Trees, shrubs and woody vines represent the woody members of the plant world. The terms “tree”, “shrub” and “vine” are non-scientific general descriptive words with no well-defined specific meaning. The American Standards for Nursery Stock, which is included with this manual, gives some definition to the terms, but in general, a “tree” is understood to be a woody plant approximately six feet to over 100 feet in height at maturity with most major branches derived from a single erect stem. Variations can include a two to five stem clump or a multi-stem form of these same species. Shrubs can be defined as almost always having branches deriving from multiple stems and generally under 15 to 20 feet in height. Vines are highly apically dominant plants, generally with few side branches. Vines have extensive, but flexible terminal growth that needs support to stay upright.

Knowledge of a plant’s classification, characteristics, and history or native habitat is essential to its production in the nursery and to its proper utilization in the landscape. Professional nursery growers, retailers, landscape architects, designers and landscape contractors should become familiar with proper nomenclature, plant identification, and the wealth of diversity among woody plants.

Plant Identification
Plant identification begins with careful observation. Although visual observations of the morphological characteristics of stems, buds, leaves, flowers, and fruits may be the most useful, all human senses should be used in plant identification. See the white, exfoliating bark of the paper birch (Betula papyrifera), the horseshoe-shaped leaf scar of the amur cork tree (Phellodendron amurense), or the large, round, purple buds of the scarlet elder (Sambucus pubens). Feel the prickly foliage of the Chinese juniper (Juniperus chinensis), the soft, fuzzy or pubescent twigs of the staghorn sumac (Rhus typhina), or the sharp ridged thorns of the rugosa rose (Rosa rugosa). Smell the pleasantly scented foliage of the savin juniper (Juniperus sabina), the acrid aroma of the fragrant sumac (Rhus aromatica), or the spicy scented blossoms of the clove currant (Ribes odoratum). Hear the distinctive rustle of quaking aspen (Populus tremuloides) leaves. Chew the twigs of the sweet birch (Betula lenta) to discern their distinct wintergreen taste. Many excellent references are available to learn the important identifying characteristics of plants, but...
also, strive to discover new characteristics, which help personalize the identification. Once familiar with the common plants available in the industry, continue to search for and learn about new plants.

The process of learning plant identification and culture should be an ongoing process. Become excited about plant materials, always observing where particular plants are growing well and where they are not, and under what conditions. Whenever possible, observe native, undisturbed plant communities to discern site requirements and understand natural plant associations. Always be on the lookout for new introductions or unfamiliar plant materials.

**Plant Selection**

Selection of plant materials should never be conducted in sheer nescience, but rather on a working understanding of site and cultural requirements. When selecting plant material, consider native plants which are adapted to existing environmental conditions. Then consider materials which are found in similar environments from other regions and have been tested locally. However, most urban landscapes, in fact most landscapes in general, have been disturbed and may no longer be appropriate for previously indigenous species. Several factors must be considered when selecting plant materials for specific sites: winter temperature or cold hardiness, summer temperature or heat tolerance, humidity, wind, exposure to sun or shade, air drainage, precipitation or drought and moisture tolerance, soil type, drainage, pH tolerance, disease and insect resistance, pollution tolerance, longevity, salt tolerance, fertility requirements, growth habit including height, form, plus aesthetic characteristics such as foliage color and texture, flowers, fruits, and fall color. In addition to knowing plant names, it is also important to know the environmental requirements of each plant. It is also vital to be knowledgeable of the cultural requirements of plant materials so this information can be passed on to customers and so plants can be matched with site conditions. Knowledgeable landscape designers and architects are better equipped to create naturally aesthetic, functional design concepts that become successful landscapes and that are sustained for years with minimal maintenance. Educated customers are also more likely to have success with the plants they purchase.

Diversity should be an important component in the selection of landscape plants. Diversity is, however, lacking in most landscapes today. Many native plants or introduced species can no longer be recommended or planted because of potential disease problems, large size and perceived characteristics such as being structurally weak or "messy". In fact, some city ordinances prohibit the planting of certain species even though they are ubiquitous in native stands and many existing landscapes. Some plant species are unavailable for landscape use because they are relatively unknown, resulting in low demand, or because their production and cultural requirements are poorly understood which limits their availability. Familiarity and production problems associated with plants that should be incorporated into landscape designs and production schedules can be addressed through education and research. Attitudes regarding particular plant characteristics and the appropriateness of using certain plants in the landscape are more difficult to address. Although new plants become available to growers, to landscape architects and designers, and to the public each year through plant selection and breeding programs, the variety of plant material actually grown and used is quite limited. This lack of diversity leads to "standard" landscape designs that lack uniqueness, and production becomes limited to easily produced species. This results in the exclusion of the more interesting species, and the planting of near monocultures that increase the potential for serious insect or disease problems such as Dutch Elm Disease. These concerns should be addressed by increasing plant diversity rather than by limiting it. Yes, cottonwood does produce annoying seeds or "cotton", and it drops twigs and branches. On the other hand, cottonwood is a native species that is well adapted to the Minnesota environment and is tolerant of tough sites. It has a valuable place in the landscape, perhaps not in the front yard of every home, but a valuable place just the same. Nearly every plant that exists has some characteristic that might be considered undesirable. Even the revered oak produces "messy" acorns and drops leaves late in the season after the raking should be done. The extremes of this trend include the desire for fruitless selections and more recent concerns about pollen production and allergies. Fruitlessness involves the selection of sterile plants or males forms of deciduous species. Avoidance of pollen favors the selection of female plants. In the absence of sterile forms, this selection process could eliminate some excellent species from landscape use. Rather than excluding plants from landscape use, diversity should be promoted through continued selection and production of new varieties and potentially valuable species not currently grown. Plants should be matched with site conditions and
design requirements. Just because a plant is easy to grow, or has attractive flowers, or doesn't produce seeds, does not make it the best plant, or even a good plant, for every site.

**Plant Tables 1 Through 17**

Tables of deciduous trees, gymnosperms, native deciduous shrubs, introduced shrubs, and vines are organized alphabetically in this chapter by scientific name and height. Tables 1 through 17 include the common name, information on plant height at maturity, tolerances to shade, moisture, drought, pH, and whether the plant has showy flowers, fruits, or fall color. Code descriptions used in Tables 1 through 17 are as follows:

- **Shaded Block** = Specific Tolerance
- **Shaded Block** = Displays Fruit or Seed

B = Blue/Purple  
E = Evergreen  
O = Orange  
P = Pink  
R = Red  
W = White  
Y = Yellow.

All of the plants that will grow in Minnesota are not listed as these tables serve as a foundation for further learning. Some cultivars have been selected from the many plant species listed, however, most cultivars have not been listed. Each table provides additional lines for individual professionals to add their favorite plants, highly used plant material and/or other plants not listed in the tables.

The MNLA Trees and Shrubs Catalog, which is included with this manual, and the many references listed at the end of this chapter provide additional information on specific and new varieties. The nursery and landscape professional needs to be well informed about plant material and must be on the constant lookout for new materials to learn about, to propagate, to grow, and to use.
