time, these devices will continue to become more widely available and better coverage by both national and private insurance is anticipated. ISPAD advocates for increased availability of CGM for children, adolescents, and young adults with diabetes. Where available, CGM should be initiated in all children, adolescents and young adults with type 1 diabetes as soon as possible after diagnosis.

This chapter has reviewed evidence on glucose monitoring technology in children, adolescents, and young adults. Recommendations on their use and practical advice regarding their applications has been provided. Since this is a rapidly evolving area of research and practice, further innovations and updates are to be expected.
